Northern redbelly dace are considered provincially secure by the ACCDC (S5). From 2015-2017, northern redbelly dace were captured in WC5 north of Crusher Lake, WC13, and the flooded portion of WL56. No northern redbelly dace were captured within watercourses along the Haul Road.

White Sucker

White sucker are generalist bottom dwellers found in warm, shallow water areas of lakes and quiet streams. They are most abundant in areas with aquatic vegetation and underwater debris that provide cover.

White sucker are active year-round, spawning in May-June when they migrate into small streams and tributaries with water temperatures of 10 to 18°C (NSSA, 2005). Preferred spawning habitat for white sucker is shallow gravel riffles of moderate water velocity. Lake populations sometimes spawn on gravel shoals where there is wave action (NSSA, 2005). The adults leave the spawning ground after a week or two and return to the river or lake from which they originated (Scott and Crossman, 1973).

Young of the year are typically found over sand and gravel substrates in moderate currents (Twomey et al., 1984). Older juveniles are typically found in shallow backwaters and riffles with moderate water velocities and sand/rubble substrate (Propst, 1982). In-stream cover in the form of rocky substrates, vegetation, and larger woody debris are important for all life stages of white sucker.

White sucker are considered provincially secure by the ACCDC (S5). From 2015-2017, juvenile white sucker were captured in Cameron Flowage, and in two watercourses along the Haul Road (WC-N and WC-AA). From 2019-2020, adult white sucker were

captured within Mud Lake/WC27, Cameron Flowage, WC13, and the Killag River. In addition, juvenile sucker were captured in WC13 and the Killag River. Schools of young of the year white sucker were also observed in the Killag River in 2020, but largely evaded capture via electrofishing.

Yellow Perch

Yellow perch are a schooling, shallow water fish that can adapt to a wide variety of warm or cool habitats. Most yellow perch do not appear to migrate, but some do in patterns which tend to be short and local (Brown et al., 2009). Adults and juveniles are found in large lakes, small ponds, or gentle rivers but are most abundant in clear, highly vegetated lakes (1 to 10 m depth) that have muck, sand, or gravel bottoms (Brown et al., 2009). They prefer summer temperatures of 21 to 24°C.

Spawning occurs in the spring, with adults moving to lake shallows or low velocity areas of rivers with moderate vegetation. Within 1 to 2 months of emergence, young of the year perch move to open water (Krieger, Terrell & Nelson, 1983).

Yellow perch are considered provincially secure by the ACCDC (S5). During the 2015-2017 fish surveys, juvenile and adult yellow perch were captured in Cameron Flowage. Along the Haul Road, a single juvenile yellow perch was captured in WC-N. During the 2019-2020 field program, juvenile and adult yellow perch were captured in Mud Lake/WC27 and Cameron Flowage. A single juvenile was captured in the Killag River during the second round of electrofishing.

Environmental DNA

The results of eDNA samples collected at the Beaver Dam Mine Site are provided in Table 6.9-6. eDNA was completed on the Cope Brook system in order to clearly assess the presence or absence of fish in the WRSA above a natural barrier. The eDNA sampling was completed as an additional methodology to increase confidence in the not fish frequented definition. The laboratory results report is available in Appendix D of the 2019-2020 Baseline Report (Appendix J.2). Sample locations and results are presented in Figure 6.9-4.

Sample results are consistent with expectations based on site knowledge and fish collection efforts to date. eDNA corroborates the capture data and there are no fish above the barrier. Fish presence was not confirmed within Sites 1 to 4, based on biologists' interpretation of results provided in Section 6.9.4.5. This was expected based on all previous fish collection and habitat survey results.

Table 6.9-6: Summary of eDNA Sample Results

Site ID	WC Number	Interpretation
1	Channelized open water within WL220	Negative
2	WC21 – connection between WL220 and WL205	Negative
3	Standing water in WL205	Negative
4	Channelized WC21 within WL205, upstream of subterranean barrier	Negative
5*	WC23, downstream of subterranean barrier	Positive
6*	WC23, downstream of subterranean barrier	Suspected (Field determination: Positive**)

Notes: Positive - presence of DNA of the target taxa in the water. Negative - presence of DNA of target taxa is not confirmed.

*Positive control sites where fish are known to be present.

**Suspected result is interpreted as positive based on confirmed presence of brook trout in contiguous watercourse upstream.

6.9.4.2.4 Touquoy Mine Site

Moose River, which runs along the western extent of the Touquoy Mine Site, was determined to provide habitat for Atlantic salmon and brook trout during surveys conducted in 2005 as part of the Environmental Assessment (CRA, 2007a). Atlantic salmon (juveniles) were observed and suitable rearing and potential spawning habitat is available for the species. It was presumed that the Atlantic salmon observed were landlocked due to their proximity to a known landlocked population within Scraggy Lake. American eel, white sucker, and minnow species were also observed in Moose River. Although not observed, surveys determined that there is good adult and juvenile brook trout feeding habitat, fair rearing habitat, and potential spawning habitat available within Moose River (CRA 2007a).

Fish observed from 2006 electrofishing surveys of Moose River as part of the EARD include; American eel, white sucker, and minnow species (CRA 2007a).

6.9.5 Consideration of Engagement Results

Key issues raised during public and Mi'kmaq of Nova Scotia engagement relating to fish and fish habitat include potential impacts to the Nova Scotia Southern Uplands population of Atlantic salmon; based on proximity of the Project to the Killag River, and Acid Mitigation Projects being completed by the NSSA, and potential indirect effects from wetland alteration or changes to surface water and groundwater quality and quantity on fish and fish habitat.

6.9.6 Effects Assessment Methodology

6.9.6.1 Boundaries

6.9.6.1.1 Spatial Boundaries

Assessment boundaries define the maximum limit within which the effects assessment and supporting studies (e.g., predictive models) are conducted. Boundaries encompass where and when the Project is expected to interact with identified VCs as well as constraints that may be placed on the assessment of those interactions due to political, social, and economic realities (administrative boundaries), and limitations in predicting or measuring changes (technical boundaries). The definition of these assessment boundaries is an integral part of the assessment process and encompasses possible direct, indirect, and induced Project effects, as well as the trends in processes that may be relevant.

The spatial boundaries used for the assessment of Project effects to Fish and Fish habitat are the PA, LAA, and RAA. These are defined below and shown in Section 6.7, Figure 6.7-11:

- The Project Area (PA) consists of the three components: the Beaver Dam Mine Site, the Beaver Dam Haul Road, and the Touquoy Mine Site, extending from Marinette to Moose River Gold Mines, Halifax County, NS (Section 6.7, Figure 6.7-11). The Beaver Dam Mine Site is located at the eastern end of the Beaver Dam Mines Road. The Haul Road spans from the Beaver Dam Mine Site to Moose River Gold Mines, where the Touquoy Mine Site (processing and exhausted pit [to be used to dispose Beaver Dam tailings]) is located. The PA has changed as a result of the expansion of the Beaver Dam Mine Site to accommodate micro-siting of mine infrastructure and ongoing modifications to the Haul Road design, as described in Section 2 (Project Description). These changes have been captured under the existing and additional desktop and field evaluations.
- The Local Assessment Area (LAA) includes the Project Area and further encompasses watersheds that could be potentially directly affected by mine development and operation and comprises tertiary watersheds which intersect each component of

the Project (Section 6.7, Figures 6.7-4 and 6.7-11). The LAA surrounding the Touquoy Mine Site incorporates the Moose River to the west, and only includes the portion of the Square Lake watershed which interacts with the PA. No Project related aquatic effects are expected in the headwater portions of these watersheds. The lakes and watercourses that are included as part of the baseline programs and/or predictions of effects are located within the LAA boundary.

- The Regional Assessment Area (RAA) encompasses the three secondary watersheds that the PA is located within. The RAA is broader than expected Project impacts and considers other project boundaries as per the cumulative effects assessment methodology. Watersheds comprising the RAA are:
    1. West River Sheet Harbour secondary watershed (1EM-2, incorporating the Beaver Dam Mine Site and Haul Road);
    2. Tangier River secondary watershed (1EL-2, incorporating the Haul Road); and
    3. Fish River-Lake Charlotte secondary watershed (1EL-5, which incorporates the Touquoy Mine Site).

As the Project has the potential to cause direct and indirect effects to fish and fish habitat outside of the PA, the LAA is the appropriate boundary for evaluation of this VC.

In addition to the assessment boundaries described above, a Fish Habitat Assessment Area (FHAA) was established to facilitate the field evaluation of watercourses predicted to be indirectly affected by the Project downstream of the PA boundary. This FHAA includes watercourses WC23, WC26, and WC27 to their respective downstream receiving environments (Cope Brook, and the Killag River), Cameron Flowage, and the Killag River downstream to the NSSA Lime Doser. Figure 6.9-1 shows the FHAA in the context of the LAA. In short, the FHAA s a broader spatial area than the Beaver Dam Mine Site that was established to guide field baseline surveys where predicted indirect impacts were identified stemming from the mine infrastructure (Figure 6.9-1).

6.9.6.1.2 Temporal Boundaries

Temporal boundaries reflect those periods during which planned Project activities are reasonably expected to potentially affect a VC. The temporal boundaries used for the assessment of effects to Fish and Fish Habitat are the Construction phase, Operations phase, and Active Closure and Post-closure

To support the effects assessment for the Surface Water VC, and by extension Fish and Fish Habitat, predictive models for were developed for the end of operations model (i.e., max build out) as well as Post-closure. The End-of-mine model (EOM) represents the Project stage with the highest potential for significant effects to the receiving environment and thus the prediction and assessment of potential effects at EOM, and applying to the whole of operations, is a conservative approach. Results of surface water modelling are detailed in the Surface Water Effects Assessment (Section 6.7), and appendices referenced therein.

6.9.6.1.3 Technical Boundaries

The Fish and Fish Habitat effects assessment was developed to incorporate quantitative data from baseline reports as well as predictive surface water modelling including sensitivity analyses; the modelling domains of predictive surface water models represent a technical boundary for the effects assessment; additional discussion in this regard is presented in Section 6.7.7.1

6.9.6.1.4 Administrative Boundaries

Fish and fish habitat were evaluated for the Project within the framework offered by the *Fisheries Act* (2019) and supporting policy statements and documents from DFO, including those referenced herein. DFO interpretation of HADD of fish and fish habitat supports the evaluation of this VC for the purpose of this EIS.

DFO's *Fisheries Act* (RSC, 1985, c.F-14) states:

- Under Section 35(1) that No person shall carry on any work, undertaking or activity that results in harmful alteration, disruption or destruction of fish habitat.
- Also, Section 34.4(1) states No person shall carry on any work, undertaking or activity, other than fishing, that results in the death of fish.
- Under subsection 35(1) a person may carry on such works, undertakings or activities without contravening this prohibition, provided that they are carried on under the authority of one of the exceptions listed in subsection 35(2), and in accordance with the requirements of the appropriate exception. In most cases, this exception would be Ministerial authorizations granted to proponents in accordance with the Authorizations Concerning Fish and Fish Habitat Protection Regulations.

The Policy for Applying Measures to Offset Adverse Effects on Fish and Fish Habitat Under the *Fisheries Act* (DFO 2019) states the following:

> *Works, undertakings or activities resulting in the death of fish or the harmful alteration, disruption or destruction of fish habitat are prohibited under the Fisheries Act unless otherwise authorized. Before approving works, undertakings or activities that will result in the death of fish and/or the harmful alteration, disruption or destruction of fish habitat, Fisheries and Oceans Canada (the Department), must consider if there are alternatives that avoid adverse effects on fish and fish habitat. If the adverse effects on fish and fish habitat are unavoidable, the Department must consider if there are measures to mitigate that would reduce or minimize those adverse effects. Finally, if there are any residual effects, then the Department must consider measures to offset or counterbalance the death of fish and the harmful alteration, disruption or destruction of fish habitat.*

The Department will apply a risk-based approach when evaluating the impacts of works, undertakings or activities on fish habitat. Following from the definition of fish habitat noted above, the Department interprets "harmful alteration, disruption or destruction" as any temporary or permanent change to fish habitat that directly or indirectly impairs the habitat's capacity to support one or more life processes of fish (DFO 2019 [Fish and Fish Habitat Protection Program]).

The Project is currently undergoing federal and provincial environmental assessment under the *Canadian Environmental Assessment Act* 2012 and *Nova Scotia Environment Act,* respectively. Section 6.9.9 describes the residual effects on fish and fish habitat when project mitigations have been considered. As part of the planning and permitting process, this Updated EIS and the draft Fish Habitat Offset Plan will be reviewed by DFO to confirm the likely residual effects of the Project on fish and fish habitat and the need for a Federal Fisheries Authorization. Subsequently, a *Fisheries Act* Application for Authorization including a detailed final offsetting plan will be developed (Appendix J.3 draft Fish Habitat Offset Plan).

6.9.6.2 Thresholds for Determination of Significance

In response to IAAC (CEAA 2019) IR2 CEAA 2-02, the significance determination is revised and is described in Table 6.9-7.

Overall, a significant adverse effect from the Project on fish and fish habitat is defined as an effect that results in an unmitigated or uncompensated net loss of fish habitat as defined under the *Fisheries Act,* and its associated no-net loss policy. Specifically, the residual effects of the Project on Fish and Fish Habitat VC is characterized using standard criteria, including magnitude, geographical extent, duration, frequency, reversibility, and context of the effect (Table 6.9-7). The residual effects assessment concludes with a determination of significance. The screening of project effects, mitigation measures, and the subsequent fish and

fish habitat results are assessed in aggregate to determine whether the residual impacts are "Not Significant" or "Significant" according to the following definitions:

- **Significant Residual Effect:** residual effects have high magnitude, be of potential regional geographic extent and of medium to long term duration, occur at any frequency and only be partially reversible to irreversible.
- **Not Significant Residual Effect:** is defined as negligible to moderate magnitude, are restricted to the PA or near-field receiving environment, are of sporadic or short-term duration, occur at any frequency and are reversible to partially reversible.

Overall, a significant adverse effect from the Project on fish and fish habitat is defined as an effect that results in an unmitigated or uncompensated net loss of fish habitat as defined under the *Fisheries Act,* and its associated no-net loss policy.

Table 6.9-7: Definitions of Characterization Criteria for Residual Effects on Fish and Fish Habitat

Criteria	Description of Ratings
Magnitude	• **Negligible:** no measurable change in fish and fish habitat quantity or quality described as one or more of the following (and/or): o Less than one percent change in surface flow volumes. o No direct loss of fish habitat; and o predicted change of surface water quality indicator is less than 10% of background conditions, (i.e., no measurable change of state of indicator from background conditions). • **Low:** a measurable change in fish habitat area or quality, but within the range of natural variation described as one or more of the following (and/or): o Less than 10% flow reduction and not affecting the ability of documented fish species to use the habitat to carry out one or more life processes; o direct loss of to up to 20 m^2 of fish habitat in any individual fish-bearing wetland or watercourse; and o water quality in the receiving environment is predicted to be greater than guidelines and increase by greater than 10% over baseline levels but remains well within the observed range of natural variation (defined as 25^{th} to 75^{th} percentile baseline water quality). • **Moderate:** a measurable change in fish habitat area or quality, above the range of natural variation, which partially limits the ability of fish to use the habitat to carry out one or more life processes described as one or more of the following (and/or): o Less than 10% flow reduction but greater than a 10% net increase in the duration (number) of days below the 30% MAD (based on daily flows), which partially limits the ability of fish to use the habitat to carry out one or more life processes; o Direct loss of fish habitat, greater than 20 m^2, up to 100 m^2 in any individual fish bearing wetland or watercourse; and o Water quality in the receiving environment is predicted to be greater than guidelines and differ substantially from baseline levels and approaches upper observed limits of natural variation (defined as percentile baseline water quality). • **High:** a measurable change in fish habitat area or quality to an extent which limits the ability of fish to use the habitat to carry out one or more life processes described as one or more of the following (and/or): o Greater than a 10% flow reduction and a greater than 10% increase in number of days below the 30% MAD (based on daily flows), which limits the ability of fish to use the habitat to carry out one or more life processes; o Direct loss of fish habitat greater than 100 m^2 in any individual fish-bearing wetland or watercourse; and o Water quality in the receiving environment is predicted to be greater than guidelines and differ substantially from baseline water quality (outside of 75^{th} to 95^{th} baseline water quality), resulting in a detectable change beyond the range of natural variation.
Geographical Extent	• **Discrete:** effect is limited to receiving environments in the immediate footprint or Project Area (PA). • **Local:** effect is limited to the FFHA/LAA. • **Potential** Regional: effect persists to the Regional Assessment Area.

Table 6.9-7: Definitions of Characterization Criteria for Residual Effects on Fish and Fish Habitat (continued)

Criteria	Description of Ratings
Timing	• Timing represents seasonal occurrence of the effect (e.g., spring vs winter; high flows vs. low flows) and represents effect criteria for designated water users (aquatic resources, human health). The characterization of effect of changes to fish and fish habitat is based on life cycles and is considered in the assessment.
Duration	• **Short term:** effect is restricted to Construction Phase and/or EOM modelling. • **Medium term:** effect occurs in Construction Phase and EOM Phase. • **Long term:** Effect occurs in Construction Phase and EOM Phase and/or persists in PC.
Frequency	• **Sporadic:** VC interaction or effect will occur at irregular intervals throughout any Project Phase. • **Regular:** effect occurs on a regular basis but not continuous basis. • **Continuous:** effect occurs constantly (e.g., every model timestep in a given Project Phase).
Reversibility	• **Reversible:** effect can be reversed. • **Partially reversible:** effect can be partially reversed. • **Irreversible:** effect cannot be reversed, is of permanent duration.

6.9.7 Project Activities/Interactions with Fish and Fish Habitat

6.9.7.1 Overview of Potential Fish and Fish Habitat Interactions

The purpose of this section is to identify how the Fish and Fish Habitat VCs may be affected by interactions with the Project's components and activities and to identify the extent and duration of potential Project-related Harmful Alteration Disruption and Destruction (HADD) of fish habitat, through both direct and indirect pathways of effects.

A direct effect is any Project interaction that results in direct loss or removal (destruction) of fish habitat, through direct imprinting of Project infrastructure on fish habitat, or through complete removal of a stream's entire catchment area or water source. An indirect impact is a Project-related effect which does not result in complete removal of a habitat; however, the quality or suitability of that habitat is altered or disrupted through pathways (a change in groundwater or surface water quality or quantity, for example).

The Project is part of the Moose River Consolidated (MRC) Project, which includes the existing and fully permitted Touquoy Gold Project, located in Moose River Gold Mines, Nova Scotia. The Project will operate as a satellite surface mine to the MRC Project, and crushed ore from the will be transported by truck via the Haul Road to the existing and fully permitted Touquoy Mine. In general, the Project has the potential to effect Fish and Fish Habitat by:

- discharges, including direct discharge to the receiving environment and management of contact water;
- water management activities, including diversions of contact and non-contact water;
- groundwater upwellings and seepage from Project components to receiving environment;
- ML/ARD generated from excavating or exposing material with the potential for ML/ARD, or in runoff from temporary stockpile or road cuts;
- erosion and sedimentation during site clearing, construction, and maintenance activities; and
- dust deposition along the Haul Road Corridor (CEAA 2-37).

Note, during review of Project activities and their expected direct and potential indirect effects to Fish and Fish Habitat, it was understood that authorization under the *Fisheries Act* would be required for Project development due to the presence of fish habitat underlying the proposed pit and due to additional direct and predicted indirect impacts such as flow reductions. Alternatives for all other site infrastructure were considered, focusing specifically on impacts to Fish and Fish Habitat, with the goal of reducing impact to fish and fish habitat. The Fish Habitat Offset Plan is provided in Appendix J.3.

A summary of Project activities and potential interactions with Fish and Fish Habitat by Project Phase is presented in Tables 6.9-8 to 6.9-10. Where Project components/activities are not expected to interact with Fish and Fish Habitat VCs, these components and activities are considered to have no potential effects and are not considered further in the assessment. These include effects to Fish and Fish Habitat as resulting from hazardous waste materials and potential spills well as potential failures of water management structures (e.g., failure settling pond); these are related to occurrences of low likelihood outside of normal operating conditions. These potential effects are addressed in Section 6.18, Accidents and Malfunctions, as well as the draft Spill Contingency Plan (Appendix P.1).

The effects of the Project on Fish and Fish Habitat were determined considering the modelling efforts and effects predictions of the Project on groundwater, surface water and wetlands. This underlying sections are informed by conclusions presented in these other VC sections and should be read in sequence after Sections 6.5 (Geology, Soils and Sediment), 6.6 (Groundwater), and 6.7 (Surface Water).

Table 6.9-8: Potential Project Activities/Interactions with Fish and Fish Habitat at Beaver Dam Mine Site

Project Phase	Duration	Project Interactions
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of construction • Watercourse and wetland alteration in preparation of construction • Mine Site road construction • Surface infrastructure installation and construction • Collection and settling pond construction • Topsoil, till and waste rock transport and storage from site preparation • Surface infrastructure installation and construction • Collection ditch and water management pond construction • Local traffic bypass road construction • Culvert and bridge upgrades and construction • Environmental monitoring • Water collection, treatment and monitoring as required
Operation	5 years	• Rock blasting to access and extract ore • Open pit dewatering, interaction between groundwater drawdown and wetlands • Alteration of surface water hydrology (i.e., ditching of site surface water runoff and surface mine pumped water) and surface water management • Dust and noise management • Emergency Response/Spill Contingency • Explosives management • Environmental monitoring • Water collection, treatment and monitoring as required

Table 6.9-8: Potential Project Activities/Interactions with Fish and Fish Habitat at Beaver Dam Mine Site (continued)

Project Phase	Duration	Project Interactions
Active Closure	2 years	• Site reclamation • Earthworks and replanting • Water collection, treatment, and monitoring • Biophysical monitoring of reclamation landforms • Adaptive Management
Post-closure	10+ years (monitoring, adaptive management)	• Water treatment monitoring and adaptive management, as required

Table 6.9-9: Potential Project Activities/Interactions with Fish and Fish Habitat along the Haul Road

Project Phase	Duration	Project Interactions
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of construction • Watercourse and wetland alteration in preparation of construction • Haul Road construction and upgrades • Local traffic bypass road construction • Culvert and bridge upgrades and construction • Sediment and Erosion Control Management • Environmental Monitoring • General waste management
Operation	5 years	• Haul Road maintenance and repairs • Dust and noise management • Emergency Response/Spill Contingency • Sediment and Erosion Control Management • Environmental monitoring • General waste management
Active Closure	2 years	• N/A[(a)]
Post-closure	10+ years (monitoring, adaptive management)	• N/A

Note: [(a)] Decommissioning and Reclamation of the Haul Road is not expected. The Haul Road will be returned to owner for forestry industry.

N/A = not applicable.

Table 6.9-10: Potential Project Activities/Interactions with Fish and Fish Habitat at the Touquoy Mine Site

Project Phase	Duration	Project Interactions
Construction	1 year	• N/A
Operation	5 years	• Tailings and Water Management • General waste management • Environmental monitoring
Active Closure	2 years	• Site reclamation • Earthworks and replanting • Water collection, treatment and monitoring • Biophysical monitoring of reclamation landforms • Adaptive Management
Post-closure	10+ years (monitoring, adaptive management)	• Post closure interaction with discharge from Touquoy Mine Site pit to Moose River

N/A = not applicable.

6.9.7.2 Beaver Dam Mine Site, Fish and Fish Habitat Effects

In this section-describes potential Project effects to Fish and Fish Habitat VCs identified above by Project phase (Tables 6.9-8 to 6.9-10) are further categorized as either:

1. Direct Effects: is any Project interaction that results in direct loss or removal (destruction) of fish habitat, through direct imprinting of Project infrastructure on fish habitat, or through complete removal of a stream's entire catchment area or water source

2. Indirect Effects: a Project-related effect which does not result in complete removal of a habitat; however, the quality or suitability of that habitat is altered or disrupted through pathways (a change in groundwater or surface water quality or quantity, for example).

Table 6.9-11 identifies direct and indirect effects of all fish-bearing aquatic habitats potentially impacted by Project development at the for the Project, including the Beaver Dam Mine Site. These aquatic habitats/fisheries resources are shown on Figure J.4-3 of Appendix J.4.

Further, a summary of all fish-bearing aquatic habitats identified within the Beaver Dam Mine Site is provided in Table 6.9-12 to clearly show which habitats have potential direct or indirect impacts associated with the Project. Fisheries resources that are carried through the effects assessment have been determined to have a potential interaction with the Project and are presented in Table 6.9-13. Within Table 6.9-13, the commencement of potential effects to fish habitat is provided, along with the temporal duration of impacts. For some interactions, the effect commences during operation, but may not be fully realized through operations, such as indirect effects from flow reduction. The residual effects characterization with a focus on magnitude and significance of each direct and indirect interaction are described in Section 6.9.8.

Table 6.9-11: Potential Direct and Indirect Impacts to Fish and Fish Habitat within the Project Area

Impact Type	Direct Impact	Project Phase	Indirect Impact	Project Phase
Destruction of fish habitat	Removal of watercourse, and open water features within the Beaver Dam Mine Site and Haul Road to support mine development including the pit resulting in direct loss of fish habitat.	C	N/A	N/A
Fish mortality	Loss of habitat within the Beaver Dam Mine Site and Haul Road (removal of, watercourse, open water) to support mine development could result in incidental mortality to fish for various species and life stages.	C	N/A	N/A
Changes in composition and characteristics of fish populations	N/A	N/A	Loss of watercourse and/or open water habitat or indirect operational impacts within the mine footprint may result in fish population changes including composition and characteristics of various fish species	C
			Potential for change in fish populations due to changes in water quality or quantity, including effects associated with groundwater to surface water interactions	O, CL
Vibrations from Blasting	Vibrations and pressure from blasting activities within the Beaver Dam Mine Site could result in mortality or affect fish behaviour, spawning and migration	C, O	Blasting adjacent to open water and watercourses has the potential for vibrations/pressure wave and fly rock which could affect fish.	C, O
Mine Activities			Mining activities adjacent to wetlands and watercourses has the potential to alter surface and/or subsurface water flows/hydraulic conductivity which could affect fish behaviour, spawning and migration.	C, O

Table 6.9-11: Potential Direct and Indirect Impacts to Fish and Fish Habitat within the Project Area (continued)

Impact Type	Direct Impact	Project Phase	Indirect Impact	Project Phase
Alteration of fish habitat (hydrology): If the hydrological regime of a wetland, watercourse, or open water feature is altered, fish habitat can be negatively affected	Complete dewatering, infilling or flooding of a wetland, watercourse, or open water feature to facilitate Project development resulting in direct loss of fish habitat.	C, O	Wetlands, watercourses, open water features, and associated fish habitat are also at risk of indirect impacts as a result of management and collection of mine contact water, drainage basin hydrologic adjustments, land elevation changes, blasting etc. causing dewatering. Inadvertent damming of up-gradient wetlands, watercourses, and open water features from construction related infrastructure (i.e., roads with lack of flow through infrastructure) can also affect downstream fish habitat. Changes in surface hydrology can impact downstream water quantity which can affect fish habitat.	C, O, CL
	Alteration of hydrological inputs and outputs into partially altered wetlands, watercourses, or open water has the potential to alter remaining (undeveloped) associated fish habitat.	C, O, CL	Removal of on-site watercourses or outflow and throughflow wetland habitat has the potential to alter the localized hydrology in down-gradient surface water systems and associated fish habitat.	C, O, CL
			Hydrological changes can impact the use of a wetland, watercourse, or open water feature by fish and other aquatic organisms as a habitat resource.	C, O, CL
			Surface water ditching can reduce inputs into wetlands, watercourses, and open water features, reducing water levels, collecting mine contact water, and potentially affecting fish and fish habitat.	C, O, CL
Alteration of fish habitat (water quality): If water quality within upland riparian habitat, riparian wetlands, watercourses, or open water features is altered, the capacity for habitat to support fish can be negatively affected.	Removal (alteration) of riparian wetlands, upland riparian zones, and watercourses from the landscape leading to a change in water quality in down-gradient aquatic receivers (i.e., streams, additional wetlands and lakes) resulting in an adverse change to fish or fish habitat.	C, O, CL	Alteration of riparian habitat (upland and wetland), watercourses, or open water features increases the risk of down grade sedimentation which could affect fish and fish habitat.	C, O, CL
			The effect of increased sedimentation as a result of up-gradient activities (i.e., earth moving, removal of vegetation, soil stockpiling) has the capacity to suffocate existing plant life and increase nutrient levels in downgrade surface water systems. Dust created as a result of construction activities can have a similar impact.	C, O, CL
			Runoff from acid producing rock exposed during construction activities has the potential for negatively altering water quality within down-gradient fish habitat through closure (NSE-2-44).	CL
			Operational discharge of water has potential to negatively affect water quality.	O, CL

Note: C = Construction Phase; O = Operation Phase; CL = Active Closure Phase.

Table 6.9-12: Summary of Fish Resources Evaluated in the Effects Assessment: Beaver Dam Mine Site

Tertiary Watershed	Fish Habitat[1]	Predicted Interactions with Fish and Fish Habitat[2]	Description of Interaction	Carried Forward through Effects Assessment
Cope Brook (1EM-2-J)	WC-23	Indirect	Flow reduction from contact water collection	Yes
	Cope Brook	No direct impact. Indirect impacts evaluated below.	This system is carried through the effects assessment as a downstream receiving environment to upstream impacts	Yes
Killag River (1EM-2-D)	WC-2	No impact	No Impact	No
	WC-3	No impact	No impact	No
	WC-4	No impact	No impact	No
	WC-5	Direct and Indirect	Internal Haul Road, and potential flow reduction from contact water collection	Yes
	WC-6	No impact	No impact	No
	WC-7	No impact	No impact	No
	WC-8	No impact	No impact	No
	WC-9	No impact	No impact	No
	WC-12	Direct	Direct impact to support pit development	Yes
	WC-13	Direct	Pit perimeter berm and loss of catchment area	Yes
	WC-14	Direct	Internal haul road and loss of catchment area	Yes
	WC-17	No impact	No impact	No
	WC-25	Direct	Pit perimeter berm	Yes
	WC-26	Indirect	Flow reduction from contact water collection	Yes
	WC-27	Indirect	Flow reduction from contact water collection	Yes
	Killag River/ Cameron Flowage	No direct impact. Indirect impacts evaluated below.	This system is carried through the effects assessment as a downstream receiving environment to upstream impacts	Yes
	Crusher Lake	Indirect	Crusher Lake is being evaluated for potential effects related to flow reduction	Yes
	Mud Lake/ WL17	Indirect	Mud Lake & WL17 are being evaluated for potential effects related to flow reduction	Yes
	WL-4	No impact	No impact	No
	WL-8	No impact	No impact	No
	WL-10	No impact	No impact	No

Table 6.9-12: Summary of Fish Resources Evaluated in the Effects Assessment: Beaver Dam Mine Site (continued)

Tertiary Watershed	Fish Habitat[1]	Predicted Interactions with Fish and Fish Habitat[2]	Description of Interaction	Carried Forward through Effects Assessment
	WL-15	No impact	No impact	No
	WL-20	No impact	No impact	No
	WL-29	No impact	No impact	No
	WL-44	No impact	No impact	No
	WL-56	Direct	Direct impact to support development of open pit	Yes
	WL-59	Direct	Direct impact to support development of open pit	Yes
	WL-61	Direct	Direct impact to support development of open pit	Yes
	WL-62	No impact	No impact	No
Killag River/ Paul Brook (1EM-2-D/ 1EM-2-H)	WC-11	No impact	No impact	No
Tent Brook (1EM-2-F)	WC-28	No impact	No impact	No
	Tent Brook	No direct impacts. Indirect impacts evaluated below.	This system is carried through the effects assessment as a downstream receiving environment	Yes

Notes: 1 Includes fisheries resources only. Non-fish bearing, provincially regulated watercourses (identified in Section 6.9.4.2) and wetlands identified as inaccessible to fish (described in Section 6.9.4.2) have been excluded from this table.

2 Includes impacts to fish habitat only. In wetlands, where impacts may be proposed in portions of the wetland which have been determined to be inaccessible to fish, the response in this table will be 'No impacts'; however, impacts to the wetland habitat itself will be described in detail in Section 6.8.

Table 6.9-13: Commencement of Effects to Fish Habitat by Construction Phase, and Duration of Effect

Tertiary Watershed	Fish Habitat[1]	Predicted Interactions with Fish and Fish Habitat[2]	Phase When Effects Will Commence	Duration of Potential Impact to Fish and Fish Habitat[2]

Tent Brook (1EM-2-F)	Tent Brook	No direct impact. Indirect impacts evaluated below.	Construction*	Permanent

Notes: Impacts are expected to commence during construction as water collection facilities are constructed. The effect may not be fully realized until operation.

[1]Non-fish bearing, provincially regulated watercourses (identified in Section 6.9.4.2), and wetlands identified as being inaccessible to fish (described in Section 6.9.4.2) have been excluded from this table.

[2] All potential Beaver Dam Mine Site impacts are described here. The evaluation of magnitude or significance of effects is not quantified or described in this table.

6.9.7.2.1 Direct Effects

The Project will result in direct effects to fish habitat; Table 6.9-14 presents potential direct fish habitat impacts within the Beaver Dam Mine Site. Direct impacts to fish and fish habitat will occur during the construction phase of the Project through activities such as mine site infrastructure and road construction and will be permanent.

Direct impacts include fish inhabited waters which will either be directly imprinted by Project infrastructure or are expected to experience complete loss of flow due to complete loss of catchment from infrastructure placement. Watercourses determined to be inaccessible to, and uninhabited by, fish are not included in direct impacts to fish and fish habitat. Details associated with reach-level measurements, including justification for any determination of 'inaccessible to fish' are provided in the 2019-2020 Baseline Report (Appendix J.2), and Section 6.9.4.

Table 6.9-14 shows the estimated surface area (m^2) and habitat units (HU; 100 m^2) of the expected total direct impact to fish in response to IR2 CEAA 2-06 and CEAA 2-07. A list of species known or expected to be present within each system is provided; as this information is used to select appropriate species for Habitat Suitability Indexing (HSI) within the draft Fish Habitat Offset Plan (Appendix J.3). Methods used to measure impact areas are summarized in Section 6.9.3.3.2 and described in further detail (including raw data from each individual transect measurement) in the 2019-2020 Baseline Report (Appendix J.2).

As outlined in Table 6.9-14, five watercourses and three wetlands within the Beaver Dam Mine Site comprising fish habitat will be directly impacted by the mine development and have either confirmed fish habitat, fish presence, or are accessible to fish. While WC1 is located within the Beaver Dam Mine Site, the Project interaction with that watercourse is the construction of the Haul Road, (i.e., where the Haul Road component of the PA meets the Beaver Dam Mine Site component of the PA). Since the impact is related to Haul Road construction, this impact is presented within the Haul Road evaluation of Project interactions. The total quantity of fish habitat directly lost by the Beaver Dam Mine Site is 39,443.44 m^2 (394.43 habitat units) which will require a *Fisheries Act* authorization and therefore will be included in the draft Fish Habitat Offset Plan (Appendix J.3). All direct impacts to fish and fish habitat within the Beaver Dam Mine Site are shown on Figure J.4-6 of Appendix J.4.

Impacts related to the development of the open pit, pit perimeter berm and internal haul roads are expected to be permanent. This includes impacts to Wetlands WL56, WL59, and WL61 and Watercourses WC5, WC12, WC13, WC14 and WC25. As part of the open pit development, the fish access between Wetlands 56/59 and Cameron Flowage via Watercourse WC13 will be removed. A road around the open pit will impact the open water fish habitat within Wetland WL61 and Watercourse WC25. The internal haul road will also impact Watercourse WC14 (CEAA 2-07).

Based on the results of fishing surveys and fish habitat assessments, no Atlantic salmon have been confirmed or are anticipated to reside in any of the fish-bearing aquatic features anticipated to be directly impacted by Project development. No direct impacts to Atlantic salmon will result from the Project.

Full descriptions of fish habitats proposed for direct impact are outlined in 2019-2020 Baseline Report (Appendix J.2). A summary of fish habitat of systems proposed for direct impact (Table 6.9-14) is provided in Section 6.9.4.3.1.1 and shown on Figure J.4-6 of Appendix J.4.

Table 6.9-14: Direct Fish Habitat Impacts within the Beaver Dam Mine Site

Fish Habitat	Fish Species known or Expected (for HSI)[a]	Infrastructure	Length (m)	Average Width (m)	Area (m^2)	Habitat Units	Fish Rescue Release Point
WC5	BKT, LKC, EEL, BKF, BBH, GSH, 9SP, NRD, WHS, YLP	Internal Haul Road (culvert installation)	70	2.2	154.0	1.54	WC5
WC12	BKT	Pit	40	1.0	93.00	0.93	WC5 or Killag

WL61	EEL, BKF, GSH, WHS, YLP	Pit Perimeter Road	n/a	n/a	173.67	1.74	
Total					**39,443.44**	**394.43**	

Notes: [a] HSI: Habitat Suitability Index.

[b] Species codes: American Eel (EEL), Atlantic Salmon (ATS), Banded Killifish (BKF), Brook Trout (BKT), Brown Bullhead (BBH), Creek Chub (CKC), Golden Shiner (GSH), Lake Chub (LKC), Ninespine Stickleback (9SP), Northern Redbelly Dace (NRD), White Sucker (WHS), Yellow Perch (YLP).

6.9.7.2.2 Indirect Effects

Potential indirect effects on Fish and Fish Habitat are summarized in Table 6.9-11. To support a response to IR2 CEAA 2-06 and CEAA 2-07, a thorough evaluation of indirect effects to the Fish and Fish Habitat VCs as been completed.

A series of detailed studies have been completed to support this evaluation of changes to the Surface Water VC and associated indirect effects on Fish and Fish Habitat VC and HADD. Surface Water predictions for the Project were produced through the development of deterministic water balance modelling for both the Beaver Dam Mine Site and the existing Touquoy Mine. Summaries of model approaches, assumptions, and sensitivity analyses as they relate to surface water predictive efforts are provided in Section 6.7.7.3. Full details and results of surface water studies conducted to support the environmental assessment are appended here as:

- Appendix D (Predictive Water Quality Assessment) of Appendix P.4 Mine Water Management Plan;
- Appendix A (Water Balance Analyses) of Appendix P.4 Mine Water Management Plan;
- Appendix F.8 Beaver Dam Gold Project Assimilative Capacity Study of Moose River – Touquoy Pit Discharge; and
- Appendix G.3 Additional Water Quality Modelling to Support the Mine Site Water Management Plan.

The results of the above studies, including results of the residual effects assessment for Surface Water VCs, are summarized in the underlying sections to support the assessment to Fish and Fish Habitat VC. Fulsome discussion of the effects assessment to Surface Water VCs is provided in Section 6.7.

Surface Water Quantity

Proposed Project activities that will affect the Surface Water Quantity VC include construction of water management and water diversion features, dewatering activities, and management of contact water (including discharges of treated effluent to the Killag River).

Surface runoff from mine features will be directed to settling ponds for treatment prior to being released into the Killag River and Tent Brook systems. The north settling pond will receive and treat runoff from the waste rock, low-grade ore and topsoil stockpiles, the crusher pad, administrative building area and site roads. Surface water and groundwater collected in the pit sump will also be dewatered to the north settling pond. The east settling pond will receive runoff from the till stockpiles, part of the organic stockpile and site roads. The north and east settling ponds discharge to the Killag River. The south settling pond will receive runoff from another other part of the organic stockpile and a topsoil stockpile. The south settling pond discharges to WC19 of the Tent Brook system.

The Water Balance model indicates that mine site development will increase the Killag River catchment area, and decrease the Mud Lake, Tent Brook and Cope Brook catchments due to the placement of mine features in their baseline drainage areas. A summary of catchment areas at EOM, including the change relative to baseline, are presented in Section 6.7.8.2, Table 6.7-24. Section 6.7.8.2, Table 6.7-25 through Table 6.7-29 present the monthly and annual metrics for identified assessment points in the receiving environment relative to baseline conditions. The key observations are:

- The development of the Beaver Dam Mine Site results in small increases in streamflow volume at the Killag River assessment point defined in the water balance analysis (Appendix A [Water Balance Analysis] of Appendix P.4 Mine Water Management Plan). The predicted increase in annual streamflow is 2.2% in EOM conditions and 1.1% in PC conditions. The small increases are a result of the change in land cover and the diversion away from the adjacent watersheds to the Killag River.

- There will be a 4.4% decrease in annual discharge from Crusher Lake due to the proposed water extraction to meet the domestic water demand. The proposed development results in a <1% increase in Crusher Lake discharge in PC conditions, and 18.3% and 13.7% decreases in Mud Lake discharge in EOM and PC conditions, respectively. The hydrologic impacts to Mud Lake are due to the placement stockpiles and influence of the open pit on groundwater flow patterns in the catchment.
- The proposed development results in a 1.1 to 1.2% and 5.7% reduction in annual streamflow volume at the Tent Brook and Cope Brook assessment points, respectively, in both EOM and PC conditions. The impacts to the Tent Brook system are considered to be low. The impacts to the Cope Brook system are due to the placement of the waste rock stockpile in its baseline catchment.
- Addition discussion of Project effects on MAD flows, as well as additional assessment of potential base flow reduction of the Cameron Flowage and Killag River, is presented in the underlying sections.

Project Effects on Mean Annual Discharge Flows

An evaluation of the potential Project effects on mean annual discharge (MAD) flows was completed by GHD. The methods and results of this evaluation are provided in the Water Balance Analysis (Appendix A of Appendix P.4 [Mine Water Management Plan]) and summarized in Section 6.7.7.3.1. The objectives of the Water Balance Analysis are to assess the impacts of the mine on drainage patterns in surrounding watercourses, and also to provide inputs to the predictive water quality analysis to determine the type and level of treatment required at the proposed Site discharge locations. Monthly and annual streamflow volumes were compared between three mine development stages at sixteen assessment points where the Site will discharge or impact flows in the natural environment. In addition, a water balance analysis of the open pit mine was performed to determine the time required for the pit to fill with water and form a lake as part of the proposed Project draft Reclamation and Closure Plan (Appendix P.2).

Under EOM conditions, open pit inputs include pit wall runoff generated by precipitation falling directly on the pit and groundwater inflows. Outputs include evaporation and dewatering to the north settling pond. The pumping rate to the north settling pond is set equal to the difference between the inputs and evaporation from the pit, based on the assumption that the pit will be kept dry during operations (Appendix A [Water Balance Analysis] of Appendix P.4 [Mine Water Management Plan]).

Post-closure, the open pit inputs include direct precipitation, Site runoff, and groundwater inflows. Output includes evaporation. Open pit water balance calculations were performed under two PC scenarios: (1) following formation of the pit lake, and (2) while the pit is being filled with water. Under PC Scenario 1, pit lake discharge occurs when the balance between the inputs, outputs and stored water exceeds the permanent pool storage volume of the lake, which is approximately 16,000,000 m^3 at a containing elevation of 127 metres above sea level (masl). The permanent pool storage volume of the pit lake was assumed to be full at the beginning of the simulation (Appendix A [Water Balance Analysis] of Appendix P.4 [Mine Water Management Plan]).

A simulation for PC Scenario 2 was performed to estimate the pit filling time. Depth-varying groundwater inflow rates were obtained from the groundwater model (Appendix A [Water Balance Analysis] of Appendix P.4 [Mine Water Management Plan]). Precipitation and evaporation volumes were calculated by multiplying the difference between precipitation and evaporation by the surface area of the water in the pit. The surface area of the water in the pit varies based on the stage of the water. Surface areas are provided at 10 m increments. Pit wall runoff was calculated as the product of precipitation, surface area of the pit above the water surface, and the runoff coefficient of the pit wall. A runoff coefficient of 0.85 was used based on studies completed at the Touquoy Mine Site (Stantec pers. comm., 2018). The time to fill the pit was calculated as the sum of the volume of water in the pit divided by the total inflow rate to the pit at each stage. Based on these calculations the predicted pit filling time is approximately 13 years. The Water Balance Analysis provides detailed results of all monthly flow modelling methods and results. Domestic withdrawal of water

from Crusher Lake during operations is incorporated into this analysis, along with all groundwater baseflow interactions (Appendix A [Water Balance Analysis] of Appendix P.4 [Mine Water Management Plan]).

The Projects' impacts to lake water levels in Mud Lake and Crusher Lake were assessed by converting instantaneous (average daily) flow rates of the historical record to flow depths at the WC5 and WC27 upstream assessment points using the Manning's equation. The change in flow depths at the lake outlet assessment points were then used to estimate the change in lake water levels. Flow depths were computed for various flow statistics and compared between the mine development stages.

Daily Flows

Watercourses within and adjacent to the Beaver Dam Mine Site that may be indirectly affected by flow reduction have been identified and have been assessed as to whether predicted indirect habitat losses would be considered alterations to fish habitat, as described in Section 6.9.7.2. The evaluation of monthly average discharge is an important exercise, however when an evaluation is based on averages, the full range of the impact can be overlooked. As such, the Project team completed an additional evaluation of the Project's potential indirect effects on surface water quantity by further refining the GHD model as described in in Appendix P.4 to a daily time step. The Project team used the results of the preliminary Water Balance Analysis to identify additional surface water flow assessment points, to inform revisions to the Water Balance Analysis . The majority of the assessment points (fifteen of sixteen) presented in the Water Balance Analysis have been selected to identify both the magnitude and spatial extent of flow reduction effects, using the daily flows rather than monthly averages. The daily flow evaluation assessment points are provided in Figure 6.9-5. The additional surface water assessment points were selected on main receiving environments (i.e., Cope Brook, Tent Brook and the Killag River), to confirm whether flow reductions on smaller tributaries were substantial enough to affect flows in the downstream receiving environments. Wherever possible, daily flows in downstream receiving environments were compared with upstream reference points. As the Project is located at the top of the Tent Brook watershed, no upstream reference point was available. The assessment points used to analyze flow reductions and potential impacts to fish are shown in Figure 6.9-5.

The assessment quantified the change in habitat availability and related it to existing habitat within the affected streams. This was accomplished using two approaches; comparison of reduced flows to DFO guidelines on cumulative alterations and comparison of reduced flows to habitat point-of-inflection based on wetted perimeter method (DFO, 2013).

Hydrologic methods included a review of the instantaneous (daily) flows within each watercourse against the DFO framework related to ecological flow requirements (DFO 2013). That is, the review of instantaneous (daily) flow data to determine if:

- Cumulative flow alterations >10% in amplitude of the instantaneous flow in the river relative to a "natural flow regime" are predicted (a cumulative flow alteration of <10% is considered to have a low probability of detectable impacts to ecosystems); and/or
- Cumulative flow alterations that result in instantaneous flows <30% of the MAD are predicted (these may have a heightened risk of impacts).

If either condition is identified, a more rigorous level of assessment is recommended to evaluate potential impacts on ecosystem functions which support fisheries. Streams that did not exceed these criteria were not included in further hydraulic analysis.

A comparison between existing and predicted flow alterations relative to an increase beyond 10% MAD is straight forward. Because estimated flow reductions are based on relatively permanent changes to watercourse conditions caused by changes in water balance, any watercourse that naturally contains a period of time with flows <30% MAD will continue to have instantaneous flows <30% MAD (by definition). The potential cumulative decrease in flow beyond 30% MAD, however, needs to be considered in terms of the relative change in duration (frequency) that may occur below 30% MAD.

An increase in the duration of instantaneous flow that is <30% MAD may be important in habitat reaches or regions where water temperatures, or some other water quality parameter, could reach sub-lethal or lethal limits for a portion of the year. Simultaneous monitoring of such habitat parameters (e.g., thermal) and flow monitoring/modelling for small streams to correlate thermal limits and decreased flows would be challenging and may not identify the habitat limiting factor. A reasonable assumption is that moderate increases in the number of days where flows are reduced to <30% might affect fish populations and habitat productivity/sustainability due to cumulative reductions in water and/or habitat quality.

A review of the instantaneous flow data indicates that additional days with flows <30% MAD occur either directly before or after a day, or series of days, already containing flows <30% MAD, that is they extend an existing period of lower flows. For example, Figure 19 in the draft Fish Habitat Offset Plan (Appendix J.3) shows the MAD as well as the predicted flow reductions in WC27. While all extensions are at most two days, this could cumulatively affect fish within the affected habitat and it is recognized that this can result in a habitat alteration. Similar to the DFO framework approach where a cumulative flow alteration <10% would have a low probability of detectable impacts to ecosystems, a <10% increase in the frequency of instantaneous flow days occurring below 30% MAD for an average flow year (or <5% for a dry year) will likely have a low probability of detectable impacts to ecosystems. However, increases above this would have greater potential to indirectly impair the habitat's capacity to support one or more life processes.

It is noted that the uncertainty regarding criteria set at 10% increase in the number of days where flows occur at <30% has not yet been fully validated by extensive literature review or manipulations. However, a relative increase of 10% in the number of days below what is a relatively high flow threshold (flows below 30% MAD are regularly encountered within natural streams) is conservative and can therefore be considered reasonable. It may also require a rigorous monitoring program associated with a Fisheries Act authorization within habitats considered indirectly affected to provide greater certainty going forward. Consideration might also be given to stream reductions that occur only during the life of the mine (up to EOM) but are then restored upon PC; these might require less offsetting or increased monitoring to determine if offset is required.

Hydraulic analysis was completed on all watercourses that exceeded either the 10% MAD flow reduction or a 10% increase in number of days where flows were <30% MAD (or both). Transects within each watercourse as well as stream measurements were used to generate stream cross section models. The existing habitat (wetted perimeter) on each transect was determined at the MAD as well as 30% MAD. The discharge at 30% MAD represented the flow where cumulative reductions may have a heightened risk of greater potential to indirectly impair the habitat's capacity to support one or more life processes and therefore HADD that would require offsetting measures to avoid significant negative effects on fish and fish habitat. The potential habitat alteration as a result of flow reductions were therefore calculated in metres squared for each watercourse based on the predicted wetted perimeter at 30% MAD as a conservative quantity of indirect impact. That actual amount of the altered habitat that is considered harmful will be determined by DFO during the fisheries Authorization application process.

The Wetted Perimeter Method (WPM) equation validations and supporting information is provided in Appendix A of the draft Fish Offset Plan. Field data collection on WPM transects (including raw data) is provided in the 2019-2020 Baseline Report (Appendix J.2) and summarized in Section 6.9.4.2.2.

Daily Flow Modelling Approach

Detailed, long-term, direct flow data from the PA is not available given the small size of the watercourses. Therefore, streamflow conditions for each affected watercourse were modelled. Streamflow within a watercourse is equal to surface runoff plus baseflow. Surface runoff and baseflow were generated using a conceptual hydrologic model in GoldSim which runs on a daily time step. Rainfall and snowmelt were added to a soil storage element as inputs, and evapotranspiration was subtracted from the soil storage

element as an output on dry days. A "surplus" from the soil storage element was generated after the soil's available water capacity had been exceeded. The "surplus" was partitioned into surface runoff and baseflow recharge into a groundwater aquifer according to a baseflow index (BFI). The BFI was determined from the groundwater model results. Baseflow discharges from the groundwater aquifer at a rate based on the baseflow recession constant, also determined from the groundwater model.

Lakes were also modelled as storage elements in GoldSim, which were assumed to be full in initial conditions. Inputs to the lake include surface runoff, baseflow, and precipitation falling directly on the lake. Output is lake evaporation. Lake discharge is calculated as the overflow from the lake storage element.

The hydrologic model was used to model streamflow and lake discharge from non-site features in EOM/PC conditions. EOM and PC were used as these represent "worse-case" scenarios in terms of effect on streamflow. End-of-Mine would be at a time when mine pits and waste rock would be at a maximum and therefore having maximum influence on baseflow as well as surface flow conditions. Post-closure conditions represent a time period after full mine pit flooding and no remaining active water management/pumping and/or discharges. Variations in baseflow due to the influence of mine development on groundwater flow patterns were determined in the groundwater model. These impacts were incorporated in the GoldSim model as percent changes from baseline conditions.

Daily Flow Data Screening Results

Estimates of daily flows for an average flow year were determined based on the median annual precipitation within the dataset (2003). The estimate for a dry flow year were based on lowest annual precipitation within the dataset (1992).

Table 6.9-15 outlines the results of flow alterations at both End of Mine and Post Closure scenarios. The results indicate that three watercourses, WC 23, 26 and 27, exceed the 10% change in MAD flow. These habitats are therefore selected for further evaluation of indirect impacts to fish habitat. A fourth watercourse, WC5, does not exceed the 10% flow reduction, however, this system has a greater than 10% increase in the number of days at which the flow drops below 30% MAD. As a result, WC5 is screened into the evaluation of indirect impacts to fish habitat. Further details regarding impacts to fish habitat within WC5, 23, 26, and 27 are presented in Section 6.9.7.1.7

As shown, watercourses WC-5, WC-23, WC-26, and WC-27 all have exceedances of at least one criterion and were carried forward to be assessed and quantified. While the predicted reductions within WC-26 and WC-27 were predicted to be moderate, the change in flows within the Killag River immediately downstream of each confluence is predicted to be relatively low at less than 3.5% showing the overall low contribution of each tributary to the Killag River.

The total number of days when the flow within the Killag River just downstream of each confluence was also reviewed under baseline (non-project) and EOM/PC conditions. The Killag River would incur one additional day below the 30% MAD at the confluence of WC-26 (during dry flow conditions) and only three or four additional days a year below the confluence of WC-27 (average and dry years, respectively). Additionally, at the upriver end of Cameron Flowage, approximately 2.0 km downriver from the confluence of WC-27, there is only one additional day below 30% MAD (in both average and dry years). The Killag River had a predicted increase in flow and decrease in number of days <30% MAD within and downstream of Cameron Flowage likely because baseflow losses to the nearby pit will be augmented by the collection, treatment, and release of all pit water back to the Killag River which would include flows from around the full mine pit from other watercourses. Therefore, flow reductions within the northern portion of the Killag River as a result of flow reductions in WC-26 and WC-27 is considered low magnitude, negligible and not a harmful alteration of habitat.

While the Killag River is not screened into the indirect effects assessment based on flow reduction; the following section will outline any broader potential indirect effects associated with the Project on this system; as it is the nearest, most substantial receiving environment, and it is of vital importance to Atlantic salmon.

Table 6.9-15: Summary of Flow Reduction in Downstream Receiving Aquatic Habitats for Screening Purposes

Cameron Flowage – Killag River, Additional Assessment

Methods and results of predictive water balance and water quality modelling is summarized above in Section 6.9.7.2.2 (Indirect Effects, Beaver Dam Mine Site) and detailed in Surface Water Effects Assessment (Section 6.7) and references presented therein. The most salient points specific to the Cameron Flowage and surface water quantity is presented in this section; surface water quality is disused in Section 6.9.7.2.2.2.

The simulated change in baseflow throughout the Cameron Flowage watershed is presented in Table 7.4 of Appendix F.5 (Hydrogeologic Modelling Report). The simulated baseflow reduction ranges from 677 to 754 m^3/d at EOM and from 446 to 620 m^3/d at PC. The range in baseflow reduction represents 2 to 3% of total baseflow in the Cameron Flowage watershed and is under 1% of the total average annual flow in Cameron Flowage. Approximately 50 to 60% of the total baseflow reduction is simulated to occur within the Beaver Dam Mine Site Property Boundary, and the remaining 40 to 50% of total baseflow reduction is simulated to occur between the Property Boundary and the LAA, indicating that Beaver Dam Mine Site operations will not impact the baseflow contribution to Cameron Flowage beyond the LAA.

The range in simulated baseflow reduction to the Cameron Flowage watershed is from 2 to 3% of average annual baseflow and is under 1% of total average annual flow. Potential effects of this baseflow reduction to Cameron Flowage are discussed in further detail in the draft Fish Offset Plan (Appendix J.3).

AMNS commits to maintaining compliance with all applicable water quality guidelines at the site discharge points, and within the receiving aquatic environment (Cameron Flowage/Killag River), given the proposed contact water collection and treatment plan. Provided treatment and mitigation measures outline throughout the EIS and associated management plans are followed, no indirect impacts to fish and fish habitat are predicted based on effluent discharge from the Project. Furthermore, there are no predicted impacts to the NSSA Acid Mitigation Project (NSSA AMP) (IR2 NSE 2-43) as a result of predicted water quality from the Project within Cameron Flowage/Killag River. Finally, Project effluent will be released within a pH range of 6.0 to 9.5, as per MDMER requirements, which is neutral compared with the naturally acidic background levels found within the Killag River. As a result, addition of treated effluent is not expected to exacerbate the current acidity of the Killag River. Given that water treatment will occur prior to release and considering all of the associated contingencies for water management outlined in the MWMP, adverse impacts (harmful alteration) on fish and fish habitat are not expected in Cameron Flowage/Killag River due to predicted changes in water quality. These conclusions will be confirmed by an Aquatic Effects Monitoring Program (AEMP) which includes the EEM specific to MDMER, and any necessary refinements to geochemical source terms, and groundwater and surface water predictive modelling throughout the life of the mine. Adaptive management measures will be provided within the final AEMP during permitting should monitoring determine that actual effluent quality does not match with predictions provided within this EIS.

In addition to possible reductions in flow within Killag River due to reduced flows within watercourse tributaries and baseflow (groundwater) changes due to pit influences, several other possible interactions between the Beaver Dam Mine Site and the Killag River were assessed including the location of the North Pond discharge into Cameron Flowage, possible habitat dewatering and habitat accessibility due to water release delays, thermal effects of reduced groundwater inflow, and possible water quality alterations. These additional assessments are provided in the Fish Offset Plan (Appendix J.3) and include consideration of:

- Augmentation at the North Pond Discharge Location: flow augmentation will mitigate any flow impacts that a reduction in baseflow would have on the total flow in Cameron Flowage and further downriver within the Killag River.
- Sensitivity Analysis – Effect from a Cessation of Discharge to Cameron Flowage/Killag River; and
- Sensitivity Analysis - Habitat Accessibility Due to Water Release Delays.

Surface Water Quality

The Surface Water Quality VC and identified indicators were either assessed quantitatively by predictive water modelling (total and dissolved metals, anions, and nutrients; mg/L) or qualitatively based on geochemical characterization studies and professional judgement and experience (e.g., pH, TSS). For surface water quality, predictive modelling was performed on a monthly basis for the average year climatic conditions. Performing the water quality assessment on a monthly basis allows for the prediction of the seasonality characteristics of water quality in the Killag River. This allows for the assessment of the wet and dry months to determine the month with the highest effect on the water quality in the Killag River and will assist with the design of water quality treatment options at the Project Site. The only discharge points with potential for discharge of impacted mine effluent into the Killag River system are the north settling pond (EOM) and the pit (PC). There are three discharge points proposed during EOM conditions and PC conditions (Figure 6.7-13 and 6.7-14). Thus, in the model, receiving water quality predictions were generated for:

1. EOM: near-field mixing zone (100 m downstream of each discharge point with the potential for constituent transport);
2. PC: near-field mixing Zone on Killag River for the Pit; and
3. EOM and PC: far-field mixing zone (approximately 1 km downstream of Near Field - Pit - PC discharge point in the Killag River).

Surface Water Quality predictions are presented in Section 6.7.8.2.3, Tables 6.7-30 through 6.7-38. The key observations are:

- For the Killag River under the EOM scenarios, water quality predictions for near-field mixing zone and far-field mixing in the base case are consistently below selected water quality benchmarks. The initial analysis assumed no treatment of mine contact water in the north settling pond and only analyzed the results from a mass balance (dilution) calculation at the extent of the predicted mixing zone. The results indicated that, while concentrations for some parameters are anticipated to increase above baseline levels, at the near-field mixing zone there are no exceedances of either CCME, NSE Tier 1 criteria. As water quality criteria are defined by national and international entities as protective of the receiving environment and all water users, there are no anticipated effects to surface waters are a result of discharges from the Project to the Killag River.
- In the EOM upper case scenario, nitrite is predicted to exceed CCME FAL guidelines in three months of the year. In response to IR2 CEAA-2-35, potential nitrite removal technologies have been identified and evaluated for the Project (Appendix F.2 [Water Treatment Assessment Operation] of Appendix P.4 [Mine Water Management Plan]). Further note that a treatment system will be designed to ensure that all site effluent water meets MDMER and will reflect assimilation capacity of the receiving environment, such that any potential effects from nitrite to Fish and Fish Habitat, will be fully mitigated (Section 6.7.9).
- Treatment will occur, as required, prior to discharge into the receiving environment to ensure discharge meets MDMER regulations and will reflect assimilation capacity of the receiving environment, such that concentrations in the Killag River do not exceed exceedances of either CCME, NSE Tier 1 criteria. or site-specific guidelines, as applicable.
- It is unlikely ARD onset will occur during the operations phase (5 years). An engineered cover will be placed immediately following operations during active closure.

Total Suspended Sediments (TSS)

The potential effects on surface water quality, and by extension Fish and Fish Habitat, from increased erosion and sedimentation are qualitatively assessed in this section. Erosion and sedimentation effects on surface water quality can be indicated primarily by changes in turbidity and total suspended solids (TSS) in surface waterbodies. However, for the Project there is generally minimal risk of effects from erosion and sedimentation on surface water quality due to the limited extent of planned surface disturbances and the proposed use of pre-existing infrastructure such as roads, camp, and the processing facility.

Mitigation and management strategies for erosion and sediment control will follow best management practices (BMPs). General strategies for erosion prevention are described in Section 6.7.9; specific details of mitigation and management strategies for the minimization of erosion and control of sediment, including specific BMPs to be applied during Project Construction, Operations, and Closure, are discussed primarily in the draft Erosion and Sediment Control Plan (Appendix C of the Mine Water Management Plan [Appendix P.4]). Where soil erosion may still occur despite preventative measures, sediment control strategies may be implemented to capture sediments before they are released to the receiving environment. The success of erosion management and sediment control measures would be monitored by regular inspection and maintenance of all water management and sediment control structures, which will include prompt attention to potential erosion sites, ditch or culvert failure and blockage, or outside seepage. Accumulated sediment would also be routinely removed from ditches and retention structures.

Potential effects from sedimentation and erosion are most likely to occur during the Construction and Active Closure phases, when surface materials will likely be disturbed during construction or reclamation activities. As TSS loads are generally low in Project area streams, any additional sediment loading has the potential to increase TSS and turbidity in the receiving environment. Potential effects due to sedimentation and erosion have the greatest potential to occur during periods of significant overland flow, such as freshet and rainfall events. However, planned disturbances in the Project Area are limited, and implementation of BMPs and mitigation measures as summarized in Section 6.7.9 and detailed in the draft Erosion and Sediment Control Plan (Appendix C of the Mine Water Management Plan [Appendix P.4]) and will prevent substantial change of surface water quality near the proposed access corridor and other planned site upgrades. Further, water quality responses to run-off include increased concentrations of TSS but tend to be temporary and localized (Forman 1998).

Habitat Quality/Suitability – Thermal

Cold-water fish, including salmonids, require that surface water temperatures remain within a certain range for maximal suitability and survival. Under low-flow conditions during summer months, groundwater discharge (baseflow) to Cameron Flowage may sustain a significant portion of the total flow within Cameron Flowage; therefore, the potential reduction in baseflow as a result of the Beaver Dam Mine Site development may impact the average temperature within Cameron Flowage. While all water pumped from the proposed open pit will be rerouted via surface water ditches to maintain the same total flow within Cameron Flowage relative to baseline conditions, water entering Cameron Flowage via the surface water ditches may be at a higher temperature than if that water reached Cameron Flowage through subsurface baseflow. Therefore, measured groundwater and surface water temperatures were evaluated relative to the predicted reduction in baseflow to predict the potential average temperature change in Cameron Flowage under low-flow conditions that could result from development of the Beaver Dam Mine Site (Appendix P.4).

The potential temperature change in Cameron Flowage as a result of the development of the Beaver Dam Mine Site based on the measured flow rates and temperatures in Cameron Flowage, the measured groundwater temperatures and the predicted baseflow reduction at EOM and PC as presented in Appendix H (Baseflow Mitigation Assessment) in Appendix P.4 (Mine Water Management Plan). Cameron Flowage will likely be most sensitive to potential reductions in baseflow during low-flow conditions in summer months when baseflow makes up the largest proportion of total stream flow and surface water temperatures within

Cameron Flowages are near their maximum. Therefore, GHD selected the two-week period with the lowest average flow rate recorded at surface water monitoring stations (SW-1A and SW-2A), corresponding to August 16 through August 29, 2019, as being representative of low-flow conditions in Cameron Flowage. By applying heat and mass balance modelling, the predicted temperature increase during the identified low-flow conditions is 0.5°C under EOM conditions relative to baseline, and 0.26°C under PC conditions relative to baseline. These predicted increases correspond to an increase from mean baseline water temperature 20.21 to 20.71°C and 20.47°C for EOM and PC, respectively.

Monitoring will be completed to demonstrate that temperature changes within Cameron Flowage are within the predicted range. These monitoring commitments will be confirmed in the Preliminary Aquatic Effects Monitoring Program (AEMP), which is included in Appendix P.5.

The resolution of baseflow modeling within Cameron Flowage cannot determine if existing groundwater inflows to Cameron Flowage are diffuse or provide concentrated "upwelling" area(s). Field surveys to confirm the absence (or presence) of groundwater upwelling area(s) along the west shore of Cameron Flowage have been partially completed; however, icing conditions just prior to surveys limited the ability of the thermal drone to detect possible groundwater upwelling sites. Therefore, additional surveys are scheduled during the 2021 open water season and the uncertainty around existing groundwater seepages can be addressed prior to final offset design.

The thermal regime of a river or reach is tied to its landscape geomorphology, geology, and vegetation (O'Sullivan et al. 2019); however, studies on the spatial distribution of thermal refuges have found greater occurrences of them to be significantly associated with areas of higher channel curvature, close proximity of incoming tributaries, and channel confinement (ratio of valley width to channel width) (Dugdale et al. 2015; Larken and Sharp 1992; van Balen et al. 2008; Winter et al. 1998). While the Cameron Flowage can be described as a semi-confined river channel section, given the general topography (i.e., low river valley relief, lack of river channel curvature, and limited inflow tributaries near the Open Pit area) concentrated groundwater upwelling locations are not likely. While the overall change in water temperature is not predicted to increase more than 0.5°C, over baseline, if groundwater upwelling(s) are confirmed, a portion of the west shoreline would be altered and therefore a portion of the estimated total area may be included in the fish habitat affected (Appendix J.3).

Effects of Blasting on Fish

Indirect impacts to fish and fish behavior, spawning grounds and migration patterns are possible from blasting activities associated with mine development. The detonation of explosives near watercourses within the Project Area can produce post-detonation shock waves which involves a rise to a high peak pressure and then a subsequent fall to below ambient hydrostatic pressure. This pressure deficit can cause impacts in fish (Wright and Hopky, 1998). An overpressure in excess of 100 kPa can result in effects in fish including damage to the swim bladder in finfish, and potential rupture and hemorrhage to the kidney, liver, spleen and sinus venous. It is also possible that fish eggs and larvae can be damaged (Wright and Hopky, 1998). The degree of damage is related to the type of explosive, size and pattern of the charges and the distance to the watercourse, depth of water within the watercourse, and species, size and life stage of the fish.

Wright and Hopky (1998) provide guidelines on methods and practices for blasting which are "intended to prevent or avoid the destruction of fish, or any potentially harmful effects to fish habitat that could result from the use of explosives". Included in these guidelines are recommended setback distances from the land-water interface to ensure explosive charges do not result in an instantaneous pressure change greater than 100 kPa, the pressure at which damage to fish is likely to occur (Wright, 1982). Wright and Hopky (1998) provide additional blasting setback recommendations to avoid impacts to spawning beds (peak particle velocities >13 mm/s) during periods of egg incubation.

An Explosives Management Plan will be developed to ensure adherence to all applicable setbacks outlined within Wright and Hopky (1998). At the Beaver Dam Mine Project, the following Explosive Management Best Management Practices are considered to minimize potential impacts to waters frequented by fish including the Cameron Flowage/Killag River:

- Determine final power factor based on 50 kPa as per guidelines.
- Excavate 1 to 2 m trench below the blast area and internal to the open pit to create an air void to attenuate/direct vibration and pressure away from Cameron Flowage/Killag River. Once the void is created, blasts will be oriented perpendicular to the river to further mitigate vibration and pressure wave propagation away from Cameron Flowage/Killag River.
- Use of line drilling will be considered;
- Use of electronic detonators for more accurate detonator timing to reduce the potential for fragmentation and minimize vibrations.
- Blast parameters such as hole size, drilling pattern, use of decked loads will be evaluated on a regular bases.
- Monitoring program will include a combination of seismograph with geophones microphones, and hydrophones will be implemented and blasting practices will be adaptively managed based on outcomes.
- Use of blast mats should be considered to limit any flyrock being thrown into the river.
- A detailed explosive management plan will be developed as part of the permitting process.

6.9.7.3 Haul Road, Fish and Fish Habitat Effects

In this section-potential Project effects to Fish and Fish Habitat VCs identified above by Project phase (Table 6.9-9) are further categorized as either as direct or indirect, for the Haul Road area.

Table 6.9-11 identifies direct and indirect effects of all fish-bearing aquatic habitats potentially impacted by Project development at the for the Project, including along the Haul Road.

A summary of potential direct and indirect effects carried forward for the effects assessment for the Haul Road is provided in Table 6.9-16 and Table 6.9-17. Construction of the Haul Road has the potential to directly affect fish habitat through upgrading the existing road, and through installation of watercourse crossings. These impacts will occur during the construction phase and are permanent. As a result, the commencement of effects and temporal extent of impacts are not repeated in Table 6.9-13. Predicted impacts to fish habitat includes all direct impact (i.e., loss of habitat to support mine infrastructure and haul road crossings), and all potential indirect impacts.

Table 6.9-16: Summary of Fish Resources Evaluated in the Effects Assessment: Haul Road

1Non-fish bearing, provincially regulated watercourses (identified in Section 6.9.3.3.1.1.2), and wetlands identified as being inaccessible to fish (described in Section 6.9.4.3.2.2) have been excluded from this table.

2 Includes impacts to fish habitat only. In wetlands, where impacts may be proposed in portions of the wetland which have been determined to be inaccessible to fish, the response in this table will be 'No impacts'; however impacts to the wetland habitat itself will be described in detail in Section 6.8.

6.9.7.3.1 Direct Effects

The Project is expected to result in direct impacts to fish and fish habitat through construction of the Haul Road and associated watercourse crossings (Table 6.9-16). A preliminary road design has been completed, with cut and fill lines, alignment and construction materials identified. The Haul Road will be two lanes, with single lane bridges, following the existing forestry road to the greatest extent possible. Corrugated steel pipe culverts are not the preferred option for watercourse crossings in Nova Scotia due to corrosion issues; so concrete culverts will be used in fish habitats, wherever bridges are not practicable. Corrugated steel pipe culverts may be used for general cross drainage outside of fish habitat. The conceptual Haul Road design is described in the Project Description (Section 2).

To address IR2 CEAA 2-06, all watercourses and wetlands along the Haul Road identified as potential fish habitat are considered fish habitat for the purposes of the direct impact estimates (wetlands with contiguous and/or open water areas). The methods used to describe watercourses and fish habitat along the Haul Road are provided in the 2015-2017 Baseline Report, which is appended to the 2019-2020 Baseline Report (Appendix J.2).

A total of 36 watercourses located at or near crossings and/or road expansion of the Haul Road. Three watercourse crossings are expected to impact wetland habitat accessible to fish as well (WCA and WL64, WCB and WL66, and WCAA which is associated with WL159 and WL160).

- Of the 29 watercourse crossings required, 22 have existing crossings. Seven will require new culvert installations (no impacts to fish passage expected).
- Of the 22 existing crossings, three bridges are present and will be replaced, with no impact to fish habitat and no improvement to fish passage.
- Of the 19 culvert crossings, five culverts are properly installed, and currently allow fish passage. Culvert replacements will continue to allow fish passage, with no improvement to fish passage.
- Of the remaining 14 culverts are all currently limiting fish passage, due to improper installation and/or maintenance (hung, crushed, blocked or buried). By upgrading culvert crossings at each of these locations, fish passage to upstream systems is expected to improve.

In addition to watercourse crossings, impacts to wetlands accessible to fish are proposed in three wetlands (aside from those associated with watercourse crossings listed above). These are wetlands WL73, WL149 and WL159. Fish habitat is present on both sides of the proposed Haul Road in WL73 and WL147, so installation of culverts is expected to provide fish passage where it is currently lacking. Fish habitat is only present on one side to he proposed Haul Road at WL154, so installation of a new culvert here is not expected to improve fish passage (as no fish resource exists on the upstream side of the Haul Road).

A summary of habitat suitability by species and life history stage for watercourses along the Haul Road is provided in Table 6.9-4. None of the proposed direct effects to fish habitat along the haul road are expected to occur in suitable habitat for Atlantic salmon.

As outlined in Table 6.9-17, eight wetlands that are expected or confirmed to support fish habitat will be partially altered within the Haul Road to support road upgrades, widening and re-alignment as required. Two wetlands are known to support fish (Wetland 159 and 160) based on direct connectivity with Watercourse WC-AA. The six remaining wetlands have been identified as potential fish habitat and have been conservatively included in the total direct impact to fish habitat and associated Offset Plan.

Additional wetlands that are expected to provide fish habitat that overlap with the proposed Haul Road re-alignment include Wetlands WL68, WL74, and WL157. However, potential fish habitat (contiguous surface water or open water features) within these wetlands are not located within the proposed Haul Road footprint and thus are not included in Table 6.9-16:

- **WL68:** Potential fish habitat restricted to an area adjacent to NSTDB mapped watercourse, located approximately 60 m east of road. Proposed Haul Road re-alignment overlaps approximately 2 m^2 of wetland edge habitat only, inaccessible to fish.
- **WL74:** Fish habitat potential in open water marsh habitat located east of exiting forestry road only – no overlap with proposed Haul Road re-alignment. The Haul Road footprint does overlap wetland lobe on western side of road, but fish habitat is confined to the throughflow, entrenched watercourse (WC-F) only. Direct impacts to fish habitat from the Haul Road are therefore only calculated for WC-F.
- **WL157:** Two lobes of wetland (north and south) separated by existing forestry road, both riparian to NSTDB mapped waterbodies. Fish habitat within wetland is confined to areas immediately adjacent to waterbodies – no fish habitat (contiguous surface water/open water features) associated with these wetlands is currently overlapped by the Haul Road footprint. Wetland habitat immediately adjacent to the existing forestry road is dry. No culvert/bridge currently exists between these two lobes. Proponent will consider installation of a culvert to re-establish natural wetland hydrology which may provide upstream/downstream fish access into NSTDB waterbodies.

Direct impacts to Wetlands WL68, WL74, and WL157 are discussed in Section 6.8. Impacts to wetlands which do not provide fish habitat (i.e., isolated wetlands, wetlands lacking surface water) are fully evaluated in Section 6.8. Fish habitat within wetlands was described in a conservatively inclusive manner. Since the Haul Road Study Area was relatively narrow and linear in nature; watercourses were not typically assessed beyond the PA to confirm connectivity; as a result, where open water or watercourses were observed, they were presumed to be accessible to fish.

All areas of wetland with confirmed or expected fish habitat (contiguous surface water and/or open water areas) overlapped by the Haul Road re-alignment cut and fill extent (maximum direct impact area of Haul Road) have been calculated using average width and length measurements recorded during qualitative habitat evaluation (i.e., width of watercourse x length of impacted watercourse = area of directly impacted waterbody). Haul Road impacts are provided in m^2, as requested in IR2 CEAA 2-20, and they include new culvert installations, and replacement of existing culverts to accommodate widening of the road. Impact areas were assessed on a case-by-case basis, considering the context of whether a crossing was new or existing, and considering the condition of existing culverts. In instances where a culvert was present but deemed based on condition to be impassable to fish, the upgraded culvert proposed was determined to be a net benefit to fish and fish habitat; these are identified in Table 6.9-16 below as improvements to fish passage, with no direct impact to fish habitat. While the improvement of fish passage is acknowledged; the benefits to fish related to access to new habitats have not been quantified or considered in the Fish Habitat Offset Plan (Appendix J.3). This impact area also includes an allowance for a multi-use bypass road, which has been added to the Project Description. All expected direct impacts to fish and fish habitat from the Haul Road and bypass road are shown on Figure J.4-6 (Appendix J.4).

Some wetlands that are expected to provide fish habitat have been excluded from direct impact calculations based on the Haul Road re-alignment where the road will not impact portions of wetlands accessible to fish. For example, WL169 is contiguous with John's Pond; but proposed impacts to this wetland are in a portion of the wetland inaccessible to fish; meaning that portion of the wetland lacks standing water at any time of the year (in this example, the impact is proposed on the south side of the existing forestry road with no hydrologic connectivity between that portion of the wetland and John's Pond. A similar situation would involve impacts to a portion of a wetland complex which lacks standing water at all times of the year, such as a treed swamp component of a wetland complex). In other examples, the presence of the existing forestry road has resulted in a backup of water on one side of the road. In these situations (i.e., Wetlands WL64 and WL66), the wetland boundaries and flooded waters accessible to fish are

different sizes on each side of the existing road, based on installation of inadequate drainage structures at the time of road construction. In these situations, wetland impacts, and impacts to fish habitat in those wetlands, will not be consistent on each side of the road. Wetlands that were assessed as isolated with no surface water connectivity to fish-bearing systems and/or open water features are considered non-fish bearing and do not provide fish habitat (i.e., WL89). In addition, wetlands with throughflow watercourses are not discussed further if fish habitat was determined to the be confined to the watercourse channel (entrenched), and not provided within the wetland itself (i.e., WL74 is contiguous with WCF, which is highly entrenched. Impact to fish habitat here is described in relation to WCF, not WL74) (IR2 CEAA 2-20).

The proposed cut and fill line for the upgraded haul road and a multi-use bypass road was used to calculate impact areas to fish habitat. Inconsistencies in direct impact areas on each side of the Haul Road, as displayed on Figure J.4-6 of Appendix J.4, should be expected. Wetlands/fish habitat areas (m^2) that overlap the Haul Road re-alignment are based on wetland habitat on either side of the road, with any irregular buffering of impact occurring based on cut and fill extents and local topographic relief (IR2 CEAA-2-20).

Expected direct impacts to fish and fish habitat that may result in a habitat alteration from the Haul Road and bypass road are presented in Table 6.9-17. The Preferred Alternative Haul Road has been removed from the Project Description (IR2s CEAA 2-21, CEAA-2-22, NSE-2-48).

Table 6.9-17: Potential Direct Fish Habitat Impacts within the Haul Road

Watercourse Location	Current Crossing (Condition)	Plan for Upgraded Haul Road*	Direct Footprint Impact (m^2)	Impact to Fish Passage
WC-1	Culvert (functioning)	Proposed upgraded road alignment perpendicular to WC. Extend existing culvert, following standard mitigation measures.	0	None
WC-A	Culvert (buried)	Proposed upgraded road alignment perpendicular to WC. Replace buried culvert. Standard mitigation will apply to limit impact to fish habitat and overall improve fish habitat through removal of buried culvert.	0	Improvement
WC-B	Culvert (crushed)	Proposed upgraded road alignment perpendicular to WC. Replace crushed culvert. Standard mitigation will apply to limit impact to fish habitat and overall improve fish habitat through removal of crushed culvert.	0	Improvement
WC-C	Culvert (functioning)	Proposed upgraded road alignment perpendicular to WC on eastern side of road. Replace functioning culvert. On western side of road, alignment expected to have direct impact on WC through ditching. Standard mitigation will apply to limit impact to fish habitat.	7.4	None
WC-D	None	Proposed upgraded road alignment perpendicular to WC. Install new culvert at crossing location. Standard mitigation will apply to limit impact to fish habitat.	10.5	None – no mapped aquatic feature upstream of road

Table 6.9-17: Potential Direct Fish Habitat Impacts within the Haul Road (continued)

Watercourse Location	Current Crossing (Condition)	Plan for Upgraded Haul Road*	Direct Footprint Impact (m^2)	Impact to Fish Passage
WC-E	Culvert (blocked)	Proposed upgraded road alignment perpendicular to WC, east of existing road. Remove blocked culvert on existing road and install new culvert downstream at new crossing location. Standard mitigation will apply to limit impact to fish habitat and overall improve fish habitat through removal of blocked culvert.	0	Removal of old buried culvert: Improvement New culvert: None
WC-F	Culvert (crushed)	Proposed upgraded road alignment perpendicular to WC, west of existing road. Remove blocked culvert on existing road and install new culvert downstream at new crossing location. Standard mitigation will apply to limit impact to fish habitat and overall improve fish habitat through removal of crushed culvert.	0	Removal of old crushed culvert: Improvement New culvert: None
WC-G	Culvert (crushed)	Proposed upgraded road alignment perpendicular to WC. Replace crushed culvert. Standard mitigation will apply to limit impact to fish habitat and overall improve fish habitat through replacement of crushed culvert.	0	Improvement
WC-H	Bridge (functioning)	Proposed upgraded road alignment perpendicular to WC. Existing bridge to be expanded to facilitate multi-use bypass road, and parallel new bridge for Haul Road. Standard mitigation will apply to limit impact to fish habitat.	0	None
WC-I	Culvert (buried)	Proposed upgraded road alignment perpendicular to WC. Replace buried culvert. Standard mitigation will apply to limit impact to fish habitat.	0	None – no mapped aquatic feature upstream of road
WC-J	Culvert (buried)	Proposed upgraded road alignment perpendicular to WC on eastern side of road. Replace buried culvert. On western side of existing road, alignment overlaps approximately 19 m of parallel stream that flows into western ditch. Proposed road upgrade will funnel the WC directly across the road to the eastern side and away from the ditch network associated with the road. Standard mitigation will apply to limit impact to fish habitat.	21.6	Improvement
WC-K	Culvert (buried)	Proposed upgraded road alignment perpendicular to WC. Install new culvert. Replace buried culvert. Standard mitigation will apply to limit impact to fish habitat and overall improve fish habitat through installation of culvert.	0	Improvement

Table 6.9-17: Potential Direct Fish Habitat Impacts within the Haul Road (continued)

Watercourse Location	Current Crossing (Condition)	Plan for Upgraded Haul Road*	Direct Footprint Impact (m^2)	Impact to Fish Passage
WC-L	Culvert (functioning)	WC runs parallel to current road in western roadside ditch. Proposed road upgrade will require the functioning culvert to be replaced to funnel the WC directly across the road to the eastern side and away from ditch network associated with the road. Proposed road alignment overlaps approximately 53 m of parallel ditched stream. Standard mitigation will apply to limit impact to fish habitat.	15.9	None
WC-M	Culvert (functioning, North), None (South)	Proposed upgraded road alignment is perpendicular to WC at two locations (north and south). Northern crossing will require an extension to existing culvert which is functioning. Southern crossing will require installation of a new culvert. Standard mitigation will apply to limit impact to fish habitat.	10.9	None – no aquatic features mapped upstream of southern crossing
WC-N- West River	Bridge (functioning)	Proposed upgraded road alignment perpendicular to WC. Existing bridge to be expanded to facilitate multi-use bypass road, and parallel new bridge for Haul Road. Standard mitigation will apply to limit impact to fish habitat.	0	None
WC-O	None	Proposed new road designed perpendicular to WC. Requires culvert installation. Standard mitigation will apply to limit impact to fish habitat.	29.3	None
WC-P	None	Proposed new road designed perpendicular to WC. Requires culvert installation. Standard mitigation will apply to limit impact to fish habitat.	10.2	None
WC-T	Culvert (buried)	Proposed upgraded road alignment perpendicular to WC. Replace buried culvert. Standard mitigation will apply to limit impact to fish habitat and overall improve fish habitat through removal of buried culvert.	0	Improvement
WC-U	Culvert (functioning)	Proposed upgraded road alignment perpendicular to WC. Replace functioning culvert. Standard mitigation will apply to limit impact to fish habitat.	0	None
WC-V	Culvert (buried)	Proposed upgraded road alignment perpendicular to WC. Replace buried culvert. Standard mitigation will apply to limit impact to fish habitat and overall improve fish habitat through removal of buried culvert.	0	Improvement
WC-W	Culvert (hung)	Proposed upgraded road alignment perpendicular to WC. Replace hung culvert. Standard mitigation will apply to limit impact to fish habitat and overall improve fish habitat through replacement of hung culvert.	0	Improvement

Table 6.9-17: Potential Direct Fish Habitat Impacts within the Haul Road (continued)

Watercourse Location	Current Crossing (Condition)	Plan for Upgraded Haul Road*	Direct Footprint Impact (m^2)	Impact to Fish Passage
WC-X	None	Proposed upgraded road alignment is perpendicular to WC and will require a new culvert installation. Standard mitigation will apply to limit impact to fish habitat and overall improve fish habitat through providing fish access to upstream aquatic resources.	12.1	Improvement
WC-Y	Culvert (buried)	Proposed upgraded road alignment is perpendicular to WC. Replace buried culvert. Standard mitigation will apply to limit impact to fish habitat and overall improve fish habitat through replacement of buried culvert.	0	Improvement
WC-AA	Culvert (hung)	Proposed upgraded road alignment perpendicular to WC. Replace hung culvert. Standard mitigation will apply to limit impact to fish habitat and overall improve fish habitat through removal of hung culvert.	0	Improvement
WC-AC	None	Proposed upgraded road alignment overlaps with the top end of this watercourse (3.7 m). This area may be altered to support road upgrades. Standard mitigation will apply to limit impact to fish habitat.	8.3	None
WC-AD-Morgan River	Bridge (functioning)	Proposed upgraded road alignment perpendicular to WC. Existing bridge to be expanded to facilitate multi-use bypass road, and parallel new bridge for Haul Road. Standard mitigation will apply to limit impact to fish habitat.	0	None
WC-AE	Culvert (buried)	Proposed upgraded road alignment perpendicular to WC. Replace buried culvert. Standard mitigation will apply to limit impact to fish habitat and overall improve fish habitat through replacement of buried culvert.	0	Improvement
WC-AF	None	Proposed upgraded road alignment overlaps with the bottom end of this watercourse (40.2 m), at which point the watercourse currently empties into the southern ditch along the existing road. Current ditch drains east towards culvert at WC-AE. Proponent will consider installation of a culvert to funnel the watercourse directly across the road north towards WC-AH, away from the ditch network associated with the road. Standard mitigation will apply to limit impact to fish habitat.	46.3	Improvement
WC-AG	None	Proposed upgraded road alignment overlaps with the bottom end of this watercourse (18.4 m), at which point the watercourse currently empties into the southern ditch along the existing road. Current ditch drains east towards culvert at WC-AE. Proponent will consider installation of a culvert to funnel the watercourse directly across the road north towards WC-AH, away from the ditch network associated with the road. Standard mitigation will apply to limit impact to fish habitat.	12.0	Improvement

Table 6.9-17: Potential Direct Fish Habitat Impacts within the Haul Road (continued)

Watercourse Location	Current Crossing (Condition)	Plan for Upgraded Haul Road*	Direct Footprint Impact (m^2)	Impact to Fish Passage
WL64	Culvert (buried) – see WC-A	Buried culvert associated with WC-A located at wetland crossing. Proposed upgraded road alignment overlaps surface water features (presumed fish habitat) both sides of road. Replacement of buried culvert likely to improve fish access into wetland.	48.7	Improvement
WL66	Culvert (crushed) at northern crossing – see WC-B, None at southern crossing	Proposed upgraded road alignment overlaps wetland complex at two locations – a northern crossing (associated with WC-B) and a southern crossing. At northern crossing, proposed upgraded road alignment overlaps surface water features (presumed fish habitat) on both sides of road. Replacement of crushed culvert on WC-B likely to improve fish access into wetland. No culvert/bridge currently exists at southern crossing. Proposed upgraded road alignment overlaps surface water features (presumed fish habitat) on west side of road. Proponent will consider installation of a culvert to re-establish natural wetland hydrology which may provide fish access into previously inaccessible fish habitat.	487.0	Improvement
WL73	None	No culvert is present at current wetland crossing. Proposed upgraded road alignment overlaps surface water features (presumed fish habitat) currently exist on both sides of road, likely caused by road impoundment. Proponent will consider installation of a culvert to re-establish natural wetland hydrology which may provide fish access into previously inaccessible fish habitat.	185.2	Improvement
WL76	Culvert (crushed) – see WC-G	Crushed culvert associated with WC-G located at wetland crossing. Proposed upgraded road alignment overlaps surface water features (presumed fish habitat) both sides of road. Replacement of crushed culvert likely to improve fish access into wetland.	398.6	Improvement
WL146	None	No culvert is present at wetland crossing. Proposed upgraded road alignment overlaps surface water feature (presumed fish habitat) on both sides of road – extensive flooding on west side likely caused by road impoundment. Proponent will consider installation of a culvert to re-establish natural wetland hydrology which may provide fish access into previously inaccessible fish habitat from WC-Z.	106.4	Improvement

Table 6.9-17: Potential Direct Fish Habitat Impacts within the Haul Road (continued)

Watercourse Location	Current Crossing (Condition)	Plan for Upgraded Haul Road*	Direct Footprint Impact (m^2)	Impact to Fish Passage
WL154	None	Headwater wetland confined to west side of road. Proposed upgraded road alignment overlaps surface water feature (presumed fish habitat). No culvert proposed.	176.9	None
WL159	Culvert (hung) – see WC-AA	Hung culvert associated with WC-AA located at wetland crossing. Proposed upgraded road alignment overlaps surface water feature (confirmed fish habitat). Replacement of hung culvert likely to improve fish access upstream to WL160.	6.5	Improvement
WL160	Culvert (hung) – see WC-AA	Hung culvert associated with WC-AA located at wetland crossing. Proposed upgraded road alignment overlaps surface water feature (confirmed fish habitat). Flooding observed in wetland likely caused by improper culvert sizing. Replacement of crushed culvert likely to improve fish access and re-establish natural wetland hydrology.	836.5	Improvement
Total			**2,430.3**	

* For all reaches requiring fish rescue prior to culvert installation, fish will be released within the same watercourse or waterbody, typically in an area downstream of the proposed impact unless site conditions necessitate otherwise.

6.9.7.3.2 Indirect Effects

Sedimentation/Erosion as well as mortality from blasting represent the primary pathways of potential indirect effects to Fish and Fish Habitat VC along the Haul Road. These are discussed in the following sections.

Total Suspended Solids (TSS)

Surface disturbance during Project activities has the potential to increase sedimentation and erosion of soils and overburden materials. As described above for the Beaver Dam Mine Site, potential effects on surface water quality from increased erosion and sedimentation are qualitatively assessed; erosion and sedimentation effects on surface water quality can be indicated primarily by changes in turbidity and total suspended solids (TSS) in surface waterbodies. However, for the Project there is generally minimal risk of effects from erosion and sedimentation on surface water quality due to the limited extent of planned surface disturbances and the proposed use of pre-existing infrastructure such as roads, camp, and the processing facility.

To avoid indirect effects to fish habitat due to construction of the Haul Road, the sub-base will be constructed with 600 mm thick Type 2 (sub-50 mm crushed material), rather than fill available from on-site construction. This sub-base will likely need to be imported from a commercial quarry to meet the specification and drainage requirements, and to minimize potential for sedimentation by purchasing washed stone. The road base will be constructed from a wearing course, quantified as a 200 mm thick Type 11 (sub-25 mm crushed stone). Similar to the sub-base, this will be sourced from a commercial quarry to ensure the rock is clean, and the potential for sedimentation is reduced.

All culverts will be installed in accordance with NSE and DFO regulations and approvals. Careful selection of construction material, and strict adherence to the Erosion and Sediment Control Plan and approval conditions will minimise the potential for indirect impacts to watercourses through construction and operation of the Haul Road.

At the Haul Road, potential effects from sedimentation and erosion are most likely to occur during the Construction and (active) Closure phases, when surface materials will likely be disturbed during construction or reclamation activities. As TSS loads are generally low in Project area streams, any additional sediment loading has the potential to increase TSS and turbidity in the receiving environment. Potential effects due to sedimentation and erosion have the greatest potential to occur during periods of significant overland flow, such as freshet and rainfall events. However, planned disturbances in the Project Area are limited, and implementation of BMPs and mitigation measures as summarized in Section 6.7.9 and detailed in Environmental Management and Monitoring Plans will prevent substantial change of surface water quality near the proposed access corridor and other planned site upgrades. Further, water quality responses to run-off include increased concentrations of TSS but tend to be temporary and localized (Forman 1998). As such, all potential indirect effects to fish habitat through construction of the Haul Road are expected to be negligible, as AMNS commits to adhering to the site-specific draft Erosion and Sediment Control Plan (Appendix C of Appendix P.4 Mine Water Management Plan). The clear, porous sub-grade identified above will support natural cross-drainage, supplemented by drainage culverts and watercourse culverts wherever necessary. Where required, fish rescues will be completed in advance of culvert installation to reduce the likelihood of death of fish by means other than fishing. As such, no residual indirect effects are expected following mitigation of impacts along the Haul Road.

The likelihood of indirect hydrological alteration to fish habitat along the Haul Road is low and these potential impacts have not been included in quantitative evaluation of impacts from the Project. With appropriate mitigation measures in place, the Project will not indirectly affect fish and fish habitat along the Haul Road

6.9.7.4 Indirect Effects to Adjacent Streams

As described in Section 6.9.7.3.2, development of the Project may result in indirect effects to downstream receiving environments. Project infrastructure has been designed to minimize direct impacts to fish to the greatest extent practicable, and revisions to mine water management has allowed AMNS to update the Water Balance Analysis across the site and reduce impacts to key fisheries resources including the system from Crusher Lake to Mud Lake, compared with that presented in the 2019 EIS. The Water Balance Analysis is provided in Appendix A of Appendix P.4 (Mine Water Management Plan) and the Project effects for the monthly flows are described in Section 6.7.8. To fully evaluate the effect to fish and fish habitat, surface runoff and baseflow were generated using a conceptual hydrologic model in GoldSim which runs on a daily time step. The effect of the Project on daily instantaneous flows is further evaluated here for WC5, 23, 26, and 27 based on the results of screening (Section 6.9.7.2.2.1). These systems were selected for further evaluation because the surface water modelling results indicated that either the monthly average flows are predicted to change by more than 10%, and/or there is a predicted >10% increase in the number of days where flow drops below the 30% MAD.

This analysis of these four systems includes effects assessment relating to the predicted flow reductions and any associated changes in quality of the fish habitat because of the predicted changes within the stream systems (WC5, WC23, WC26, WC27) and the associated waterbodies (Crusher Lake and Mud Lake). This section also describes any indirect impacts to fish and fish habitat along the Haul Road from the construction of the road and associated watercourse crossings. Finally, this section provides analysis of groundwater seepage predictions which may affect fish and fish habitat outside of Cameron Flowage/Killag River, which has already been addressed through the predictive surface water modelling and associated evaluated of fish and fish habitat in Cameron Flowage/Killag River in Section 6.9.7.2.2.

A total of 15 transects were completed using the WPM to model estimates of flow at each habitat transect to quantify potential habitat alterations due to flow reductions. Appendix J.4, Figure J.4-2 provides the location of each transect within the Project area that were selected during 2019-2020 Baseline surveys. Each transect represents a portion of its respective watercourse near the transect survey location. The potential habitat alterations within watercourses determined to have flow reductions with a moderate

probability of detectable impacts has been quantified as the area below the 30% MAD and is approximately 7,728.88 m^2 . The entire habitat area below 30% MAD was identified to account for the uncertainty associated with the complex interactions between stream low flow, depth and physicochemical parameters such as temperature and dissolved oxygen. Although the entire area below 30% MAD has been quantified as potentially altered, the final determination of how much area is deemed as harmfully altered will need to be determined by DFO during the fisheries authorization process. As shown by the limited aerial reduction in habitat within each watercourse, the habitat's capacity to support one or more life processes is not likely to be significantly impacted, The flow reductions represent a partial and mostly reversible alteration and not a loss to the entire stream habitat.

6.9.7.4.1 WC5

Estimates of daily flows within WC5 are predicted to decrease by 4.7% of MAD flow. This flow reduction is of moderate magnitude; however, a more detailed evaluation of daily flows indicates that this represents a 12.2% increase in the number of days where flow remains below the 30% MAD. The Project is anticipated to exacerbate the natural low flow period by extending it from 113 days per year below 30% MAD at baseline to 129 days below 30% MAD at EOM (Tables 6.9-18 and 6.9-19). During PC, the predicted number of low flow days decreases to 115, which is only a 1.8% increase in number of days below 30% mad (representing a low magnitude of change). Using the WPM to calculate loss of habitat due to flow reduction, WC5 is predicted to have aerial reduction of 17.40 m^2 during EOM, and only 4.26 m^2 at PC; however, as discussed above the total potentially altered habitat was quantified as the entire 30% MAD wetted width or 1,700.19 m^2. Based on the limited magnitude, duration and spatial extent of flow reduction, it is expected that the remaining habitat within WC5 will maintain capacity to support life history phases of fish (e.g., remaining habitat quantity, temperature regime).

Crusher Lake is part of the Mud Lake catchment; and WC5 is the main inlet and outlet to Crusher Lake. Impacts to Crusher Lake have been modelled with consideration of changes in baseflow, and changes in daily and monthly flows. During operations, water will be extracted from Crusher lake at a rate of 3 m^3/hr to support domestic and truck wash water demands. The mine impacts to lake water levels were assessed by converting instantaneous (average daily) flow rates to the historical record to flow depths within WC5 upstream assessment point using Manning's equation (Table 6.9-20). The change in flow depths at the lake outlet assessment points were then used to estimate the change in water levels. Flow depths were computed for various flow statistics and compared between the mine development stages. These results show that the water levels within Crusher Lake are not anticipated to change as a result of the Project. Details of this analysis are presented in the Water Balance Analysis (Appendix A of Appendix P.4 Mine Water Management Plan).

Table 6.9-18: Summary of End-of-Mine (EOM) Wetted Perimeter Analysis using Modelled Daily Flows

Stream ID	Represented Habitat Length (m)	MAD			30% MAD		Modelled Flow Alteration at EOM				
		m^3/s	Existing Habitat Area (m^2)	Days <30% MAD	m^3/s	Existing Habitat Area (m^2)	(% MAD)	(m^3/s)	Habitat Area Change at 30% MAD (m^2)	Days <30% MAD	Increase Days <30% (%)
WC-23	1053	0.054	4487.64	115	0.016	3541.36	-17.4	0.045	161.53	132	+14.8

WC-5	832	0.025	2075.04	113	0.007	1700.19	-4.7	0.023	17.40	129	+12.2
WC-27	228	0.070	1146.74	112	0.021	932.83	-18.5	0.058	37.54	136	+21.4
Total Habitat Alteration (m^2)			**9636.47**			**7,728.88**			**322.41**[1]		

Notes: EOM represents habitat change over moderate duration (until End of Mine), average flow year.

Positive flow alteration in Cameron Flowage therefore habitat losses not applicable

Through discussion with DFO the entire area below 30% MAD is considered potentially altered due to uncertainty associated with extreme low flow and physicochemical habitat parameters. The amount of this habitat considered harmfully altered with be determined with DFO during the fisheries authorization process.

1 EOM has greater habitat loss than PC scenario. Values represent aerial reduction in 30% MAD area due to flow reductions.

Table 6.9-19: Summary of Post-Closure (PC) Wetted Perimeter Analysis using Modelled Daily Flows

Stream ID	Represented Habitat Length (m)	MAD			30% MAD		Modelled Flow Alteration at PC				
		m^3/s	Existing Habitat Area (m^2)	Days <30% MAD	m^3/s	Existing Habitat Area (m^2)	(% MAD)	(m^3/s)	Habitat Area Change at 30% MAD (m^2)	Days <30% MAD	Increase Days <30% (%)
WC-23	1053	0.054	4487.64	115	0.016	3541.36	-17.4	0.045	161.53	132	+14.8
WC-26	805	0.023	1927.05	115	0.007	1554.50	-19.6	0.019	48.54	133	+15.7
WC-5	832	0.016	2075.04	113	0.005	1700.19	-1.2	0.024	4.26	115	+1.8
WC-27	228	0.070	1146.74	112	0.021	932.83	-13.7	0.061	27.39	128	+14.3

Notes: PC represents habitat change over long duration (after all influence of mine operations and closure), average flow year.

Positive flow alteration in Cameron Flowage therefore habitat losses not applicable

1 EOM has greater habitat loss than PC scenario

Table 6.9-20: Flow Depth Comparison at the WC-5 Assessment Point (Crusher Lake)

Flow Depth Statistic	Flow Depth (m)		
	Baseline Conditions	EOM Conditions	PC Conditions
Minimum	0.00	0.00	0.00
10th Percentile	0.04	0.00	0.04
25th Percentile	0.04	0.00	0.04
50th Percentile	0.06	0.06	0.06
75th Percentile	0.10	0.09	0.10
90th Percentile	0.14	0.14	0.14
Maximum	0.43	0.43	0.43
Mean	0.11	0.11	0.11

6.9.7.4.2 WC23

Estimates of daily flows within WC23 were determined to decrease by 17.4% of MAD flow during EOM and PC scenarios, and a 14.8% increase in number of days where daily flow drops below the 30% MAD (Tables 6.9-18 and 6.9-19). This translates to an increase in number of days below 30% MAD flow from 115 days per year at baseline conditions, to 132 days per year at EOM and PC phases. This change in flow is expected to extend the duration of the low flow period by a total of 17 days. As a result of predicted monthly and daily flow reductions, the magnitude of this effect is determined to be high. This effect limits the ability of the habitat to sustain one or more life processes, and as a result, the habitat loss is quantified and included in the draft Fish Habitat Offset Plan (Appendix J.3).

Using the WPM to calculate loss of habitat due to flow reduction, this results in an aerial reduction below 30% MAD of 161.53 m^2 but a potential habitat alteration to the entire 30% MAD area of 3,541.36 m^2. As shown in Tables 6.9-18 and 6.9-19, the flow reduction in WC23 results in a low magnitude of effect to Cope Brook, considering both monthly and daily flows (i.e., change is below the detection limit of 10%). Based on the limited magnitude and spatial extent of flow reduction, it is expected that the remaining habitat within WC23 will maintain life history phases of fish.

6.9.7.4.3 WC26

Estimates of daily flows within WC26 were determined to decrease by 25% of MAD flow during EOM, and 19.6% at PC, representing a high magnitude of change in flow. The daily flow alteration assessment indicates that this would result in a chance from 115 days below the 30% MAD flow in baseline to 144 days and 144 days below MAD flow in EOM and PC, respectively, representing a 25.2% and 15.7% increase in the number of days below 30% MAD flow

Using the WPM to calculate loss of habitat due to flow reduction, WC26 is predicted to have an aerial reduction below 30% MAD of 105.4 m^2 during EOM and decreases during PC to 48.54 m^2. However as discussed above, a larger area associated with the entire 30% MAD has been identified as potentially altered, and is quantified as 1,554.50 m^2. Based on the limited magnitude and spatial extent of flow reduction, it is expected that the remaining habitat within WC26 will maintain capacity to support life history phases of fish.

6.9.7.4.4 WC27

Estimates of daily flows within WC27 were determined to decrease by 18.5% of the MAD at EOM, and 13.7% at PC. The predicted number of days which experience a decrease below 30% MAD is expected to increase from 115 at baseline to 132 days at EOM, and 128 days at PC. This represents a 21.4% increase in the number of low flow days at EOM, and a 14.3% increase in the number of low flow days at PC (Tables 6.9-18 and 6.9-19). The downstream effects to the Killag River are expected to be low in magnitude, with <10% change in MAD flow and a less than 10% increase in the number of days below 30% MAD. Using the WPM to calculate of the aerial extent of habitat change due to flow reduction, WC27 is predicted to have a 30% MAD area reduction of 37.54 m^2 during EOM, and only 4.26 m^2 at PC. However, again recognizing that an uncertainty remains in the low flow habitat conditions during extreme low flow, we have quantified the entire area below 30% MAD (932.83 m^2) as potentially altered. Based on the limited magnitude, duration and spatial extent of flow reduction, it is expected that the remaining habitat within WC5 will maintain capacity to support life history phases of fish.

In both development stages, the percent change in total inflow is less than the percent changes in surface runoff and baseflow, because the Crusher Lake discharge is included in the total inflow volume, and the Crusher Lake discharge is less impacted by Site development.

Although the results show there is a reduction in total inflow, and correspondingly, lake discharge under EOM and PC conditions, the lake water levels are not anticipated to drop below the invert of the outlet channel during EOM and PC conditions on a monthly basis (i.e., the outlet channel should never run dry). This is because the monthly lake inputs, including direct precipitation, Crusher Lake discharge through WC5, surface runoff, and baseflow exceed the monthly losses by evaporation. As a result, the lake will continue to discharge to WC27. However, water levels in the outlet channel, and therefore the lake, are anticipated to drop marginally compared to baseline conditions as described in Table 6.9-21.

Table 6.9-21: Flow Depth Comparison at the WC27 Upstream Assessment Point (Mud Lake)

Flow Depth Statistic	Flow Depth (m)		
	Baseline Conditions	EOM Conditions	PC Conditions
Minimum	0.00	0.00	0.00
10th Percentile	0.07	0.05	0.06
25th Percentile	0.10	0.09	0.09
50th Percentile	0.16	0.15	0.15
75th Percentile	0.24	0.22	0.22
90th Percentile	0.32	0.28	0.29
Maximum	0.59	0.54	0.55
Mean	0.20	0.18	0.19

The Mine impacts to lake water levels were assessed by converting instantaneous (average daily) flow rates to the historical record to flow depths within WC27 upstream assessment point using Manning's equation (Table 6.9-21). The change in flow depths at the lake outlet assessment points were then used to estimate the change in water levels. Flow depths were computed for various flow statistics and compared between the mine development stages. These results show that the water levels within Mud Lake are predicted to change by a maximum of 0.05 m as a result of the Project. This represents a maximum potential water level change

of less than 10% of the natural baseline modeled range. Details of this analysis are presented in the Water Balance Analysis (Appendix A of Appendix P.4 Mine Water Management Plan).

6.9.7.5 Summary of Direct Effects to Fish and Fish Habitat

The Fish and Fish Habitat Protection Policy (DFO 2019) outlines the prohibitions under the *Fisheries Act* related to the death of fish by means other than fishing, and to the harmful alteration, disruption and destruction of fish habitat. Through various Project revisions, AMNS has been able to reduce the direct loss of fish habitat to the extent practicable. The measures taken to avoid impacts to fish habitat are outlined in greater detail in Section 6.9.8.

Death of fish is expected to be low, once mitigation measures are implemented, including development and implementation of a fish rescue plan prior to commencement of construction activities in confirmed fish habitat. Mortalities are not expected, except through incidental mortalities associated with fish rescue activities. Details associated with the fish rescue approach are provided in Section 6.9.8.2.2. Recent and past experience suggests that mortality of fish during fish rescues is typically in the range of 1 to 3%. Furthermore, AMNS commits to adhering to approved timing windows for construction to minimize impact to eggs, larvae, and juvenile fish, wherever practicable.

Direct alteration within the Beaver Dam Mine Site is restricted to small first and second order streams and open water wetlands, which lack suitable habitat for Atlantic salmon. Road crossings to be constructed along the Haul Road will follow all avoidance, minimization and standard mitigations to reduce direct impacts to fish and fish habitat and limited direct impact. There is no expectation of change to the composition of populations of fish from direct loss and alteration of fish habitat. Furthermore, the larger waterbodies present within the Beaver Dam Mine Site (Mud Lake, Crusher Lake) will be avoided during Project development, limiting impact to fish populations present in these relatively larger systems.

Road crossings to be constructed along the Haul Road will follow all avoidance, minimization and standard mitigations to reduce direct impacts to fish and fish habitat and limited direct impact. There is no expectation of change to the composition of populations of fish from direct loss and alteration of fish habitat. Furthermore, the larger waterbodies present within the Beaver Dam Mine Site (Mud Lake, Crusher Lake) will be avoided during Project development, limiting impact to fish populations present in these relatively larger systems.

6.9.7.6 Summary of Indirect Effects to Fish and Fish Habitat

The assessment of Surface Water Quality results indicated that, while concentrations for some parameters are anticipated to increase above baseline levels, at the near-field mixing zone there are no exceedances of either CCME, NSE Tier 1 criteria. As water quality criteria are defined by national and international entities as protective of the receiving environment and all water users, there are no anticipated effects to surface waters are a result of discharges from the Project. Further note that a treatment system will be designed to ensure that all site effluent water meets MDMER and will reflect assimilation capacity of the receiving environment, such that any potential effects from nitrite to Fish and Fish Habitat, will be fully mitigated (Section 6.7.8).

Based on reduced flow comparisons to DFO framework for ecological flow, it was determined that reductions in four watercourses would have a moderate probability of detectable impacts to ecosystems that support fisheries. Flow reduction is anticipated due to drainage area and/or baseflow reductions in Crusher Lake Outflow (WC5), South Tributary (WC23), West Tributary (WC26), and Mud Lake Outflow (WC27). Although the actual area of reduced wetted channel due to the flow reductions is quantified at 322.41 m^2 we have quantified a much larger area as potentially altered. Through discussion with DFO the entire area below 30% MAD (approximately 7,728.88 m^2) is considered potentially altered due to uncertainty associated with extreme low flow and physicochemical habitat parameters. The amount of this habitat considered harmfully altered with be determined with DFO during

the fisheries authorization process and is expected to be reduced or require less offsetting given that the habitats are expected to maintain the ability to support the existing fish communities.

These areas of flow reduction will be included in the site monitoring plans (AEMP) to verify the predictions and confirm that the systems continue to support the existing fish populations. Water quality predictions, and associated ecotoxicity evaluation, during both operations and closure phases conclude low ecological risk (including fish) in the receiving environment (Cameron Flowage). Figure 6.9-5 and Table 6.9-22 shows a summary of fish habitat impacts by type (direct and indirect).

Table 6.9-22: Summary of Potential Habitat Alterations and Mitigations for Beaver Dam Project

Habitat Measure	Project Area	Habitat Type	Habitat Units (m^2)	Habitat / Condition Description
Habitat that may be Altered, Disrupted or Destructed	Infrastructure Footprint Direct Habitat Descruction	Mine Site Streams	652.80	Riffle, pool, rapid, and run habitats dominated by intermittent reaches, heavy vegetation, and high summer water temperatures and low dissolved oxygen levels.
		Mine Site Open Water	38,790.64	Waterbodies dominated by muck/detritus substrates, most formerly disturbed by historic mining activities.
		Haul Road Stream	184.50	Small streams
		Haul Road Open Water	2,245.80	Small open water within wetlands
	Indirect Downstream Potential Alteration	Mine Site Streams	7,728.88	Pool and run habitat with varying substrates and cover. Water quality ranging from low to suitable. Some high water in summer and low pH but overall better condition than those in direct footprint.
		Open Water	-	n/a
Total			**49,602.62**	
Mitigation	Regained Habitat Connectivity	Stream	-	17 locations along haul road have unpassable culverts. Replacment will mitigate habitat fragmentation but has not been quantified.
	Groundwater Upwelling Station	Stream	3,300.00	If groundwater upwelling location idenfied in Cameron Flowage, groundwater pump or modification to the North Pond outflow will be installed. **Note:** This is not considered offseting.
Total			**3,300.00**	

6.9.7.7 Fish and Fish Habitat Effects: Touquoy Mine Site

The Touquoy Mine Site is currently operational. The use of the Touquoy Mine Site for the processing of Beaver Dam Mine ore and tailings management (exhausted pit) will not involve modification to the current footprint or further impacts to fish and fish habitat. The exhausted pit has the capacity to store all mine tailings until scheduled release post-closure. Moving the existing tailings pipeline from the permitted Tailings Management Facility (TMF) to direct water to the exhausted pit will occur within the disturbed footprint of the permitted Touquoy Project and will not result in additional impacts to fish and fish habitat.

Potential impacts to surface water quality and quantity as a result of the storage of Beaver Dam tailings in the exhausted Touquoy open pit mine were examined. The Touquoy Mine Site open pit will naturally fill which will result in water covering the tailings surface. Pit water will be treated via the existing Touquoy effluent treatment plant and downstream treatment discharge facilities

and once the water meets MDMER discharge criteria it will be naturally released via a spillway into Moose River (Appendix F.8 Project Assimilative Capacity Study of Moose River – Touquoy Pit Discharge).

The use of the exhausted Touquoy pit for tailings storages will result in the accelerated filling of the pit from that of the Touquoy reclamation plan.

- Tailings will be deposited in the open pit for approximately 41 months. The spillway and conveyance channel are designed to accommodate the inflow design flood in accordance with the Canadian Dam Association (CDA) guidelines. The spillway invert is set at elevation 108 m relative to the Canadian Geodetic Vertical Datum of 2013 (CGVD2013), approximately 2 m below the lowest Touquoy pit elevation to prevent overtopping. The final water cover over the deposited tailings will limit oxygen availability, reduce metal leaching conditions and further improved water quality. A spillway at the top of the open pit will be constructed to divert water a closure (Appendix F.8 Project Assimilative Capacity Study of Moose River – Touquoy Pit Discharge).
- No water will be discharged from the exhausted Touquoy open pit until the pit reaches the final spillway elevation, which is estimated to be in Year 13.
- Water withdrawal from Scraggy Lake may be required for processing Beaver Dam Mine ore at start-up however the intent is to use recycle water from the pit and the site for processing.

The use of the exhausted Touquoy pit for tailings storage of Beaver Dam tailings may affect the receiving environment of Moose River through seepage and effluent discharge. Water within the pit lake will not be discharged until it meets the WQOs (CCME 2003 and NSEQS 2010) and MDMER (Schedule 4) limits, the magnitude of the effect is expected to be low to negligible on Moose River quality and downstream tributaries.

- The predicted receiving environment concentration of arsenic of 0.021 mg/L; risks to aquatic life associated with predicted arsenic concentrations are anticipated to be low.
- The aluminum concentration of 0.183 mg/L for aluminum is well with the natural variation of existing conditions of the Moose River (i.e., predicted below the 75th percentile receiver quality in Moose River).
- Concentrations of key parameters of interest (arsenic, cobalt, copper and nitrite) in groundwater were predicted in the model to meet CCME FAL/NSE EQS after mixing with Moose River 100 m downstream of the discharge point (Section 6.6.7.3 and Appendix F.8).

There are no further effects to fish and fish habitat anticipated to be caused by the processing of ore and the management of tailings (exhausted pit) from the Beaver Dam Mine. Surface water quality and quantity will continue to be monitored over the life of the Touquoy facility as part of existing approval for the Touquoy mine life and the revised approval for the proposed extended life of the Touquoy site associated with processing of Beaver Dam ore. Therefore, with the exception of the above and continued potential for accidents and malfunctions and environmental monitoring, there are no direct or indirect effects to fish and fish habitat anticipated from the Project at the Touquoy Mine Site during the construction and operations phases. For further information regarding Touquoy Mine Site and fish and fish habitat interactions, refer to the EARD (CRA 2007b) and Focus Report (CRA 2007a). Fish mitigations and monitoring are presented in Sections 6.9.8 and 6.9.10 and will be further addressed as part of the permitting process.

6.9.8 Avoidance and Mitigation

6.9.8.1 Avoidance

Measures to Avoid for the conservation and protection of fish habitat is the first and most important step in the hierarchy of measures and therefore have been the major focus of this Project to date. There have been a number of measures put in place to avoid and minimize the effects on fish and fish habitat.

Through the iterative process of Project design, a revised site layout has been assessed and implemented through changes to the Project Description (Section 2). Although components such as the open pit are fixed due to the location of the resource, other Project infrastructure such as stockpiles and road networks have some flexibility in their location and have been optimized in the site layout. Prior to adjusting the site infrastructure layout following issuance of the Round 1, Information Requests (CEAA 2017), a review of environmental constraints was completed, incorporating all biophysical and regulatory findings identified during baseline surveys to date; primarily driven by avoidance of fish habitats and regulated setbacks on lichen Species at Risk. The most prominent revision to the Revised 2019 EIS (AMNS, 2019) infrastructure layout is that the waste rock storage area (WRSA) has been moved to the west of Crusher Lake to avoid impact to aquatic habitats contiguous with Crusher Lake (WC2-5), and the associated indirect impacts from flow reduction (Appendix A [Water Balance Analysis] of Appendix P.4 [Mine Water Management Plan]). This has resulted in new predicted indirect impacts to fish habitat in WC23, WC26, and WC27; however, these effects have been fully assessed and incorporated into the draft Fish Habitat Offset Plan (Appendix J.3).

In the Revised 2019 EIS (AMNS 2019), indirect impacts to fish habitat were predicted through flow reduction to Crusher Lake and Mud Lake, and through increases in flow to the Tent Lake watershed. Through the revised infrastructure layout and associated revision to the Water Balance Analysis (Appendix A of Appendix P.4 Mine Water Management Plan), these changes in flow have been moderated, and currently no significant change in flow are predicted in Crusher Lake or Tent Lake (IR2 NSE-2-122) (or associated watercourses), and the flow reduction in the Mud Lake outlet is predicted to be moderate in magnitude. This avoidance of impacts to the Crusher Lake and Mud Lake systems has resulted in new indirect impacts to Watercourses WC5, WC23, WC26 and WC27; these effects have been fully assessed, quantified as part of the overall impact assessment, and included in the draft Fish Habitat Offset Plan (Appendix J.3).

An additional revision to the Project infrastructure is the segregation of NAG and PAG waste rock stockpiles, and relocation of the PAG stockpile directly south of the pit. Placement of the PAG stockpile south of the pit allows for predicted groundwater seepage to drain into the pit, where water is managed and treated as needed, prior to discharge. In addition, a Metal Leaching and Acid Rock Drainage Management Plan (Appendix E.5) is being developed to monitor acid rock drainage during the life of mine. AMNS will adaptively manage the placement and long-term reclamation of acid rock drainage on-site.

The predicted changes in inflow, discharge and water level at Mud Lake are incorporated in the revised Water Balance Analysis document (Appendix A of Appendix P.4 Mine Water Management Plan) to support the response to IR2 NSE-2-120. Mud Lake water levels are controlled by the elevation of the outlet, and are not anticipated to drop below the existing invert of the outlet channel during EOM and PC conditions. A summary of predicted changes to Mud Lake is provided in Section 6.9.7.4.4, and provided in detail in the final Water Balance Analysis (Appendix A of Appendix P.4).

Crusher Lake is part of the Mud Lake catchment; however, its catchment area remains unchanged from baseline conditions. As such, there is no predicted changes in runoff volumes to Crusher lake from baseline conditions. There will be minor impacts to total inflow to Crusher Lake, attributed to small changes in baseflow contributions due to the influence of the mine pit development on groundwater flow patterns in the area. There is no predicted change in water level within Crusher lake, and the depth of Mud Lake is predicted to decrease by a maximum of 0.05 m.

Through the revisions to Project infrastructure, efforts were made to improve the water balance results, to moderate surface water flows through the Beaver Dam Mine Site and reduce indirect impact to downstream receiving environments. Table 6.9-23 provides the updated water balance results which demonstrate minimization of indirect impacts through reconfiguration of the infrastructure layout and associated mine water management facilities. Detailed monthly predictions and modelling methods are provided in the Water Balance Analysis (Appendix A of Appendix P.4 Mine Water Management Plan).

Table 6.9-23: Summary of Water Balance Analysis Changes from 2019 to 2021

Catchment Area	2019 EIS Predictions: Change in Annual Runoff from Baseline Conditions		Current Predictions: Change in Annual Runoff from Baseline Conditions	
	EOM	PC	EOM	PC
Killag	0.91%	0.03%	2.2%	(-2.2%)*, 1.1%
Mud Lake – WC27	-43.0%	-35.5%	-18.3%	-13.7%
WC27	-	-	-17.3%	-13.0%
Crusher Lake	-52.1%	-52.1%	-4.7%	-1.2%
Tent Lake	53.1%	53.1%	-1.1%	-1.2%
West Tributary – WC26	No impact	No impact	-22.2%	-17.5%
South Tributary – WC23	No impact	No impact	-15.2%	-15.2%

Notes: EIS = environmental impact statement; EOM = end-of-mine; PC = post-closure; WC = watercourse; % = percent. * Represents prediction during pit filling.

As shown in Table 6.9-23, through revisions to infrastructure layout, AMNS has been able to achieve substantial improvements in the water balance analysis in Mud Lake/WC27, Crusher lake and Tent Lake. The adjusted placement of the WRSA has resulted in new indirect impacts to flow in the WC26 (west) and WC23 (south) tributaries; however, this adjustment was a net benefit to fish and fish habitat through avoidance of direct impacts to tributaries to Crusher Lake and Mud Lake. Moderate levels of flow reduction are anticipated in the Mud Lake-WC27 catchment area, West Tributary-WC26 and South Tributary-WC23. These impacts have been quantified and accounted for in the draft Fish Habitat Offset Plan (Appendix J.3).

Given the sensitivity of Atlantic salmon in the Killag River, AMNS briefly considered alternative effluent release locations. The entire Mine Site component of the PA is located within the West River Sheet Harbour, with the majority lying within the Killag River tertiary watershed. Cameron Flowage/Killag River was identified as an effluent release location because of proximity to the proposed pit and water collection ponds, that minimal disturbance would be required to allow water to flow in this direction. Predictive water quality assessments indicated that all predicted exceedances in constituents of concern could be effectively treated to meet compliance with MDMER guidelines at the discharge point, and federal and provincial regulatory guidelines which are protective of aquatic health at the 100 m mixing zone, given the assimilative capacity of Cameron Flowage/Killag River.

Alternative discharge locations such as Cope Brook and Paul Brook would result in release of effluent upstream of the Beaver Lake IR 17 and both of these watersheds have lower assimilative capacities. The Project is located at the top of the Tent Brook watershed, which flows into the West River Sheet Harbour downstream of the Beaver Lake IR 17; however, it is anticipated that this system has lower assimilative capacity. Furthermore, all three of these locations would still ultimately flow into the West River Sheet Harbour; regardless, so the key objective at this time is to manage water quality within site, prior to release.

Another potential alternative would involve pumping effluent into the East River Sheet Harbour watershed, into a habitat such as Como Lake, only 2 km northeast of the pit. This was not strongly considered, as AMNS is capable of meeting compliance at the release point. Releasing effluent into another secondary watershed, or even into any of the alternative tertiary watershed would introduce another suite of indirect effects related to increased flow at the release point and potentially morphological adaptations

depending on the resilience of the receiving environment, along with exacerbating potential for flow reduction in the Killag River, by cutting off the circular flow path used as a mitigative measure for predicted baseflow reductions in Cameron Flowage. For these reasons, AMNS has determined that effluent release within Cameron Flowage is the most technically defensible option, and water treatment will ensure compliance within the mixing zone.

The Preferred Alternative Haul Road has been removed from the Project Description (Section 2) to minimize potential impacts. The movement of ore will be transported between the Beaver Dam Mine Site and the Touquoy Mine Site for processing using an existing road network. A portion of the network requires upgrading and some re-alignment to allow safe movement of large ore-carrying vehicles. Additionally, an ATV bypass road will be constructed parallel to the haul road to allow for safe non-mine, recreational vehicle use. As a result, direct HADD can be minimized and existing impacts due to damaged, non-functioning crossings can be mitigated.

6.9.8.2 Mitigation

Measures to mitigate any adverse effects on fish and fish habitat include both standard best practices that are implemented through all phases of the Project (e.g., construction, operation, decommissioning) and site-specific mitigation designs. Measures to Mitigate and minimize losses or reduced productivity of fish habitat have been established at several locations within the Project. Site-specific mitigation designs include a potential groundwater pump at Cameron Flowage, a groundwater interceptor trench (if required based on water quality) west of the PAG Stockpile, and fish relocation activities.

To avoid or mitigate additional loss of waters frequented by fish or harm to fish habitat during Project construction, operations and closure phases, a combination of site-specific mitigation measures as defined through permitting, approvals and environmental assessment commitments and best management practices will be used. Measures and standards will include, but are not limited to, construction water management; erosion and sedimentation controls; and adherence to timing windows to protect sensitive life cycle periods.

6.9.8.2.1 Surface Water Quantity and Quality Mitigation

Design and operation of surface water management infrastructure represents a key aspect of planned mitigation and management activities; surface water management infrastructure at the existing Touquoy Mine and the proposed Beaver Dam Mine Project have been developed to attain the following performance objectives:

1. minimize the amount of precipitation and runoff that comes into contact with potential contaminant sources during mine operations through surface water diversions;

2. avoid effects to surface water and downstream water users by collecting and capturing all potentially contaminated water for mine reuse (reclaim water) or directing to water treatment prior to offsite discharge; and

3. manage and control other non-contaminated surface water on the Project site.

This description mitigation measures is detailed in the Mine Water Management Plan (MWMP) plan provided in Appendix P.4. In summary, the objective of the MWMP is to support and guide mine water management through the construction, operation, active closure, and post-closure phases of the Project. The primary objectives of water management at the Beaver Dam Mine Site are to reduce operational risks and environmental impacts of mining. The following strategies are planned to achieve the primary objectives:

- Mitigate water quality and quantity impacts on receiving waters.
- Reduce the water inventory at the Beaver Dam Mine Site through off-site drainage of non-mine contact water.
- Incorporate system flexibility to manage water under variable climatic conditions.
- Reduce water quality monitoring requirements through the establishment of minimal effluent discharge points.
- Provide an effective adaptive monitoring program to manage mine water quantity and quality, throughout various stages of Beaver Dam Mine Site development and maintain the mine in compliance with regulatory requirements and approval conditions.
- Water treatment will be designed to ensure that concentrations of surface water within Cameron Flowage/Killag River meet regulatory requirements during operations and post-closure phases of the Project (Appendix P.4 Mine Water Management Plan).

The updated Predictive Water Quality model results from adjusted nitrate, nitrite and ammonia source terms demonstrate a decrease in constituents of concern concentrations under EOM conditions as compared to the 2019 EIS submission. Treatment will be required at the North Settling Pond to ensure compliance with Nitrite levels at the discharge point in July, August and September. Nitrate and ammonia continued to have no predicted exceedances (Appendix D Predictive Water Quality Assessment in Appendix P.4). It has been determined that an aeration lagoon and polishing pond associated with the North Settling Pond will allow AMNS to meet CCME objectives for water quality (Appendix D Predictive Water Quality Assessment in Appendix P.4).

The Water Balance Analysis indicated that the Killag River is expected to see a 2.2% and 1.1% increase in annual runoff volume under EOM and PC conditions (Appendix A Water Balance Analysis in Appendix P.4). However, this assessment does not account for the potential impact to baseflow within the Killag River due to drawdown from the open pit and the potential impacts to Cameron Flowage during the approximately 13 years it will take for the open pit to fill with water, when there is no direct discharge from the site planned.

The predicted reduction in baseflow under operating conditions is mitigated by flow path of the groundwater that discharges to proposed site infrastructure (i.e., the open pit). Groundwater will flow into the open pit where it will be pumped to the North Pond before it is discharged back into Cameron Flowage. The impact that the baseflow reduction during operation conditions will have on the total flow in the Killag River is expected to be mitigated by this circular flow path in which all groundwater that discharges to Site infrastructure is collected, treated, as necessary, and then discharged back into Cameron Flowage. During pit filling, surface flows are predicted to decrease by 2.2%.

During the closure phase, water from the North Settling Pond will be discharged into the pit to expedite pit filling. During times of low flow in Cameron Flowage while the pit is filling, treated water from the North Settling Pond will be diverted to the northern end of Cameron Flowage as necessary, to supplement flow. The baseflow reduction under pit filling conditions is to be mitigated by continuing operation of the North Pond while the pit is being filled with water. All site surface water will be directed first towards the North Pond with an overflow leading to the Pit. This overflow discharge has been designed to direct surface water discharge at the northern end of Cameron Flowage. AMNS has located the discharge location upstream of the open pit and north of the topsoil pile in order to minimize impact on baseflow reduction in Cameron Flowage/Killag River. Ninety-nine percent of the predicted baseflow

reduction will occur downstream of the discharge location. The North Pond will be maintained at full capacity with the purpose of providing surface water discharge to Cameron Flowage during the months of July, August and September, as required. This flow augmentation will mitigate the impacts that a reduction in baseflow would have on the total flow in Cameron Flowage, as these are the months in which baseflow dominates the total flow volume.

Once the pit has been filled, Cameron Flowage is still anticipated to see a decrease in baseflow due to a reduction in hydraulic gradient between the proposed footprint of the open pit and Cameron Flowage. The reduced baseflow in Cameron Flowage will be mitigated by the discharge point of the pit lake. While the discharge point of the pit lake occurs near the downstream end of Cameron Flowage, the overall runoff to the Killag River is expected to increase by 1.1% (Appendix H Baseflow Mitigation Assessment in Appendix P.4), resulting in an increase in total flow in the Killag River, despite the reduction in baseflow. As described in Section 6.9.7.2.2.1, baseflow reduction, and changes in surface flow (monthly and daily flows) are anticipated to result in a low magnitude of effect to Cameron Flowage and the Killag River.

Project scheduling will provide time to confirm existing groundwater predictions within the Cameron Flowage near the Open Pit area. Therefore, the uncertainty around losses of existing groundwater seepages will be addressed prior to any potential Open Pit operations. Should groundwater upwelling locations be identified during ongoing monitoring and used within Cameron Flowage, further mitigation and adaptive management will be considered including the design and installation of groundwater pump(s) during Project Operations. Details on possible locations would require additional site-specific details such as groundwater depth, temperature, access, groundwater recharge rate, power requirements, and geology, would be required prior to final determination as a feasible mitigation option during Project operations.

The following mitigation may be implemented to reduce the risk of contaminant transport to fish and fish habitat:

- Implementation of an interceptor trench to achieve hydraulic containment of potential COC migration west from the PAG waste rock stockpile in the event that groundwater quality monitoring indicates COC concentrations are approaching the Tier 2 PSS in this area.

6.9.8.2.2 Fish Rescue

Wherever avoidance of direct impacts is not practicable, a fish rescue will be completed to avoid death of fish. Prior to completion of in-stream work related to the Project, fish rescue and relocation will be required in habitats proposed for direct alteration, as outlined in Table 6.9-14 and Table 6.9-16 (Mine Site and Haul Road, respectively). The fish rescue approach is provided herein, with the goal of outlining the framework of fish rescue activities.

The primary goal of fish rescue work is to capture and relocate as many fish as is reasonably practicable, considering habitat area and complexity, access, and safety considerations as the key constraints. As the extent of those constraints is somewhat unknown, a quantitative estimate of fish mortality is not provided herein. Fish rescue work will not occur without permission granted under the *Fisheries Act* (2019) for a HADD, and death of fish by means other than fishing. As such, it is expected that a small proportion of fish present may not be successfully rescued; however, it is the goal of a fish rescue operation to minimize the death of all fish in habitat to be lost. This is completed by following the framework outlined herein, which describes a series of approaches to be used in an adaptive management capacity based on the constraints present. It is our professional opinion, based on experience with EISs and EAs throughout Canada, that a specific depletion target or mortality estimate is not typically required, or accurate, at the EIS stage. AMNS commits to a reasonable level of effort to rescue as many fish as practicable, and that the details surrounding reasonable depletion efforts is completed at the permitting phase in consultation with DFO.

Guidance for the approach to a fish rescue was obtained from Fisheries and Oceans Canada (2015); Appendix F, Fish Rescue Guidelines. A fish rescue plan will be provided to DFO for approval at the permitting phase of the Project and prior to any fish rescue activities. While the specific capture methods will be finalized during permitting, the general approach will involve a combination of passive trapping, seine netting, dip netting, and electrofishing in habitats where each is effective. Timing of fish rescue activities will be closely coordinated with habitat dewatering or other water diversion/infilling activities during construction. While eggs, larvae and small young-of-year life stages of fish are very difficult to successfully locate, collect, and relocate, habitat construction activities will be planned to avoid periods of egg incubation whenever possible; however, it is known that many fish rescue programs cannot successfully guarantee the loss of these small life stages.

The fish rescue will be completed by a team of aquatic ecologists, experienced in the collection, handling and transfer of fish. The team will obtain a scientific research license which allows for collection of fish, including collection for fish rescue purposes. A fish transfer license will only be required if fish are to be transferred from one watershed to another, which is not being considered. Release locations within the same watercourse, or those watercourses where natural connectivity exists will be used. The team will adhere to all specific terms and conditions of the Scientific Licence.

For linear and open water features which are safely wadeable and easily isolated, the following approach to fish rescue will be taken. The license holder will identify the area to be isolated and barrier nets (or similar) will be installed on the upstream and downstream ends of the habitat. The specific fish rescue methodology will vary based on factors such as depth, substrate, wadeability, water temperature and turbidity of the water. The following techniques will be used either alone or in combination, until an appropriate depletion target is reached. The effectiveness of this approach is expected to be high, with little to no mortalities expected. Recent and past experience suggests that mortality of fish that have been captured and handled during relocation activities is typically in the range of 1 to3%. Standard Operating Procedures (SOP) for each method as well as an overall plan that will describe methods of holding, transporting, and monitoring fish during rescue will be provided as part of the permitting process. Contingencies for reducing fish stress from high water temperatures and/or low dissolved oxygen will also be provided. Included in typical capture programs are:

- Passive trapping (minnow traps, eel pots, fyke nets);
- Seining;
- Electrofishing; and
- Dip-netting.

All fish collection methods were selected based on inherent low mortality (i.e., gill nets and other lethal fish collection methods will not be used). The rescue will be completed to minimize handling and stress to fish, particularly if completed during warmer months. Measures such as oxygen supplementation and water cooling will be used as needed. A sub-sample of individuals per species will be sampled (physical measurements recorded), with the remaining to be identified and enumerated only. To reduce handling and stress to fishes, measurements of length, weight and age class, will not be recorded, unless requested by DFO (in consideration of Atlantic salmon, if caught). Fish will be released into the natural environment as soon as possible, and the rescue team will closely monitor fish for signs of stress.

For fish rescue work to support road crossings and culvert installations along the Haul Road, fish will be released on the downstream side of each crossing. Within the Beaver Dam Mine Site, fish rescue work to support road crossings will follow the same methodology, with the release point downstream of the impact area (e.g., watercourses 1 and 5). Fish captured in smaller watercourses which are tributaries to Cameron Flowage (WC12, 13, 14, 25, and WL61) will be released within Cameron Flowage, as close as possible to the rescue reach. While fish abundance is anticipated to be low in WL56, its proximity to Cameron Flowage

will also mean that these fish will also be targeted for release there. The rescue team of fisheries biologists will be supported by 'porters' as necessary, to facilitate quick transport and releases of fish back into the natural environment.

For open water features where safe wading is not possible due to water depth and soft substrate, AMNS will consider the use of a barge or boat-based electrofisher or rely on passive trapping. Within the open water portion of WL59, abundant standing dead trees and snags present challenges for both access, safety, and fishing efforts, particularly electrofishing. In this habitat, the fish rescue will likely occur through successive isolation of sections where possible, using repeated days of extensive trapping efforts and seine netting. This work will be conducted immediately prior to, and during dewatering efforts, to facilitate isolation of fish in smaller, shallower portions, where fishing efforts can be concentrated.

Fish captured in WL59 will be released primarily into Cameron Flowage, as it is the nearest contiguous watercourse. Based on the catch results, the team will consider releasing some fish into Crusher Lake and/or Mud Lake, to reduce competition for resources in a single release location. Due to the physical parameters of this habitat, a moderate to high level of effectiveness is predicted for fish rescue efforts, and some mortalities may be inevitable. Trapping efforts to date have identified (in decreasing abundance) Banded Killifish, Golden Shiner, Brown Bullhead, Brook Trout and Ninespine Stickleback. Water temperature is believed to be a limiting factor for coldwater species within this habitat, and suitable habitat for Atlantic salmon was not observed within this wetland.

AMNS commits to implementing all practicable methods and a reasonable level of effort to rescue all fish from habitat that will be dewatered, diverted, and/or infilled. During the completion of each rescue reach, personnel will remain on site during all de-watering to dip-net any fish remaining in the reach, wherever safely practicable. This will allow an estimate of mortalities to be provided to DFO in a summary report outlining results of the fish rescue. Fish release locations for each individual fish habitat within the Mine Site are identified in Table 6.9-14. Along the Haul Road, wherever fish rescues are required, the release point will be within the same watercourse, typically downstream of the rescue reach.

6.9.8.2.3 Mitigation Measures Summary

To mitigate and reduce overall loss of function of fish and fish habitat, the actions provided in Table 6.9-24 will be implemented by AMNS within wetlands and watercourses where direct impacts and potential indirect impacts to fish and fish habitat are expected. Mitigation measures will be confirmed and adaptively managed through ongoing monitoring requirements, as described at the permitting stage. Considering the extensive planning, the ongoing engagement with the Mi'kmaq of Nova Scotia and stakeholders, and the use of proven mitigation measures/best management practices, AMNS is confident that the Project can be constructed, operated, rehabilitated, and closed, in an environmentally responsible and safe manner that minimizes and mitigates impacts to fish habitat.

Where possible the offset and compensation measures will be constructed in advance of major Project impacts. This approach will allow for the initial development and stabilization of the works to be achieved, and significant colonization of the new replacement habitats by adjacent fish communities while fisheries impacts occur. Any changes to the approximate time periods specified in the final plan would require notification and approval by DFO in advance of a revised schedule.

Table 6.9-24: Proposed Mitigation Measures for Fish and Fish Habitat

Project Phase	Mitigation Measure
C, O, CL	Complete site meetings with relevant staff/contractors to educate and confirm policies related to working around fish bearing surface water systems including schedule of construction activities to minimize unauthorized disturbance and limit vegetation clearing
C	Provide signage on fish habitat streams

Table 6.9-24: Proposed Mitigation Measures for Fish and Fish Habitat (continued)

Project Phase	Mitigation Measure
C	Complete micro siting of mine infrastructure to avoid or minimize fish habitat impact as necessary
C	Complete fish rescue within all fish bearing streams to be impacted by the Project, prior to commencement of mine development, with DFO approval if required
C	Implement construction methods that reduce potential interaction with fish habitat and limit vegetation clearing around watercourses
C	Complete culvert installations and upgrades in accordance with the NSE Watercourse Standard (2015) or as updated at time of construction. Limit vegetation clearing
C, O	Maintain 30 m riparian wetland and watercourse buffers, where practicable.
C, O	Use vegetated buffers and aquatic vegetation wherever practicable to provide shade to on-site ponds.
C, O	Install groundwater pumps to supplement baseflow in Cameron Flowage, if necessary
C, O, CL	Implement a groundwater interceptor trench on the west side of the PAG stockpile, if necessary
C	Minimize the removal of vegetation upgradient of watercourses and stabilize shorelines or banks disturbed by any activity associated with Project activities
C	Minimize the temporal extent of in-stream works as much as practicable
C, O	Follow DFO-advised *Measures to avoid causing harm to fish and fish habitat* pertaining to blasting (DFO 2019)
C, O	A detailed explosive management plan will be developed as part of the permitting process.
C, O	Use an emulsion-type explosive that will minimize nitrogen release to surface water and groundwater
C, O	Use clean, non-ore-bearing, non-watercourse derived and non-toxic materials for erosion control methods
C, O	Incorporate drainage structures, where necessary, to dissipate hydraulic energy and maintain flow velocities sufficiently low to prevent erosion of native soil material
C, O	Limit clearing within confirmed fish habitat outside of approved alteration areas to within approved areas.
C, O	Acquire and follow watercourse alteration permits
C, O	Adhere to applicable timing windows, as directed by DFO, for construction where infilling has been approved in wetlands and watercourses where fish habitat is present
C, O	Ensure fueling areas are a minimum of 30 m from waterbodies
C, O	Use and maintain properly sized screens on any water intakes or outlet pipes to prevent entrainment or impingement of fish (DFO, 2020)
C, O	Ensure that machinery arrives on site in a clean condition and is maintained and free of fluid leaks
C, O	Develop and implement Mine Water Management Plan
C, O, CL	Collect and treat all contact water, as required
C, O, CL	Implement Erosion and Sediment Management Plan
C, O, CL	Maintain pre-construction hydrological flows into and out of down-stream surface water habitats, to the extent practicable, to limit indirect impacts to fish habitat
C, O, CL	Complete offsetting for HADD including for permanent loss of fish habitat through fish habitat restoration activities, subject to DFO approval, as required under the *Fisheries Act*
C, O, CL	Develop and implement the Aquatic Effects Monitoring Program to identify and further mitigate any additional adverse impacts to fish and fish habitat

Notes: C = Construction; O = Operations; CL = Active Closure; DFO = Fisheries and Oceans Canada; HADD = Harmful Alteration, Disruption or Destruction; NSE = Nova Scotia Environment.

Monitoring of standard mitigations described above will be supported by the MWMP (Appendix P.4) and AEMP (Appendix P.5), both of which will be in place prior to construction activities to minimize possible disturbances of fish and fish habitat. To ensure that the measures and standards described are implemented as proposed, AMNS onsite monitors (or designates) will monitor

construction and implementation of this plan. Monitoring will clearly be defined in the final Offset Plan, and DFO Authorizations, and be reported to DFO in an "as constructed" report provided following the works being completed. The "as constructed" monitoring report will document the construction of the offset and works as per the approved plans, and a summary of the mitigation measures and any contingency measures implemented to prevent further impacts to fish habitat. A detailed photographic record will be taken during implementation of the plan using consistent vantage points prior to, during and post construction.

6.9.8.3 Offsetting

A summary of the potential impacts quantification is provided above (CEAA 2-07). Standard mitigations as well as project-specific avoidances and redesigns have minimized the impacts to only those habitats where avoidance and further mitigation is not possible. It is understood that the final HADD determination will be determined by DFO; however, this preliminary quantification is provided to show that the offset concepts described herein can be designed to meet anticipated HADD quantity expectations, including any offset ratios. It should be noted that most of the impacted lacustrine habitat is degraded due to past disturbances by others and contains substandard water quality for fish (e.g., DO, temperature, substances).

6.9.8.3.1 Conceptual Habitat Offsets

The Project as proposed would result in the permanent impact to fish habitat and its associated productive capacity, through a portion of waterbodies and watercourses within the Project Mine site as well as along the Haul Road. It also would result in indirect alterations to habitat downstream of the Project infrastructure footprint due to partial flow reductions. Proven techniques in similar geographic settings for similar fish species provide the greatest likelihood of offsetting lost productive capacity for the long term, are least likely to fail structurally, and require the least amount of maintenance. Low-risk options that are biologically relevant were prioritized during the development of offsetting concepts. In addition to offsetting using proven methods, a focus on habitat improvements and rehabilitation around Atlantic Salmon, a fish species of local and provincial importance, was also incorporated wherever possible in each offset option.

Several concepts have been identified for preliminary assessment and are presented in the draft Fish Habitat Offset Plan, (Appendix J.3). Each measure was assessed using a ranked scale across numerous categories that describe various aspects of option feasibility. Potential options were evaluated by consideration of multiple criteria including:

- Adherence to DFO's principles and policy for offsetting;
- Location within the Beaver Dam watersheds (e.g., Killag River) and close to the Beaver Dam Mine Site;
- Self-sustaining;
- Technically feasible and economically viable; and
- Provide similar "in-kind", or higher quality, habitat as an offset.

The identified potential offsetting concepts identified in the draft Fish Habitat Offset Plan, (Appendix J.3) were developed without detailed engagement with the Mi'kmaq of Nova Scotia, agencies, or public groups and are therefore considered preliminary; however, the options identified conform to the criteria and provide offset habitat located within the same ecological unit / watershed and provide habitat types and suitabilities similar to, or greater than, the habitat being lost.

Some of the key offset measure considered and proposed include:

- offsite and onsite habitat rehabilitation and enhancement;
- offsite and onsite habitat development (pools / ponds);

- Musquodoboit River channel enhancements; and
- complementary measures (research orientated).

6.9.9 Significance of Residual Effects

This effects assessment was developed to be consistent with Fish and Fish Habitat Protection Policy (DFO, 2019), which states "*the Department interprets "harmful alteration, disruption or destruction" as any temporary or permanent change to fish habitat that directly or indirectly impairs the habitat's capacity to support one or more life processes of fish*." However, it is recognized that the total impacts determined within this assessment will be further reviewed and determination of the amount of HADD will be made by DFO during the authorization application process.

This effects assessment includes:

- impact assessment criteria, Section 6.9.5.2, developed in consideration of the policy and relevant scientific literature (DFO, 2013b; DFO, 2019; DFO, 2005; Newbury and Gaboury, 1993; Fosse, Brown, Scruton and Beersing, 2001, for example).
- Site specific mitigation measures to avoid and/or minimize the duration or extent of indirect effects to fish and fish habitat are provided in Section 6.9.8.
- Direct and indirect impacts to fish and fish habitat have been quantified through detailed habitat evaluations, and hydrologic and hydraulic analyses. A conservative approach for quantifying indirect impacts due to flow reductions has been taken to identify potential alteration of the wetted areas below the 30% MAD, recognizing that the channels are expected to maintain existing fish communities. Furthermore, all areas with proposed direct and indirect impact have been accounted for in the Offsetting Plan, to meet the no-net-loss policy under the *Fisheries Act*. Work associated with fish and fish habitat will be completed in accordance with DFO and NSE regulatory approvals.
- Potential impact quantification and offsets have been provided within the Offset Plan (Appendix J.3) and will require confirmation of the HADD determinations by DFO.
- The assessment carefully considered potential impacts to the Atlantic salmon population and their habitat throughout both direct and indirect interactions resulting from the Project.
- An aquatic effects monitoring program (AEMP) is being developed to validate impact predictions as well as to identify adaptive management measures that may be required during construction, operations, and closure.

A significant adverse environmental effect for fish and fish habitat has not been predicted for the Project for the following reasons, with consideration of the ecological and social context of the LAA surrounding the Project:

- During construction:
  - Direct impacts to fish and fish habitat will occur. However, the current Project infrastructure layout has allowed AMNS to achieve complete avoidance of first order tributaries to Crusher Lake and Mud Lake, and a more equalized site-wide water balance which reduces indirect impacts to downgradient fish habitat.
  - Direct loss of habitat within the Beaver Dam Mine Site will be required to allow for development of the Pit and pit perimeter berm primarily, with small direct impacts related to internal haul roads and loss of upstream flow (i.e., WC5, WC13, WC14). The majority of direct habitat loss within the Beaver Dam Mine Site is within WL59, which is an open water wetland constructed to support historic mine activities.

  - Direct impacts to fish habitat along the Haul Road are minimal in scale, and required to allow for upgrades to the existing forestry road. This involves installation of 29 watercourse crossings; 12 of which are expected to improve fish passage through upgrading culverts which are currently either crushed, buried, blocked or hung.
  - The water collection and treatment system will be constructed, and collection of contact water will commence near the end of the construction phase of the project.
  - Strict adherence to the Erosion and Sediment Control plan will limit the potential indirect effects to fish and fish habitat commencing in the construction phase, and continuing throughout the operational life of the Project.
  - The death of fish by means other than fishing will be limited by the completion of fish rescue wherever direct impact is required.
- During operations:
  - All direct impacts to fish habitat will have been completed, and no new direct impacts are expected.
  - Water collection, treatment and effluent release will occur, resulting in indirect effects to four watercourses through reduction of both daily and monthly average flows. Mud Lake is also predicted to experience a small reduction in water level (maximum 5 cm). Where flow reduction is of a magnitude that it is predicted to result in alteration of fish habitat; the impact area has been incorporated into the offset plan.
  - With appropriate treatment of effluent discharge, the magnitude of the residual effect to the Killag River at the Beaver Dam Mine Site is considered negligible (within established criteria or background concentrations at the 100 m compliance point).
  - Effluent is predicted to be of neutral pH, limiting potential impact to Killag River.
  - Changes in flow to the Killag River and resultant changes to fish habitat quality from pit operations and dewatering have been predicted to be low.
- During closure:
  - With appropriate treatment of effluent discharge, the magnitude of the residual effect to the Killag River at the Beaver Dam Mine Site is considered negligible (within established criteria or background concentrations at the 100 m compliance point).
  - Effluent is predicted to be of neutral pH, limiting potential impact to Killag River, a low pH river with current efforts to increase pH to support salmon restoration.
  - During pit filling, flows in the Killag River are expected to decrease by 2.2% MAD flows; however, the duration of low flow period based on daily flows is expected to decrease (fewer low-flow days compared to baseline). Following pit filling, the Killag River is expected to observe a surplus in surface water on the order of 2.2%. These interactions are low in magnitude and not expected to result in any harmful alteration of fish habitat within the Killag River.

Table 6.9-25: Residual Effects for Fish and Fish Habitat

Project VC Interactions	Parameter	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
			Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility

6.9.10 Proposed Compliance and Effects Monitoring Program Update

An Environmental Effects Monitoring Plan (EEM) has been initiated and will be fully implemented to support compliance with the monitoring requirements in MDMER. This will form one component of the broader Aquatic Effects Monitoring Program (AEMP), which will monitor all aquatic ecosystems where Project effects are predicted to validate impact predictions as well as to identify adaptive management measures that may be required during construction, operations, and closure. A conceptual AEMP is provided in Appendix P.5. Baseline data to support the EEM and AEMP has, and continues to be, collected to support ongoing effects assessment over the life of mine.

The purpose of the AEMP is to identify potential changes the Project may have on the surrounding aquatic environment. This includes the following specific objectives:

- to determine any short- and long-term aquatic effects of the Project on downstream aquatic receptors;
- to evaluate the accuracy of impact predictions made in the EIS;
- to assess the efficacy of impact mitigation measures;
- to provide the data necessary to report on state of the environment on an annual basis, and to inform adaptive management approaches to reduce or eliminate Project-related effects; and
- to recommend any necessary and appropriate changes to future versions of the AEMP.

Proposed study areas include watercourses and waterbodies adjacent to planned infrastructure within the Beaver Dam Mine Site including WC5/Crusher Lake, WC23, WC26, WC27/Mud Lake, and Cameron Flowage/Killag River. Study areas also incorporate those selected for Environmental Effects Monitoring (EEM) downgradient of proposed effluent discharge locations as required under the MDMER (Cameron Flowage/Killag River).

In accordance with the federal *Fisheries Act,* mines in Canada regulated under the MDMER are required to conduct periodic EEM studies as part of their authority to deposit effluent. The objective of EEM under MDMER is to evaluate the effects of metal and diamond mining effluents on fish, fish habitat, and the use of fisheries resources. EEM programs consists of two general components, namely biological monitoring studies (fish population study, fish tissue study, and benthic invertebrate community survey) and effluent and water quality monitoring studies (effluent characterization, water quality monitoring, and sublethal toxicity testing). The components of EEM monitoring have been brought forward into the Conceptual AEMP Design Plan.

The scope of the AEMP involves monitoring of water quality, water quantity, sediment quality, periphyton, benthic invertebrates, fish habitat and community, and fish health and fish tissue. The AEMP describes the proposed sampling frequency, schedule and intensity, as well as identified significance thresholds, action levels and suggested responses should significant thresholds be exceeded. The AEMP also provides a proposed reporting schedule to federal and provincial regulators. The Conceptual AEMP can be found in Appendix P.5.

6.10 Habitat and Flora

6.10.1 Introduction

6.10.1.1 Summary of Habitat and Flora Before the Update

The Project is located in the Eastern Ecoregion of the Acadian Ecozone and lays within the Eastern Interior Ecodistrict (previously subdivided into the Eastern Interior and Eastern Drumlins Ecodistricts). Habitat surveys confirmed 10 different ecosites (AC1, 2, 4, 5, 7, 8, 10, 11, 13) within the Beaver Dam Mine Site (n=6) and Haul Road (n=9). Dominant ecosites identified within the Beaver Dam Mine Site generally support vegetation types from the spruce-pine and spruce-hemlock forest groups, with some associated with a natural disturbance regime. Ecosites identified within the Haul Road generally support a broader variety of vegetation types from the spruce-pine, intolerant and tolerant hardwood, mixed wood, open woodland, spruce-hemlock and intolerant hardwood forest groups. Habitat within the Project Area (PA) is largely disturbed as a result of timber harvesting, historic mining and/or road and trail networks. An interior forest analyse was conducted to quality Project impacts through habitat fragmentation.

A total of 294 vascular plant species were identified, five of which were considered priority species: lesser rattlesnake plantain (*Goodyera repens*, S3), southern twayblade (*Neottia bifolia*, syn. *Listera australis*, S3) appalachian polypody (*Polypodium appalachianum*, S3), and highbush blueberry (*Vaccinium corymbosum*, S3S4). No Species at Risk (SAR) vascular plants were observed. Eleven priority lichen species were observed, three of which were SAR: boreal felt lichen (*Erioderma pedicellatum*), blue felt lichen (*Pectania plumbea)*, frosted glass whisker lichen (*Sclerophora peronella*).

The Project was assessed to impact 45 hectares (ha) of interior forest within the Beaver Dam Mine Site and 116 ha of interior forest within Old Forest Unit 582 along the Haul Road. Project development will directly impact vascular and non-vascular flora, predominantly during the construction phase. Indirect effects to vascular and non-vascular flora could include altered hydrology, dust deposition, sedimentation and erosion, accidents and malfunctions, and the introduction of invasive species. As a result of mitigations and detailed design planning, the predicted residual environmental effects of Project development and production on habitat and flora are assessed to be adverse, but not significant. Project effects to priority species are discussed in Section 6.13.

6.10.1.2 Summary of Updates to Habitat and Flora

As a result of PA modifications and continued infrastructure micro-siting since the 2019 Environmental Impact Statement (EIS) submission, additional habitat surveys observed an additional two ecosites (AC3 and AC9) within the Beaver Dam Mine Site, totalling 12 ecosites within the Beaver Dam Mine Site (n=10) and Haul Road (n=9). General habitat trends and dominance did not change since the 2019 EIS. A habitat desktop analysis was conducted to quality the habitat types and disturbed areas presented within the Beaver Dam Mine Site, Haul Road and Local Assessment Area (LAA). The interior forest analyse was updated in the Updated 2021 EIS (AMNS 2021) and further assessment of Old Forest Unit 582 and potential Old Growth was conducted. One additional vascular plant species, Nova Scotia Agalinis (*Agalinis neoscotica*, S3S4), was observed during supplementary field surveys for the Updated 2021 EIS (AMNS, 2021). A total of 295 species of vascular plants species were observed, including six priority species. No additional priority lichen were observed.

Impacts to habitat and flora were reassessed based on changes to the PA and Project infrastructure. The desktop habitat analysis shows that the Project related habitat impacts in relation to the LAA are low to moderate and the Project predominantly impacts previously disturbed areas. As a result of infrastructure changes, the Project is will affect a total of 237 ha of interior forest habitat, which accounts for 9% of predicted interior forest in the LAA and 0.3% within the Regional Assessment Area (RAA). Further assessment of Old Forest Unit 582 found that the proposed Haul Road alignment may impact 0.22 ha Potential Old Growth, which

was delineated during a preliminary survey. A potential alternative Haul Road route option is presented to avoid the Potential Old Growth.

No new direct or indirect impacts to flora are expected. Project effects to habitat and flora remain adverse, but not significant.

6.10.2 Rationale for Valued Component Selection

Flora species and ecosystem habitats, and the fauna species which rely upon these communities, may be altered, either directly or indirectly, by proposed Project activities. Field programs were developed to identify priority species, in particular SAR, which are protected under federal and provincial SAR legislation.

6.10.3 Baseline Program Methodology

Methodology of habitat and flora surveys within the Beaver Dam Mine Site and Haul Road (excluding the existing Mooseland Road portion) are discussed below. Information pertaining to Touquoy Mine Site has been brought forward from the EARD and Focus Report (CRA 2007a,b). Methods and results are summarized in subheadings within the applicable sections and are carried forward into the effects assessment as appropriate.

In 2019, the PA was modified to allow for the micro-siting of infrastructure within the Beaver Dam Mine Site, as described in Section 6.8. As a result, targeted habitat and flora surveys were conducted within the modified PA (Section 5.5, Figure 5.5-1) in July and August 2019 to identify and record additional flora species and ecosystem habitats.

6.10.3.1 Priority List Methodology and Desktop Evaluation

A detailed desktop study to examine potential for presence of and effects on SAR within the vicinity of the Beaver Dam Mine Site and Haul Road was completed. This desktop evaluation for SOCI and SAR was completed in advance of field programs to advise the detailed methodologies outlined in Section 6.13 SOCI and SAR are collectively referred to as priority species.

As outlined in the EA guidance documented cited above, the compilation of a priority species list is habitat driven, rather than observation driven (based on information provided in reports from Atlantic Canada Conservation Data Centre (ACCDC) or the Maritime Breeding Brid Atlas (MBBA), for example). This is based on the recognition that observation-based datasets are not comprehensive lists of species identified in any given area. As such, the information provided observation driven sources are supplementary to the priority species list, rather than forming the basis of the priority species list.

Sightings of priority species recorded within 5 kilometres (km) and 100 km by ACCDC were reviewed (reports included in Appendix I.1 and I.2). Original reports were prepared for the Beaver Dam Mine Site on September 8, 2014, for the Haul Road on June 3, 2016, and an additional report was prepared for the Touquoy Mine Site on September 10, 2015. An updated ACCDC report was attained and reviewed for the Beaver Dam Mine Site and Haul Road on January 4, 2021 in order to consider new species occurrences and potential impacts (IR2 NSE 2-184).

When the ACCDC prepares a rare species report, they provide the user with georeferenced shapefile points of rare species records within 5 km of the center of the study area. However, NSL&F has classified several species as 'location sensitive', meaning that ACCDC is not permitted to provide specific location data for these species in their reports. Concern about exploitation of location-sensitive species precludes inclusion of coordinates in the rare species reports. Location sensitive species in Nova Scotia include black ash (*Fraxinus nigra*), Blandings turtle (*Emydoidea blandingii*), wood turtle (*Glyptemys insculpta*), peregrine falcon anatum/tundrius populations (*Falco peregrinus*, pop.1), and any bat hibernaculum. If any of these species are present within 5 km of the center of the study area, the ACCDC report will simply identify that they are present, but will not provide specific location data. No location sensitive species were documented within 5 km of the Beaver Dam Mine Site and Haul Road in any of the ACCDC reports. The NSL&F Significant Species and Habitats Database was reviewed as well.

The Nova Scotia Department of Communities, Culture and Heritage provided an Environmental Screening Report including a list of flora and fauna SAR and SOCI documented by their staff within the vicinity of the Beaver Dam Mine Site and Haul Road. The Nova Scotia Special Places Environmental Screening report is provided in Appendix I.4. Additional priority lichen data were received from the Mersey Tobeatic Research Institute in 2019, and incorporated in the desktop evaluation. This data was used to advise field methodology and targeted lichen surveys for additional field programs completed, as well as inform Project impact assessments and mitigation approaches.

The compilation of the priority species list and the review of all other available desktop resources for priority species observations is done primarily to advise field methodology, and they inform field staff to the species they are likely to encounter during field surveys. The desktop review for priority species provided the study team with information that directly guided the methods and the timing of all field programs. All field staff reviewed the desktop evaluation for priority species prior to commencing field work. This allowed field staff to review field identification guides and ensured that they were familiar with priority species identification and their status ranks.

6.10.3.2 Habitat Survey

Habitat assessments were completed in October 2014, May 2015 and July/August 2019 within the Beaver Dam Mine Site, and in May 2016 within the Haul Road. Using available forestry and wetland databases, habitat survey routes were created with the goal of assessing all of the major habitat types and landscape features throughout the Beaver Dam Mine Site and Haul Road. During the 2019 field evaluations, 14 additional habitat survey points (HSP) were established within the Beaver Dam Mine Site, totaling 51 HSPs in the Beaver Dam Mine Site and Haul Road (Figures 6.10-1A to 6.10-1D).

The habitat survey methods and results are presented with the acknowledgment of three biases built into the survey methods.

- One bias is towards upland habitat. This bias was purposefully built into the survey methods with the understanding that all wetlands within the Beaver Dam Mine Site and Haul Road will be delineated and described in detail and their function as habitats within the landscape of the Beaver Dam Mine Site and Haul Road would be captured in the wetland program (Section 6.8).
- The second bias is towards forested landscape as opposed to non-forested landscapes. In this context, clear cut lands, or those which have experienced timber harvesting of any sort, are still considered forested because the removal of timber is only a temporary disturbance. Non-forested portions of the landscape, such as roads or extensive gravel areas, often associated with historic mine workings, were not assessed during the habitat survey simply because they lack forest cover to be described and their capability for supporting forest cover in the foreseeable future is low based on the level of disturbance.
- The third bias in this survey is that habitat surveys were completed at discrete points and no effort was made to delineate the extent of that habitat type around those points. As such, the ability to extrapolate habitat survey results across the entire PA is limited. These HSPs are meant to describe habitat in 'snapshots' of specific locations. The results of the habitat survey are meant to describe the diversity of habitat types present throughout the Beaver Dam Mine Site and Haul Road and the relative abundance thereof, rather than absolute percent cover of each habitat type throughout the Beaver Dam Mine Site and Haul Road.

Two surveyors walked the habitat survey routes. HSPs were established along the survey route based on anticipated and observed habitat types. The distance between HSPs was dependent upon the complexity of major habitat types across the landscape, approximately 250 metres (m) for the Beaver Dam Mine Site and approximately 1 km along the Haul Road.

Document Name: BD_EIS_Figure6-10-XHSP

The Forest Ecosystem Classification (FEC) for Nova Scotia guide book was used to describe habitat characteristics within the HSPs. The following information was collected at each HSP:

- Vegetation type was determined using Part 1 of the FEC guide (Neily et al. 2011). Each stand was classified by overall forest group code and vegetation type using the keys provided in the guide book. Forest groups are general groupings of vegetation types. Within each forest group (open woodland or tolerant hardwood, for example), there are several specific vegetation types. Vegetation types are recurring and identifiable plant communities which reflect differences in site conditions, natural disturbance regimes, and successional stage. For example, TH4 is a tolerant hardwood forest group dominated by sugar maple and white ash vegetation type, while TH6 is a tolerant hardwood forest group dominated by red oak and yellow birch vegetation type.
- Ecosite was determined using Part 3 of the FEC guide (Keys et al. 2011). This guide provides keys to identify ecosites using an edatopic grid, which is a two-dimensional diagram used to plot ecosystems and ecosites based on their relative moisture and nutrient regimes. Ecosites are units which represent ecosystems that have developed under a particular nutrient and moisture regime. A finite range of vegetation types will naturally grow in any given ecosite.
- An approximation of forest stand age was determined using broad classifications for stand age (regenerating, immature, mature, over mature). This approximation is based on a combination of factors, such as total basal area, level of canopy coverage, senescence of older trees and presence of cavity trees, and species composition of the canopy, shrub and understory vegetation.
- Natural or anthropogenic disturbance is recorded in each site. The level and type of disturbance is identified and the timing of the disturbance is noted as well if it is apparent. Examples of natural disturbances include timber harvesting or road development. Natural disturbance regimes include fire, pests, wind throw, and natural senescence.
- Representative photos were taken of each site.

Habitat survey results were purposefully biased towards upland habitats, based on the fact that the wetland program would collect detailed information about each individual wetland within the Beaver Dam Mine Site and Haul Road. The habitat surveys were completed early in the field evaluation, prior to other survey efforts (i.e., October 2014, May 2015). These surveys provide valuable insight into the overall habitat composition of the Beaver Dam Mine Site and Haul Road, while helping to inform methodologies of other field programs.

6.10.3.2.1 Touquoy Mine Site

Habitat surveys were completed at the Touquoy Mine Site from 2004 to 2006 as part of the EARD process (CRA 2007a).

6.10.3.3 Vascular Plant Survey

As described in the Guide to Addressing Wildlife Species and Habitat in an EA Registration Document (NSE, 2009b) and the Beaver Dam Mine Project EIS Guidelines (CEAA, 2015), a complete vascular plant inventory is not typically required for an environmental assessment. In accordance with the documents referenced above, the vegetation survey focused on the identification of vegetative communities, with particular attention to identifying priority species. Priority species methodologies, including desktop review, are described in detail in Section 6.13.3.

Habitat types were identified on a broad scale within the Beaver Dam Mine Site and Haul Road and then meander transects through each habitat type were conducted to ensure that a variety of habitat types were surveyed for vegetation. Vascular plant assessments occurred early and late in the growing season to capture plant species with different phenology. Spring surveys to

capture spring ephemerals and early developers were completed on June 22 to 23, 2015 at the Beaver Dam Mine Site and on June 22 to 23 2016 along the Haul Road. Late season surveys to capture late developing species were completed on September 8, 12, and October 9, 2014 at the Beaver Dam Mine Site and on September 11 to 12, 2016 along the Haul Road. An additional vascular plant survey was conducted within the 2018 western expansion to the Beaver Dam Mine Site on September 18, 2018. Further vascular plant surveys were conducted in August 22 and 30, 2019 as a result of the continued PA modification, within the western and southeastern expansions of the Beaver Dam Mine Site.

For these surveys, a list of all priority species records found within 100 km of the Beaver Dam Mine Site and Haul Road was assembled prior to the survey being undertaken (from ACCDC and Environmental Screening results) to provide additional information and support the priority species list regarding the potential presence of priority species within the PA. The specific timing of field surveys was determined based on the identification of priority species that were documented within 20 km of the Beaver Dam Mine Site and Haul Road by the ACCDC.

6.10.3.3.1 Touquoy Mine Site

Vascular plant surveys were conducted in August 2004, May and June 2005, and September 2006 as part of the EARD process.

6.10.3.4 Lichen Survey

Specific methods for lichen surveys were determined based on identification of SOCI and SAR lichens through the desktop review (e.g., ACCDC reports). The Project Team did not complete a comprehensive list of all lichen species within the Beaver Dam Mine Site and Haul Road. The survey area included the Haul Road and was extended beyond the PA in the vicinity of the Beaver Dam Mine Site, defined as the lichen study area (LSA), so the Project Team could understand the distribution of rare lichens in a broader context. The lichenologist did record several opportunistic observations of common lichen species during the focused surveys for priority lichen species at the Beaver Dam Mine Site, surrounding LSA, and Haul Road. As a result of PA modifications, in 2019, additional lichen surveys, focused on SOCI and SAR, were conducted within the western and southeastern expansions of the Beaver Dam Mine Site. The LSA has been expanded to incorporate these new areas (Section 6.13, Figure 6.13-2A).

Detailed methods for lichen SOCI and SAR field surveys and desktop evaluation are presented in Section 6.13.3 and lichen results are described in Sections 6.10.4.4 and 6.13.4.3, respectively.

6.10.3.4.1 Touquoy Mine Site

Lichen surveys were conducted at the Touquoy Mine Site in 2004 and 2005 as part of the EARD process (refer to CRA 2007 for further methodological details). An additional survey, at the request of NSLF, was conducted in February 2007 at the Touquoy Mine Site in areas where blue felt lichen (*Degelia plumbea*) was previously observed.

6.10.3.5 Habitat Desktop Analysis

The Forest Inventory database (NSL&F, 2016) was reviewed within the LAA (see Section 6.10.6.1 for definition) and overlayed with the Haul Road (excluding Mooseland Road) and Beaver Dam Mine Site. Since the Touquoy Mine Site is an existing mine site, and the existing Mooseland Road portion of the Haul Road will not result in changes to habitat and flora, they were excluded from this analysis. The purpose of this analysis was to determine the percent cover of each habitat type within the LAA and compare to the predicted disturbance (direct habitat loss) to each habitat type from Project infrastructure. The predicted disturbance by habitat type from the Haul Road and Beaver Dam Mine Site was calculated as a percentage of that habitat type available within the LAA to determine the magnitude of direct impacts to habitat (Section 6.10.7.1).

The Forest Inventory database is a snapshot of Nova Scotia's forested and non-forested communities including anthropogenic disturbances. This database reflects aerial interpretation of photographs from 1992 – 2016 which includes data on wetlands, forested uplands, managed forests (e.g., cutblocks, selective cuts, plantations etc.), urban development and open waterbodies. During this analysis, data retrieved from this database was then grouped into four main categories which are: upland natural forests, wetlands and waterbodies, non-forested upland communities and disturbed. The four main habitat categories and provides descriptions is summarized in Table 6.10-2.

Table 6.10-2: Habitat Type Categories and Descriptions

Habitat Type Category	Habitat Type Sub-category	Description
Upland Forests	Natural Forests Stand	Natural forest stands are any forested stand which have no history of silviculture practices (e.g., clear cut, plantations, old field etc.). Within this sub-category, these stands are broken down further into hardwood and softwood dominant stands.
	Managed Forests	Managed forest is a catch-all term for forested landscapes which have history of silviculture practices, which include: • Cut-blocks • Old fields • Treated silviculture activity • Partial cuts/selective cuts
	Other	This sub-category includes forested stands which either have no data on species composition or are classified as brush (unmerchantable timber which is often regenerative forests)
Wetlands and Waterbodies	Lakes, Ponds and Beaver flowage	In land lake features and beaver flowages are included in this category.
	Wetlands	This sub-category includes all wetland classes identified within the database. The wetland types classified in the Forestry Inventory Database includes: • Open bogs • Treed bogs • Lake wetlands (lacustrine wetlands) • Wetlands (all wetland classes which are not defined above)
Non-forested Upland Communities	Barrens	This subcategory includes barrens and rock barrens which are defined below: • Barrens – any area with less than 25% of live tree cover containing ericaceous vegetation with less than 50% rock out crops • Rock barren – any area covered by at least 50% exposed rock outcrop and/or boulders with less than 25% live tree cover
Disturbed	Anthropogenic Disturbance	Includes gravel pits, old quarries, rail road corridors, urban development and road corridors.

6.10.3.6 Old Forest and Interior Forest Desktop Analysis

A desktop mapping exercise was conducted to identify mature forest and interior forest habitat in relation to Project infrastructure. The NSDNR Old Forest Policy 2012 definition of old forest and interior forest were used to determine these habitat types.

Interior forest is defined as area within a forest sheltered from edge effects. The Old Forest Policy uses an edge effect distance of 200 m from disturbance. Any patch that is suitably outside of this edge effect but is under 15 ha is considered as incapable of supporting interior forest. In reality, interior forest is dependent on the condition being measured and the nature of the edge interface (NSDNR, 2012). For this review, patches of interior forest were identified by buffering the NSL&F road and rail layer by 200 m to

represent existing disturbance and associated edge effect. Any patch outside this buffer, greater than 15 ha, and within the LAA was considered potential interior forest habitat.

Old Forest is defined as a stand or collection of stands containing Old Growth and/or mature climax conditions (NSDNR, 2012). Mature climax is a forest stand of trees aged 80 to 125 years old and Old Growth forest is a stand with trees 125 years or older. Old Forest was used as a representation of mature forest for this review. Stands of Old Forest were identified using the Nova Scotia Old Forest Layer. This dataset identifies crown land forest stands that meet the Old Forest criteria under the Old Forest Policy. (NSFA 2016).

To determine potential Project impact on interior forest and Old Forest, Project infrastructure and the Haul Road centerline were buffered by 200 m to represent the extent of edge effect influence from disturbance. This area was referred to as the Project Influence Zone.

6.10.3.6.1 Potential Old Growth Field Survey

Field surveys were conducted within Old Forest Unit 582 which interacts with the Project, as determined by Section 6.10.3.6, to assess for potential Old Growth. The survey, and resulting analysis, was conducted by a Registered Professional Forester. Individual forest stands or polygons with common characteristics, within Old Forest Unit 582, were identified and characterized using photo interpretation of recent (2017) aerial imagery. Representative stands which contained any significant characteristics of Old Forest were then field assessed. Structural characteristics assessed to quantify Old Forest include, detailed aging, disturbance, diameter distribution, canopy layers and patches, snags and fallen woody debris. Forest stands were assigned a class using the general criteria in the NSLF Old Forest Policy: Class 1 – Old Growth, Class 2 – Mature Climax, Class 3 – Immature Climax and Class 4 – Non-Climax.

6.10.4 Baseline Conditions

Updates to habitat and flora (total number, location, etc.) reflected within this section are as a result of additional surveys required by changes to the Beaver Dam Mine Site and Haul Road in order to incorporate the micro-siting of Project infrastructure.

6.10.4.1 Desktop Evaluation

Three priority vascular plants have been observed within 5 km of the Beaver Dam Mine Site and Haul Road according to the ACCDC report (Appendix I.1 and I.2); southern twayblade (*Neottia bifolia*, syn. *Listera australis*), flat-stemmed pondweed (*Potamogeton zosteriformis*) and Nova Scotia agalinis (*Aglinis neoscotica*). No priority vascular plants have been observed within 5 km of the Touquoy Mine Site according to the ACCDC report (Appendix I.3). In regard to lichens, boreal felt lichen (*Erioderma pedicellatum*) was cited within 5 km of the PA in all ACCDC reports. Additional priority lichen species observed within the ACCDC reports within 5 km of the PA are listed in the Table 6.10-3.

The priority lichen dataset received from the Mersey Tobeatic Research Institute (MTRI) identified four priority species within the PA and surrounding LAA, inclusive of the dedicated LSA: boreal felt lichen, blue felt lichen, blistered jellyskin lichen (Leptogium corticola) and salted shell lichen (Coccocariai palmicola) (Table 6.10-3).

The Nova Scotia Department of Communities, Culture and Heritage provided a list of flora and fauna SAR and SOCI documented by their staff within the vicinity of the PA. The priority flora species are as follows; Michaux's dwarf birch (*Betula michauxii*), showy lady's slipper (*Cypripedium reginae*), flat-stemmed pondweed (*Potamogeton zosteriformis*), alder-leaved buckthorn (*Rhamnus alnifolia*), northern bog violet (*Viola nephrophylla*), and golden alexanders (*Zizia aurea*) (Table 6.10-3).

6.10.4.2 Habitat Survey Results

The PA is located in the Eastern Ecoregion of the Acadian Ecozone. Ecoregions are subdivisions of the larger ecozones and express macroclimate as a distinctive ecological response to climate through soils and vegetation (Neily et al., 2005).

Ecoregions are further subdivided into ecodistricts, which reflect macroelements of the physical and biological attributes of ecosystems which will ultimately influence biodiversity. The PA lays within the Eastern Interior Ecodistrict (previously subdivided into the Eastern Interior and Eastern Drumlins Ecodistricts). The Eastern Interior Ecodistrict is generally characterized by highly visibly bedrock where glacial till is very thin, exposing the ridge topography. Where till is thicker, ridged topography is masked and thick softwood forests occur. There are a few drumlins and hills scattered throughout the ecodistrict and fine textured soils are derived from slates (NSLF 2017).

Ecosites are units which represent ecosystems that have developed under a variety of conditions and influences, but which have similar moisture and nutrient regimes. An ecosite is associated with a finite range of soil and site conditions and a finite range of vegetation types that grow naturally under those conditions. Ecosites represent general productivity units and provide an ecological setting through which vegetation and soil types can be grouped and compared. In this application, the value in ecosite classification lies in wildlife habitat analysis and biodiversity considerations. For example, ecosite classification can be used to help determine the likelihood of finding particular rare plants that prefer specific moisture or nutrient regimes.

Within the PA, there are confirmed 12 ecosites, of which 10 were observed in the Beaver Dam Mine Site (six ecosites previous to additional 2019 surveys) and nine within the Haul Road. No additional HSPs were completed within the Haul Road in 2019. Eighteen vegetation types (VT) were observed during habitat surveys. Collectively, and as a result of the dominance of nutrient poor acidic soils, predominant VTs comprised of conifer species as the dominant canopy layer, often with sparse, low diversity herbaceous layers. The single most dominant VT is SH5 which is dominated by red spruce – balsam fir and Schriber's moss. The HSPs within the Beaver Dam Mine Site and Haul Road is shown in Table 6.10-4. The following sections describe the ecosites identified throughout the Beaver Dam Mine Site and Haul Road, grouped by predominant nutrient regime.

The 10 ecosites identified within the Beaver Dam Mine Site are within the dry to fresh moisture regimes, with very poor to rich nutrient regimes. The spruce-hemlock (AC10) and spruce-pine (AC3, AC6, AC7) forest groups dominate the Beaver Dam Mine Site. Spruce-hemlock forest groups are characterized by red spruce (*Picea rubens*), white pine (*Pinus strobus*), and eastern hemlock (*Tsuga canadensis*). These species have high shade tolerance and are long lived species, which can support old growth conditions. Spruce-hemlock forest groups generally do not support many species of rare plants but provide good quality habitat for a diversity of mammals and birds. Generally, spruce-pine forest groups are associated with a natural disturbance regime of fire, which leads to stands dominated by spruce, pine, and understorey vegetation tolerant of acidic, nutrient poor conditions.

Within the Beaver Dam Mine Site, less abundant ecosites include spruce-tamarack (AC4), pine-oak (AC5), spruce-fir-maple (AC8), maple-spruce (AC9), spruce-birch (AC11) and maple-beech (AC13). Spruce-tamarack and spruce-fir-maple forest groups are typically associated with poorly drained soils of coniferous and mixedwood treed swamps. While pine-oak and maple-spruce forest groups support similar species assemblages, the greater nutrient availability of the maple-spruce group creates more fertile and diverse understory conditions. The spruce-birch and maple-beech forest groups commonly support climax forests with limited natural stand disturbance and resultant uneven-aged forests. Climax softwood and mixedwood forests area typical of the spruce-birch forest group, whereas the maple-beech group supports climax hardwood forests.

Of the 31 established HSPs within the Beaver Dam Mine Site, the most abundant ecosite was AC10, accounting for 36% of all survey points (Figure 6.10-2). The next most abundant ecosite within the Beaver Dam Mine Site is AC6 (19%), followed by AC5 and AC11 (each 10%).

Table 6.10-4: Habitat Survey Results within the Beaver Dam Mine Site and Haul Road

Habitat Survey Point	PA Component	Ecosite	VT[a]	Stand Age	Level and Type of Disturbance	Comments
HP001	Beaver Dam Mine Site	AC10	SH4	Regenerating	Moderate -harvested	Overstory dominated by red spruce and balsam fir with white pine, yellow birch, and red maple. Understory dominated by sapling red spruce and balsam fir with velvet-leaved blueberry, bracken fern, bunchberry, and goldthread groundcover.
HP002	Beaver Dam Mine Site	AC7	SP6	Immature	Low	Overstory dominated by balsam fir and black spruce with tamarack, red maple, and white birch. Understory dominated by regenerating balsam fir and black spruce with raisin, bracken fern, sheep laurel, goldthread, and creeping snowberry.
HP003	Beaver Dam Mine Site	AC6	SP4	Regenerating	Moderate - harvested	Some remnant mature white pine in overstory with black spruce, tamarack, black spruce, balsam fir, and red maple. Understory dominated by regenerating balsam fir and bracken fern with black spruce, red maple, wild raisin, mountain holly, sheep laurel, bunchberry, and velvet-leaved blueberry.
HP004	Beaver Dam Mine Site	AC11	SH3	Immature	Low	Softwood stand. Overstory dominated by red spruce and balsam fir with red maple, yellow birch, and white pine. Understory dominated by regenerating balsam fir and hay-scented fern with red spruce, bunchberry, evergreen wood fern, and lady fern.
HP005	Beaver Dam Mine Site	AC11	SH5	Regenerating	Harvested	Disturbed stand. Overstory dominated by red spruce and red maple with yellow birch and white birch. Understory dominated regenerating balsam fir with red maple and wild raisin.
HP006	Beaver Dam Mine Site	AC8	WC7	Immature	Low	Treed coniferous swamp. Overstory dominated by tamarack with red maple, balsam fir, black spruce, and white birch. Understory dominated by spinulose wood fern, balsam fir, speckled alder, bunchberry, and creeping snowberry.
HP007	Beaver Dam Mine Site	AC10	MW1	Regenerating	Harvested	Disturbed stand. Overstory dominated by red spruce with yellow birch, red maple, and white birch. Understory dominated by regenerating balsam fir and strawberry with red spruce, red maple, yellow birch, sheep laurel, Labrador tea, creeping snowberry, and white meadowsweet.

Table 6.10-4: Habitat Survey Results within the Beaver Dam Mine Site and Haul Road (continued)

Habitat Survey Point	PA Component	Ecosite	VT[a]	Stand Age	Level and Type of Disturbance	Comments
HP008	Beaver Dam Mine Site	AC10	TH7	Regenerating	Harvested	Disturbed stand. Overstory dominated by yellow birch with balsam fir and white birch. Understory dominated by regenerating yellow birch and balsam fir. Mature trees are entirely absent, as is herb layer due to leaf litter/canopy cover.
HP009	Beaver Dam Mine Site	AC10	SH8	Immature	Low	Softwood stand. Overstory dominated by balsam fir with red maple and yellow birch. Understory dominated by balsam fir, red maple, and bunchberry.
HP010	Beaver Dam Mine Site	AC11	SH4	Immature	Low	Softwood stand. Overstory dominated by white pine with red spruce, balsam fir, and red maple. Understory dominated by bunchberry with sheep laurel and balsam fir.
HP011	Beaver Dam Mine Site	AC10	MW2	Regenerating	Harvested	Disturbed stand. Overstory dominated by red spruce with white pine, balsam fir, red maple, and white birch. Understory dominated by red spruce saplings and sheep laurel with red maple saplings, wild raisin, bunchberry, mayflower, and bracken fern.
HP012	Beaver Dam Mine Site	AC10	MW2	Regenerating	Harvested	Disturbed stand. Overstory dominated by red spruce with red maple, balsam fir, white birch, white pine, and yellow birch. Understory dominated by regenerating balsam fir and bunchberry with pin cherry, tamarack, sheep laurel, bracken fern, mayflower, and velvet-leaved blueberry.
HP013	Beaver Dam Mine Site	AC10	MW2	Regenerating	Harvested	Disturbed stand. Overstory dominated by red maple with white birch, red spruce, and yellow birch. Understory dominated by regenerating balsam fir with twinflower, bunchberry, low-bush blueberry, red raspberry, and New York fern.
HP014	Beaver Dam Mine Site	AC10	MW2	Regenerating	Harvested	Disturbed stand. Overstory dominated by balsam fir with red spruce, red maple, yellow birch, and white birch. Understory dominated by regenerating balsam fir, red maple, and bunchberry with red spruce, yellow birch, bracken fern, and twinflower.
HP015	Beaver Dam Mine Site	AC10	SH5	Mature	Low	Balsam fir and black spruce. Very little understory vegetation.

Table 6.10-4: Habitat Survey Results within the Beaver Dam Mine Site and Haul Road (continued)

Habitat Survey Point	PA Component	Ecosite	VT[a]	Stand Age	Level and Type of Disturbance	Comments
HP016	Beaver Dam Mine Site	AC4	WC2	Immature	Low	Treed coniferous swamp. Overstory dominated by black spruce with tamarack, red maple, and balsam fir. Understory dominated by wild raisin and Labrador tea with red maple, black spruce, tamarack, sheep laurel, bunchberry, twinflower, cinnamon fern, and steeplebush.
HP017	Beaver Dam Mine Site	AC6	SP4a	Regenerating	Harvested	Disturbed stand with remnant mature white pine in overstory. Overstory dominated by black spruce, balsam fir, white pine, and red maple. Understory dominated by regenerating balsam fir and sheep laurel with wild raisin, bunchberry, bracken fern, velvet- leaved blueberry, mountain holly, and teaberry.
HP018	Haul Road	AC6	SP4a	Regenerating	Harvested	Disturbed- cut. Overstory dominated by balsam fir, black spruce, red maple, white pine. Understory dominated by sheep laurel, wild raisin, bracken fern, and teaberry.
HP019	Haul Road	AC1	SP3a	Immature	Low	Overstory dominated white birch and balsam fir, red and black spruce, white pine. Understory dominated mayflower, bracken fern, and sheep laurel.
HP020	Haul Road	AC6	IH6	Regenerating	Harvested	Disturbed. Overstory dominated by red maple and white birch.
HP021	Haul Road	AC10	MW4	Immature to mature	Low	Overstory dominated white birch, yellow birch.
HP022	Haul Road	AC7	SH5	Immature to mature	Harvested	Disturbed. Overstory dominated by red spruce.
HP026	Haul Road	AC5	SP4	Mature	Low	Overstory dominated by white pine and red spruce. Understory dominated by red maple and balsam fir, occasionally.
HP027	Haul Road	AC2	OW2	Mature	Low	Overstory has abundant cover of red spruce. Shrub layer dominated by white birch. Understory dominated by sheep laurel, teaberry, and bracken fern.
HP028	Haul Road	AC7	SP4	Mature	Low	Overstory dominated by white pine.
HP029	Haul Road	AC10	TH7	Mature	Low	Overstory dominated by yellow birch. Understory dominated by evergreen wood fern.
HP030	Haul Road	AC6	SH5	Mature	Low	Overstory dominated by balsam fir.
HP031	Haul Road	AC10	MW1	Immature to mature	Low	Overstory has abundant cover of balsam fir, white birch, and yellow birch.

Habitat Survey Point	PA Component	Ecosite	VT[a]	Stand Age	Level and Type of Disturbance	Comments
HP032	Haul Road	AC6	SH5	Immature to mature	Low	Overstory has abundant red spruce. Understory dominated by cinnamon fern.
HP033	Haul Road	AC1	OW2	Mature	Low	Overstory dominated by black spruce. Understory dominated by teaberry and bracken fern.
HP034	Haul Road	AC5	SH5	Mature to over mature	Low	Overstory dominated by black spruce. Understory dominated by sheep laurel and bracken fern.
HP035	Haul Road	AC6	SH5	Mature to over mature	Low	Overstory dominated by red spruce and red maple. Understory dominated by sheep laurel.
HP036	Haul Road	AC6	SP5	Mature	Low	Overstory dominated by black spruce. Understory dominated by bracken fern.
HP037	Haul Road	AC11	SH4	Mature	Low	Overstory dominated by red spruce and black spruce. Understory dominated by sheep laurel.
HP038	Beaver Dam Mine Site	AC3	OW2	Mature	Low	Softwood stand. Overstory dominated by black spruce with balsam fir and northern wild raisin. Understory dominated by rhodora, Schrebers moss and sphagnum.
HP039	Beaver Dam Mine Site	AC9	IH6	Immature	Low	Mature hardwood stand. Overstory dominated by red maple with white birch.
HP040	Beaver Dam Mine Site	AC13	MW2	Mature	Low	Mixed wood stand. Overstory dominated by balsam fir with red maple, red spruce, and white birch. Understory is sparse but dominated by bunchberry and twinflower.
HP041	Beaver Dam Mine Site	AC4	MW4	Immature	Low	Mixed wood stand. Overstory dominated by balsam fir with yellow birch and red maple. Understory dominated by regenerating balsam fir.
HP042	Beaver Dam Mine Site	AC13	MW2	Immature	Harvested	Mixed wood stand. Overstory dominated by red maple with white pine and balsam fir. Understory dominated by bunchberry and black huckleberry.
HP043	Beaver Dam Mine Site	AC6	SP6	Mature	Low	Mixed wood stand. Overstory dominated by red spruce with balsam fir and white birch. Sparse herbaceous layer with Schreber's moss

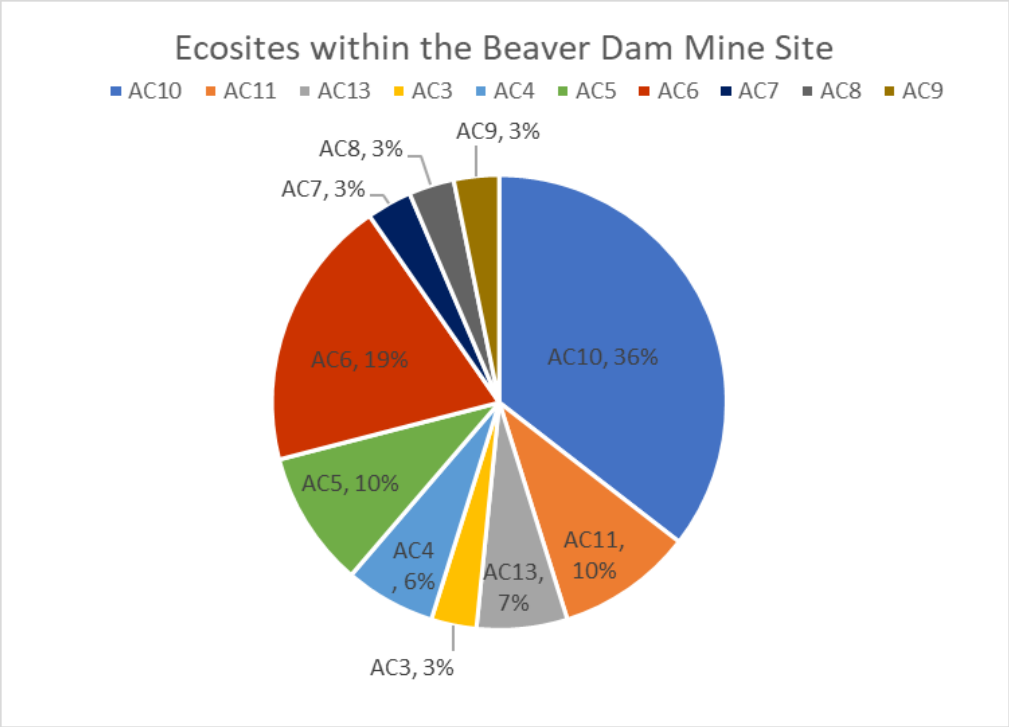

Table 6.10-4: Habitat Survey Results within the Beaver Dam Mine Site and Haul Road (continued)

Habitat Survey Point	PA Component	Ecosite	VT[a]	Stand Age	Level and Type of Disturbance	Comments
HP044	Beaver Dam Mine Site	AC6	SP6	Mature	Low	Mixed wood stand. Overstory dominated by red spruce with white birch. Sparse herbaceous layer dominated by creeping snowberry.
HP045	Beaver Dam Mine Site	AC10	IH7	Mature	Low	Mixed wood stand. Overstory dominated by red maple with scattered balsam fir. Understory dominated by hay scented fern and bunchberry.
HP046	Beaver Dam Mine Site	AC5	SH8	Mature	Low	Softwood stand. Dominated by balsam fir with a closed canopy. Sparse herbaceous layer dominated by bryophytes including stair step moss and Schreber's moss.
HP047	Beaver Dam Mine Site	AC6	SP6	Regenerating	Harvested	Disturbed. Scattered regenerating red spruce, mountain holly, bracken fern, and black huckleberry.
HP048	Beaver Dam Mine Site	AC6	SH4	Mature	Low	Softwood stand. Overstory dominated by red spruce with small amounts of white pine. Understory dominated by mountain holly, bracken fern, and sheep laurel.
HP049	Beaver Dam Mine Site	AC5	SH8	Mature	Low	Softwood stand. Overstory dominated by a closed canopy of balsam fir. Sparse herbaceous layer with scattered starflower.
HP050	Beaver Dam Mine Site	AC5	SH8	Mature	Moderate	Softwood stand. Overstory dominated by balsam fir with scattered red spruce. Sparse herbaceous layer dominated by Schreber's moss.
HP051	Beaver Dam Mine Site	AC10	IH7	Mature	Moderate-Harvested	Mixed wood stand. Overstory dominated by red maple. Understory dominated by dwarf red raspberry and giant goldenrod.

[a] VT: Vegetation Type

Note: HP01-HP17 and HP38-HP51 are within the Beaver Dam Mine Site Mine. HP18-37 (excluding HP23-HP25) are within the Haul Road. HP23-HP25 were along an alternate Haul Road design, which is no longer being consider. These HPs have been removed from this assessment.

Figure 6.10-2: Relative Abundance of Ecosites within the Beaver Dam Mine Site

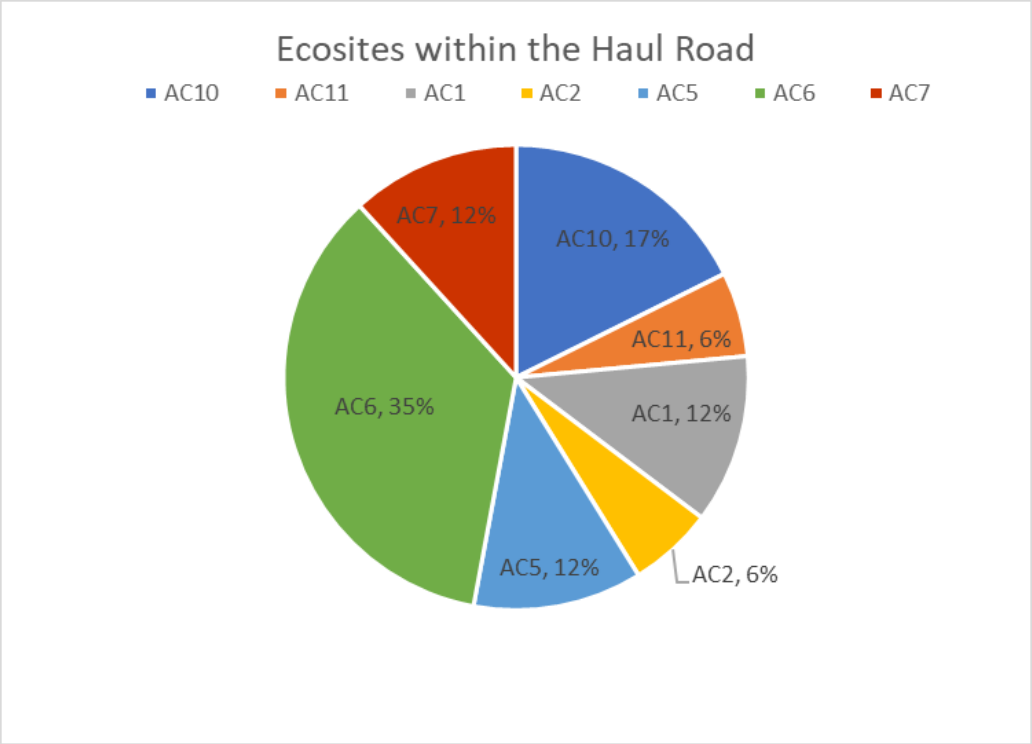
Within the Haul Road, HSPs fell within nine different ecosites. Ecosites identified within the Haul Road were within the very dry to wet moisture regime, with very poor to rich nutrient regimes. These ecosites generally support a broader variety of vegetation types from the spruce-pine, intolerant and tolerant hardwood, mixed wood, open woodland, spruce-hemlock and intolerant hardwood forest groups.

Similar to the Beaver Dam Mine Site, the spruce-hemlock (AC10) and spruce-pine (AC2, AC6, AC7) forest groups also dominate the Haul Road. Most Haul Road forest groups were observed within the Beaver Dam Mine Site and are described previously. The pine-spruce (AC1) group was only observed within the Haul Road and is associated with upland areas with near-surface bedrock and nutrient poor, coarse textured soils.

Of the 17 established HSPs within the Haul Road, the most abundant ecosite was AC6, accounting for 35%. The next most abundant ecosite within the Haul Road is AC10 at 17%, followed by AC1, AC5, AC7, and AC11 at 12% each (Figure 6.10-3).

A summary of ecosite abundance across the PA is presented in Figure 6.10-4. Of the 48 established HSPs within the Beaver Dam Mine Site and Haul Road. AC10 and AC6 make up 54% of the ecosites observed within the PA and account for 29% and 25%, respectively.

Figure 6.10-3: Relative Abundance of Ecosites within the Haul Road



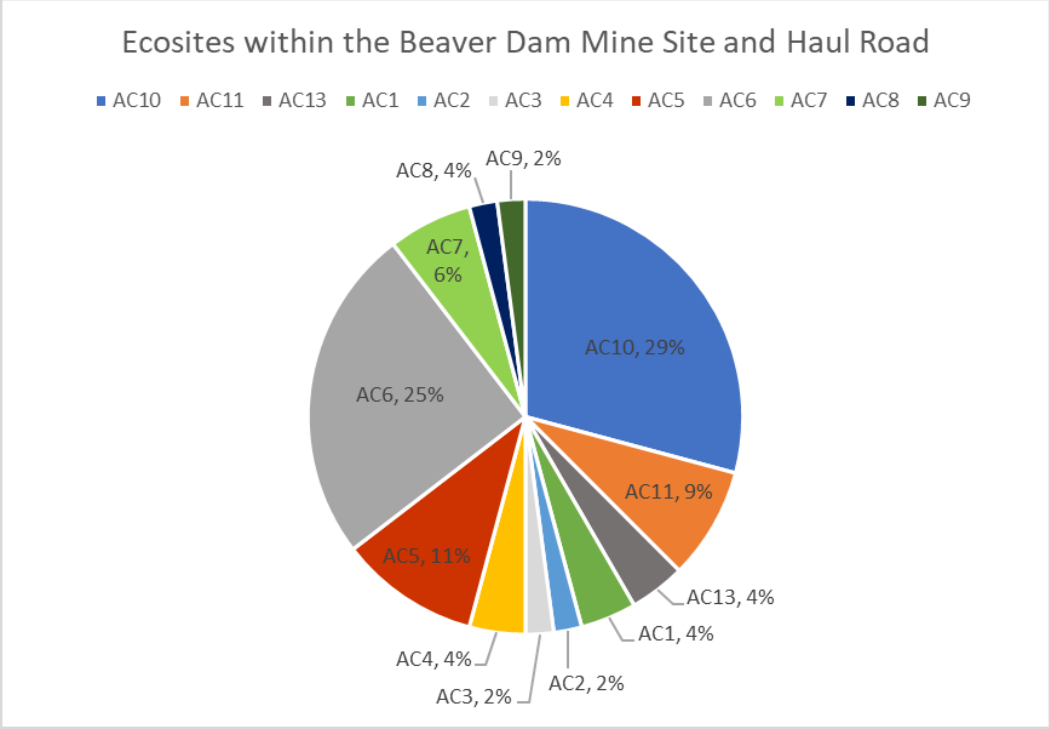


Figure 6.10-4: Ecosites within the Beaver Dam Mine Site and Haul Road

6.10.4.2.1 Very Poor Nutrient Regime

Ecosites with very poor nutrient regimes encountered within the Beaver Dam Mine Site and Haul Road include AC1, AC2, AC3 and AC4. These ecosites represent very dry, fresh, moist and wet moisture regimes, respectively. Ecosite AC1 was observed twice within the Haul Road. At the survey points, the Beaver Dam Mine Site and Haul Road supported open woodland and spruce-pine vegetation types, typical of dry moisture regimes within the very poor nutrient regime. This ecosite occurs mainly on upper slopes or crests of exposed bedrock. Ecosite AC2, also observed within the Haul Road, supported an open woodland forest type as well. Ecosite AC3 was observed once within the Beaver Dam Mine Site and supported an open woodland is supported, typical of a poor nutrient regime. This ecosite mainly occurs on level, upper or middle slopes where there is moderate exposure to weather conditions. One of the HSPs assessed was classified as ecosite AC4, which occurs mainly on poorly to very poorly drained level areas and depressions with coarse textured glacial till and/or organic deposits. This ecosite has wet, very nutrient poor to very poor soils, which generally support poorly stocked stands of black spruce with tamarack (sometimes stunted).

6.10.4.2.2 Poor Nutrient Regime

Forty percent of HSPs were classified under a poor nutrient regime. Ecosites AC5, AC6, AC7, and AC8 represent dry, fresh, moist, and wet moisture regimes, respectively.

Ecosite AC5 occurs on well- to rapidly-drained sites and generally supports a canopy of white pine, red spruce, black spruce, or red maple. This ecosite mainly occurs on higher or level topographies. Within the Beaver Dam Mine Site and Haul Road, this ecosite supported spruce-pine and spruce-hemlock vegetation types. Ecosites AC6 and AC7 occur primarily on well drained to imperfectly-drained slopes with coarse textured glacial till deposits and fresh to moist, nutrient poor soils. These conditions generally support closed canopy stands of white pine and black spruce. When balsam fir is present, it is generally intermediate in the canopy and of low vigor. Early successional stands are dominated by large-toothed aspen (*Populus grandidentata*), red oak (Quercus rubra), and red maple. Within the Beaver Dam Mine Site and Haul Road, HSPs within these ecosites were identified to be within the spruce-pine, intolerant hardwood, and spruce-hemlock forest groups.

Ecosite 8 typically occurs in depressions or areas with poorly or very poorly drained soils, generally supporting wetland habitat. Typical canopy coverage within this ecosites can range from spruce, balsam fir, and larch, and occasionally red maple and white ash. Within the Beaver Dam Mine Site and Haul Road, this ecosite supported a wet coniferous forest group.

6.10.4.2.3 Medium Nutrient Regime

Within the Beaver Dam Mine Site and Haul Road specifically, and within Nova Scotia more generally, the majority of Acadian climax softwood and mixed wood forests are found on sites with medium nutrient regimes, which include AC9, AC10 and AC11. AC9 occurs on dry, well drained steep slopes with shallow glacial till and generally supports an early successional forest. Within the Beaver Dam Mne Site, this ecosite supported hardwood stands dominated by red maple with white birch. Occurring mainly on well-drained slopes with medium textured glacial till deposits, AC10 has fresh, nutrient-medium soils which generally support late successional forests dominated by red spruce, eastern hemlock, and yellow birch. Earlier successional forests contain balsam fir, white birch, red maple, and trembling aspen (*Populus tremuloides*). Within the Beaver Dam Mine Site and Haul Road, a variety of vegetation types and forest groups were found within AC10 ecosites, including mixed wood, spruce-hemlock, and tolerant hardwood forest groups.

Occurring mainly on imperfectly drained lower slopes and level areas with medium textured glacial till deposits, AC11 ecosites have moist, nutrient-medium soils which generally support mixed wood climax communities dominated by red spruce, hemlock and yellow birch. Earlier successional forests are similar in nature to those found in AC10. Within the Beaver Dam Mine Site and Haul Road, four of the HSPs within ecosite AC11 were identified within the spruce-hemlock forest group, while a single site was identified within the spruce-pine forest group.

6.10.4.2.4 Rich Nutrient Regime

Ecosite AC13 was observed in two locations within the Haul Road. This ecosite occurs on well drained slopes with a fresh to moist water regime. This ecosite typically supports late successional forests dominated by sugar maple, American beech, yellow birch, white ash, and red maple. Early successional stands may be dominated by aspen or white birch. In each location observed within the Haul Road, this ecosite supported an intolerant hardwood vegetation type, dominated by mature red maple and yellow birch.

6.10.4.2.5 Habitat Survey Conclusions

The current condition of the Beaver Dam Mine Site is disturbed and fragmented habitat based on timber harvesting and historic mining activity. The level of disturbance within the Beaver Dam Mine Site disproportionately affects uplands over wetlands. Large, natural, undisturbed wetland habitats do exist within the Beaver Dam Mine Site (particularly Wetlands 2 and 29). A network of roads and trails is present throughout the site, with parts of the Beaver Dam Mine Site characterized by un-vegetated gravel and crushed stone, and a large fabricated settling pond used during mining activities (wetland 59) exists in the Beaver Dam Mine Site.

Upland forests in the Beaver Dam Mine Site have experienced relatively high levels of disturbance from timber harvesting. Of the 31 HSPs in the Beaver Dam Mine site, 42% (n=13) have experienced some level of disturbance, typically timber harvesting, within the recent past. While mature, undisturbed habitats are present in the Beaver Dam Mine Site, particularly in large wetland complexes, generally, the Beaver Dam Mine Site has experienced significant levels of disturbance. As mentioned in the methodology section, portions of the Beaver Dam Mine Site have experienced significant levels of disturbance from historic mining practices as well.

The level of disturbance identified within the Haul Road is significantly lower, with only 15% of HSPs having experienced timber harvesting. However, 80% of the survey was completed within approximately 50 m of an existing road. This means that many natural forest stands are present, but the overall landscape is still somewhat disturbed, based on habitat fragmentation by the presence of an existing road. The effect of habitat fragmentation and disturbance to terrestrial fauna is described in further detail in Section 6.10.7.

In areas affected by natural or anthropogenic disturbance (e.g., wind throw or tree harvesting, respectively), early successional stands were determined to be in the mixed wood forest group. The dominant disturbance regime in the PA is timber harvesting, which is present in patches throughout upland forests. Generally speaking, uplands within the PA contain immature or unevenly aged coniferous stands or mixed wood stands. Several pockets of mature coniferous forests are scattered throughout the PA, but over-mature stands were generally uncommon. Pure deciduous stands (including both tolerant and intolerant hardwood forests) are infrequent within the Beaver Dam Mine Site, though they do occur occasionally within the Haul Road.

The ecosites and vegetation types observed are representative of the Eastern Ecoregion of the Acadian Ecozone as described in Section 6.10.3.2. The habitat survey results indicate a greater diversity of ecosites and vegetation types within the Haul Road compared with the Beaver Dam Mine Site. This is to be expected given the broader geographic extent of the Haul Road and the relatively disturbed nature of the Beaver Dam Mine Site. None of the ecosites or vegetation types across the Beaver Dam Mine Site and Haul Road are unique or rare in the local or regional context. Furthermore, none of the ecosites observed are known to

have an elevated potential to support rare vegetation species (for instance, ecosites AC14, AC16 and AC17 are all documented as having higher potential to support rare and at risk vegetation species).

Overall, current and historic land use throughout the PA has resulted in a patchwork of mature, immature, regenerating, and disturbed stands. The PA contains a diversity of habitat types and landscape features, but has experienced a considerable amount of disturbance and habitat fragmentation as a result of historic mine operations and current and historic timber harvesting practices.

6.10.4.2.6 Touquoy Mine Site

Habitat present within the Touquoy Mine Site include coniferous forest, deciduous forest, mixed forest, cutover forest, wetlands, rural residential areas, and areas to be cleared (CRA 2007a).

6.10.4.3 Vascular Plants

A total of 295 species of vascular plants were identified within the Beaver Dam Mine Site and the Haul Road (Appendix K.1). One additional vascular plant species, Nova Scotia Agalinis (*Agalinis neoscotica*, S3S4), was observed during additional field surveys in 2019. The diversity of species is moderate to high, especially considering the low fertility of soils within the PA; however, this is attributed to the range of habitat types encountered, from natural aquatic systems, a variety of wetland types, and both intact and disturbed upland habitats. The vegetation species observed are largely native species, with relatively low diversity and abundance of roadside exotic or invasive species. The species and communities of vascular plants encountered were typical given the eco-regional context, nutrient regimes, moisture regimes, and disturbance regimes. Invasive species were documented whenever observed.

Of the 295 species identified, six are considered priority species; lesser rattlesnake plantain (*Goodyera repens*, S3), southern twayblade (*Neottia bifolia*, syn. Listera australis, S3) appalachian polypody (*Polypodium appalachianum*, S3), highbush blueberry (*Vaccinium corymbosum*, S3S4) and Nova Scotia agalinis (*Agalinis neoscotica*, S3S4; Section 6.13, Figure 6.13-2A). These will be discussed further in Section 6.13.

Upland habitat throughout the PA is characterized by exposed granite boulders and coarse-textured, well-drained soil. The soil shows evidence of an impoverished condition, with low nutrient levels. This is evident in the forest groups and vegetation types that are found, as outlined in Section 6.10.4.2 (habitat survey results). Ericaceous shrub species such as sheep laurel (Kalmia angustifolia) and black huckleberry (*Gaylussacia baccata*) are frequent, along with other species which thrive in impoverished soil, such as mountain holly (*Nemopanthus mucronatus*), wild raisin (Viburnum nudum), and black spruce (*Picea mariana*). Where somewhat richer, finer soil till deposits are present, mixed wood to tolerant hardwood forests occur and include dominant species such as yellow birch (Betula alleghaniensis), red maple (Acer rubrum) and occasionally large-toothed aspen (*Populus grandidentata*).

Overall, understory vegetation layers are characteristic of low to medium soil fertility forest ecosystems described in Nova Scotia's Forest Ecosystem Classification system. Indicator species occurring in medium fertility sites include northern long beech fern (*Phegopteris connectilis*) and Christmas fern (*Polystichum arctostichoides*), while species occurring in poorer conditions include trailing arbutus (Epigaea repens), bracken fern (Pteridium aquilinum), and pink lady's-slippers (*Cypripedium acaule*). Large portions of the PA, particularly within the Beaver Dam Mine Site, have undergone large-scale anthropogenic disturbance in the form of clearcutting, which has resulted in a much younger forest landscape with less valued, more shade-intolerant and opportunistic tree species. Much of the diversity of vascular plants is attributed to wetland habitat. Wetlands have been described in detail in Section 6.8. The wetlands encountered generally supported vascular plant communities typical of nutrient poor peatlands and treed swamps, such as leatherleaf (*Chamaedaphne calyculata*), Atlantic sedge (*Carex atlantica*) and tussock sedge (*Carex stricta*)

dominated low shrub bogs, and black spruce (*Picea mariana*), mountain holly (*Nemopanthus mucronatus*), and cinnamon fern (*Osmunda cinnamomea*) swamps. Open wetlands are primarily dominated by sphagnum moss with scattered and dwarfed black spruce, red maple (Acer rubrum), and speckled alder (*Alnus incana*). Several common species of Atlantic coastal plain flora were observed within wetlands throughout the Beaver Dam Mine Site and the Haul Road. These include species such as branched bartonia (*Bartonia paniculata*), Atlantic sedge, dwarf huckleberry (*Gaylussacia bigeloviana*), bog fern (*Thelypteris simulata*), and purple bladderwort (Utricularia purpurea). Vegetation communities identified throughout the Beaver Dam Mine Site and Haul Road generally exhibit low fertility and low potential for rare species. Priority species will be discussed in detail in Section 6.13. A complete list of all vascular plants identified within the Beaver Dam Mine Site and the Haul Road is included in Appendix K.1.

6.10.4.3.1 Touquoy Mine Site

Coniferous forest is the most common forest habitat type within the Touquoy Mine Site. These forests are dominated by red spruce, balsam fir, bunchberry (*Cornus canadensis*) and goldthread (*Coptis trifolia*). No SOCI plants were observed during vascular plant surveys conducted in August 2004, May and June 2005, and September 2006 as part of the EARD process (CRA 2007a). One black ash (*Fraxinus nigra*) was discovered within the Touquoy Mine Site incidentally during wetland surveys in September 2015. It is discussed in further detail within Section 6.13.

6.10.4.4 Lichens

The LSA shown on Figure 6.13-2A was established based on increased potential for rare lichens in the general vicinity of the Beaver Dam Mine Site and the level of proposed ground disturbance within the Beaver Dam Mine Site. Both the Beaver Dam Mine Site and the LSA are located within the LAA. The goal of the expanded study area for lichens around the Beaver Dam Mine Site was to determine, if rare lichens were identified within the Beaver Dam Mine Site, whether these species were unique to that specific location or whether they were present within the broader geographical context.

A comprehensive list of lichen species was not completed, as the primary focus was in identifying SOCI and SAR lichen. However, common lichen species observed opportunistically during priority lichen surveys were recorded and are presented in the table below. Twenty-three species were recorded within the LSA (Beaver Dam Mine Site, surrounding area, and Haul Road [Figure 6.13-2A]) and during the targeted 2019 surveys in the expanded LSA (western and southeastern expansions of the Beaver dam Mine Site). Of these species, 11 are listed as SAR or SOCI. More details on priority species results, including location details and habitat associations, are presented in Section 6.13. A list of species observed within the LSA and Haul Road are provided in Table 6.10-5, priority species are bolded.

While the specific habitat requirements of each of priority lichen species varies slightly, they all require mature to over-mature forests. Stand age is one of the greatest determinants of lichen diversity (McMullin, Duinker, Cameron, Richardson, & Brodo, 2008). Within the Beaver Dam Mine Site and broader LSA, small to moderate scale disturbance is abundant in the form of timber harvesting, particularly to the north and east of the PA; however, where mature, intact natural stands within the Beaver Dam Mine Site support several rare species of lichen. According to lichen specialist, Chris Pepper, the habitat along the Haul Road generally lacked over-mature red maple and balsam fir required to support rare lichen species. This habitat is present within and surrounding the Beaver Dam Mine Site, where forest stands supported a diversity of cyanolichen species. According to Mr. Pepper, the diversity and abundance of lichen species observed within the entire Beaver Dam Mine Site and Haul Road, including priority species is typical of similar habitats

Table 6.10-5: Lichen Species Observed within the Lichen Study Area

Common Name	Scientific Name	COSEWIC	SARA	NSESA	SRank**	BDMS/HR or LSA*

Notes: * BDMS/HR: observed within the Beaver Dam Mine Site or Haul Road. LSA: Identified within the broader lichen study area only.

**S-Ranks have been updated to reflect changes in rankings since original submission

***A follow up survey conducted in the fall of 2016 determined that all three BFL thalli were no longer present. Their absence was reconfirmed on December 4, 2017.

6.10.4.4.1 Touquoy Mine Site

Lichen surveys conducted in the Touquoy Mine Site in 2004 and 2005 as part of the EARD process found the presence of blue felt lichen (*Degelia plumbea*). An additional lichen survey in 2007 found 20 additional species (CRA 2007a). Eight of the 21 species identified in 2007 are priority species, further detail within Section 6.13.

6.10.4.5 Habitat Desktop Analysis

Within the LAA, the Upland Forest category was the dominant habitat type and accounted for 74% of the total habitat type cover. A breakdown of the percent cover of each habitat type within LAA and impact area is presented in Table 6.10-6 and Figures 6.10-5A to 6.10-5E. Furthermore, the percent of habitat expected to be directly impacted by the Beaver Dam Mine Site and Haul Road compared to the LAA is presented below. The expected impact (percent habitat cover proposed to be directly impacted by the Beaver Dam Mine Site and Haul Road) was then used to calculate the magnitude of impacts to each habitat type, as described in Section 6.10.7.

Table 6.10-6: Habitat Cover Type within the Beaver Dam Mine Site, Haul Road and the Local Assessment Area

Habitat Cover	Area within the LAA (Ha)	% Area within the LAA	Area within Project Area (BD Mine Site and HR) (Ha)	% within the Project Area (BD Mine Site and HR)
Upland Forest				
Hardwood Dominant Stands	637.3	10.7	42.2	17.3
Softwood Dominant Stands	3,081.3	51.8	92.1	37.8

Lakes, Ponds, Beaver flowage	227.5	3.8	4.6	1.9
Wetlands (includes all wetland classes)	825.4	13.9	8.2	3.4
Non-forested Upland Communities				
Barrens (includes rock barrens)	16.3	0.3	0	0
Disturbed				
Anthropogenic Disturbances[c]	20.3	0.3	13.4	5.5
TOTAL	**5,947.1**	**-**	**244**	**-**

[a] Includes unmerchantable timber, often which is regenerative stands and stands which were not categorized as hardwood or softwood stands.

[b] Managed forests include plantations, cutblocks, selective cuts etc.

[c] Includes roads, railways, urban development, quarries, gravel pits, mining activity etc.

This desktop analysis is limited by the accuracy of the Nova Scotia Forestry Inventory and mapped wetlands layers, but provides a coarse scale representation of the habitat types and forest condition within the LAA, the Beaver Dam Mine Site, and Haul Road. It is acknowledged that certain habitats which are presented in the database may be over or under-represented compared to the current ground conditions.

6.10.4.6 Old Forest and Interior Forest

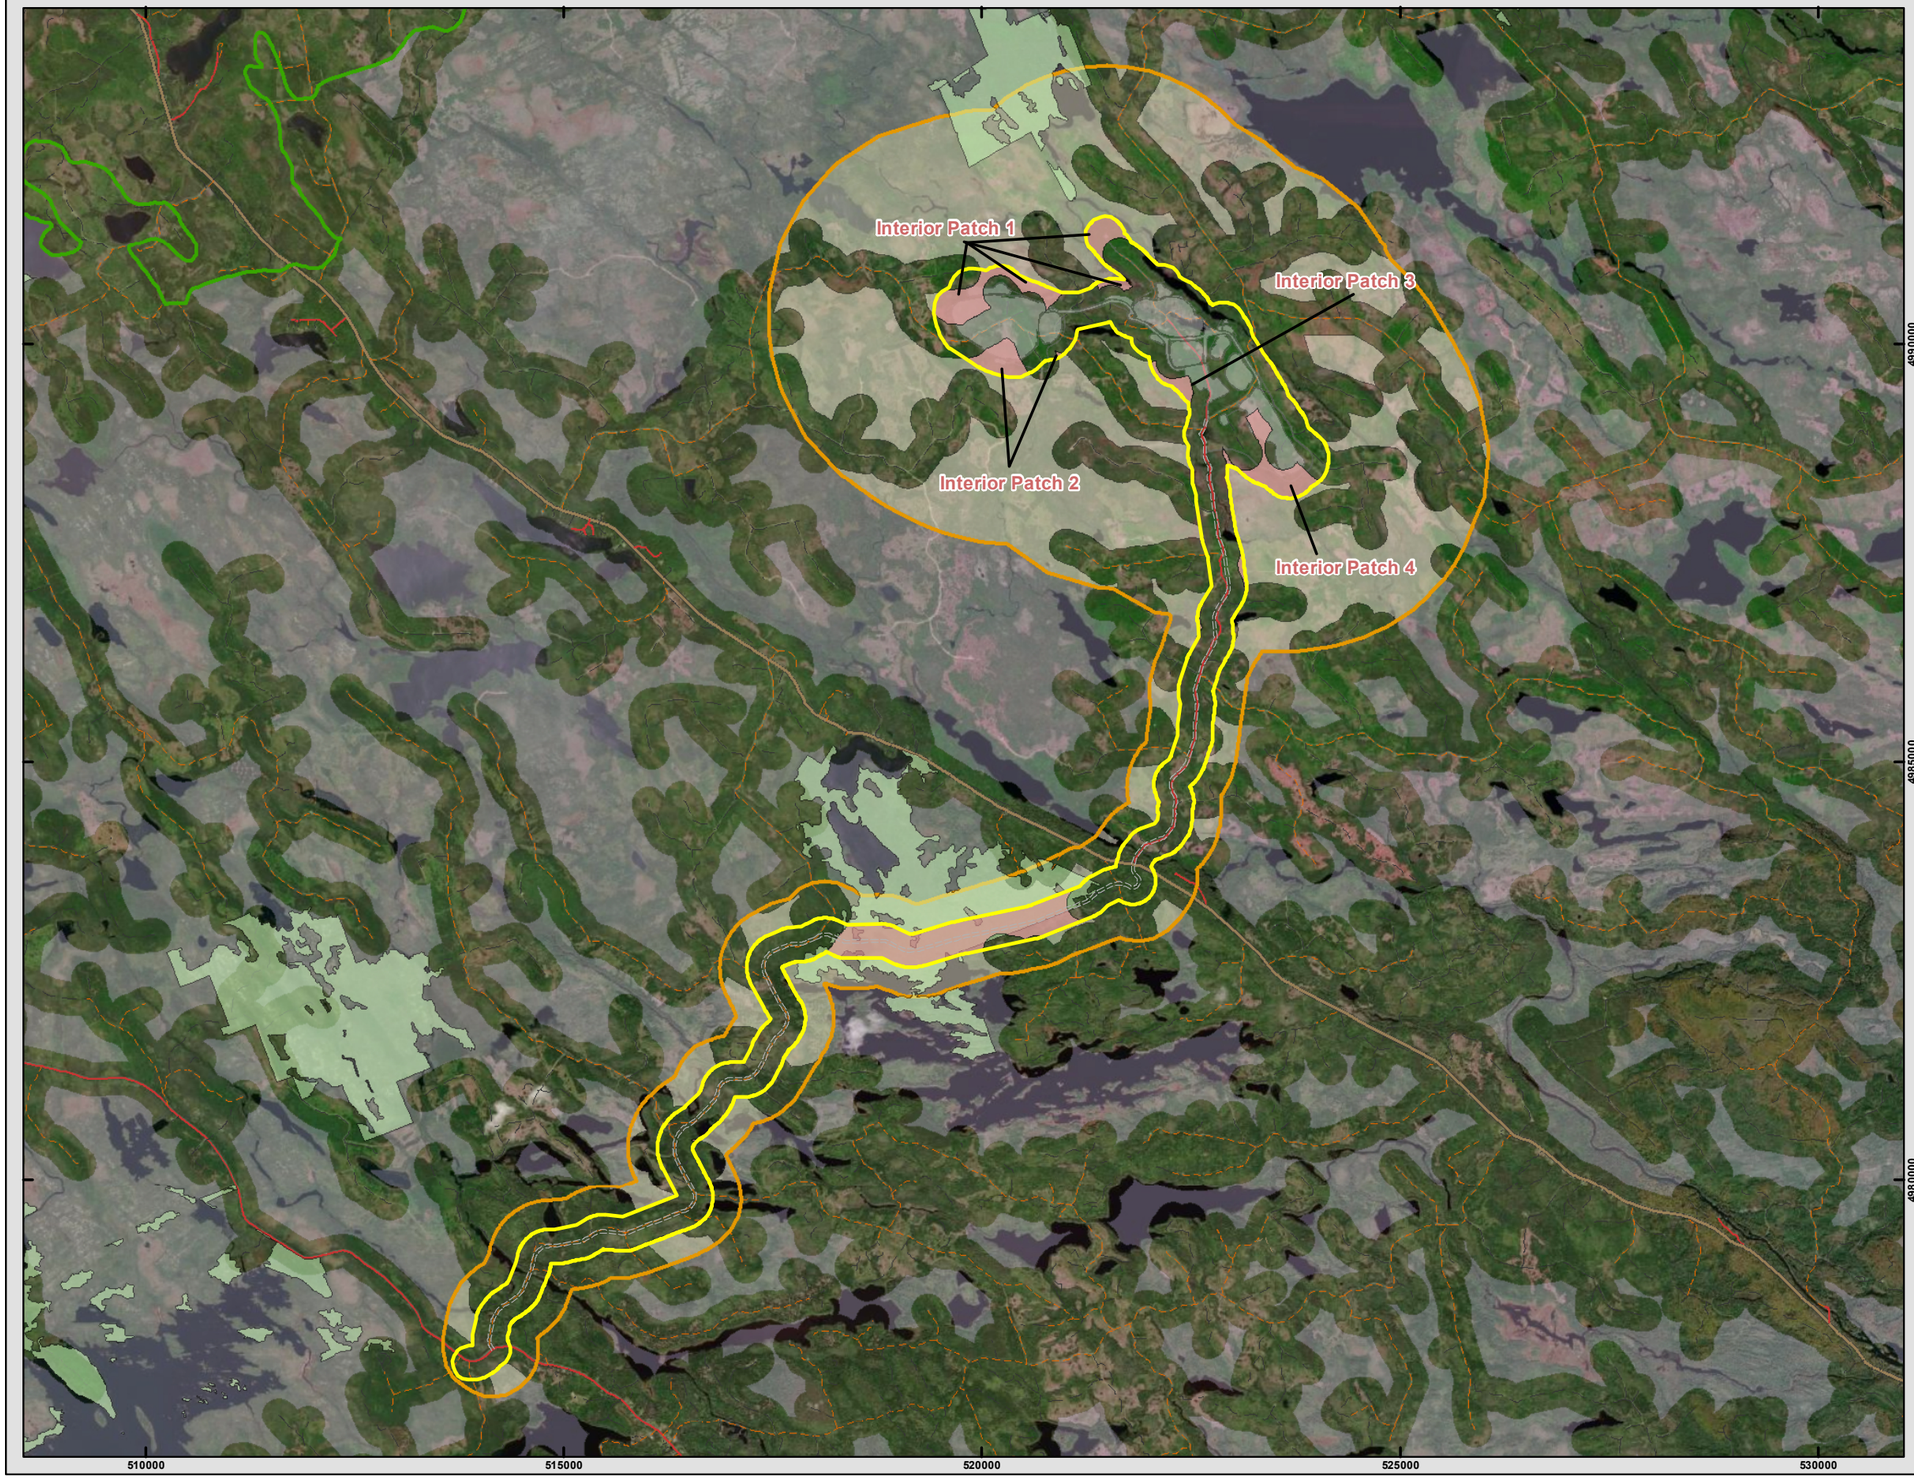
The Old Forest stands in close proximity to the LAA as shown in Figure 6.10-6. The Haul Road bisects one Old Forest stand (Unit 582) indicated in the Old Forest layer. Old Forest Unit 582 is 437.4 ha but it should be noted that this area is an estimate based on the Old Forest layer and the stand boundaries were not field delineated. Old Forest Unit 582 is made of three forest elements: Red and Black Spruce Hummocks, Spruce Pine Hummocks and Tolerant Mixedwood Hills. This stand also provides interior forest habitat.

The LAA is covered with a network of roads and forestry trails creating a largely disturbed forest landscape. The extent of the existing edge effect largely covering the majority of the LAA, including most of the Haul Road, is shown in Figure 6.10-6. Five potential interior forest patches fall within the Project Influence Zone, as defined in Section 6.10.3.6, one along the Haul Road within Old Forest Unit 582, and four within the Beaver Dam Mine Site, along the northern edge of the PA (patch 1); to the south of the western waste rock stockpile (patch 2); east of the crusher pad (patch 3); and west of the organic material stockpile (patch 4). Impacts to other areas of interior forest along the Haul Road will be limited to patches less than 1 ha, as the rest of the alignment follows existing roads. There were no other impacted patches within the Beaver Dam Mine Site that were large enough (more than 15 ha) to support interior forest conditions.

6.10.4.6.1 Potential Old Growth Field Survey

The following forest stand classes were observed and delineated during the Old Forest Unit 582 survey:

- Class 1 – Potential Old Growth: 7 ha (2%);
- Class 2 – Mature Climax: 76 ha (17%);
- Class 3 – Immature Climax: 320 ha (73%); and
- Class 4 – Non-Climax: 33 ha (8%).



The structure of the forest within the Class 1 and Class 2 stands varies considerably. The main stand component is typically a mixture of immature red spruce and mature balsam fir, 13 to 15 m in height, 40 to 80 years old and a crown closure of 40 to 60%. Scattered throughout the majority of these stands, in singles, patches and irregular groups, are larger red spruce and white pine, aged from 80 to 125 years and older. Where the density of these older trees is sufficient (at least 30% of the stand basal area), the patch or stand can be classified as Potential Old Growth (Class 1) or Mature Climax (Class 2), depending on the detailed age. The location of Potential Old Growth, based on preliminary field surveys, in relation to the Haul Road is shown in Figures 6.10-6.

The Old Forest Unit 582 field survey and Class assignments reflect preliminary findings. AMNS will work with NSLF to confirm the classification of Old Forest Unit 582 and the locations of Old Growth through the Integrated Resources Management Process.

6.10.5 Consideration of Engagement Results

Key issues raised during public and Mi'kmaq engagement relating to habitat and flora include potential effect on biodiversity and permanent loss of habitat associated within the Beaver Dam Mine Site and Haul Road. Potential effects on traditional uses of land and resources by the Mi'kmaq were noted, including medicinal food and plants.

The results of the public and Mi'kmaq engagement have been considered in the environmental effects assessment, including AMNS's commitments on mitigation and monitoring measures and proposed compliance and effects monitoring programs, as well as AMNS's broader commitment to ongoing public and Mi'kmaq engagement. Specific to evaluating the effect on habitat and flora, these are found within the following environmental effects assessment.

6.10.6 Effects Assessment Methodology

6.10.6.1 Boundaries

6.10.6.1.1 Spatial Boundaries

The spatial boundaries used for the assessment of Project effects to habitat and flora is described below.

The PA (Section 5.5, Figure 5.5-1) consists of the three project components; Beaver Dam Mine Site, Touquoy Mine Site, and the Haul Road and extends from Marinette to Moose River Gold Mines, Halifax County, NS. The Beaver Dam Mine Site is located at the eastern end of the Beaver Dam Mines Road. The Haul Road spans from the Beaver Dam Mine Site to Moose River Gold Mines, where the Touquoy Mine Site [processing and exhausted pit (to be used to dispose Beaver Dam tailings)] is located. The PA has changed as a result of the expansion of the Beaver Dam Mine Site to accommodate micro-sitting of mine infrastructure and ongoing modifications to the Haul Road design, as described in Section 2. These changes have been captured under the existing and additional desktop and field evaluations.

The LAA (Figure 6.10-7) consists of a 2 km buffer surrounding the Beaver Dam Mine Site and a 500 m buffer surrounding the Haul Road (excluding Mooseland Road). The LAA includes the focused LSA surrounding the Beaver Dam Mine Site. This area encompasses the maximum expected extent of Project direct and indirect impacts to habitat and flora. The LAA has been modified to reflect the changes in the PA. The Touquoy Mine Site and the Mooseland Road portion of the Haul Road were not included in the LAA because there is not expected to be a change to habitat and flora from current conditions.

The RAA (Figure 6.10-7) encompasses NSL&F's Ecological Land Classification Ecodistrict 440 (Eastern Interior) within Halifax Regional Municipality (HRM), east and north of Lake Charlotte. Where the Ecodistrict boundary approached the northern extent of the Beaver Dam Mine Site, the RAA was enlarged to include a 5 km buffer around the PA. This Ecodistrict spans an area broader than the expected Project impacts and considers other project boundaries as per cumulative effects methodology. These spatial boundaries will help to identify the direct or indirect impacts to flora species and critical habitats, and the effects of the Project on distribution and abundance of these species.

Assessment of habitat and flora will be completed in consideration of the LAA as the primary spatial boundary. All spatial boundaries will help to identify the direct or indirect impacts to flora and habitat and the effects of the Project on distribution and abundance of these species.

6.10.6.1.2 Temporal Boundaries

The temporal boundaries used for the assessment of effects to habitat and flora are the construction, operational, active closure and post-closure phases.

6.10.6.1.3 Technical Boundaries

No technical boundaries were identified for the effects assessment of habitat and flora.

6.10.6.1.4 Administrative Boundaries

There are no administration boundaries (specific legislation) that guided the evaluation of flora and habitat for this EIS.

6.10.6.2 Thresholds for Determination of Significance

A significant adverse effect from the Project on habitat is defined as an effect that is likely to cause a permanent, unmitigated, alteration to habitat that supports flora species distribution. An adverse effect that does not cause a permanent alteration of habitat is considered to be not significant. Significance criteria related to impacts to flora SOCI and SAR are presented in Section 6.13. A detailed analysis and definition of significance criteria for wetland habitat are presented in Section 6.8.

For the purposed of this analysis, habitat is defined as:

- A natural environment composed of both living organisms (biotic) and non-living components (abiotic) which function together as an ecological unit and includes managed forests (e.g., treated stands, cutblocks, plantations). Urban and industrial developments (e.g., roads, houses, quarries etc.) are excluded from this definition.

The magnitude of a predicted direct change in habitat is determined by the habitat analysis results described in Section 6.10.3.5.

- **Negligible** – the Project is predicted to result in less than one percent direct loss of habitat types within the LAA.
- **Low** – the Project is predicted to result in 1-5% direct loss of a habitat type within the LAA, and the loss of habitat is mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.
- **Moderate** – the Project is predicted to result in 5 to 25% direct loss of a habitat type within the LAA and the loss of habitat is mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.
- **High** – the Project is predicted to result in greater than 25% direct loss of a habitat type within the LAA and the loss of habitat is not mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.

The timing of residual effects for habitat considers when the residual environmental effect is expected to occur, considering seasonal aspects. The duration of residual effects considers the time frame over which the effects are likely to last, ranging from short-term to permanent. For the purpose of the effects' assessment related to habitat, long term reflects the commencement of reclamation activities. The frequency of residual effects considers the rate of recurrence of the effects, ranging from once to continuous. The reversibility of residual effects considers the time required for habitat to recover to naturalized conditions, or whether the changes to habitat, if identified, are permanent.

6.10.7 Project Activities/Interactions with Habitat and Flora

Potential interactions between Project activities and physical and cultural heritage resources within the Beaver Dam Mine Site and Haul Road are outlined in Tables 6.10-7 and 6.10-8.

Development of the Beaver Dam Mine Site and the Haul Road will cause direct impacts to habitat and flora, including upland forested habitat and wetlands. This will occur within the construction phase of the Project. Habitat within the PA and surrounding landscape currently exhibits fragmented conditions based on historic mine operations, existing road and trail networks, and current and historic forestry activity. Project activities are likely to result in increased habitat fragmentation and a decrease in habitat quality. A portion of this disturbance is expected to impact interior forest and Old Forest.

Table 6.10-7: Potential Project Activities/Interactions with Flora at Beaver Dam Mine Site

Project Phase	Duration	Project Interactions
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Till and waste rock from site preparation transport and storage • Watercourse and wetland alteration in preparation of construction • Mine Site road construction • Surface infrastructure installation and construction • Collection and settling pond construction • Sedimentation and erosion from construction activities • Generation of dust from construction activities • Invasive species introduction or spread
Operations and Maintenance	5 years	• Sedimentation and erosion from mining activities • Generation of dust from mining activities • Invasive species introduction or spread
Active Closure	2 years	• Site reclamation activities • Sedimentation and erosion from reclamation activities • Generation of dust from mining activities
Post-closure	+10 years (monitoring)	• N/A

Table 6.10-8: Potential Project Activities/Interactions with Flora along Haul Road

Project Phase	Duration	Project Interactions
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Watercourse and wetland alteration in preparation of construction • Haul Road construction and upgrades • Sediment and erosion from Haul Road activity • Dust from Haul Road activity • Invasive species introduction or spread
Operations and Maintenance	5 years	• Haul Road maintenance and repairs including sanding for traction control and snow removal • Sediment and erosion from Haul Road activity • Dust from Haul Road activity • Invasive species introduction or spread
Closure	2 years	• Generation of dust
Post-closure	+10 years (monitoring)	• N/A[(a)]

[(a)] Decommissioning and Reclamation of the Haul Road is not expected. The Haul Road will be returned to owner for forestry industry.

6.10.7.1 Direct and Indirect Impacts of the Project on Habitat and Flora

6.10.7.1.1 Direct Impacts

Direct impacts of the Project on habitat were determined by the desktop analysis described in Section 6.10.4.5. Based on the definitions of magnitude of impact, it is anticipated that all impacts to the habitat types identified in the desktop analysis have an expected negligeable to moderate impact magnitude with the exception to anthropogenic disturbances (Table 6.10-9).

Development of the Beaver Dam Mine Site and upgrading and construction of new sections of the Haul Road (Section 2, Figure 2.3-3) will result in direct impacts to vascular and non-vascular individuals and to flora communities at the full or partial forest stand level. The effects of the Project on flora encompass vascular and non-vascular flora in aquatic, wetland, and upland habitats. As such, many of the effects described in Section 6.8 specific to wetland habitat will directly relate to effects on flora. The majority of direct mortality to flora will occur during site preparation and construction. Impacts to flora SOCI and SAR are presented in Section 6.13.

The high percent (66%) impact to anthropogenic disturbances shows that the Project utilizes the existing disturbed areas within the LAA. Since this category is already disturbed and provides limited natural habitat for species, the high percent does not equal a determination of high magnitude of impact to habitat. Anthropogenic impact has only been included in Table 6.10-9 for comparison purposes - only natural habitat types have been carried forward for the habitat effects assessment.

Table 6.10-9: Habitat Type within the Project Area, Local Assessment Area and Magnitude of Impacts

Habitat Type	Area within the LAA (Ha)	Area within Project Area (BD Mine Site and HR) (Ha)	% of habitat type within the LAA directly impacted by the Project	Magnitude of Impacts to Habitat within LAA
Upland Forest				
Hardwood Dominant Stands	637.3	42.2	6.6	Moderate
Softwood Dominant Stands	3,081.3	92.1	3.0	Low
Other[a]	470.4	73.8	15.7	Moderate
Managed Forests[b]	668.6	9.6	1.4	Low
Wetlands and Waterbodies				
Lakes, Ponds, Beaver flowage	227.5	4.6	2.0	Low
Wetlands (includes all wetland classes)	825.4	8.2	1.0	Low
Non-forested Upland Communities				
Barrens (includes rock barrens)	16.3	0	0.0	Negligible
Disturbed				
Anthropogenic Disturbances[c]	20.3	13.4	66.0	N/A
TOTAL	**5,947.1**	**244**	**4.1**	**Low**

[a] Includes unmerchantable timber, often which is regenerative stands and stands which were not categorized as hardwood or softwood stands.

[b] Managed forests include plantations, cutblocks, selective cuts etc.

[c] Includes roads, railways, urban development, quarries, gravel pits, mining activity etc.

6.10.7.1.2 Direct Impacts of the Project on Old Forest and Interior Forest

Direct impacts to Old Forest Unit 582 will occur where the new section of the Haul Road (Section 2, Figure 2.3-3) is to be constructed. This area is unavoidable as the Haul Road was re-routed through this area to avoid impacts to the Beaver Lake IR and has been placed to avoid the waterbodies in the area. The Haul Road will be designed along the southern side of this stand, keeping the core area of this stand intact. This stand also has interior forest properties. One hundred and ten hectares of interior forest would be directly impacted, or face edge effects, from this new section of Haul Road.

As mentioned above, the landscape in this region is a patchwork mosaic of different levels of disturbance dominated by varying successional ages of regrowth from forestry activities. A large network of trails and roads have resulted from this forestry and other anthropogenic activity throughout this region. The LAA has largely been affected from these disturbances, as well as historical mining activities, which has reduced the amount of interior forest present within the LAA.

The Project Influence Zone, as defined in Section 6.10.3.6, interacts predominantly with five potential interior forest patches within the LAA. One is 112 ha along the Haul Road, which include 102 ha of the Old Forest Unit 582 polygon, as discussed above and in Section 6.10.3.5. This section of Old Forest Unit 582 is entirely located within the Tolerant Mixedwood element and primarily impacts Class 3 Immature Climax forest (more than 60%). The western portion of the Old Forest Unit 582 Influence Zone is composed of Class 1 Potential Old Growth (4%) and Class 2 Mature Climax (31%) stands. Impacts to Potential Old Growth are described in Section 6.10.7.1.1.2 below. The other four patches are within the Beaver Dam Mine Site, where the infrastructure will directly impact or create edge effects within 55 ha of interior forest along the northern edge of the PA (patch 1); 20 ha to the south of the western waste rock stockpile (patch 2); 8 ha east of the crusher pad (patch 3); and 38 ha west and south of the organic material stockpile (patch 4). There are a few patches each under 1 ha along the Haul Road. Of the 2,660 ha of predicted interior forest that has been identified within the LAA, the Project is will affect a total of 237 ha of interior forest habitat, which accounts for 9% of predicted interior forest in the LAA and 0.3% within the RAA.

While the baseline quantity of interior forest unaffected by edge effects from roads and other anthropogenic disturbance within the PA may be limited, there is still documented Old Forest available within the region, especially to the north and southwest of the PA. Overall, the increase in physical fragmentation is expected to be low, based on the current high level of disturbed habitat as discussed.

6.10.7.1.3 Direct Impacts of the Project on Potential Old Growth

Preliminary field surveys documented two patches of Potential Old Growth with the Old Forest Unit 582. The southernmost portion interacts with the proposed alignment of the new construction section of Haul Road (Figure 6.10-8 and Section 2, Figure 2.3-3). Based on preliminary surveys, a total of 2.40 ha of Potential Old Growth is located within the PA. The current proposed Haul Road design is expected to impact 0.22 ha of this Potential Old Growth area.

The Project will work to avoid and/or mitigate impacts to defined Old Growth wherever practicable. A potential alternative Haul Road route option is presented to avoid the Potential Old Growth, and will be considered depending on NSLF consultation and assessment of preliminary survey results, engineering constraints and road design considerations.

6.10.7.1.4 Indirect Impacts

Project activities have the ability to indirectly affect flora in the construction, operational, and decommissioning phases of the Project. The vast majority of Project interactions with flora will occur during construction, specifically during clearing, grubbing, and grading. Indirect impacts could include altered hydrology as a result of activity (including dewatering) in close proximity to wetland habitat; increased edge effects through habitat fragmentation; erosion and sedimentation from Project activities; emissions and dust accumulation; accidental spills involving deposition of a deleterious substance, including fuel oil, lubricants, or engine oil, and impoundment of up-gradient wetlands if inadvertent dams are built as part of the mine development (roads can act as dams if not constructed properly to allow water flow through them).

Movement of equipment during site preparation, operation, and maintenance can result in deposition of dust on vegetation within close proximity of roads when conditions are dry. This affects flora through the deposition of dust on leaves, which temporarily reduces evapotranspiration, photosynthesis and can bioaccumulate within tissue, particularly for non-vascular flora such as lichen (Degtjarenko, 2016; Naeth and Wilkinson 2008; Farmer, 1993). Over time this may reduce overall growth rates and alter vegetation communities. Similarly, winter maintenance of the Haul Road and site roads can affect plant growth adjacent to roads by placement of sand or stockpiling of snow. Further discussion on indirect impacts to flora SOCI and SAR is presented in Section 6.13.

Additional indirect impacts to native plant communities include the potential for introduction of invasive species. Seeds and roots of invasive species can be transferred from construction equipment, transportation vehicles, or workers (footwear and clothing) into adjacent habitat during construction and operational activities. Introduction of invasive species can occur when equipment or people enter vascular plant communities, or indirectly via runoff or dust from the roads. Invasive species, such as purple loosestrife (*Lythrum salicaria*), can severely degrade habitat quality and outcompete many native species, particularly along roadsides. Construction of the Project within the Beaver Dam Mine Site, upgrades to the Haul Road, and operations/trucking along the Haul Road will result in increased traffic levels. As a result, the likelihood of introduction of invasive species is elevated within the Beaver Dam Mine Site and along the entire length of the Haul Road, including the section of the Mooseland Road to the Touquoy Mine Site, where although no road upgrades are necessary, truck traffic will increase. No purple loosestrife, a common invasive species known to impact wetland, was noted during field surveys in the Beaver Dam Mine Site or Haul Road. Refer to Section 6.10.4.3 and 6.10.8 for discussions on invasive species and mitigations.

Table 6.10-10: Direct and Indirect Impacts on Habitat and Flora

Impact Type	Direct Impact	Project Phase	Indirect Impact	Project Phase
Vegetative and Habitat Integrity	Direct loss of individual vegetation (vascular and non-vascular) and the habitats which support them. In some cases (particularly in the Beaver Dam Mine Site) forest stands (upland and wetland) will be removed. See Table 6.10-9 for impact by habitat type. Impact to Old Forest and Potential Old Growth through Haul Road construction.	C	Hydrologically connected upstream wetlands may also be at risk of indirect impacts as a result of downstream alteration activities (e.g., water outflow changes, land elevation changes, blasting, etc. causing dewatering). Inadvertent damming of up-gradient wetlands from construction related infrastructure (e.g., roads with lack of flow through infrastructure). Removal of tree cover in one area can increase risk of wind damage in immediately adjacent habitats. Edge effects from habitat fragmentation (including effects to interior forest) resulting in stress to vascular plants and non-vascular plants (including lichens) potentially resulting in harm to individuals and/or changes in vegetation community structure.	C, O, CL
	Extensive ground works, including activities such as blasting in and adjacent to wetlands has the potential to destabilize land surfaces and the root zone of vegetative areas, including wetland buffers.	C, CL	Introduction of invasive species can occur indirectly into wetlands when equipment or people move around the PA or via runoff or dust from the roads. Introduction of mine and Haul Road traffic during construction and operation can elevate this risk. Invasive species, such as purple loosestrife (*Lythrum salicaria*), can severely degrade wetland habitat and function. No purple loosestrife was noted during field surveys in the Beaver Dam Mine Site or Haul Road.	C, O, CL
	Introduction of invasive species. Seeds and roots of invasive species can be transferred from construction equipment, transportation vehicles, or workers into adjacent wetland habitat during construction and operational activities.	C, O, CL	Dust accumulation on vegetation can smother and stress plants and provide minerals and nutrients into the wetland habitat.	C, O, CL

Notes: C = Construction; O = Operations; CL = Active Closure; m = metre; PA = Project Area.

6.10.7.2 Touquoy Mine Site

The Touquoy Mine Site is currently operational. The use of the Touquoy Mine Site for the processing of Beaver Dam ore and tailings management (exhausted pit) will not involve modification to the current footprint or further direct impacts to habitat and flora. Moving the existing tailings pipeline from the permitted TMF to direct water to the exhausted pit will occur within the disturbed footprint of the permitted Touquoy Project and will not result in additional impacts. Potential interactions between Project activities and habitat and flora within the Touquoy Mine Site are outlined in Table 6.10-11.

Based on work completed as part of the 2007 Focus Report, air emissions are not anticipated to have an adverse effect on flora and lichens are not anticipated to be affected by the continued use of the Touquoy Mine Site for the processing of Beaver Dam ore. Lichens are susceptible to air pollution, including deposition of contaminants in air emissions and particulate matter. It was concluded in the Focus Report that total suspended particulate from the processing facility at Touquoy Mine Site will not have a significant adverse effect on any lichen species associated with the Project.

Project operations and trucking of ore from the Beaver Dam Mine Site to the Touquoy Mine Site, along the Haul Road, has the potential to spread invasive species. Invasive species are currently monitored at the Touquoy Mine Site during the existing wetland monitoring program (IR2 NSE-2-181).

Table 6.10-11: Potential Project Activities/Interactions with Flora at Touquoy Mine Site

Project Phase	Duration	Project Interactions
Construction	1 year	• N/A
Operations	5 years	• Generation of dust • Invasive species introduction or spread
Active Closure	2 years	• Generation of dust
Post-closure	+10 years (monitoring)	• N/A

Note: N/A = not applicable.

6.10.8 Mitigation

Th mitigation provided in Table 6.10-12 to reduce overall loss of function of habitat used by flora will be implemented by AMNS where direct impacts and potential indirect impacts to habitat and flora are expected.

Project activities will result in direct mortality of vascular and non-vascular flora within the PA, in both upland and wetland habitat. Compensation and mitigation for flora related to wetland habitat are described in Section 6.8 and for flora SOCI and SAR are described in Section 6.13. The long-term reclamation and remediation will involve re-vegetation of the Touquoy Mine Site and Beaver Dam Mine Site at the end of the life of the mine. Revegetation will involve establishment of native vegetation communities. Stockpiled soils will be used in reclamation efforts. This soil will contain a seedbank of native species to increase the establishment of native communities. Loss of individual plants within the Haul Road is expected to be permanent, as the Haul Road will not be decommissioned or reclaimed at the completion of the Project.

Table 6.10-12: Mitigation for Habitat and Flora

Project Phase	Mitigation Measure
Construction, Operation	Intact forest stands and wetlands will be avoided wherever practicable during detailed Project planning and design in favor of previously disturbed areas (e.g., stands disturbed by timber harvesting, roads, or other development).
	Where natural, intact habitat cannot be avoided, maintain existing vegetation cover whenever practicable and minimize overall areas of disturbance.
	A wetland alteration application will be submitted during Project planning and design to request an authorization to alter wetland habitat and to address loss of wetland function.
	Compensation for permanent loss of wetland function will be completed through wetland restoration activities to support no net loss of wetland function, subject to NSE approval.
	Topsoil will be salvaged and stored for use in site restoration where possible. Upland and wetland soils should be stockpiled separately.
	Conduct vegetation management by cutting (e.g., no use of herbicides)
	Implement Erosion and Sediment Control Plan and measures to ensure site runoff is not directed towards unaltered habitat where possible to ensure existing drainage patterns are maintained.
	Avoid frequent or unnecessary travel over erosion prone areas through communication with personnel and project planning
	Monitor dust conditions and implement dust suppression mitigation (refer to air mitigation) when normal precipitation levels are not enough to suppress fugitive dust. In addition to water suppression, provincially approvable chemical dust suppressants will be used along the Haul Road. Implement Dust Control Plan (Appendix C.3)
	Haul trucks will be equipped with spill kits and instructed on their use and spill prevention and appropriate site personnel will be trained in spill isolation, containment, and recovery.
	Winter road maintenance will include conventional snow clearing and deposition of sand for traction control where necessary.
	Employ measures to reduce the spread of invasive species (particularly by vehicles) and retain habitat integrity. Inspect vehicles regularly, particularly vehicles arriving from outside the PA. If necessary, cleaning will be undertaken at a designated cleaning station, away from wetlands and watercourses.
	Confirm Potential Old Growth areas with NSLF and asses possible avoidance through the alternative Haul Road route, dependant on NSLF findings.
	Consider on-site opportunities for progressive reclamation during construction and operations to avoid viability issues with long-term stockpiling of organic material.
Active Closure	Hydroseed areas that have erosion potential to return the area to pre-disturbance conditions in a timely fashion upon final reclamation
	Alternatives to traditional hydroseeding methods will be reviewed to advance vegetation re-establishment and reclamation methods. Consideration will be given to native species with Indigenous significance.
	Implement reclamation program within the Beaver Dam Mine Site to re-establish native vegetation communities
	Consider on-site opportunities for progressive reclamation during construction and operations to avoid viability issues with long-term stockpiling of organic material.
Post-closure	N/A

Construction of the Haul Road will involve decommissioning remnant pieces of the existing road, where appropriate. These remnant pieces of original road will be barricaded to prevent access and encouraged to revegetate through re-grading the soil and seeding with native seed mix, where necessary. Wetland restoration or creation will be incorporated into these areas, where appropriate.

AMNS will work with NSLF to confirm the classification of Old Forest Unit 582 and the locations of Old Growth through the Integrated Resources Management Process. Dependent on NSLF consultation and assessment, a potential alternative Haul Road route option is presented in Section 6.10.8 to avoid the Potential Old Growth, as delineated by the preliminary surveys. All biophysical surveys (i.e., wetlands, watercourse, habitat type, avifauna, fish and fish habitat, flora and fauna SOCI /SAR) have been conducted within this alternative route area (9.4 ha). No consequential biophysical constrains (i.e., SOCI or SAR, fish habitat) have been identified through these baseline surveys. Impacts will be assessed and evaluated for required VCs (e.g., wetlands) should this route be considered. However, it should be noted that this route is subject to engineering and safety constrains, which will also need to be assessed should this route be considered.

A comprehensive mitigation table for all VCs is provided in Section 9.

6.10.9 Residual Effects and Significance

The predicted residual environmental effects of Project development and production on habitat and flora are assessed to be adverse, but not significant. The overall residual effect of the Project on habitat and flora is assessed as not significant after mitigation measures have been implemented and are summarized in Table 6.10-13.

A significant adverse environmental effect for habitat and flora has not been predicted for the Project for the following reasons, with consideration of the ecological and social context of the LAA surrounding the Project:

- **During construction:** Direct impacts to habitat and flora will occur. However, these impacts are limited to the construction phase (12 months) and will be limited for Haul Road constructed as a result of the planned upgrade of an existing logging road for the majority of the route. The majority of the habitat present within the Beaver Dam Mine Site is considered poor habitat as a result of historical and current forestry activities.
  - Impacts will be avoided wherever practicable during detailed Project planning and design in favor of previously disturbed areas.
  - Dependant on NSLF consultation, Old Growth, if present, may be avoided through the proposed Haul Road re-alignment (Figure 6.10-8). This re-alignment will require detailed road design that is dependent on engineering and safety constraints.
  - Micro-sighting of Project infrastructure has allowed for avoidance of the species' updated critical/core habitat as outlined within the Amended Recovery Strategy (ECCC, 2018) and the NSLF adopted Recovery Plan for Boreal Felt Lichen (NSLF 2020).
- **During Operations:** Indirect impacts to habitat and flora will be reduced through erosion and sediment control measures and dust mitigation.
- **During Closure:** Reclamation will allow for site restoration of a native assemblage of plant communities.

Table 6.10-13: Residual Effects for Habitat and Flora

Project - VC Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction – Beaver Dam Mine Site and Haul Road (clearing and grubbing, and Haul Road widening and construction)	Limit habitat disturbance and minimize Project Area during detailed design, sediment and erosion control, best-management practices, spill preparedness, dust control, re-establish habitat and associated vegetation communities during closure.	M Direct loss to habitat and flora. Partial mitigation through restoration.	PA Effects confined to the PA.	N/A VC is not expected to be affected by timing.	MT (Beaver Dam Mine Site) Effects occur beyond 5 years when closure activities commence at Beaver Dam Mine Site. P (Haul Road) Closure of the Haul Road not expected.	O Effects occur once during the construction phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Disturbance, Habitat Loss	Not Significant
Operation – Beaver Dam Mine Site, Haul Road and Touquoy Mine Site (dust from haul trucks, heavy machinery and mine operations)	Dust control, sediment and erosion control, best management practices, and spill preparedness.	M	LAA Potential effects below guideline levels beyond the PA.	N/A VC is not expected to be affected by timing.	MT Effects may occur up to 5 years.	R Effects will occur at regular intervals.	R VC will return to baseline conditions.	Disturbance	Not Significant
Closure (Active) – Beaver Dam Mine Site (re-vegetate using stockpile materials)	N/A	L Minor change from baseline conditions.	LAA Potential effects beyond the PA.	N/A VC is not expected to be affected by timing.	LT Effects extend beyond active closure phase.	O Effects occur once during the closure phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Reclamation	Not Significant

Notes: See Section 6.10.6.2 and Section 5, Table 5.11-1 for definitions of the below characteristics.

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	IR	Irreversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	PR	Partially Reversible
H	High					P	Permanent	C	Continuous		

6.10.10 Proposed Compliance and Effects Monitoring Program

The monitoring of vascular plants will be encompassed within the Wetland Monitoring Plan. This plan will be established through the life cycle of the permitting process and will commit to monitoring during baseline/pre-construction to establish baseline conditions, and through the operational, closure and post closure phases (as determined to be required). Wetland monitoring will be completed for the Project on selected representative wetlands that have been predicted to have direct or indirect effects from project development to determine the effect on wetland plants. A Preliminary Wetland Compensation Plan, with proposed methods, timing, frequency, and locations, is presented in Appendix H.3.

6.11 Terrestrial Fauna

6.11.1 Introduction

6.11.1.1 Summary of Terrestrial Fauna Before the Updates

Baseline surveys confirmed presence of ten mammalian species, including mainland moose (NSESA Endangered, S1). Mainland moose tracks were observed in three locations within the Beave Dam Mine Site. No other observations or evidence of mainland moose were observed by the Project Team. Eighteen abandoned mine openings (AMOs) within the Beaver Dam Mine Site were evaluated for their potential to provide bat hibernacula. Of the 18 AMOs evaluated, all were determined to be inaccessible to bats, with the exception of one (BED-1-003), which was identified as a potential bat hibernaculum. The BED-1-003 AMO was later determined to be inaccessible to bats through field surveys. No bat hibernacula were identified within the Haul Road. No bats, or evidence of, where observed within the Beaver Dam Mine Site or Haul Road. Nine species of herpetofauna were observed during file surveys, either directly or indirectly (through vocalizations, egg masses, cast snake skins, etc.). Dedicated wood turtle surveys were conducted within the Beaver Dam Mine Site or Haul Road; however, none were observed. Snapping turtle had been previously observed near the Touquoy Mine Site outside field surveys. No Species of Conservation Interest (SOCI) or Species at Risk (SAR) herpetofauna were observed during field surveys. SOCI and SAR fauna and Beaver Dam Mine Project (the Project) related effects are further discussed in Section 6.13.

Project related effects to terrestrial fauna include direct loss of habitat, habitat fragmentation, direct mortality, and sensory disturbance. Mitigations are proposed to reduce overall loss of function of habitat used by terrestrial fauna and reduce direct impacts on fauna within the Beaver Dam Mine Site and Haul Road. As a result of mitigations and detailed design planning, the predicted residual environmental effects of Project development and production on terrestrial fauna are assessed to be adverse, but not significant.

6.11.1.2 Summary of Updates to Terrestrial Fauna

As a result of Project Area (PA) modifications and continued infrastructure micro-siting since the 2019 EIS submission, one additional species was observed during supplementary field surveys for the Updated 2021 EIS. A snapping turtle (SARA/COSEWIC SC, NSESA V, S3) and nest were observed adjacent to Wetland 59 within the Beaver Dam Mine Site. This species is further discussed in further discussed in Section 6.13.

Impacts to terrestrial fauna were reassessed based on changes to the PA and Project infrastructure. The fauna effects assessment was updated to include a species-specific habitat assessment and improved assessment of Project related sensory disturbance.

No new direct or indirect impacts to terrestrial fauna are expected. Project effects to fauna remain adverse, but not significant.

Table 6.11-1: Updated Subsections from the 2019 Revised Environmental Impact Statement – Terrestrial Fauna

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Updated Section Number	Reason for Update
-	-	6.11.1 Introduction	• N/A
6.11.1 Rationale for Valued Component Selection	No	6.11.2 Rationale for Valued Component Selection	• N/A
6.11.2 Baseline Program Methodology	Yes	6.11.3 Baseline Program Methodology	• Addition of 2019 field surveys. • Additional survey areas as a result of PA modification for infrastructure micro-sitting. • Review and update priority species (IR NSE 2-184)
6.11.3 Baseline Conditions	Yes	6.11.4 Baseline Conditions	• Present results from 2019 field surveys. • Additional survey areas as a result of PA modification for infrastructure micro-sitting. • Review and update priority species (IR NSE 2-184)
6.11.4 Consideration of Consultation and Engagement Results	No	6.11.5 Consideration of Engagement Results	• N/A
6.11.5 Effects Assessment Methodology – **Boundaries**	Yes	6.11.6 Effects Assessment Methodology – **Boundaries**	• PA modification for infrastructure micro-sitting. • Adjusted PA description. • LAA was enlarged due to the modified PA. • RAA was enlarged where necessary due to the modified PA. Fauna assessment area changed to the RAA.
6.11.5 Effects Assessment Methodology – **Thresholds for Determination of Significance**	Yes	6.11.6 Effects Assessment Methodology – **Thresholds for Determination of Significance**	• Updated significance threshold and magnitude assessment. • Reflect changes in VC baseline conditions and improve significance assessment criteria. • Response to IR2 CEAA 2-02
6.11.6 Project Activities and Terrestrial Fauna Interactions and Effects	Yes	6.11.7 Project Activities/Interaction with Terrestrial Fauna	• Updated based on revised noise and light impact assessments. • Bolster discussion of direct and indirect impacts to fauna. Include species-specific habitat loss assessment. • Changes to project timelines
6.11.7 Preferred Alternative Haul Road	Yes	Section removed	• The Preferred Alternative Haul Road is no longer being considered and has been removed from the Project Description and EIS
6.11.8 Mitigation	Yes	6.11.8 Mitigation	• Updated based on field survey results and changes to effects assessment. • Reflects improved understanding of impacts.
6.11.9 Residual Effects and Significance	Yes	6.11.9 Residual Effects and Significance	• Updated based on field survey results and changes to significance threshold determination. • Change to magnitude determination. • Reflect changes to significance threshold and magnitude assessment.
6.11.10 Proposed Compliance and Effects Monitoring Program	No	6.11.10 Proposed Compliance and Effects Monitoring Program	• Updated monitoring program.

Notes: PA = Project Area; LAA = Local Assessment Area; RAA = Regional Assessment Area; - = no update; IR2 = Round 2, Information Requests; CEAA = Canadian Environmental Assessment Agency; EIS = environmental impact statement; N/A = not applicable.

6.11.2 Rationale for Valued Component Selection

Terrestrial fauna, and the habitat upon which they rely, may be altered either directly or indirectly by proposed Project activities. While this valued component includes understanding the potential effects of the Project on all fauna, the specific survey methods are mainly driven by identification of Species of Conservation Interest (SOCI) and Species at Risk (SAR).

6.11.3 Baseline Program Methodology

Data collection on various fauna species was from targeted field surveys and incidental observations. Beaver Dam Mine Site and Haul Road methods are discussed below. Information pertaining to Touquoy Mine Site has been brought forward from the Nova Scotia Environmental Assessment Registration Document (EARD) and Focus Report. Methods and results are summarized in subheadings within the applicable sections and are carried forward into the effects assessment, where deemed appropriate. Further information regarding fauna assessments undertaken at Touquoy Mine Site is provided in the EARD (CRA 2007a) and Focus Report (CRA 2007b).

Targeted surveys were completed for bats, mainland moose, and wood turtles, which are described in Section 6.13.4. Incidental observations were recorded for all other fauna species including mammals, reptiles and amphibians, and invertebrates (including freshwater molluscs, lepidopterans, and odonates). The goal of both targeted surveys and incidental observations was to understand species presents and habitat use within the PA, specifically the Beaver Dam Mine Site and Haul Road, to allow for a discussion of Project interactions and mitigation measures.

Incidental terrestrial fauna observations were collected throughout the field seasons in 2014, 2015, 2016, and during additional field surveys in 2019 and 2020 as a result of PA modifications (Section 2 Project Description). Incidental observations of mammals and various signs of mammals were documented and photographed during all field surveys across the Beaver Dam Mine Site and Haul Road. Signs included features such as dens and nests, scat, tracks, and forage evidence. Incidental observations for priority invertebrates occurred during all field programs, particularly wetland and watercourse delineation, and fish habitat surveys. Incidental observations of odonates and lepidopterans included live adults or larvae, or cast skins. Signs of molluscs included live or dead individuals, or shells. Other than surveys associated with the mainland moose and potential bat hibernacula (e.g., abandoned mine openings [AMOs]) described in the following sections, no targeted mammal surveys were undertaken.

Terrestrial biota methods for mainland moose, bat and wood turtle surveys are outlined in Sections 6.13.3.2.4, 6.13.3.2.5 and 6.13.3.2.6, respectively (Figures 6.11-1A to 6.11-1E). An initial habitat assessment was completed throughout the Beaver Dam Mine Site and Haul Road in October 2014, May 2015 and July/August 2019. This initial assessment combined with a desktop analysis of priority species and Atlantic Canada Conservation Data Centre (ACCDC) data, determined that additional specialized surveys (i.e., in addition to those mentioned above) for priority fauna species would not be required within the Beaver Dam Mine Site and Haul Road.

6.11.3.1.1 Touquoy Mine Site

Field surveys for terrestrial fauna were conducted concurrently with vegetation, birds, and wetlands and occurred from 2004 to 2006 (CRA 2007a). Refer to the Touquoy Mine Site EARD for detailed methodology.

6.11.4 Baseline Conditions

6.11.4.1 Mammals

Incidental observations of mammal species were documented during all field surveys during 2014, 2015, 2016, 2019 and 2020 across the Beaver Dam Mine Site and Haul Road. Specific focus was given to priority species identified as having appropriate habitat within the Beaver Dam Mine Site and Haul Road. Species that were confirmed within the Beaver Dam Mine Site and Haul Road either visually or by sign (scat, footprints, etc.) are listed in Table 6.11-2. No additional mammal species were observed during 2019 and 2020 surveys. The presence of mainland moose, bats, and priority herpetofauna in the PA is described in Section 6.13.

Table 6.11-2: Observed Mammalian Species During 2014 to 2020 Field Surveys

Common Name	Scientific Name	Sign	COSEWIC, SARA, NSESA	S Rank
Coyote	*Canis latrans*	Tracks, scat	-	S5
American black bear	*Ursus americanus*	Tracks, scat, digs	-	S5
White-tailed deer	*Odocoileus virginianus*	Tracks, scat, browse	-	S5
Mainland moose	*Alces americana*	Tracks	NSESA Endangered	S1
American red squirrel	*Tamiasciursus hudsonicus*	Seen, tracks, middens	-	s5
American porcupine	*Erethizon dorsatum*	Seen, tracks, browse	-	S5
Snowshoe hare	*Lepus americanus*	Seen, tracks, scat	-	S5
American beaver	*Castor canadensis*	Seen, tracks, dams, lodges, felled trees	-	S5
Eastern chipmunk	*Tamias striatus*	Seen, tracks, middens	-	S5
Raccoon	*Procyon lotor*	Tracks	-	S5

Notes: The ACCDC works with provincial and federal experts to develop rarity ranks (i.e., S-ranks) for species in Nova Scotia, as well as the other Maritime Provinces, see http://www.accdc.com/en/rank-definitions.html for more information. An S-rank of S5 means that the species is Secure - Common, widespread, and abundant in the province.

COSEWIC = Committee on the Status of Endangered Wildlife in Canada; SARA = *Species at Risk Act*; NSESA = *Nova Scotia Endangered Species Act;* S Rank = Species Rank.

Other common mammal species, such as red fox (*Vulpes vulpes*), bobcat (*Lynx rufus*), raccoon (*Procyon lotor*), short-tailed weasel (*Mustela erminea*), American mink (*Neovison vison*), muskrat (*Ondatra zibethicus*), and striped skunk (*Mephitis mephitis*) are likely to inhabit the Beaver Dam Mine Site and Haul Road or surrounding areas, at least periodically.

6.11.4.1.1 Touquoy Mine Site

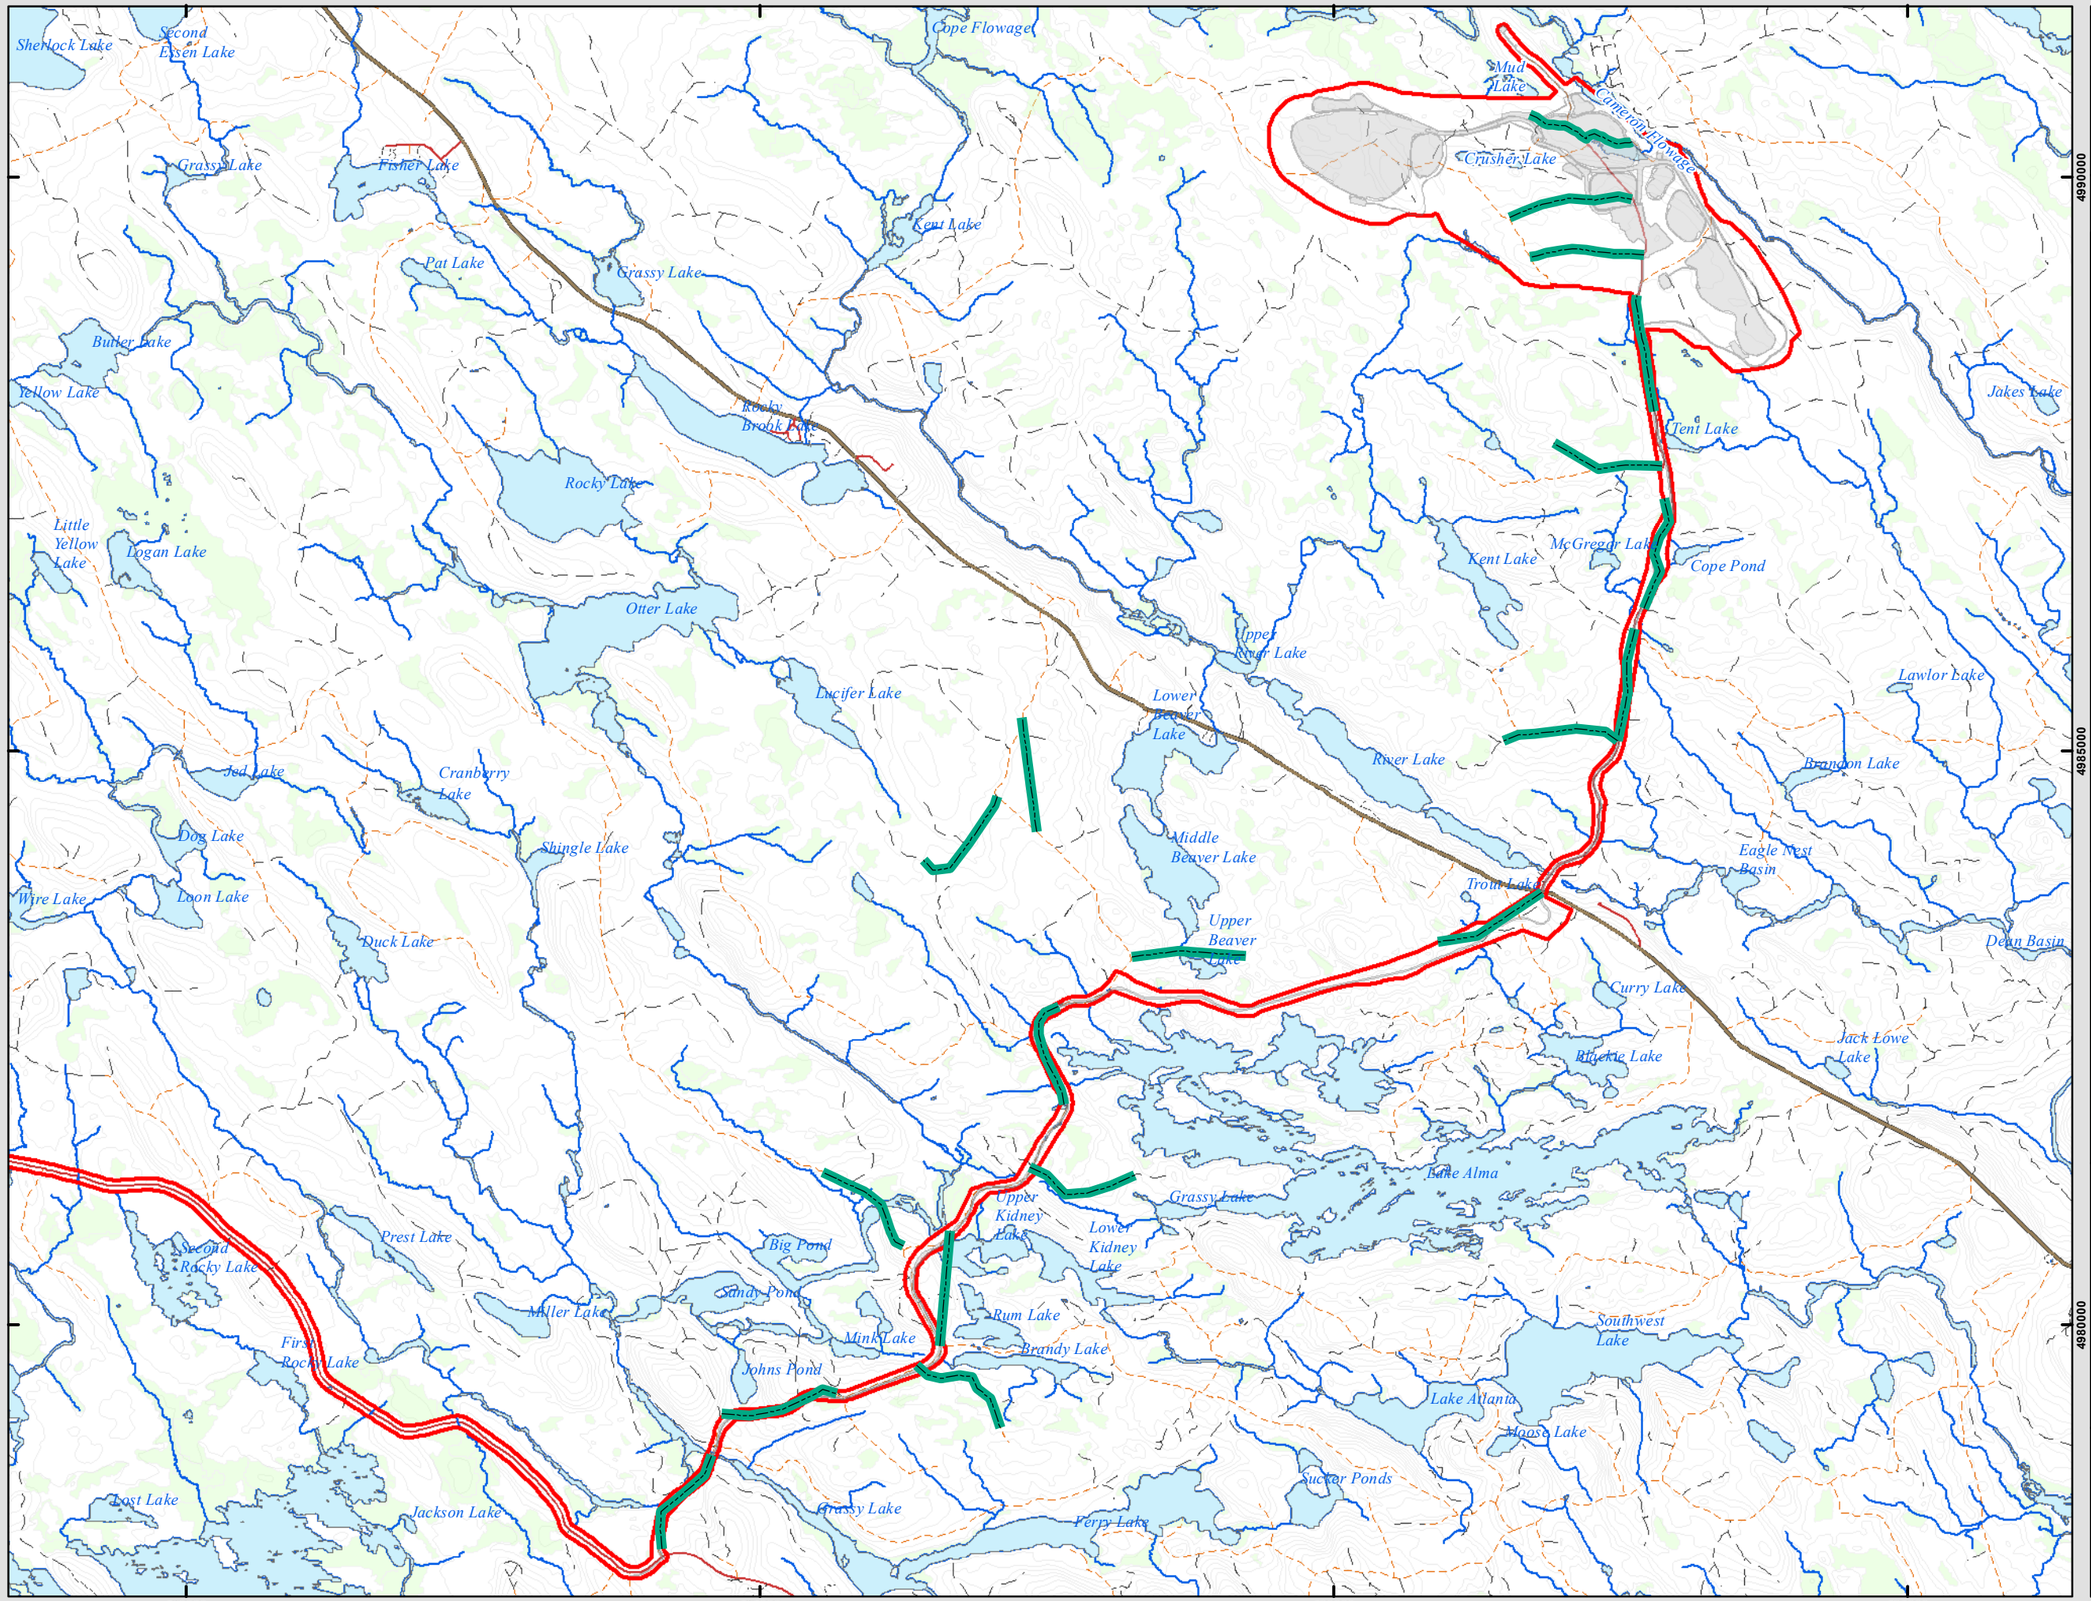
Evidence of red fox, American red squirrel (*Tamiasciursus hudsonicus*), coyote (*Canis latrans*), snowshoe hare (*Lepus americanus*), American black bear, and white-tailed deer (*Odocoileus virginianus*) were observed during field surveys in 2004, 2005, and 2006. Although not observed, suitable habitat was recognized for racoon, striped skunk, bobcat, meadow vole (*Microtus pennsylvanicus*), Southern red-backed vole (*Myodes gapperi*), Eastern chipmunk *(Tamias striatus*), and short-tailed shrew *(Blarina brevicauda*) (CRA 2007a).

6.11.4.1.2 Mainland Moose

Mainland moose have been recorded within 3.4 kilometres (km) of the Beaver Dam Mine Site, and within 7.5 km of the Haul Road (ACCDC; Appendix I.1). Tracking surveys were completed for the purpose of determining the presence of moose within the Beaver Dam Mine Site and Haul Road as per methodology described Section 6.13.3.2.4.

No mainland moose signs were observed incidentally or during dedicated moose surveys along the Haul Road, by the Project Team. While Project surveys did not confirm presence of moose along the Haul Road, a local Mooseland resident recorded a moose observation near the proposed Haul Road, which was published in the Halifax Examiner on December 23, 2020. The specific time and location of this observation was not confirmed.

Mainland moose tracks were observed within the Beaver Dam Mine Site during the dedicated PGI survey on May 24, 2015 in disturbed roadside habitat north of Wetland 56. Moose tracks were also observed incidentally in two locations on September 9, 2014. One set of tracks was observed in Wetland 210 and a second set of tracks was observed adjacent to Wetland 206, just north of the Beaver Dam Mine Site (Figure 6.11-2). These findings will be discussed further in Section 6.13.



6.11.4.1.3 Touquoy Mine Site

Mainland moose tracks were observed within the Touquoy Mine Site in a bog during field surveys to support the Touquoy EARD in 2006. Moose are known to the Tangier Grand Lake Wilderness Area, and evidence of moose is reported every year by NSL&F in the Moose River Gold Mines area during deer pellet surveys (CRA, 2007a).

6.11.4.1.4 Bats

According to the ACCDC reports, no known bat hibernaculum are present within 5 km of the Haul Road or Beaver Dam Mine Site (Appendix I.1). The closest known bat hibernacula is located at the Lake Charlotte Gold Mine, approximately 25 km southeast of the intersection of the proposed Haul Road and Mooseland Road (approximately 45 km from the Beaver Dam Mine Site) (Moseley, 2007).

Provincial government records of AMOs were reviewed within the boundary of the Beaver Dam Mine Site and Haul Road, as these AMOs potentially provide bat hibernacula. Eighteen AMOs were identified within the Beaver Dam Mine Site and 99 were identified within a 10 km buffer of the Haul Road. A desktop review (described above) identified that the cluster of 99 AMOs located 6.4 km from the Haul Road do not provide potential bat hibernacula. Eighteen AMOs within the Beaver Dam Mine Site were evaluated for their potential to provide bat hibernacula on September 18, 2014. Of the 18 AMOs evaluated at the site, all were either in-filled, contained a concrete cap blocking access, or were flooded, with the exception of one (BED-1-003), which was identified during the desktop evaluation as a potential bat hibernaculum. This AMO known as the J.H. Austin Main Shaft (AMO Database BED-1-003; NSDNR, 2010) is located on Beaver Dam Road, Halifax County at UTM Zone 20, 522256 Easting and 4990298 Northing. It is located just east of the Beaver Dam Mine Access Road at the western end of the existing settling pond southwest of Cameron Flowage. The locations of AMOs are shown in Figures 6.11-1A and 6.11-1E. It was determined to be inaccessible to bats, as described further in Section 6.13.4.4.2. No bats, or evidence thereof, were observed incidentally during biophysical surveys, particularly bird surveys which are conducted when bats are more active.

6.11.4.1.5 Touquoy Mine Site

According to CRA (2007a), NSL&F has extensively surveyed more than 100 AMOs mapped in close proximity to the Touquoy Mine Site (within 500 metres (m) of the Moose River Gold Mines Provincial Park). As per communications cited with E. Hennick; NSL&F, these openings are either blocked or filled with water, therefore, suitable habitat for bat hibernacula is not present.

6.11.4.2 Herpetofauna

Herpetofauna species were inventoried within the Beaver Dam Mine Site and Haul Road through both targeted searches of appropriate habitats and through incidental observations during all field surveys during 2014, 2015, 2016, 2019 and 2020. One additional herpetofauna species, snapping turtle (*Chelydra serpentina*, SARA Special Concern, NSESA Vulnerable, S3), was observed within the Beaver Dam Mine Site in 2019. However, snapping turtle had been previously observed near the Touquoy Mine Site outside field surveys. Specialized survey methods used to identify wood turtles and their habitat are described in Section 6.13.

Species that have been observed, either directly or indirectly (through vocalizations, egg masses, cast snake skins, etc.) within the Beaver Dam Mine Site and Haul Road during the various field programs completed throughout the site, (primarily wetland and watercourse assessments) are provided in Table 6.11-3.

Suitable habitat for the snapping turtle was observed within the Beaver Dam Mine Site and Haul Road. One female snapping turtle and active nest was observed by DFO within the Bever Dam Mine Site on June 27, 2019 (Figure 6.13-1A). Previously, one snapping turtle was observed incidentally on the Haul Road on June 26, 2016, during avifauna surveys. This snapping turtle was observed along Mooseland Road near PC45 (UTM: 20T 507085E, 4981506N). Two other incidental snapping turtle observations were made within the vicinity of the Touquoy Mine Site, as discussed below (Figure 6.13-1G). These species are discussed further in Section 6.13.

Though not observed, it is likely that other common herpetile species use habitat within the Beaver Dam Mine Site and Haul Road, at least periodically. These species include the mink frog (*Rana septentrionalis*), pickerel frog (*Rana palustris*), yellow-spotted salamander (*Ambystoma maculatum*), northern red-bellied snake (*Storeria occipitomaculata occipitomaculata*), and northern ring-necked snake (*Diadophis punctatus edwardsii*).

6.11.4.2.1 Touquoy Mine Site

No wood turtle or suitable habitat were observed within the Touquoy Mine Site during wood turtle habitat surveys conducted in 2004 (CRA 2007a). No snapping turtles were recorded within the Touquoy Mine Site during the EARD process, however, on June 26, 2016 a snapping turtle was observed within the LAA by AMNS, north of the Touquoy Mine Site, on Moose River Road (20T 504304E, 4981602N). From June 19 to mid-July, 2017 two snapping turtles were frequently observed by AMNS. One was found along Moose River Road (20T 504304E, 4981602N), at the location identified above. The second snapping turtle was observed on Higgins Mines Road (20T 504380E, 4980699N) west of the PA, but within the LAA. Snapping turtles were frequently observed (16 observations) by AMNS between June 19, 2017 and July 2, 2020, primarily on roadsides near Moose River and Scraggy Lake.

6.11.4.3 Summary of Fauna and Habitat within the Project Area

The variety of both upland and wetland habitats identified throughout the Beaver Dam Mine Site and Haul Road support a range of terrestrial fauna. The PA is located in a relatively remote, undeveloped landscape. Timber harvesting and associated forestry roads form the dominant disturbance regime within the landscape surrounding the PA. This land use within and surrounding the PA has created edge habitats and openings in the canopy coverage to provide foraging opportunities for species such as white-tailed deer, black bears, and coyote. Evidence of these species, along with snowshoe hare and porcupine, were abundant in disturbed habitats throughout the Beaver Dam Mine Site. Beavers and beaver activity have been observed in multiple waterbodies within the Beaver Dam Mine Site, particularly within Crusher Lake. All of the mammal species identified are presumed to use parts of the Beaver Dam Mine Site and Haul Road for foraging, breeding, denning, and raising young, at least periodically.

Herpetofauna species were observed throughout the Beaver Dam Mine Site and Haul Road, generally in association with an aquatic ecosystem, such as wetlands, waterbodies, and watercourses. Where improperly installed culverts are present along the existing Haul Road, many wetlands have standing water which is backed up as a result of improper culvert installation. These open-water wetlands, and natural wetlands with similar hydrologic regimes, are known to support breeding and overwintering populations of a variety of herpetofauna observed.

Incidental sightings of fauna were recorded during all field programs throughout the Beaver Dam Mine Site and Haul Road during all seasons. Aside from mainland moose tracks and snapping turtle sightings, no priority fauna species or signs thereof were observed. ACCDC records show a monarch butterfly (*Danius plexippus*, SARA Special Concern, CSEWIC Endangered, NSE Endangered, S2B) observation with the Beaver Dam Mine Site ((ppendix I.1), however no monarchs or its' host breeding species (milkweed, *Asclepias syriaca*) were recorded through all field studies (Section 6.13.4.7). Given the mobility of fauna species, the absence of observation does not confirm absence of the species within the Beaver Dam Mine Site and Haul Road. The size of a species and a species' behaviour can result in a bias against detection. For instance, very small species, such as the maritime shrew (S3) and the rock vole (S2) have been documented within 5 km of the Beaver Dam Mine Site and Haul Road but were not observed by the Project Team. As another example, the fisher (Martes pennanti, S2) is a largely nocturnal hunter, with large home ranges and elusive behaviour. They prefer dense, mature to over-mature coniferous stands with large hollow snags for den sites. Their preferred habitat and prey items (porcupine, rabbits, squirrels and other small mammals) are present within the Beaver Dam Mine Site and Haul Road. The lack of observed evidence of fisher does not confirm absence of the species. Furthermore, weather conditions can affect the detectability of species. Rain or snow can wash away or cover animal tracks and scat, while temperature affects the activity levels of herpetofauna and, therefore, their detectability. When there is a thermal advantage to staying under water or immersed in wetland vegetation, herpetofauna can be more difficult to detect, compared with warmer days when they can be found basking in the sun.

6.11.5 Consideration of Engagement Results

Key issues raised during public and Mi'kmaq engagement relating to terrestrial fauna include potential effects on fauna from permanent loss of habitat associated with the footprint of the Beaver Dam Mine Site and Haul Road, as well as direct mortality associated with the hauling operation. Potential effects on traditional uses of land and resources by the Mi'kmaq were noted, including hunting and trapping of small game and deer.

The results of the public and Mi'kmaq engagement have been considered in the environmental effects assessment, including AMNS's commitments on mitigation and monitoring measures and proposed compliance and effects monitoring programs, as well as AMNS's broader commitment to ongoing public and Mi'kmaq engagement (Sections 3 and 4). Specific to evaluating the effect on terrestrial fauna, these are found within the following environmental effects assessment.

6.11.6 Effects Assessment Methodology

6.11.6.1 Boundaries

6.11.6.1.1 Spatial Boundaries

The spatial boundaries used for the assessment of Project effects to terrestrial fauna is described below.

- The PA (Section 5.5, Figure 5.5-1) consists of the three project components; Beaver Dam Mine Site, Touquoy Mine Site, and the Haul Road and extends from Marinette to Moose River Gold Mines, Halifax County, NS. The Beaver Dam Mine Site is located at the eastern end of the Beaver Dam Mines Road. The Haul Road spans from the Beaver Dam Mine Site to Moose River Gold Mines, where the Touquoy Mine Site [processing and exhausted pit (to be used to dispose Beaver Dam tailings)] is located. The PA has changed as a result of the expansion of the Beaver Dam Mine Site to accommodate micro-sitting of mine infrastructure and ongoing modifications to the Haul Road design, as described in Section 2. These changes have been captured under the existing and additional desktop and field evaluations.
- The LAA (Figure 6.11-3) consists of a 5 km buffer surrounding the Beaver Dam Mine Site and a 500 m buffer surrounding the Haul Road and Touquoy Mine Site components of the PA. The LAA boundaries were defined considering the maximum expected extent of direct and indirect impacts to terrestrial fauna. The LAA has been modified to reflect the changes in the PA.
- The RAA (Figure 6.11-3 encompasses NSL&F's Ecological Land Classification Ecodistrict 440 (Eastern Interior) within Halifax Regional Municipality (HRM), east and north of Lake Charlotte. Where the Ecodistrict boundary approached the northern extent of the Beaver Dam Mine Site, the RAA was enlarged to include a minimum 5 km buffer around the PA. This Ecodistrict spans an area broader than the expected Project impacts and considers other project boundaries as per cumulative effects methodology. These spatial boundaries will help to identify the direct or indirect impacts to terrestrial fauna species and habitats.

Assessment of terrestrial fauna will be completed in consideration of the RAA as the primary spatial boundary. All spatial boundaries will help to identify the direct or indirect impacts to terrestrial fauna and the effects of the Project on distribution and abundance of these species.

6.11.6.1.2 Temporal Boundaries

The temporal boundaries used for the assessment of effects to terrestrial fauna are the construction, operation, active closure, and post-closure phases.

6.11.6.1.3 Technical Boundaries

No technical boundaries were identified for the effects assessment of terrestrial fauna.

6.11.6.1.4 Administrative Boundaries

Administrative boundaries for management of terrestrial fauna include the *Nova Scotia Wildlife Act*, which protects wild species diversity and abundance, and the *Canada Wildlife Act*. Further protection is offered to SAR through the provincial *Nova Scotia Endangered Species Act* and the federal *Species at Risk Act*.

6.11.6.2 Thresholds for Determination of Significance

A significant adverse effect from the Project on terrestrial fauna is defined as an effect that is likely to cause a permanent, unmitigated, alteration to habitat that supports fauna species. An adverse effect that does not cause a permanent alteration of habitat is considered to be not significant. Significance criteria related to impacts to SOCI and SAR are presented in Section 6.13.

The following logic was applied to assess the magnitude of a predicted change in terrestrial fauna, based on the habitat analysis results described in Section 6.10.4.5:

- **Negligible** – the Project is predicted to result in less than 1% direct loss of habitat types used by observed species within the LAA.
- **Low** – the Project is predicted to result in 1 to 5% direct loss of habitat types used by observed species within the LAA, and the loss of habitat is mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.
- **Moderate** – the Project is predicted to result in 5 to 25% direct loss of habitat types used by observed species within the LAA and the loss of habitat is mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.
- **High** – the Project is predicted to result in greater than 25% direct loss of habitat types used by observed species within the LAA and the loss of habitat is not mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.

The Habitat and Flora LAA was used to determine habitat type and area, and resultant habitat loss for species (Section 6.10.7.1).

The timing of residual effects for terrestrial fauna considers when the residual environmental effect is expected to occur, considering seasonal aspects. The duration of residual effects considers the time frame over which the effects are likely to last, ranging from short-term to permanent. For the purpose of the effects assessment related to terrestrial fauna, long term reflects the commencement of reclamation activities. The frequency of residual effects considers the rate of recurrence of the effects, ranging from once to continuous. The reversibility of residual effects considers the time required for habitat to recover to naturalized conditions, or whether the changes to habitat, if identified, are permanent.

6.11.7 Project Activities/Interactions with Terrestrial Fauna

The assessment of potential adverse interactions and effects of the Project on this VC takes into account the potential for the Project to result in changes to:

- permanent and temporary habitat alteration and fragmentation;
- disturbance and/or displacement;
- potential for direct and indirect mortality to individuals; and
- sensory disturbance.

The potential interactions of the Project with terrestrial fauna and their habitat are presented in Tables 6.11-4 to 6.11-6.

6.11.7.1 Habitat Use and Direct Loss

Development of the Beaver Dam Mine Site infrastructure and upgrades to the Haul Road will cause direct impacts to habitat used by terrestrial fauna, including upland forested habitat and wetlands. This will occur mostly within the construction phase of the Project. Habitat within the PA and surrounding landscape currently exhibits disturbed and fragmented conditions based on historic mine operations, existing road and trail networks, and current and historic timber harvesting activity within and adjacent to the PA (Section 6.10.4). However, project activities are still likely to result in direct habitat loss, increased habitat fragmentation and a decrease in habitat quality for those species which rely especially on interior forest conditions (Sections 6.11.7.2 and 6.11.7.4), where intact interior forest remains. The level of disturbance within the Beaver Dam Mine Site disproportionately affects uplands over wetlands. There exists large, natural, wetland habitats within the Beaver Dam Mine Site (e.g., Wetlands 2 and 29) that are not anticipated to be impacted by the Project. The habitat types and areas, including anthropologic disturbances, that will be impacted by the Project are presented in Section 6.10.7.1.

Considering the terrestrial fauna observed and expected within the Beaver Dam Mine Site and Haul Road, many are generalist that use a variety of habitat types for different life stages and functions. Many of the observed species are adaptable and commonly use anthropogenically disturbed environments (e.g., coyote, black bear, raccoon, white-tailed deer). Coyotes utilize regenerating harvested forest stands and edges of disturbed forest as well as intact forests with abundant understory which represent foraging sites for prey, such as deer and rodents (Crimmins et al. 2012). Black bears are noted to use a variety of habitats, but predominantly inhabit deciduous and coniferous forests, including recently harvest areas with high fruit and berry production (Lariviere 2001). Denning species (e.g., coyote and black bear) favour more protected sites such as shrub or forested areas for denning (Quinn 1990; Lariviere 2001). Semiaquatic species, such as beaver, utilize wetland and aquatic habitats, and adjacent uplands, for critical life functions (Allen 1982). There is currently beaver activity and suitable habitat across the Beaver Dam Mine Site. There is a recent dam and active lodge within Wetland 59, which will be directly impacted by the open pit. Ungulate species (i.e., white-tailed deer and moose) use upland forests and shrub areas for cover and foraging, including early-successional and previously harvested stands. Dense conifer stands are preferred in the winter, which provide reduced snow depth and thermal protection (Timmermann and McNicol 1988). Moose also require aquatic and wetland habitat for summer thermoregulation, calving and foraging (Timmermann and McNicol 1988).

Table 6.11-4: Potential Project Activities/Interactions with Terrestrial Fauna at Beaver Dam Mine Site

Project Phase	Duration	Project Interactions
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of construction (e.g., pre-stripping) • Till and waste rock from site preparation transport and storage • Watercourse and wetland alteration in preparation of construction, including open pit dewatering • Surface infrastructure installation and construction • Collection ditches and settling pond construction • Local traffic bypass road construction • Mine Site road construction and lighting • Culvert and bridge upgrades and construction • General noise and lighting from construction activities • Wildlife vehicle interactions/collisions
Operations and Maintenance	5 years	• Drilling and rock blasting to access and extract ore • Management of waste rock produced from crushing and preparing ore for transport • Till and waste rock from site preparation transport and storage • Open pit dewatering • Site maintenance • Treatment of site surface water runoff and surface mine pumped water • General management of wastes derived from operation and maintenance activities • Petroleum products management • Dust management • Culvert and bridge maintenance • General noise and lighting from construction activities • Wildlife vehicle interactions/collisions
Active Closure	2 years	• Site reclamation activities • Water treatment and management • Noise and lighting from decommissioning activities • Wildlife vehicle interactions/collisions
Post-closure	10+ years (monitoring)	• Water treatment and management

Table 6.11-5: Potential Project Activities/Interactions with Terrestrial Fauna along Haul Road

Project Phase	Duration	Project Interactions
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of construction • Till and waste rock from site preparation transport and storage • Watercourse and wetland alteration in preparation of construction • Haul Road construction and upgrades • Auxiliary infrastructure installation and construction • Local traffic bypass road construction • Culvert and bridge upgrades and construction • General noise and light from construction activities • Wildlife vehicle collisions
Operations and Maintenance	5 years	• Ore extraction and transport form Beaver Dam Mine Site to Touquoy Mine Site • Haul Road maintenance and repairs, including snow removal and deposition of sand for traction control • Dust management • Noise and light from Haul Road activity • Wildlife vehicle interactions/collisions
Active Closure	2 years	• N/A[(a)]
Post-closure	10+ years (monitoring)	• N/A

[(a)] Decommissioning and Reclamation of the Haul Road is not expected. The Haul Road will be returned to owner for forestry industry.

Table 6.11-6: Project Interactions for Fauna

Impact Type	Direct Impact	Project Phase	Indirect Impact	Project Phase
Vegetative and Habitat Integrity	Loss of vegetative cover through clearing and grubbing decreases wildlife habitat availability and Project development also has the potential to reduce natural surface water drainage.	C	Habitat fragmentation may alter habitat suitability for those species which rely on interior forest conditions. Within the Haul Road, this change in habitat is expected to be permanent.	C, O, CL
Sensory Disturbance	Extensive ground works, including activities such as blasting will increase noise levels. Increase in vehicular traffic will add to sensory disturbance through increased noise. This has the potential to reduce habitat for fauna.	C, O, CL	Sensory disturbance (both lights and noise) may result in further avoidance of the PA by some species.	C, O
	The Beaver Dam Mine Site and Touquoy Mine Site will have lights which are operational at all times, which can alter habitat quality and circadian cycles within the immediate vicinity of the PA. This may decrease efficiency of nocturnal hunters.	C, O	Some opportunistic wild species may be attracted to the site as a result of increased access and available food sources (natural prey or anthropogenic food sources), potentially increasing interactions between site personnel and wildlife.	C, O
Direct Mortality	Increased traffic and general activity within the PA may result in direct mortality to wild species through vehicular collisions and construction.	C, O, CL	Improved access throughout the Beaver Dam Mne Site and as a result of Haul Road construction/upgrades may increase hunting activity of licensed hunters and/or illegal poachers.	C, O, CL

Notes: C = Construction; O – Operations; CL = Active Closure; m = metre; PA = Project Area.

Herpetofauna observed ranged from aquatic to terrestrial. Aquatic and semiaquatic herpetofauna require slow moving fresh water for all or critical life functions. Snapping turtle is generally more aquatic than other turtle species, and require shallow aquatic environments for overwintering/hibernations, breeding and cover. Snapping turtle can tolerate and utilize disturbed areas, such as systems with poor water quality and anthropogenic features for nesting (e.g., berms, roadsides; ECCC 2020). Observed terrestrial reptiles (i.e., smooth greensnake and Maritime garter snake) occupy a variety of habitat types for different life functions (e.g., thermoregulation, hibernation, hunting) including uplands, wetlands and disturbed areas (CWF 2021).

A habitat loss by observed fauna species (or species group) based on the habitat analysis described in Section 6.10.4.5 is presented in Table 6.11-7. Specific habitat requirements (i.e., wetland type) were not distinguished and, conservatively, the broader habitat types from Section 6.10.3.5 were used to assess habitat loss by observed species. Based on the definitions of magnitude of impact, it is anticipated that all impacts to habitat types used by observed terrestrial fauna will be low, with the exception to anthropogenic disturbances (Section 6.10.7.1.1, Table 6.10-9). Specific habitat requirements, loss and impacts to observed SAR and SOCI (i.e., mainland moose and snaping turtle) are further discussed in Section 6.8.7.2 and Section 6.13.

	Anthropogenic Disturbances[c]	20.3	13.4	66.0	N/A[d]

[a] Includes unmerchantable timber, often which is regenerative stands and stands which were not categorized as hardwood or softwood stands.

[b] Managed forests include plantations, cutblocks, selective cuts etc.

[c] Includes roads, railways, urban development, quarries, gravel pits, mining activity etc.

[d] Not carried forwarded into impact magnitude determination (see Section 6.10.4.5)

Note: The Habitat and Flora LAA was used to determine habitat type and area, and resultant habitat loss for species (Section 6.10.7.1).

6.11.7.2 Habitat Fragmentation

Connectivity can be defined as the basic ecological requirement to be able to move freely within areas that provide critical functions for a species, and habitat fragmentation is the disturbance of this movement. Connectivity is critical for maintaining biodiversity and healthy species populations and interior forests are often an important feature that supports this movement (NSDNR, 2015b).

The methodology described in Section 6.10.3.6 was used to simulate current conditions for interior forest at the RAA level as a proxy for habitat availability and fragmentation, and wildlife movement. Road density has been identified as an excellent indicator of ecological integrity and potential predictor of habitat suitability for large mammals, like moose, as roads are closely correlated with human development (Snaith et al, 2002). Mainland moose are particularly susceptible to habitat fragmentation as it constrains their movement and habitat use, while increasing other pressures like predator and human interference (Snaith et al, 2002). Snaith et al. (2002) found that road density had a significant negative correlation with the probability of mainland moose observations in Nova Scotia, and potentially more indicative of habitat selection than habitat composition alone.

The current condition of the Beaver Dam Mine Site is disturbed and fragmented habitat based on timber harvesting and historic mining activity. A network of roads and trails is present throughout the site, with parts of the Beaver Dam Mine Site characterized by un-vegetated gravel and crushed stone. The RAA is generally remote, with a moderate network of roads and forestry activity, though large tracts of forest landscape undisturbed by roads still exist in this region (NSDNR, 2015b). The extent of the simulated existing disturbance and edge effect and remaining predicted interior forest patches for the RAA is shown in Figure 6.10-6. A total of 72,663 hectares (ha) of predicted interior forest has been identified within the RAA. The maximum Project edge effect as discussed in Section 6.10.7.1.2, and will affect 237 ha of interior forest habitat, which accounts for 0.3% of predicted interior forest in the RAA.

While Project activities are expected to result in increased habitat fragmentation and a decrease in habitat quality (e.g., sensory disturbance), the level of new fragmentation associated with the Beaver Dam Mine Site is anticipated to be low, given the current level of disturbance within the PA. The Beaver Dam Mine Site infrastructure footprint is situated primarily on an area of high existing disturbance and is expected to only have fringe effects on the interior forest availability. There will be minimal isolation of habitat that is currently contiguous, limited to the patch of potential interior forest west of the NAG waste rock stockpile (Figure 6.10-6). Undisturbed, unfragmented habitat is present in the RAA, including large tracts maintained around the PA, particularly to the north. Accessible routes to provide movement through and across the region at the LAA and RAA level still exist for wildlife and are un-impacted by the development of the Project. Those species which prefer interior forest conditions (e.g., fisher, moose) are likely already avoiding the Beaver Dam Mine Site, while those species which prefer fragmented habitat (e.g., coyote, snowshoe hare, white-tailed deer) are not expected to be adversely affected by additional habitat fragmentation.

Road construction can decrease habitat quality through direct habitat loss, degradation, and fragmentation (Underhill and Angold, 2000). For some species (e.g., porcupine), the construction can be beneficial by providing new foraging opportunities, while species that rely on interior forest conditions (e.g., fisher) are likely to avoid areas with new construction in favor of more undisturbed habitats. Local level changes in abundance and distribution of species may occur as the result of Project activities, but it is not anticipated that any of these changes will result in changes in overall fauna populations.

Construction of the Haul Road will involve a combination of new road construction (4 km) and upgrades to the existing logging road. The majority of the proposed Haul Road (i.e., approximately 30 km) follows an existing road corridor, thereby limiting new habitat fragmentation. The existing Haul Road is used by lumber trucks, but the level of traffic varies seasonally and annually depending on which areas are undergoing timber harvesting. The 4 km section of new road immediately southwest of Highway 224 will add new habitat fragmentation to an area that has very little, if any, evidence of anthropogenic disturbance. Along this section of the Haul Road, 112 ha of potential interior forest will be impacted (Figure 6.10-6), which will increase habitat fragmentation and decrease the habitat quality for those species that rely on interior forest. Much of this area is classified as Old Forest, which can provide unique habitat functions for fauna. All efforts will be made during the detailed planning of the road layout to minimize impacts to this habitat (Section 6.10.8). Other documented Old Forest areas are present within the region, unimpacted by Project development, to the north and southwest of the PA

6.11.7.3 Direct Mortality

Direct mortality of fauna species could result from Project activities, particularly due to the increase in traffic during construction and operation of the facility. Increased traffic poses a risk to wildlife along mining roads within the Beaver Dam Mine Site and along the entire length of the Haul Road between the Beaver Dam Mine Site and the Touquoy Mine Site.

According to Fahrig and Rutwinski (2009), road construction can have greater impacts on amphibians and reptiles, and large mammals, compared with small mammals and birds. Road infrastructure and traffic have a negative impact on those species which are attracted to roads but lack the speed or reaction time to avoid traffic (e.g., turtles attracted to gravel roadsides for nesting). Small mammals and birds, on the other hand, are able to avoid collisions with vehicles in general. Amphibians in particular can benefit from culvert installation where wetlands and watercourses intersect roads, as an alternative to crossing the roads, because this group can experience high mortality (Bouchard et al., 2009).

The risk of collisions with wildlife will vary depending on the season and the species. For instance, during winters with deep snow conditions, white-tailed deer are more likely to use roads and trails, putting them at an elevated risk of collisions. During spring and summer, porcupine and skunk forage on roadside vegetation at dawn and dusk, increasing the risk of collisions with those species, and turtles are drawn to the roadside to nest in the gravelly shoulders in June. As such, the risk of wildlife collisions is present at any time of year.

Traffic volumes will also increase (Section 6.1.7) due to haul truck traffic and traffic from site personnel. The Project expects a maximum of 190 round trips along the length of the Haul Road up to 16 hours a day during the first two years of operation, decreasing in subsequent years. The increased level of traffic poses an increased risk to wildlife collisions, particularly along the Haul Road, where the speed limit is proposed to be 70 kilometres per hour (km/hr). The risk of collisions within the Beaver Dam Mine Site will be lower, as the speed limit will be reduced to 40 km/hr., giving both drivers and wildlife more reaction time to avoid collisions. While no obvious wildlife corridors were observed within the Beaver Dam Mine Site and Haul Road, it is anticipated that some wild species (e.g., herpetofauna) will use watercourses and wetland complexes as travel corridors, thereby increasing the risk of collisions with wildlife along these systems where they interact with the Haul Road and interior mining roads.

Indirect impacts or mortality could also result from exposure to contaminants or spills from unplanned incidents.

6.11.7.4 Sensory Disturbance

The indirect effects of the Project on terrestrial fauna can largely be attributed to decreased habitat quality through sensory disturbance, specialty noise and light. Sensory disturbance would result from rock blasting, clearing and grubbing, infrastructure construction, lighting and operations, internal mine traffic and traffic along the Haul Road during operations. Blasting will within the Beaver Dam Mine Site during the operation phase. This along with other construction and operation activities will increase sensory disturbance above current conditions and will, as described above, reduce the habitat quality for some species.

Sensory disturbance will likely result in the localized wildlife avoidance of the PA, particularly in close proximity to the Beaver Dam Mine Site infrastructure footprint and Haul Road. Overall, Project activities will likely cause a change in usage of the PA by wildlife, with some species tending to avoid the area, while others may be attracted to the increased activity, including opportunistic species such as coyotes, raccoons, skunks, or black bears. Sensory disturbance related to Project activity will occur within the Beaver Dam Mine Site, Haul Road, and within the Touquoy Mine Site, as the addition of material from the Beaver Dam mine will extend the life of the Touquoy Mine Site by five years.

6.11.7.4.1 Noise

Existing ambient noise (measured in 2014) around the Beaver Dam Mine Site had an average value of 33 decibels (dBA) ±. As such, in the noise model, baseline noise levels were assumed to be 33 dBA during the day and 27 dBA at night (Section 6.1.7, Table 6.1-3). The predicted noise levels at the boundaries of the Beaver Dam Mine Site during operations are presented in the Noise Impact Assessment and are expected to range between 55 to 65 dBA (Appendix B.2). It should be noted that the findings within the Noise Impact Assessment are worst case (most conservative) predictions.

The Environment Code of Practice for Metal Mines (Environment Canada, 2012b) has established parameters for ambient noise levels for wildlife. These parameters indicate that ambient noise observed above 55 dBA during the day and 45 dBA at night can affect wildlife. Although the auditory capabilities of fauna species varies (Shannon et al. 2016) and fauna behavior in response to noise is largely related to perceived threats as opposed to noise intensity (Bowles 1995), changes to ambient noise levels and the presence of periodic vibrations from blasting have the potential to adversely affect fauna. Noise may simply act as a sensory disturbance resulting in avoidance (Ware et al. 2015), However, noise can also affect fauna behavioral patterns (Patthey et al. 2008), stress levels (Knight and Swaddle, 2011), affect communication and hunting success (Barber et al. 2009). Combined, these effects can negatively impact the overall population health of a particular species (Ware et al. 2015). Maier et al. (1998) and Flydal et al (2001) observed that sounds at 46 dBA and 60 dBA elicited responses in caribou and reindeer, respectively. While Drolet et al. (2016) report no changes to density of white-tailed deer when a simulated drilling noise was played at 55 to 65 dBC, a literature review conducted by Shannon et al. (2016) found that an increase in stress and decrease in reproductive success in terrestrial mammals has the potential to occur at noise levels ranging from 52 to 68 dBA. Levels from these studies are higher than those cited by Environment Canada (2012).

The predicted noise levels presented in the Noise Impact Assessment (Appendix B.2) exceed the levels outlined by Environment Canada (2012) at the Project property boundary. According to the results of the Noise Impact Assessment, noise generated from Project activities diminishes to 45 dBA (the most conservative guideline) at approximate ranges of 0 to 1,000 m outside of the Beaver Dam Mine Site property boundary. At the Haul Road, noise at that same sound level is predicted to travel approximately 100 to 350 m from the center line of the road. At the Touquoy Mine Site, noise at 45 dBA is predicted to travel approximately 0 to 850 m outside the property boundary These ranges of noise distribution are due to changes in local topography. Terrestrial fauna within these approximate ranges of noise distribution surrounding the PA have the potential to be affected by noise during the day and overnight.

6.11.7.4.2 Light

Light effects on terrestrial fauna include changes to circadian patterns, seasonal patterns, movement and distribution, and community interactions and composition (Pauwels, 2018). These impacts can result in disorientation, attraction or avoidance, and behavioral changes that can affect the success of foraging, reproduction, and communication (Langcore and Rich, 2004). Artificial light can also disrupt habitat connectivity and indirectly create habitat fragmentation (Bliss-Ketchum et al. 2016). Schirmer et al. (2019) found that light had differing impacts on nocturnal and diurnal species. While both were impacted by increased artificial lighting, generally nocturnal species exhibited a delayed, compressed active period, while the active period for diurnal species was extended. These changes in circadian patterns can cause the suppression of melatonin in mammals, particularly in nocturnal species (Schroer and Holker, 2016). However, there is limited data is available for larger mammalian species.

While effects of light on wildlife are documented, it is still an emerging area of research and artificial lighting thresholds (e.g., duration, intensity, spectrum, etc.) for fauna are not well defined. Currently there is no globally recognized or generally agreed upon standard for measuring biologically relevant light for wildlife or sky glow, which results in difficulty and inaccuracy when

comparing between metrics and methods (DEE, 2020). Light is traditionally measured and quantified for human perception. However, this does not capture all light visible to wildlife. Furthermore, the visible spectrum and sensitivities differ by taxa and species (DEE, 2020).

Type of lighting may also impact fauna. Some lights can have increased effects on fauna due to the short wavelengths they emit (e.g., white or blue LEDs, metal halides). Wildlife is generally more sensitive to short, high energy UV/violet/blue wavelengths, particularly nocturnal species. Short wavelength light also scatters more in the atmosphere than long wavelength light, increasing the effects of sky glow (DEE, 2020; Pauwels, 2018). Yellow-orange light is typically associated with long wavelength lights (e.g., High Pressure Sodium, Low Pressure Sodium, Amber LED).

Light levels from the Project have been modeled in the Light Impact Assessment (Appendix D.1) and discussed in Section 6.3. While the calculated light levels at the sensitive receptors are below the guidelines recommended by the Institute of Lighting Engineers (ILE) guidelines, nighttime light propagation from the Project may still cause sensory disturbance to fauna. Project activities are likely to result in localized avoidance of the Beaver Dam Mine Site and Haul Road and directly surrounding areas by some species. This potential avoidance would be due to changes in ambient light levels. The impact distance will also be dependent on the type of lighting used. As studies suggest (i.e., DEE, 2020; Pauwels, 2018), lights that emit more blue shortwave light (e.g., LEDs, metal halides) show greater impacts to fauna at night. These distances have been considered in the delineation of the RAA.

Light impacts from trucks on the Haul Road are expected to be insignificant compared to baseline daylight illuminance and will be blocked by the surrounding natural buffers and topography. The impacts of Haul Road lighting on fauna is expected to be less than that of noise. No permanent lighting will be installed on the Haul Road.

6.11.7.5 Touquoy Mine Site

The potential interactions of the Project with terrestrial fauna within the Touquoy Mine Site is presented in Table 6.11-8.

Table 6.11-8: Potential Project Activities/Interactions with Terrestrial Fauna at Touquoy Mine Site

Project Phase	Duration	Relevant Project Activity
Construction	1 year	• Tailings pipeline, make-up water pipeline alteration, and relocation of reclaim infrastructure
Operations and Maintenance	5 years	• Environmental monitoring • General management of waste derived from processing activities • Accidents and malfunctions to include fuel and other spills, forest fires, and a haul truck accident • Heavy machinery operation • Vehicle activity • Project lighting
Closure	2 years	• Environmental monitoring • Accidents and malfunctions to include fuel and other spills and forest fires • Heavy machinery operation • Vehicle activity • Project lighting
Post-closure	10+ years (monitoring)	• N/A

N/A = not applicable.

The Project will have no new effects on terrestrial fauna at the Touquoy Mine Site. Continued sensory disturbance caused by noise and light will occur within the Touquoy Mine Site as a result of the extended life of the Touquoy Mine Site associated with the Project. The continued sensory disturbances to fauna from the Project have been considered in the previous sections and within the Noise and Light Impact Assessments (Appendix B.1, B.2 and D.1). Increased traffic at the Touquoy Mine Site poses an elevated risk to wildlife.

6.11.8 Mitigation

In order to mitigate and reduce overall loss of function of habitat used by terrestrial fauna, and reduce direct impacts on fauna, the actions provided in Table 6.11-9 will be implemented by Atlantic Mining NS Inc (AMNS) where direct loss of habitat is expected to support development of the Project. AMNS encourages the public to report mainland moose sightings to the province at https://novascotia.ca/natr/wildlife/sustainable/msform.asp.

Where direct impacts to habitat or fauna are not expected, the Beaver Dam Mine Site and Haul Road development may still potentially cause indirect impacts through construction, operation, and closure activities. The following actions will be implemented to reduce the potential for indirect impacts to adjacent undisturbed habitat:

- for species which rely on wetland habitat, maintain pre-construction hydrological flows into and out of downstream wetland habitats, to the extent possible (post alteration wetland monitoring may be required as a result of the provincial permitting process);
- in order to protect adjacent habitats from accidental spills, ensure that spill control and contingency planning is in effect, and its procedures fully communicated to staff;
- vegetation management will be conducted by cutting (i.e., no use of herbicides);
- ensure all development related activity (construction areas, access roads, etc.) are located within areas where biophysical field evaluations have been completed and approvals/written authorizations are in place as required;
- erosion control materials shall be clean, non-ore-bearing, non-watercourse derived and non-toxic materials;
- machinery and personnel will be instructed not to enter the habitats outside of approved Project footprint; and
- slopes will be re-vegetated to stabilize them and limit erosion and sedimentation into adjacent habitats.

Mitigations for SOCI and SAR fauna will be discussed in Section 6.13.8 comprehensive mitigation table for all VCs is provided in Section 9.

Table 6.11-9: Mitigation for Terrestrial Fauna

Project Phase	Mitigation Measure
Construction, Operation	Provide wildlife awareness training to site personnel to reduce interactions between site personnel and wildlife.
	Intact forest stands and wetlands will be avoided wherever practicable during detailed Project planning and design in favor of previously disturbed areas (e.g., stands disturbed by timber harvesting, roads, or other development). Micro-site Haul Road and mine infrastructure to avoid major fauna habitat.
	Where natural, intact habitat cannot be avoided, maintain existing vegetation cover whenever practicable and minimize overall areas of disturbance.
	Minimization of impact to old forest.
	For those species reliant on wetland habitat, a wetland alteration application will be submitted during Project planning and design to request an authorization to alter wetland habitat and to address loss of wetland function.

Table 6.11-9: Mitigation for Terrestrial Fauna (continued)

Project Phase	Mitigation Measure
	Compensation for permanent loss of wetland function will be completed through wetland restoration activities to support no net loss of wetland function, subject to NSE approval.
	Habitat fragmentation will be reduced by limiting the area of new roads, favoring upgrading of existing roads where possible instead.
	Site infrastructure will be fenced in, where practical, to reduce interactions between Project infrastructure and wildlife.
	A speed limit of 40 km/hr within the Beaver Dam Mine Site and 70 km/hr along the Haul Road (or not exceeding posted speed limits) will be implemented to reduce likelihood of collisions with fauna.
	Install signage where specific wildlife concerns have been identified. Vehicles will yield to wildlife on roads.
	Monitor and manage road conditions through dust suppression and traction control (sand on icy roads) to reduce potential for collisions with wildlife. Implement Dust Control Plan (Appendix C.3)
	An un-vegetated buffer of 10 m along roadsides will be maintained, where possible, to improve visibility along roadsides and reduce the potential for collisions with wildlife.
	Clearing and construction will be limited within wetlands that could support snapping turtles during winter hibernation period;
	Erosion and sediment control planning will be completed to ensure site runoff is not directed towards unaltered habitat. Implement Erosion and Sediment Control Plan.
	Culverts installed within wetlands and watercourses will provide an alternative crossing location to amphibians and reptiles, thereby reducing direct mortality of species attempting to cross a road. Upgrade culverts along the new and upgraded Haul Road sections to improve habitat connectivity.
	Implement Emergency Response and Spill Contingency Plans to protect fauna and their habitat from accidental spills
	Store hazardous and non-hazardous waste in designated locations, in appropriate containers to reduce potential for spills, and to prevent attracting wildlife (e.g., food waste in bear proof containers).
	Follow the Pit and Quarry Guidelines to reduce impact of noise and vibration on wildlife
	Limit use of lights to the amount necessary to ensure safe operation within the PA, with the recognition that excessive lighting can be disruptive to wildlife. Install lights facing downward and wherever practicable using motion-sensing lights.
	Consider limiting use of lights that emit more blue shortwave light (e.g., LEDs, metal halides) which have greater impacts to wildlife at night, where practicable and considering operational safety.
	Restrict blasting to a specific and regular daytime schedule during weekdays to allow time for wildlife to recover from potential noise disturbance.
	Implement Wildlife Mitigation and Monitoring Plan (Appendix P.7)
	Site-specific measures to protect wildlife will be addressed in the EPP.
Closure	Implement remediation plans to restore natural habitat and food source re-establishment to support fauna
	Install signage where specific wildlife concerns have been identified. Vehicles will yield to wildlife on roads.
Post-Closure	A deterrent system will be considered at the Touquoy Mine Site when the pit fills as tailing deposition will be present. This will deter wildlife from using the pit during and after filling which may have deleterious effects resulting from long-term exposure.

6.11.9 Residual Effects and Significance Update

The predicted residual environmental effects of Project development and production on terrestrial fauna are assessed to be adverse, but not significant. The overall residual effect of the Project on terrestrial fauna is assessed as not significant after mitigation measures have been implemented and are summarized in Table 6.11-10.

Table 6.11-10: Residual Effects for Terrestrial Fauna

Project - VC Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction – Beaver Dam Mine Site and Haul Road (habitat loss and fragmentation from clearing and grubbing)	Limit habitat disturbance and minimize Project footprint during detailed design, implement speed limits, install fences where necessary, and minimize lighting.	L < 5% direct loss of habitat types used by observed species within the LAA Partial mitigation through restoration.	RAA Potential adverse effect to fauna outside of the LAA (fragmentation)	A VC interaction may affect seasonal aspects of fauna.	MT (Beaver Dam Mine Site) Effects occur beyond 5 years when closure activities commence at Beaver Dam Mine Site. P (Haul Road) Closure of the Haul Road not expected.	O Effects occur once during the construction phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Loss	Not Significant
Construction – Beaver Dam Mine Site and Haul Road (sensory disturbance (noise, light, dust deposition) and wildlife vehicle collisions from construction activities)	Implement speed limits, install fences where necessary, and minimize lighting.	M	LAA Potential adverse effect to fauna outside of the PA	A VC interaction may affect seasonal aspects of fauna.	ST Effects are limited to occur from as little as 1 day to 12 months	R Effects occur at regular intervals during the construction phase	R VC will recover to baseline conditions	Disturbance	Not Significant
Operational – Beaver Dam Mine Site, Haul Road and Touquoy Mine Site (disturbance (noise, light, dust deposition and wildlife vehicle collisions) from haul trucks, heavy machinery and mine operations)	Implement speed limits, install fences where necessary, and minimize lighting.	M Moderate changes relative to baseline conditions in remaining and surrounding habitat.	LAA Potential adverse effect to fauna beyond the PA.	A VC interaction may affect seasonal aspects of fauna.	MT Effects may occur up to 5 years.	R Effects occur at regular intervals.	R VC will recover to baseline conditions	Disturbance	Not Significant
Closure (Active) – Beaver Dam Mine Site (re-establishment of habitat for fauna)	N/A	L Minor change from baseline conditions.	LAA Potential effect to fauna outside of the PA	A VC interaction may affect seasonal aspects of fauna.	LT Effects extend beyond active closure phase.	O Effects occur once during the closure phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Reclamation	Not Significant

Notes: See Section 5.11, Table 5.11-1 for definitions of the below characteristics.

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	IR	Irreversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	PR	Partially Reversible
H	High					P	Permanent	C	Continuous		

A significant adverse environmental effect for fauna has not been predicted for the Project for the following reasons, with consideration of the ecological and social context of the RAA surrounding the Project:

- During Construction:
  - Direct impacts to fauna habitat is expected, however, impacts will be minimized through on-going Project design and micro-sighting of infrastructure footprints where ever practicable.
  - The baseline habitat of the Beaver Dam Mine Site and Haul Road is a network of existing fragmentation due to historical and present forestry activities, and the presence of the logging road that is proposed for upgrade.
  - Less than 5% of the suitable habitat in the LAA for observed species will be directly impacted by Project development. Habitat loss will be mitigated in the long term through reclamation planning.
  - The majority of Haul Road construction is road upgrades, minimizing the loss of habitat for fauna.
  - Construction work will be considerate of the breeding patterns for fauna, wherever practicable.
  - Construction noise and light will be limited to a 12-month window.
- During Operations:
  - Noise will be elevated above baseline during this period and may cause a displacement of fauna in close proximity to the Haul Road and Beaver Dam Mine Site.
- During Active Closure:
  - Noise will be elevated above baseline during reclamation activities (2 years) involving mobile equipment and then drop to baseline for the post-closure period.
  - Appropriate mitigation such as wildlife deterrents will be implemented to deter wildlife species from entering the Touquoy TMF and open pits during Post-closure.

6.11.10 Proposed Compliance and Effects Monitoring Program

Monitoring of terrestrial fauna will be completed to verify the accuracy of the predicted environmental effects and the effectiveness of the mitigation measures specific to terrestrial fauna. Mitigations are outlined in Table 6.11-9. The Wildlife Mitigation and Monitoring Plan (WMMP; Appendix P.7) outlines protocols to minimize interactions between wildlife and Project activities. This document will evolve through the regulatory permitting process, as well as public and Mi'kmaw engagement. As part of the WMP, a Mainland Moose Management Plan (MMMP) will be developed and will commit to monitoring mainland moose during baseline/pre-construction to establish baseline conditions, and through the operational phase, closure, and post-closure (as determined to be required). Monitoring associated with the MMMP will be completed for the Project on selected transects within suitable mainland moose habitat.

6.12 Avifauna

6.12.1 Introduction

6.12.1.1 Summary of Avifauna Before the Updates

Baseline surveys confirmed presence of 103 avifauna species (6,193 individuals) during dedicated survey periods or incidentally within the Beaver Dam Mine Site and Haul Road. These observations included 25 potentially priority species, determined based on observation season and breeding status qualifiers. Priority avifauna determination and discussions are preened in Section 6.13 (Species of Conservation Interest [SOCI] and Species at Risk [SAR]). Dedicated avifauna surveys included, fall migration, spring migration, breeding season, winter wildlife surveys, spring diurnal raptor surveys, spring nocturnal owl surveys and common nighthawk surveys. Surveys were conducted at set survey locations, which included point count, watch count, and call back stations. Seventy-seven species were observed to be possible, probable, or confirmed breeders within the Beaver Dam Mine Site.

Project related effects to avifauna include direct loss of habitat, habitat fragmentation, direct mortality, and sensory disturbance. Mitigations are proposed to reduce overall loss of function of habitat used by avifauna, and reduce direct impacts on avifauna within the Beaver Dam Mine Site and Haul Road. As a result of mitigations and detailed design planning, the predicted residual environmental effects of Project development and production on avifauna are assessed to be adverse, but not significant. Species of Conservation Interest (SOCI) and Species at Risk (SAR) fauna and Project related effects are further discussed in Section 6.13.

6.12.1.2 Summary of Updates to Avifauna

Supplementary field surveys were conducted for the Updated 2021 Environmental Impact Statement (EIS) (AMNS, 2021), as a result of Project Area (PA) modifications and continued infrastructure micro-siting since the 2019 EIS submission. Additional breeding bird (n=10) and Common nighthawk (n=2) surveys were completed in southeastern expansion of the Beaver Dam Mine Site in 2019. In total 6,521 individuals were observed at 118 survey locations within the Beaver Dam Mine Site and Haul Road (including the Mooseland Road portion). No additional avifauna species were observed during the 2019 surveys; however, 35 species were determined to be possible priority species (Section 6.13).

Impacts to avifauna were reassessed based on changes to the PA and Project infrastructure. The avifauna effects assessment was updated to include a function group-specific habitat assessment and improved assessment of Project related sensory disturbance.

No new direct or indirect impacts to terrestrial fauna are expected. Project effects to fauna remain adverse, but not significant.

Table 6.12-1: Updated Subsections from the 2019 Revised Environmental Impact Statement – Avifauna

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
-	-	6.12.1 Introduction	• New
6.12.1 Rationale for Valued Component Selection	No	6.12.2 Rationale for Valued Component Selection	• N/A
6.12.2 Desktop Review	Yes	6.12.3 Desktop Review	• Addition of additional Maritime Breeding Bird Atlas area: • Additional survey areas as a result of PA modification for infrastructure micro-sitting. • Review and update priority species (IR NSE 2-184)
6.12.3 Baseline Program Methodology	Yes	6.12.4 Baseline Program Methodology	• Addition of 2019 field surveys: • Additional survey areas as a result of PA modification for infrastructure micro-sitting.
6.12.4 Baseline Conditions	Yes	6.12.5 Baseline Conditions	• Present results from 2019 field surveys: • Additional survey areas as a result of PA modification for infrastructure micro-sitting • Revise breeding bird qualifier assessment methods • Review and update priority species (IR NSE 2-184)
6.12.5 Consideration of Consultation and Engagement Results	No	6.12.6 Consideration Engagement Results	• N/A
6.12.6 Effects Assessment Methodology – Boundaries	Yes	6.12.7 Effects Assessment Methodology – **Boundaries**	• PA modification for infrastructure micro-sitting. • Adjusted PA description. • LAA was enlarged due to the modified PA. • RAA was enlarged where necessary due to the modified PA. Fauna assessment area changed to the RAA.
6.12.6 Effects Assessment Methodology – Thresholds for Determination of Significance	Yes	6.12.7 Effects Assessment Methodology – **Thresholds for Determination of Significance**	• Updated significance threshold and magnitude assessment: • Reflect changes in VC baseline conditions and improve significance assessment criteria • Response to IR2 CEAA 2-02
6.12.7 Project Activities and Avifauna Interactions and Effects	Yes	6.12.8 Project Activities/Interactions with Avifauna	• Updated based on revised noise and light impact assessments. • Bolster discussion of direct and indirect impacts to fauna. Include species-specific habitat loss assessment. • Changes to project timelines.
6.12.8 Preferred Alternative Haul Road	Yes	Section removed	• The Preferred Alternative Haul Road is no longer being considered and has been removed from the Project Description and EIS
6.12.8 Mitigation and Monitoring	No	6.12.9 Mitigation	• Updated based on field survey results and changes to effects assessment • Reflects improved understanding of impacts.

Notes: PA = Project Area; LAA = Local Assessment Area; RAA = Regional Assessment Area; N/A = not applicable; IR2 = Round 2, Information Requests; CEAA = Canadian Environmental Assessment Agency; EIS = environmental impact statement.

6.12.2 Rationale for Valued Component Selection

Bird habitat may be altered or lost as a result of direct or indirect disturbances from the Project. Migratory birds and SAR are protected under federal legislation by the *Migratory Birds Convention Act* (MBCA) (Government of Canada, 1994) and SARA (Government of Canada, 2002). *The Nova Scotia Wildlife Act* protects all birds within the province by stating that, except with a permit issued by the minister, no person shall destroy, take, possess, buy or sell any egg of a bird or turtle or disturb the nest of a bird or turtle; or use a snare, net or trap to take any bird (Government of Nova Scotia, 1989, Section 51).

6.12.3 Desktop Review

A background review of potential avian species that could occur within the Beaver Dam Mine Site and Haul Road was completed prior to the start of the baseline monitoring programs. The data sources that were used are presented in Table 6.12-2. Results for priority species will be discussed in Section 6.13.

Table 6.12-2: Data Sources for the Background Review

Task	Source(s)	Product
Breeding Bird Identification	• Second MBBA	Identification of bird species considered confirmed breeders within 10 km of the Beaver Dam Mine Site and Haul Road.
Priority Species Assessment [(a)]	• ACCDC • Committee on the Status of Endangered Wildlife in Canada (COSEWIC) • SARA • Nova Scotia Endangered Species Act (NSESA) • Museum of Natural History report • Habitat mapping for the site	A priority list for SOCI and SAR with suitable habitat inside the Beaver Dam Mine Site and Haul Road and a list of species identify by ACCDC
Important Bird Areas	• Important Bird Areas of Canada	Description of nearest Important Bird Area to the Beaver Dam Mine Site and Haul Road.

(a) Priority species and the associated desktop analyses will be discussed in Section 6.13.

MBBA = Maritimes Breeding Bird Atlas; ACCDC = Atlantic Canada Conservation Data Centre; SAR = Species at Risk; SOCI = Species of Conservation Interest; km = kilometre.

6.12.3.1 Maritime Breeding Bird Atlas

The Beaver Dam Mine Site and Haul Road encompasses five MBBA squares: 20NQ17, 20NQ18, 20NQ19, 20NQ28, and 20NQ29 (Stewart et al., 2015). Square 20NQ19 was included as a result of the 2019 PA modifications to the Beaver Dam Mine Site. A summary of results for the five 10 kilometre (km) x 10 km MBBA (2006 to 2010) squares is presented in Table 6.12-3.

Table 6.12-3: Results Summary for Maritimes Breeding Bird Atlas Squares 20NQ17, 20NQ18, 20NQ19, 20NQ28, and 20NQ29

Atlas Squares[(a)]	Approximate Location in PA	Species (2nd Atlas)			
		No. Possible Breeders	No. Probable Breeders	No. Confirmed Breeders	Total
20NQ17	Southern end of the Haul Road, including Mooseland Road and the unnamed road that goes up to Highway 224, but only until near Rum Lake.	31	16	26	**73**
20NQ18	Includes Haul Road from near Rum Lake until Highway 224, about half of the new road section (western) and half the length of Highway 224 (western) between the unnamed road and Beaver Dam Mines Road.	11	19	52	**82**
20NQ19	Includes a small portion of the western-most side of the Beaver Dam Mine Site (NAG WARS).	29	13	23	**65**
20NQ28	Includes the eastern halves of Highway 224 and the new road section, as well as the southeast portion of the Beaver Dam Mine Site.	20	28	21	**69**
20NQ29	Includes most of the northern portion of the Beaver Dam Mine Site.	20	22	35	**77**

(a) Data is from the 2nd atlas (2006 to 2010).

No. = number; NAG = non-potentially acid generating; WRSA = Waste Rock Storage Area

The MBBA data summaries for squares 20NQ17, 20NQ18, 20NQ19, 20NQ28, and 20NQ29 can be found in Appendix L.1, along with avifauna species codes and breeding evidence codes.

6.12.3.2 Important Avifauna Areas

The nearest (Important Bird Area [IBA]) is the Eastern Shore Islands, located approximately 22 km southeast of the PA. The Eastern Shore Islands are situated along the southeast coast of central Nova Scotia, between 60 and 120 km east of Halifax. The site includes inshore islands roughly located between Clam Harbour and Ecum Secum. Within this rock-strewn stretch of sea are many low islands, islets, and reefs located between 2 and 15 km offshore. The vegetation on these islands varies from mostly wooded to treeless. The Eastern Shore Islands IBA supports large congregations of common eiders (*Somateria mollissima*), representing more than 2.5% of the subspecies population, as well as a wintering population of harlequin ducks (*Histrionicus histrionicus*). Other waterfowl frequent the site during spring migration, including thousands of scoters, and Leach's storm-petrels (*Oceanodroma leucorhoa*) also breed on some of the islands. (IBA Canada, n.d.). Habitat present within the PA is not consistent with habitat present on the Eastern Shore Islands. Furthermore, the PA is located a sufficient distance from the nearest IBA and is not located within a significant migratory flyway for species which rely on the Eastern Shore Islands.

6.12.4 Baseline Program Methodology

Avian baseline monitoring programs were completed by McCallum Environmental Ltd. (MEL) and included the surveys outlined in Table 6.12-4. In 2019, the PA, specify the Beaver Dam Mine Site, was modified to allow for the micro-siting of infrastructure, as described in Section 2 (Project Description). As a result, targeted avian surveys were conducted within the modified Beaver Dam Mine Site in July 2019 to identify and record additional avian species. Additional breeding bird (n=10) and Common nighthawk (n=2) surveys were completed in southeastern expansion of the Beaver Dam Mine Site. In total 118 survey locations were established within the Beaver Dam Mine Site and Haul Road (including the Mooseland Road portion). Haul Road point count stations HR-PC12 to HR-PC17 and nocturnal owl station HR-NO5 were located along an alternative Haul Road route no longer being considered. These observation locations have been removed from this assessment.

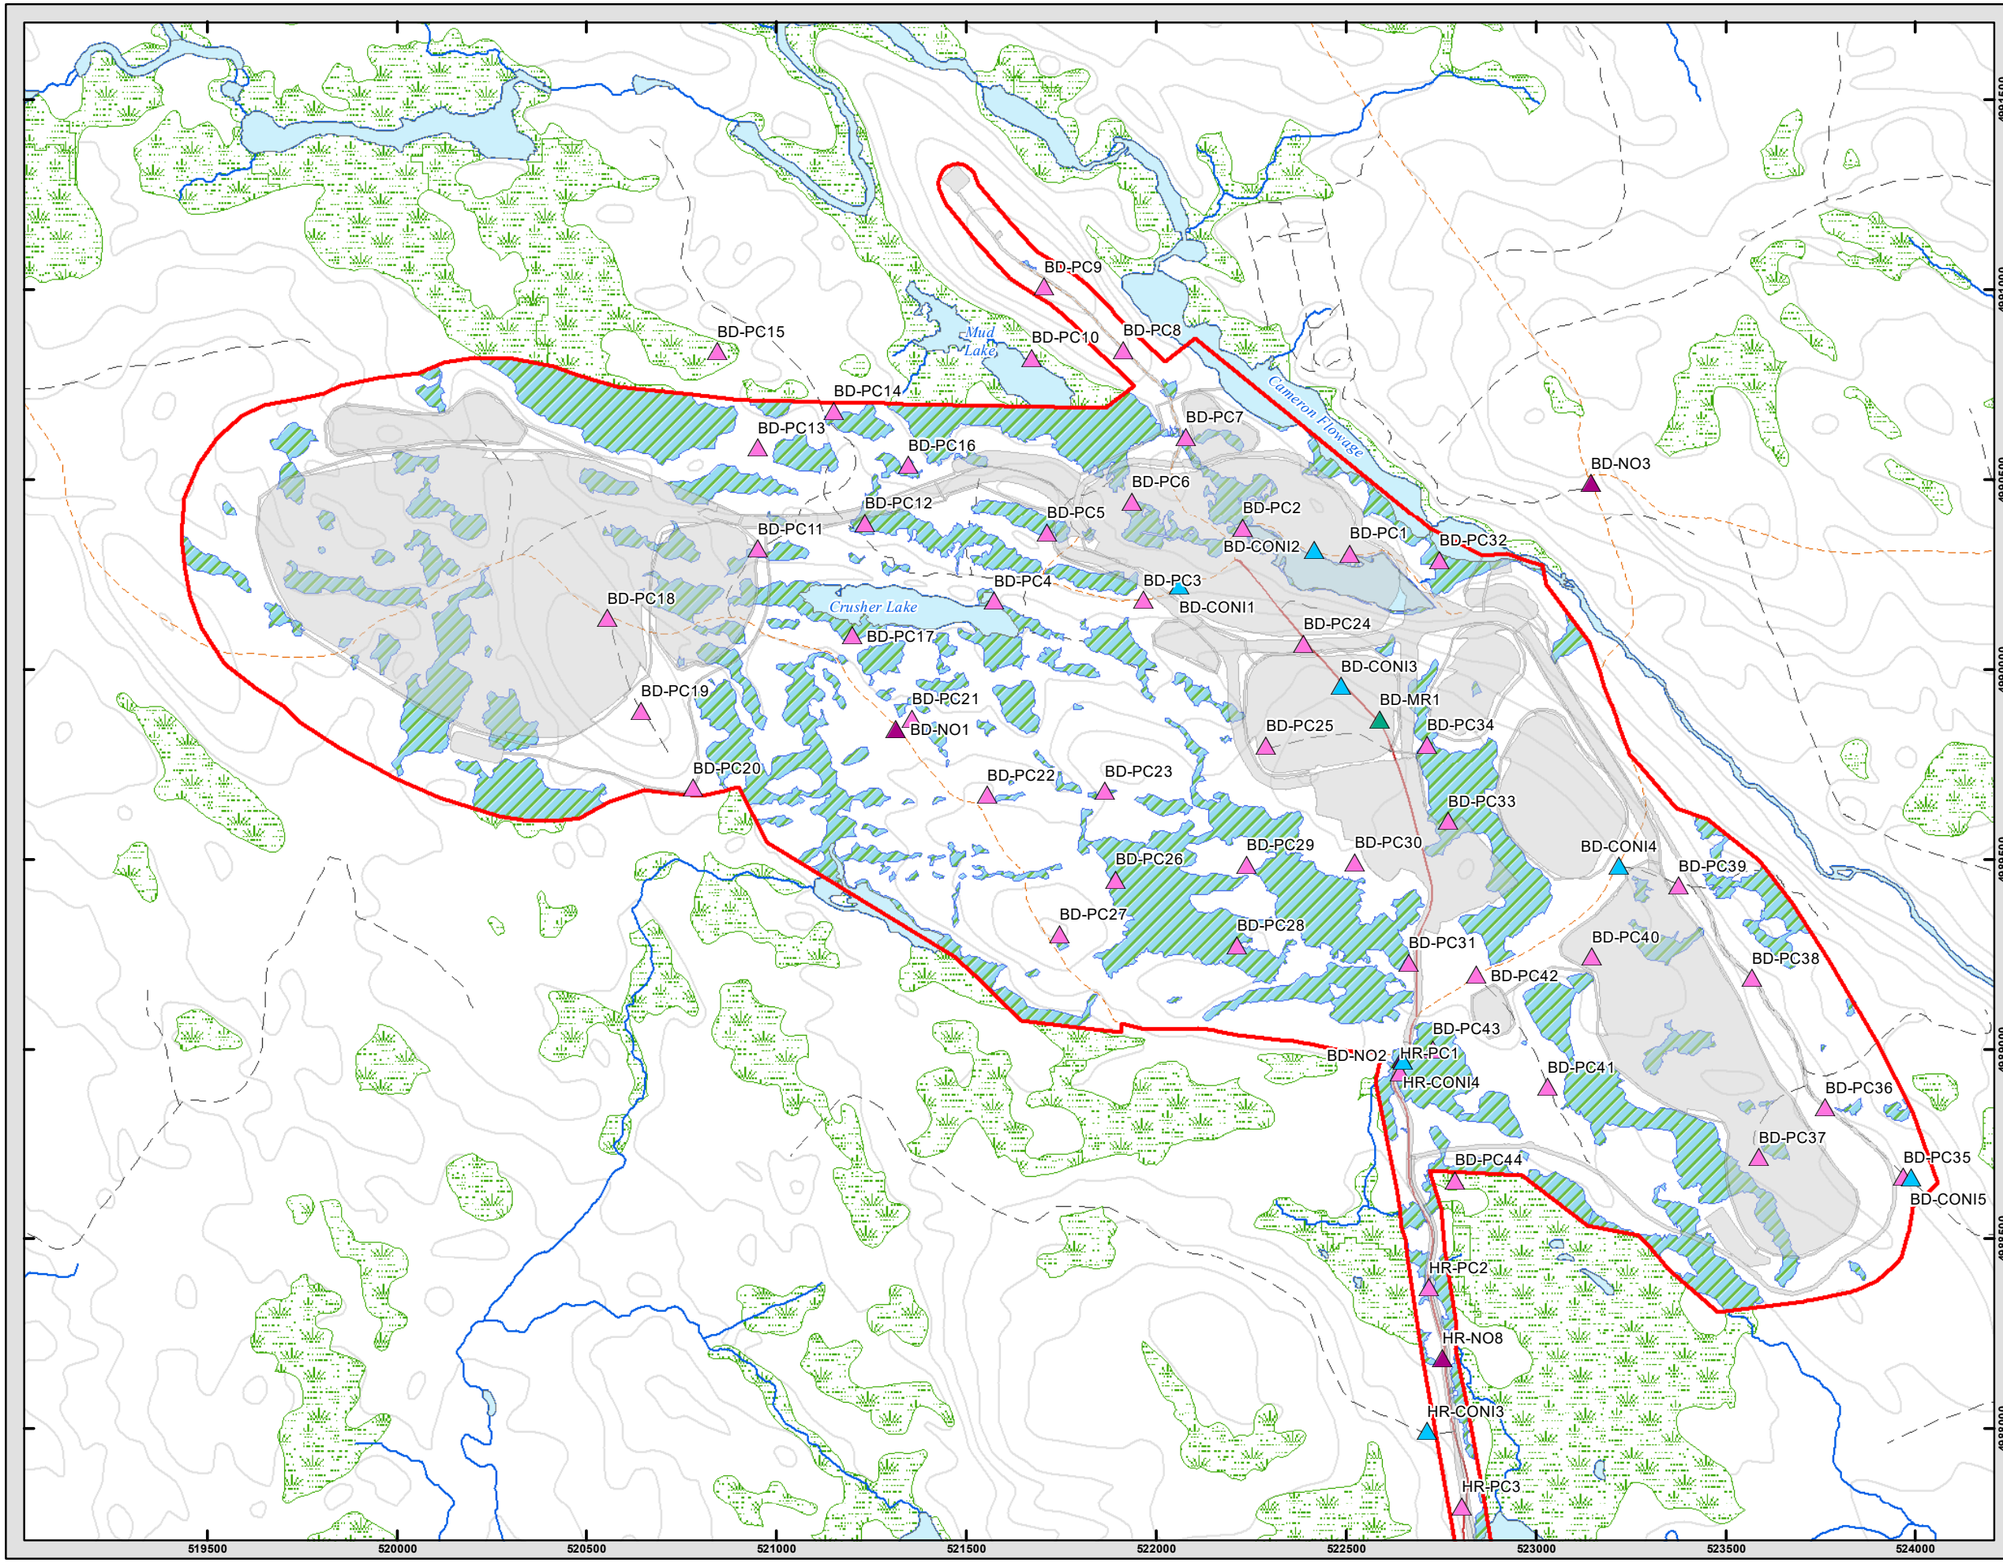
Table 6.12-4: Avian Baseline Monitoring within the Beaver Damn Mine Site and Haul Road

Survey Type	Project Area	
	Beaver Dam Mine Site	Haul Road[(a)]
Fall migration monitoring	September 17 to October 19, 2014 Thirty-two (32) point count stations Four (4) visits - weekly	N/A
Winter wildlife survey (including avifauna)	February 18, 2015 Incidental observations One (1) visit	March 2 and 31, 2016 Incidental observations Two (2) visits
Spring diurnal migrating raptor	April 15, 2015 One (1) watch count station One (1) visit	N/A
Spring nocturnal owl	April 15, 2015 Four (4) call playback stations One (1) visit	April 11, 2016 Eight (8) call playback stations One (1) visit
Spring migration monitoring	April 21 to June 4, 2015 Twelve (12) point count stations Six (6) visits - weekly	May 12 to 27, 2016 Forty-five (45) point count stations Three (3) visits - weekly
Breeding Bird	June 2015 Twenty-four (24) point count stations Two (2) visits - early and late	June 2016 Fifty (50) point count stations Two (2) visits - early and late
	July 2019 Ten (10) point count stations Two (2) visits – early and late	
Common Nighthawk	June 2015 Three (3) call playback stations Two (2) visits	June 2016 Twelve (12) call playback stations Two (2) visits
	July 2019 Two (2) call playback stations Two (2) visits	

(a) Includes the Mooseland Road portion of the Haul Road (Figure 6.12-1D and 6.12-1E).

Detailed descriptions of the survey methodologies for each of these baseline monitoring programs for the Beaver Dam Mine Site and Haul Road are provided in the following sections. Avifauna survey locations are presented in Figures 6.12-1A to 6.12-1E.

The Beaver Dam Mine Site was adjusted in 2019 to facilitate the micro-siting of Project infrastructure, which included a western expansion to include the western waste rock storage area and southeastern expansion to include the organics material stockpile. The western NAG waste rock storage area adjustment occurred after the completion of the additional 2019 avifauna surveys outlined in Table 6.12-4. Additional dedicated avifauna surveys were not completed in this area as a review of the additional habitat survey points (HSP43-49), the NSL&F Forestry Database and aerial imagery indicated that the additional area is comprised of similar cover and stand types present throughout the Beaver Dam Mine Site, and as such, the same avifauna species assemblages are expected to be present. Incidental avifauna observations were recorded during all survey efforts within this area. These general cover types include natural cover (mixed and soft wood), wetlands, clear cut and forestry roads.



Information pertaining to Touquoy Mine Site has been brought forward from the EARD and Focus Report. Methods and results are summarized in subheadings within the applicable sections and are carried forward into the effects assessment where appropriate. For further information regarding avifauna assessment undertaken at Touquoy Mine Site, are provided in the EARD (CRA 2007a) and Focus Report (CRA 2007b).

6.12.4.1 Fall Migration

Fall migration surveys were completed by McCallum Environmental Ltd. (MEL) biologists in accordance with the methods outlined by the Canadian Wildlife Service (CWS) in the Migratory Birds Environmental Assessment Guidelines (Milko, 1998). Thirty-two point count stations were established through all representative habitat types within the Beaver Dam Mine Site.

Four additional point count locations were established and surveyed during fall 2015 (Crusher Point count numbers 1 to 4, or CPC1 to CPC4). At this time, the Beaver Dam Mine Site consisted of two main areas: the pit and waste rock storage area were proposed in the current Beaver Dam Mine Site (Section 2, Figure 2.3-1), but the crusher was proposed to be in a separate area, approximately 4 km south of the Beaver Dam Mine Site along the existing Beaver Dam Mines Road. Through further detailed design of the Beaver Dam Mine Site layout, the separate crusher area was incorporated into the current Beaver Dam Mine Site. As such, the data collected in the crusher point count locations were not included in the analysis of fall 2015 migration data. Any priority species which were observed at these locations are included in the summary of priority species as incidental observations. Fall bird migration surveys were not conducted within the Haul Road because habitat types were generally similar to those observed within the Beaver Dam Mine Site. Point count locations are presented on Figures 6.12-1A to 6.12-1E.

Surveys began at, or within, half an hour of sunrise and were completed within four-and-a-half hours or by 10:00 a.m., whichever came first. Weather conditions (e.g., precipitation and visibility) were monitored and confirmed to be within the parameters required by monitoring programs such as Environment and Climate Change Canada's Breeding Bird Survey. Ten-minute point counts were conducted weekly between September 17 and October 19, 2014, during peak migration. Bird observations were recorded at four distance categories, within a 50 metre (m) radius, 50 to 100 m radius, outside the 100 m radius, and flyovers. For each point count, a record was made of the start time and a hand-held GPS unit was used to georeference its location. General observations, including the temperature, visibility, wind speed, date, start and end time, and location (UTM NAD83) were also recorded. Species recorded outside of the 100 m radius, between point counts, outside of the 10-minute survey window, and flyovers were recorded as incidentals. Bearings (in degrees) were taken for SOCI and SAR observed during dedicated survey periods and incidentally.

6.12.4.2 Winter Birds

No dedicated surveys for winter birds took place within the Beaver Dam Mine Site and Haul Road; however, incidental observations of birds were recorded during winter wildlife (primarily moose) surveys.

6.12.4.3 Spring Diurnal Raptor Migration

The objectives of the baseline spring migrating raptor survey were to determine species composition and relative abundance and to record incidental observations of other SOCI and SAR. The survey was not conducted if visibility was reduced by rain, fog, or snow.

On April 15, 2015, two observers surveyed for migrating raptors at a fixed monitoring station within the Beaver Dam Mine Site using the double-observer method (Nichols et al., 2000). Observers used binoculars and the naked-eye to scan for migrating raptors. A map of the PA, including the location of the monitoring station and a compass were used to document flight paths and estimate distances. The survey started at 12:30 p.m. and ended at 4:30 p.m. The spring raptor migration survey station is presented on Figures 6.12-2A.

Before a raptor was officially tallied, it had to demonstrate a migratory pattern as opposed to a behavior indicative of a local bird. Raptors are counted as migrants if they are: using thermals, flying a straight course northeast, or are at a very high altitude. Raptors are not counted as migrants if they are: in view for extended periods of time, actively hunting, or flying the "wrong way".

All birds considered migratory were tallied by date and hour using the Hawk Monitoring Association of North America (HMANA) Daily Report Form (HMANA, 1998). In addition to count totals of each species, observers recorded the following data hourly on the HMANA Daily Report Form: temperature, maximum visibility, sky conditions (cloud cover, precipitation), wind speed and direction, flight speed, direction and altitude, number of observers, and minutes of observation. Categories and codes for these data and brief instructions for gathering the data are available on the back of the HMANA Daily Report Form.

6.12.4.4 Spring Nocturnal Owl

The objectives of the nocturnal owl survey were to gather information on the presence and distribution of owl species within the Beaver Dam Mine Site and Haul Road, determine the location of active nests, and record incidental observations of other SOCI and SAR.

Wind can limit the ability of owls to hear a call broadcast and/or the ability of the observer to hear an owl calling. It is recommended that a survey be suspended if wind speed is Beaufort 4 or higher (i.e., greater than 20 kilometres per hour (km/hr); Takats et al., 2001). However, if there are other circumstances affecting detection, it may be necessary to reduce the wind threshold; this is at the discretion of the observer. If conditions were not suitable for surveying, then the survey was deferred or moved to a more suitable location.

Owls have been observed to be less vocal when temperatures are significantly lower than average for the season, thus surveys were also delayed in this circumstance (Takats et al., 2001). Surveys were stopped in the case of heavy precipitation; light drizzle and flurries are not likely to reduce calling rates or detectability (Takats et al., 2001).

The methods for monitoring nocturnal owls followed the Guideline for Nocturnal Owl Monitoring in North America (Takats et al., 2001). The nocturnal owl surveys took place on April 15, 2015 (Beaver Dam Mine Site; n=4) and April 11, 2016 (Haul Road; n=8), once per year when vocal activity of the majority of owl species is greatest (Takats et al., 2001), for a total of 12 call playback

stations throughout the Beaver Dam Mine Site and Haul Road. According to Greg Campbell (Senior Project Biologist with the Atlantic Chapter of Bird Studies Canada), in Nova Scotia, data collected through the Nova Scotia Nocturnal Owl Survey program shows peaks in barred (*Strix varia*) and great horned (*Bubo virginiatus*) owls in early April, while northern saw-whet owls (*Aegolius acadicus*) are late April to mid-May. Other owl species have been observed at numbers that are too low to determine peak calling periods (G. Campbell, pers. comm., 9 April, 2015).

Prior to starting the survey, the broadcaster being used (Pyle-Pro Pwma50db 50-watt portable waist band PA system) was tested to ensure that the owl calls being broadcasted from it were audible and recognizable at a distance of 400 m (Takats et al., 2001). Ensuring that the broadcast could be heard beyond 400 m minimizes bias at the next survey station due to owls hearing the recording from the previous station (Takats et al., 2001). The aforementioned test was carried out under weather and noise conditions similar to those that were likely to be encountered during the survey.

The broadcast used by the Bird Studies Canada Nova Scotia Nocturnal Owl Survey program was used for the survey. It consists of a 9.5-minute broadcast, which includes alternating owl calls with silent listening periods (BSC Atlantic Region, 2007). Only the calls of two owl species, the boreal (Aegolius funereus) and barred owls, are used in the BSC Nova Scotia Nocturnal Owl Survey program broadcast because they are particularly rare and sensitive, respectively. To date, the boreal owl has only been reported as breeding in Nova Scotia four times (Lauff, 2009). The barred owl is targeted because it has been used as an indicator of ecosystem health due to its dependence on cavities in large trees for nesting (Allen, 1987) playback stations were spaced at least 1.6 km apart in order to reduce the chances of detecting the same owl at multiple stations (Takats et al., 2001). Some of the louder owls, such as the barred owl, can be heard at distances of two kilometers or more (Takats, 1998, as cited in Takats et al., 2001). However, most of the smaller owls cannot be heard as far or as clearly (Takats et al., 2001). Surveys were conducted between half an hour after sunset and midnight (Takats et al., 2001). There are five species of nocturnal owls that could potentially breed at the Project site: the great horned, barred, long-eared (Strix varia), boreal, and northern saw-whet owls. Nocturnal owl point count locations are presented on Figures 6.12-1A to 6.12-1E.

6.12.4.5 Spring Migration

Weekly spring migration surveys were conducted at 12 point count stations within the Beaver Dam Mine Site by MEL biologists from April 21 to June 4, 2015 (six visits), and 45 point count stations within the Haul Road were completed May 12 to 27, 2016 (three visits), for a total of 57 point count stations within the Beaver Dam Mine Site and Haul Road. The scope of the spring migration survey within the Beaver Dam Mine Site was reduced because poor weather conditions and a late spring melt restricted access within the PA that season.

The surveys were conducted using the same methodology as the fall migration survey. Early morning point count surveys were conducted from 30-minutes before sunrise until 10:00 a.m. Species and number of birds observed at each point count location were recorded. Point count stations are presented on Figures 6.12-1A to 6.12-1E.

6.12.4.6 Breeding Birds

Surveys for breeding avifauna were conducted in June 2015 at 24 point count stations within the Beaver Dam Mine Site and at 50 point count stations within the Haul Road in June 2016. The breeding bird survey within the Beaver Dam Mine Site was reduced to 24 point count stations (i.e., from 32 in the fall) because of minor modifications to the PA. Five additional point count stations were added for breeding surveys along the Haul Road (i.e., up from 45 in the fall) in order to cover additional area. Ten additional point count stations were surveyed within the southeast expansion of the Beaver Dam Mine Site in July 2019. Targeted surveys for common nighthawk were also conducted during breeding bird surveys, including two additional locations in July 2019. The methodologies for these surveys are described in the following sections.

6.12.4.6.1 Touquoy Mine Site

Breeding bird surveys were conducted in June 2005 at 11 point count stations within the Touquoy Mine Site as part of the EARD process. Full details on methodology can be found in the EARD document (CRA 2007a).

6.12.4.6.2 Breeding Birds

Breeding bird surveys were conducted by MEL biologists in 2015, 2016 and 2019. Two rounds of surveys were completed at 24 point count stations within the within the Beaver Dam Mine Site in 2015, from June 8 to 11 (early) and June 25 to 26 (late). Additional surveys were conducted in 2019, on July 3 and 13, at 10 point count stations within the southeast expansion of the Beaver Dam Mine Site. Two rounds of breeding surveys were conducted at 50 point count stations within the Haul Road from June 13 to 17 (early) and June 22 to 28 (late), 2016. The surveys were conducted using the same methods as the fall and spring migration surveys. Early morning point count surveys were conducted from 30-minutes before sunrise until 10:00 a.m. Species and number of avifauna observed at each point count location were recorded. Point count stations are presented in Figures 6.12-1A to 6.12-1E.

6.12.4.6.3 Common Nighthawk

The common nighthawk prefers to nest in gravelly substrates and is best detected while foraging for insects shortly after sunset. Suitable habitat is available for this species within the Beaver Dam Mine Site and Haul Road, therefore, dedicated surveys for the common nighthawk were conducted from mid- to end of June at either dawn (1 hour before sunrise to 30 minutes after sunrise) or dusk (30 minutes before sunset to an hour after sunset), as described in the Common Nighthawk Survey Protocol (Saskatchewan Ministry of Environment, 2015). Common nighthawk are crepuscular and were detectable at both dawn and dusk survey times. Stations were spaced at least 800 m apart and a point count survey with call playback was used to detect the presence of common nighthawk within the Beaver Dam Mine Site and Haul Road. A three-minute passive point count was conducted at each station, followed by a call playback which includes 30-seconds of the conspecific common nighthawk call followed by 30-seconds of silence (or passive surveying), repeated for three-minutes (i.e., three times). The total time spent at each survey point was a minimum of six-minutes. Dedicated common night surveys were conducted at the same time as breeding bird surveys. In 2015 three call playback stations were surveyed within the Beaver Dam Mine Site and 12 call playback stations were surveyed within the Haul Road. Two additional call back stations were surveyed July 3 and 13, 2019 within the southeast expansion of the Beaver Dam Mine Site. A total of 17 call playback stations were surveyed within the Beaver Dam Mine Site and Haul Road.

Common nighthawks require open ground or clearings for nesting. The species breeds in a wide range of open habitats, including sandy areas (e.g., dunes, eskers, and beaches), open forests (e.g., mixed wood and coniferous stands, burns, and clear cuts), grasslands (e.g., short-grass prairies, pastures, and grassy plains), wetlands (e.g., bogs, marshes, lakeshores, and riverbanks), gravelly or rocky areas (e.g., outcrops, barrens, gravel roads, gravel rooftops, railway beds, mines, quarries, and bare mountain tops and ridges), and some cultivated or landscaped areas (e.g., parks, military bases, airports, blueberry fields, orchards, cultivated fields) (New Hampshire Fish and Wildlife Department, 2015; Campbell et al., 2006; and COSEWIC, 2007a).

Within both the Beaver Dam Mine Site and the Haul Road, habitats surveyed for common nighthawk breeding activity were located at widened roadsides with expansive gravel areas and clear-cuts. Common nighthawk survey points are presented on Figures 6.12-1A to 6.12-1E.

6.12.5 Baseline Conditions

Baseline assessments for avifauna were completed from September 2014 through June 2016 and July 2019 by MEL biologists. A total of 4,990 minutes (83 hours) of dedicated surveys were completed over six seasons. These surveys resulted in the observation of 4,900 individuals during the dedicated survey periods, representing 94 identified species observed within the Beaver Dam Mine Site and Haul Road. Including incidental observations 6,521 individuals and 103 species were observed within the Beaver Dam Mine Site and Haul Road. Within each survey, observations determined to be 'incidental' were not included in the analysis. These included individuals observed at a distance greater than 100 m, those which simply flew over the point count location, those observed outside of the 10-minute survey window, and those observed outside of a designated point count location.

During the fall 2014 surveys, individuals observed at any of the four crusher point count locations (CPC1 to CPC4) were determined to be incidental observations. Those point count locations are outside of the current Beaver Dam Mine Site and are not relevant to the current design of the Project. As such, the proportion of incidentals in the fall 2014 survey is relatively higher than in other seasons. Priority species observed at these locations are still included in the priority species summaries (Section 6.13.4.8). The total number of individuals and species observed in each season, the number carried forward to analysis in the upcoming sections (column titled 'Included in Analysis'), and a list of species that were only observed incidentally are identified in Table 6.12-5.

Table 6.12-5: Summary of Avifauna Observations for each Survey

Survey	Total # of Individuals	Total # of Species	Individuals Observed During Surveys	Incidental Individuals (Not Included in Analysis)	Species Observed Only Incidentally
Fall Migration 2014	950	45	534	418	American black duck, Canada goose, common loon, great horned owl, pine siskin, purple finch, red crossbill, rusty blackbird
Spring Migration 2015	874	57	550	324	Common raven, wood duck, common merganser, American crow
Spring Raptor Migration 2015	3	3	3	0	N/A
Winter Wildlife Survey (including avifauna) 2015	7	7	7	0	N/A
Breeding 2015	424	51	332	92	Canada goose, northern parula, olive-sided flycatcher
Common Nighthawk 2015	4	4	4	0	N/A
Spring Migration 2016	2269	71	1702	567	American crow, barn swallow, common goldeneye, common loon, red crossbill, mourning dove, northern waterthrush, pine siskin, ring-necked pheasant
Spring Nocturnal Owl 2015 and 2016	0	0	0	0	N/A

Breeding 2019	218	35	217	0	N/A
Common Nighthawk 2019	0	0	0	0	N/A

Across all survey seasons, a total of 34 possible priority species, including nine SAR, were observed either during dedicated survey periods or incidentally:

- Common nighthawk (*Chordeiles minor*);
- Chimney swift (*Chaetura pelagica*);
- Wilson's snipe (*Gallinago delicate*);
- Greater yellowlegs (*Tringa melanoleuca*);
- Northern harrier (*Circus cyaneus*);
- Northern goshawk (*Accipiter gentilis*);
- Black-backed woodpecker (*Picoides arcticus*);
- Peregrine falcon (*Falco peregrinus*);
- Eastern wood-pewee (*Contopus virens*);
- Olive-sided flycatcher (*Contopus cooperi*);
- Yellow-bellied flycatcher (*Empidonax flaviventris*);
- Canada jay (*Perisoreus canadensis*);
- Barn swallow (*Hirundo rustica*);
- Boreal chickadee (*Poecile hudsonicus*);
- Red-breasted nuthatch (*Sitta canadensis*);
- Ruby-crowned kinglet (*Regulus calendula*);
- Swainson's thrush (*Catharus ustulatus*);
- Gray catbird (*Dumetella carolinensis*);
- Red crossbill (*Loxia curvirostra*);
- Pine siskin (*Spinus pinus*);
- Tennessee warbler (*Oreothlypis peregrine*);
- Bay-breasted warbler (*Setophaga castanea*);
- Blackpoll warbler (*Setophaga striata*);
- American robin (*Turdus migratorius*);
- Brown-headed cowbird (*Molothrus ater*);
- Purples finch (*Hemorhous purpereus*);
- American coot (*Fulica Americana*);
- American kestrel (*Falco sparverius*);
- Evening grosbeak (*Coccothrautes vespertinus*);
- Spotted sandpiper (*Actitis macularius*);

- Pine grosbeak (*Pinicola enucleator*);
- Common goldeneye (*Bucephala clangula*);
- Canada warbler (*Cardellina canadensis*); and
- Rusty blackbird (*Euphagus carolinus*).

During data analysis, the Project Team uses breeding status qualifiers to identify which avian species are considered SOCI, based on the season in which they were observed. Breeding status qualifiers are defined by the Maritime Breeding Bird Atlas and assigned to each species by the ACCDC. SAR are considered priority species, regardless of the seasonality of their observation. For instance, a bird with an S-Rank of S2S3B, S5N (such as the pine grosbeak) would not be considered a priority species if observed overwintering (the N qualifier represents a non-migratory, or overwintering population). Conversely, a species ranked S5B, S3N (such as the American robin) would not be considered a priority species if observed during migration or breeding season and would only be considered a priority species if observed overwintering. Some species do not have a compound rank assigned with varying seasonal considerations, such as the turkey vulture (ranked S2S3B). This species has no alternate ranking status for migratory or overwintering populations, therefore this species, by default, would be considered a priority species regardless of its' observation date.

The above listed species and their breeding status qualifications are discussed in detail in the SOCI and SAR section (Section 6.13).

Avifauna species were identified based on functional groups to understand how each group of avifauna is using the Beaver Dam Mine Site and Haul Road and to help identify trends in the data. These functional groups include:

- **Waterfowl**: Ducks, geese, or other large aquatic birds, especially when regarded as game;
- **Shorebirds**: Waders, from the Order Charadriiformes;
- **Other waterbirds:** Includes seabirds (i.e., marine birds), grebes (Order Podicipediformes), loons (Order Gaviiformes), Ciconiiformes (i.e., storks, herons, egrets, ibises, spoonbills, etc.), pelicans (Order Pelicaniformes), flamingos (Order Phoenicopteriformes), Gruiformes (i.e., cranes and rails), kingfishers, gulls and dippers (the only family of passerines considered waterbirds);
- **Diurnal Raptors:** Avifauna within the families Accipitridae (i.e., hawks, eagles, buzzards, harriers, kites and old-world vultures), Pandidonidae (i.e., Osprey), Sagittariidae (i.e., Secretary bird), Falconidae (i.e., falcons, caracaras, and forest falcons), Cathartidae (i.e., new world vultures), and one species from the Order Strigiformes (i.e., Hawk Owl);
- **Nocturnal Raptors:** Avifauna of the Order Strigiformes (i.e., owls; with exception of the Hawk Owl, which is a diurnal species of owl);
- **Passerines:** Any avifauna of the Order Passeriformes, which includes more than half of all avifauna species. This is with exception of the dippers, which are a passerine considered a waterbird; and
- **Other Landbirds:** Avifauna within the Orders Galliformes (i.e., quail, pheasant, and grouse), Columbiformes (i.e., pigeons and doves), Cuculiformes (i.e., cuckoos), Caprimulgiformes (i.e., nighthawks and whip-poor-wills), Apodiformes (i.e., swifts and hummingbirds), and Piciformes (i.e., woodpeckers, flickers and sapsuckers).

All species observed during seasonal dedicated avifauna surveys (excluding incidental observations), including seasonal and total abundance is presented in Table 6.12-6. Species exclusively observed during species-specific avifauna surveys (raptor, nocturnal owl, common nighthawk) are discussed in the following respective sections. The relative abundance of avian species is also provided in Appendix L.2.

Table 6.12-6: Seasonal and Total Abundances of Avian Species Identified during the 2014, 2015, 2016 and 2019 Baseline Assessments for Dedicated Fall Migration, Spring Migration, and Breeding Surveys

Total	92 species[b]			532	550	332	1,702	1,539	217	4874[b]

[a] Priority species observed during dedicated surveys.

[b] Total counts only include observations during Spring Migration, Fall Migration and Breeding surveys. Total counts do not include unidentified or incidental species.

Notes: Species numbers in the table are only for those observed within the 100 m point count radius and within the dedicated point count periods. Avifauna observed during owl, common nighthawk, diurnal migrating raptor, and winter wildlife surveys are not included, but discussed below.

6.12.5.1 Winter Birds

Seven confirmed species and two unidentified species (i.e., a woodpecker and a sparrow) were observed incidentally during winter wildlife surveys along the Haul Road: black-capped chickadee (*Poecile atricapillus*), ruffed grouse (*Bonasa umbellus*), dark-eyed junco (*Junco hyemalis*), cedar waxwing (*Bombycilla cedrorum*), black duck *(Anas rubripes*), common grackle (*Quiscalus quiscula*), and goldencrowned kinglet (*Regulus satrapa*). Five species were observed within the Beaver Dam Mine Site during winter wildlife surveys: black-capped chickadee, cedar waxwing, northern saw-whet owl (*Aegolius acadicus*), downy woodpecker (*Picoides pubescens*), and American crow (*Corvus brachyrhynchos*). No priority overwintering bird species were observed.

6.12.5.2 Spring Diurnal Raptor Migration

Three raptors were observed during the dedicated spring migrating raptor survey that took place on April 15, 2015 within the Beaver Dam Mine Site. The first raptor was a migrating adult bald eagle (*Haliaeetus leucocephalus*), which was observed flying southeast at high altitude, though it could still be identified easily with the unaided eye. The other two raptors, which were determined to be local non-migrating birds due to their behaviours (actively hunting and in view for extended periods of time), were an adult male northern harrier (*Circus cyaneus*) and an adult female American kestrel (*Falco sparverius*). None of the species observed were priority species. The northern harrier is considered a priority species when observed during breeding season surveys (S-Rank is S3S4B). A targeted survey for spring diurnal raptor migration was not conducted within the Haul Road. Targeted surveys within the Beaver Dam Mine Site completed in 2015 suggest that the broader PA does not fall within a major migration route for spring migrating raptors, and thus targeted surveys for raptors were not necessary within the Haul Road in 2016.

6.12.5.3 Nocturnal Owl

No owls were observed during the dedicated nocturnal owl call playback surveys within the Beaver Dam Mine Site or along the Haul Road. However, owls were observed in the Beaver Dam Mine Site and Haul Road (Table 6.12-5) during other dedicated avian surveys, including the great horned owl (*Bubo virginianus*), northern saw-whet owl (*Aegolius acadicus*; observed outside avifauna surveys), and barred owl (*Strix varia*).

6.12.5.4 Fall Migration

The fall migration survey consisted of 32 point count stations and dedicated surveys were conducted weekly from September 17th to October 19th, 2014, for a total of four visits within the Beaver Dam Mine Site. During fall migration, 830 individuals representing 44 species were observed. Following the removal of incidental observations (Table 6.12-5; including all individuals identified in the CPC1 to CPC2 point counts) 412 individuals from 36 species, were carried forward for analysis. Relative species abundance can be found in Appendix L.2. An additional eight species were observed incidentally, listed in Table 6.12-5. In total, six priority species were observed during fall migration surveys. Priority species observed during spring migration monitoring is discussed in Section 6.13.

The most commonly observed species were black-capped chickadee (*Poecile atricapillus*; n=69), followed by golden-crowned kinglet (*Regulus satrapa*; n=68), and yellow-rumped warbler (*Setophaga coronata*; n=57). Most observations documented groups of up to two individuals, though there were a few groups ranging between three and six individuals. Two observations of obvious migrants were documented on September 30, 2014. On this date, one flock of 50 pine siskins and another flock of 25 were observed at PC24 and PC26, respectively. These observations are the only obvious migrants noted based on their abundance. These observations are recorded as incidentals and not included in the analysis provided herein because they were identified as flyovers.

The most abundant group observed on site during the fall migration period was passerines (songbirds), which accounted for 62.2% of species and 88.4% of individuals. Non-passerine landbirds were the next most abundant group on-site, followed by waterfowl.

Fall migration surveys were not conducted within the Haul Road because habitat types identified within this section of the PA were generally similar to those observed within the Beaver Dam Mine Site. Overall Project interactions with migrating avifauna are expected to be low along the Haul Road due to the linear nature of the Haul Road and its proposed upgrade to support mine development and trucking of ore from Beaver Dam Mine Site to Touquoy Mine Site for processing. There are no known significant migratory flyways, nor were there any observed during surveys along the Haul Road or the Beaver Dam Mine Site. Wetlands, often habitat considered important for avifauna, are also consistent in type and habitat characteristics along the Haul Road and within the Beaver Dam Mine Site.

6.12.5.5 Spring Migration

Due to poor weather conditions (delayed spring thaw and melt), significant snow cover, and access challenges, the 2015 spring migration survey had a reduced scope of 12 point count stations within the Beaver Dam Mine Site. Spring migration surveys were conducted weekly from April 21 to May 24, 2015, for a total of five visits. During spring migration, 873 individuals, representing 56 species were observed. Following the removal of incidental observations (Table 6.12-5) 549 individuals from 52 species were carried forward for analysis. Four priority species were observed during spring migration surveys within the Beaver Dam Mine Site. Priority species observed during spring migration monitoring is discussed in Section 6.13.

During spring migration surveys completed in 2015 within the Beaver Dam Mine Site, common grackle was the most commonly observed species (*Quiscalus quiscula*, n= 110), followed by magnolia warbler (*Setophaga magnolia*, n=46), Dark-eyed Junco (*Junco hyemalis*, n=38), and white-throated sparrow (*Zonotricha albicollis*, n= 29). The most abundant and diverse group of avifauna observed during spring surveys in the Beaver Dam Mine Site was passerines, which accounted for 88.8% of individuals, followed by non-passerine land birds (5.86%), and shorebirds (3.55%).

Within the Haul Road, 45 point count stations were surveyed during the spring bird migration period. Spring bird migration surveys were conducted from May 12 to 27, 2016, for a total of three visits. During spring migration, 2,269 individuals representing 71 species were observed Following the removal of incidental observations (Table 6.12-5) 1,702 individuals from 62 species, were carried forward for analysis. Nine priority species were observed during spring migration surveys completed within the Haul Road. Priority species observed during spring migration monitoring is discussed in Section 6.13.

The species most commonly observed was magnolia warbler (Setophaga magnolia; n=167), followed by black-throated green warbler (Setophaga virens; n= 153), and yellow-rumped warbler (Setophaga coronata; n=140). No obvious concentration of ducks or shorebirds was observed. The most abundant and diverse group of birds observed in spring migration surveys within the Haul Road is passerines, which accounted for 95.9% of individuals, followed by non-passerine land birds (3.34%).

The majority of observations were of single individuals and the largest groups of birds observed were two flocks of common grackle in 2015. One flock contained 50 individuals and was observed on June 4th and the second flock contained 30 individuals and was observed on May 1, both in 2015 within the Beaver Dam Mine Site. No obvious migrants were documented within the Haul Road. The abundances of species observed during spring migration surveys completed in 2015 and 2016 within the Beaver Dam Mine Site and the Haul Road are presented in Appendix L.2.

6.12.5.6 Breeding Birds

The 2015 breeding survey consisted of 24 point count stations, which were surveyed twice in the month of June 2015 within the Beaver Dam Mine Site. A total of 442 species representing 50 species were recorded during breeding season in the Beaver Dam Mine Site. Following the removal of incidental observations (Table 6.12-5) 330 individuals from 47 species were carried forward for analysis. Thirty-four possible priority species were observed during the breeding season surveys completed within the Beaver Dam Mine Site, which are discussed in detail in Section 6.13.4.3.

The most abundant species observed was the magnolia warbler (Setophaga magnolia, n=34), followed by the common yellowthroat (*Geothylpis trichas*, n=31), the black-and-white warbler (*Mniotilta varia*, n = 22), and the palm warbler (*Setophaga palmarum*, n=22). Passerines represented the most abundant and diverse group of avifauna observed, accounting for 95.2% of all individuals, followed by non-passerine landbirds (3.0%).

In June 2016, 50 point count stations were surveyed within the Haul Road. A total of 1,772 individuals representing 68 species were observed during the breeding season within the Haul Road. Following the removal of incidental observations (Table 6.12-5) 1,539 individuals representing 64 species were carried forward for analysis. Fourteen priority species were observed during breeding season surveys within the Haul Road, which are discussed in detail in Section 6.13.4.8.

The most commonly observed species in the breeding season of 2016 was the common yellowthroat (*Geothylpis trichas*, n=141), followed by the white-throated sparrow (*Zonotricha albicollis*, n=133), and the dark-eyed junco (*Junco hyemalis*, n=104). Similar to results obtained in the breeding season in 2015, passerines represented the greatest abundance and diversity of all avifauna groups in the breeding season of 2016. Passerines accounted for 96.5% of individuals, followed by non-passerine landbirds, which accounted for 1.9% of individuals.

Ten additional point count stations were surveyed in July 2019 within the Beaver Dam Mine Site. A total of 217 individuals representing 35 species were observed and carried forward for analysis. Six priority species were observed during the 2019 breeding surveys, which are discussed in detail in Section 6.13.4.8.

The most abundant species observed was the Hermit thrush (*Catharus guttatus*, n=31), followed by the White-throated Sparrow (*Zonotrichia alicollis*, n=18), the Black-throated Green Warbler *(Setophaga virens*, n=18), and the Magnolia Warbler (*Setophaga magnolia*, n=14). Passerines represented the most abundant and diverse group of avifauna observed, accounting for 96%, followed by non-passerine landbirds (2%). This trend is similar to what was observed during both 2015 and 2016 breeding season surveys.

Breeding evidence was recorded for all species observed during 2015, 2016 and 2019 breeding season surveys, in accordance with guidance provided by the Maritime Breeding Bird Atlas (see breeding codes, Appendix L.1). Since the surveyed area is a relatively small part of the surrounding area, it is not possible to confirm that all species listed were actually nesting within the boundaries of the PA. For instance, if a bird was observed carrying food (i.e., example of confirmed breeding evidence, based on MBBA, Bird Studies Canada, n.d.), it is possible that the bird was nesting on an adjacent parcel of land. A summary table is presented below (Table 6.12-7), which identifies the highest breeding evidence recorded for each species in surveys completed in 2015 and 2019 in the Beaver Dam Mine Site and 2016 in the Haul Road. Breeding evidence codes were determined for all species observed during each annual survey, including those observed incidentally during avifauna surveys.

Table 6.12-7: Breeding Summary within the Beaver Dam Mine Site and Haul Road

Code	Common Name	2015 Breeding Evidence	2016 Breeding Evidence	2019 Breeding Evidence
ABDU	American black duck	-	Confirmed	-

YEWA	Yellow warbler	Probable	Possible	Possible
YRWA	Yellow-rumped warbler	Probable	Probable	-

Note: - = indicates no observation. * = Priority species, see Section 6.13.

All of the species identified are native species expected to be found in this area of Nova Scotia and the province in general, and within the typical and common habitat associated with the Project and surrounding landscape. The majority of observations were of a single individual. The largest flock observed was common grackle (n=10). The most abundant group observed on site during the breeding bird period was passerines (songbirds), non-passerine landbirds were the next most abundant group on-site, followed by waterfowl, shorebirds, and raptors, which were all observed in small numbers. No incidental observations of raptor nests were made on either the Beaver Dam Mine Site or Haul Road.

Results of spring and fall migration and breeding bird surveys are provided in Appendix L.2. Priority species avifauna observations are shown in Section 6.13, Figures 6.13-1A to 6.13-1G.

6.12.5.6.1 Touquoy Mine Site

The 2005 breeding bird surveys of the Touquoy Mine Site found 398 birds representing 52 species over 11 point count stations. The most abundant species were the magnolia warbler (Setophaga magnolia, 7.5% of the total) and the common grackle (*Quiscalus quiscula*, 7.3%) (CRA 2007). Ten of the 52 species observed are priority species. They are as follows; pine grosbeak (*Pinicola enucleator*), willow flycatcher (*Empidonax traillii*), yellow-bellied flycatcher, barn swallow, boreal chickadee, ruby-crowned kinglet, rusty blackbird, bay-breasted warbler, Swainson's thrush, and pine siskin.

6.12.5.7 Common Nighthawk

Four common nighthawks were observed within the Haul Road. One observation was recorded during a breeding bird survey at Haul Road PC26, while three were observed during dedicated call playback surveys along the Haul Road in 2016. None were observed within the Beaver Dam Mine Site. No additional observations of common nighthawk occurred in 2019 during dedicated common nighthawk surveys or incidental observations.

Common nighthawks were observed calling, but no evidence of breeding behavior was documented (i.e., booming, or displaying females). Common nighthawks were observed within the Haul Road, in habitats with expansive gravelly areas adjacent to clear cuts, or disturbed areas (Haul Road PC26, CONI1, CONI9). Suitable habitat is present within the Beaver Dam Mine Site and Haul Road for this species, so their presence during the breeding season indicates that breeding is likely to be occurring within these areas.

6.12.5.8 Discussion

Of the 92 avian species observed during dedicated fall migration, spring migration and breeding surveys (excluding incidentals) within the Beaver Dam Mine Site and Haul Road, 77 (75% of species) are protected under the *Migratory Bird Convention Act* (1994). Avifauna observed that are not protected under the Migratory Bird Convention Act (1994) were from the Accipitridae (e.g. harriers and hawks), Alcedinidae (e.g., kingfisher), Corvidae (e.g., jays, crows and ravens), Phasianidae (e.g., grouse and pheasants), and Strigidae (e.g., owls) families. Two species, bald eagle and northern saw-whet owl, were only observed during dedicated raptor and winter surveys, respectively.

Avian diversity was relatively higher along the Haul Road than within the Beaver Dam Mine Site. This is likely attributable to the fact that the Beaver Dam Mine Site is more extensively disturbed and fragmented as a result of historic mine operations and current and historic timber harvesting practices. Overall, avian diversity and abundance was moderate and fell within expectations for the habitats available and for forests in Halifax County in general.

Passerines were the dominant species group across all seasons within the Beaver Dam Mine Site and Haul Road accounting for 67% of total observations, which is expected based on the variety of suitable habitats present. The order Passeriformes includes more than half of all avifauna species, so their relative abundance within the Beaver Dam Mine Site and Haul Road falls within expectation. Furthermore, the Passerine family contains the highest diversity of species. Preferred stand age and density can vary be species and life stage. Generally passerine species inhabit forested areas with access to wetlands and water features. The landscape across the Beaver Dam Mine Site and Haul Road is dominated by forest cover (both deciduous and coniferous of different maturity levels) with harvested areas at different stages of regeneration and wetlands interspersed throughout. Passerine species such as American crow, common raven and blue jay can tolerate and use anthropogenically disturbed environments, which are present within Beaver Dam Mine Site and Haul Road (i.e., historical mining, timber harvesting, road and trail networks).

Non-passerine landbirds were the second most abundant species group observed within the Beaver Dam Mine Site and Haul Road, accounting for 12% of total observations, and consisted primarily of grouse and woodpecker species. Habitats for these species are present throughout the Beaver Dam Mine Site and Haul Road. Woodpecker habitat preferences differ depending on the species; therefore, the variety of species observed (n=6) is an indicator of habitat types and diversity within the Beaver Dam Mine Site and Haul Road. For example, northern flickers (*Colaptes auratus*) are ground feeders and favour woodland edges near open areas, downy woodpeckers (*Picoides pubescens*) favour riparian woodlands, and pileated woodpeckers (*Dryocopus pileatus*) prefer mature hardwood and coniferous forests. Two species of grouse, the ruffed (Bonasa umbellus) and spruce grouse (*Falcipennis canadensis*), were observed. The ruffed grouse is considered to be dependent on subclimax deciduous forests, whereas the spruce grouse is considered dependent on climax coniferous forests (Pietz and Tester, 1982).

Waterfowl and shorebirds were observed in lesser abundance, 8% and 4% of total observations, respectively. No large congregations of waterfowl or shorebirds were observed roosting or staging within the Beaver Dam Mine Site and Haul Road during either the spring or fall migration periods. Wetland habitats suitable for migrating shorebirds and waterfowl were limited within the Beaver Dam Mine Site and Haul Road (open water wetlands with shallow areas for foraging). The only shorebird that was likely breeding within the Beaver Dam Mine Site and Haul Road was the greater yellowlegs; this species breeds in muskeg, wet bogs with small wooded islands, and forests with abundant clearings (Elphick and Tibbits, 1998). The only waterfowl species observed during the breeding season within the Beaver Dam Mine Site and Haul Road was the American black duck (*Anas rubripes*) and its habitat preferences during the breeding season are influenced by wetland fertility, cover, and invertebrate densities (Merendino and Ankney, 1994). In Nova Scotia, American black ducks commonly nest along streams and contiguous freshwater marshes (Seymour, 1984), as well as coastal salt marsh (Reed and Moisan, 1971).

Raptors, both diurnal and nocturnal, were observed in low numbers within the Beaver Dam Mine Site and Haul Road throughout the year, totaling 9% of total observations. Throughout the migration period, this suggests that there are no major migration corridors over the PA. As for the breeding season, suitable breeding habitat is present for several forest raptors, including northern goshawk, Cooper's hawk, sharp-shinned hawk, red-tailed hawk, merlin, American kestrel, great horned owl, barred owl, and northern saw-whet owl. Raptor species generally prefer open habitat (i.e., meadows, cut blocks, wetlands, open water) with adjacent mature forest. Many of these forest raptor species are difficult to census; therefore, it is not surprising that documented species richness and abundance were low within the Beaver Dam Mine Site and Haul Road.

6.12.6 Consideration Engagement Results

Key issues raised during public and Mi'kmaq engagement relating to birds include potential for direct mortality associated with the hauling operation and indirect effects on other VCs, such as dust, noise and light, as well as potential effects on birds associated with permanent loss of habitat from construction of the Beaver Dam Mine and the Haul Road. Potential effects on traditional uses of land and resources by the Mi'kmaq were noted, including fowling.

The results of the public and Mi'kmaq engagement have been considered in the environmental effects assessment, including AMNS's commitments on mitigation and monitoring measures and proposed compliance and effects monitoring programs, as well as AMNS's broader commitment to ongoing public and Mi'kmaq engagement. Specific to evaluating the effect on birds, these are found within the following environmental effects assessment.

6.12.7 Effects Assessment Methodology

6.12.7.1 Boundaries

6.12.7.1.1 Spatial Boundaries

The spatial boundaries used for the assessment of Project effects to terrestrial fauna is described below.

- The PA (Section 5.5, Figure 5.5-1) consists of the three project components; Beaver Dam Mine Site, Haul Road and Touquoy Mine Site and extends from Marinette to Moose River Gold Mines, Halifax County, NS. The Beaver Dam Mine Site is located at the eastern end of the Beaver Dam Mines Road. The Haul Road spans from the Beaver Dam Mine Site to Moose River Gold Mines, where the Touquoy Mine Site [processing and exhausted pit (to be used to dispose Beaver Dam tailings)] is located. The PA has changed as a result of the expansion of the Beaver Dam Mine Site to accommodate micro-sitting of mine infrastructure and ongoing modifications to the Haul Road design, as described in Section 2 (Project Description). These changes have been captured under the existing and additional desktop and field evaluations.
- The LAA (Figure 6.12-2) consists of a 5 km buffer surrounding the Beaver Dam Mine Site and a 500 m buffer surrounding the Haul Road and Touquoy Mine Site components of the PA. The LAA boundaries were defined considering the maximum expected extent of direct and indirect impacts to avifauna. The LAA has been modified to reflect the changes in the PA
- The RAA (Figure 6.12-2) encompasses NSL&F's Ecological Land Classification Ecodistrict 440 (Eastern Interior) within Halifax Regional Municipality, east and north of Lake Charlotte. Where the Ecodistrict boundary approached the northern extent of the Beaver Dam Mine Site, the RAA was enlarged to include a minimum 5 km buffer around the PA. This Ecodistrict spans an area broader than the expected Project impacts and considers other project boundaries as per cumulative effects methodology.

Assessment of avifauna will be completed in consideration of the LAA as the primary spatial boundary. All spatial boundaries will help to identify the direct or indirect impacts to terrestrial fauna and the effects of the Project on distribution and abundance of these species.

6.12.7.1.2 Temporal Boundaries

The temporal boundaries used for the assessment of effects to birds are the construction phase, operational phase, and decommissioning and reclamation phases.

6.12.7.1.3 Technical Boundaries

No technical boundaries were identified for the effects assessment of avifauna.

6.12.7.1.4 Administrative Boundaries

Administrative boundaries for evaluation and management of birds include the *Nova Scotia Wildlife Act*, which protects all birds within the province and the *Migratory Birds Convention Act* (MBCA) which offers protection for migratory birds. Further protection is offered to SAR through the provincial *Nova Scotia Endangered Species Act* and the federal SARA.

A significant adverse effect from the Project on birds is defined as an effect that is likely to cause a permanent alteration to any bird species distribution or abundance. An adverse effect that does not cause a permanent alteration in distribution or abundance of any bird species is considered to be not significant.

6.12.7.2 Thresholds for Determination of Significance

A significant adverse effect from the Project on avifauna is defined as an effect that is likely to cause a permanent, unmitigated, alteration to habitat that supports avian species. An adverse effect that does not cause a permanent alteration in distribution of any avifauna species is considered to be not significant. Significance criteria related to impacts to SOCI and SAR are presented in Section 6.13.

The following logic was applied to assess the magnitude of a predicted change in avifauna, based on the habitat analysis results described in Section 6.10.4.5:

- **Negligible** – the Project is predicted to result in less than 1% direct loss of habitat types used by observed species within the LAA.
- **Low** – the Project is predicted to result in 1 to 5% direct loss of habitat types used by observed species within the LAA, and the loss of habitat is mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.
- **Moderate** – the Project is predicted to result in 5 to 25% direct loss of habitat types used by observed species within the LAA and the loss of habitat is mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.
- **High** – the Project is predicted to result in greater than 25% direct loss of habitat types used by observed species within the LAA and the loss of habitat is not mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.

The Habitat and Flora LAA was used to determine habitat type and area, and resultant habitat loss for species (Section 6.10.7.1).

The timing of residual effects for avifauna considers when the residual environmental effect is expected to occur, considering seasonal aspects and sensitive time periods for avifauna. The duration of residual effects considers the time frame over which the effects are likely to last, ranging from short-term to permanent. For the purpose of the effects assessment related to avifauna, long term reflects the commencement of reclamation activities. The frequency of residual effects considers the rate of recurrence of the effects, ranging from once to continuous. The reversibility of residual effects considers the time required for habitat to recover to baseline conditions, or whether the changes to habitat, if identified, are permanent.

6.12.8 Project Activities/Interactions with Avifauna

The assessment of potential adverse interactions and effects of the Project on this VC takes into account the potential for the Project to result in changes to:

- permanent and temporary habitat alteration and fragmentation;
- disturbance and/or displacement;
- potential for direct and indirect mortality to individuals; and
- sensory disturbance.

The potential interactions of the Project with avifauna and avifauna habitat is presented in Tables 6.12-8 to 6.12-10.

Table 6.12-8: Potential Project Activities/Interactions with Avifauna at Beaver Dam Mine Site

Project Phase	Duration	Project Interactions
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of construction (e.g., pre-stripping) • Till and waste rock from site preparation transport and storage • Watercourse and wetland alteration in preparation of construction, including open pit dewatering • Surface infrastructure installation and construction • Collection ditches and settling pond construction • Local traffic bypass road construction • Mine Site road construction and lighting • Culvert and bridge upgrades and construction • General noise and lighting from construction activities • Wildlife vehicle interactions/collisions
Operations and Maintenance	5 years	• Drilling and rock blasting to access and extract ore • Management of waste rock produced from crushing and preparing ore for transport • Till and waste rock from site preparation transport and storage • Open pit dewatering • Site maintenance • Treatment of site surface water runoff and surface mine pumped water • General management of wastes derived from operation and maintenance activities • Petroleum products management • Dust management • Culvert and bridge maintenance • General noise and lighting from construction activities • Wildlife vehicle interactions/collisions
Active Closure	2 years	• Site reclamation activities • Water treatment and management • Noise and lighting from decommissioning activities • Wildlife vehicle interactions/collisions
Post-closure	+10 years (monitoring)	• Water treatment and management

Table 6.12-9: Potential Project Activities/Interactions with Avifauna along Haul Road

Project Phase	Duration	Project Interactions
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of construction • Till and waste rock from site preparation transport and storage • Watercourse and wetland alteration in preparation of construction • Haul Road construction and upgrades • Auxiliary infrastructure installation and construction • Local traffic bypass road construction • Culvert and bridge upgrades and construction • General noise and light from construction activities • Wildlife vehicle collisions
Operations and Maintenance	5 years	• Ore extraction and transport form Beaver Dam Mine Site to Touquoy Mine Site • Haul Road maintenance and repairs, including snow removal and deposition of sand for traction control • Dust management • Noise and light from Haul Road activity • Wildlife vehicle interactions/collisions
Active Closure	2 years	• N/A[(a)]
Post-closure	+10 years (monitoring)	• N/A

[(a)] Decommissioning and Reclamation of the Haul Road is not expected. The Haul Road will be returned to owner for forestry Industry.

Table 6.12-10: Impacts of the Project on Avifauna

Impact Type	Direct Impact	Project Phase	Indirect Impact	Project Phase
Vegetative and Habitat Integrity	Loss of vegetative cover through clearing and grubbing decreases bird habitat availability and Project development also has the potential to reduce natural surface water drainage.	C	Habitat fragmentation may alter habitat suitability for those species which rely on interior forest conditions. Within the Haul Road, this change in habitat is expected to be permanent.	C, O, CL
Sensory Disturbance	Extensive ground works, including activities such as blasting will increase noise levels. Increase in vehicular traffic will add to sensory disturbance through increased noise. This has the potential to reduce habitat for fauna.	C, O, CL	Sensory disturbance (both lights and sounds) may result in further avoidance of the PA by some species.	C, O
	Birds may become attracted to or disoriented by open pit lighting at night, particularly during periods of migration, which could lead to mortality (Jones and Francis, 2003).	C, O	Artificial lighting at night has been shown to influence the seasonal start of bird vocalizations, which could affect individual fitness (Da Silva et al., 2014).	C, O
Direct Mortality	Increased traffic and general activity within the PA may result in direct mortality to wild species through vehicular collisions and construction.	C, O, CL	Improved access throughout the Beaver Dam Mne Site and as a result of Haul Road construction/upgrades may increase hunting activity of licensed hunters and/or illegal poachers.	C, O, CL

Notes: C = Construction; O = Operations; CL = Active Closure; m = metre; PA = Project Area.

6.12.8.1 Habitat Use and Direct Loss

Development of the mine infrastructure and upgrades to the Haul Road will cause direct impacts to habitat used by avifauna, including upland forested habitat and wetlands. This will occur mostly within the construction phase of the Project. Habitat within the PA and surrounding landscape currently exhibits fragmented conditions based on historic mine operations, existing road and trail networks, and current and historic timber harvesting activity within and adjacent to the PA. However, project activities are still likely to result in direct habitat loss, increased habitat fragmentation and a decrease in habitat quality (e.g., sensory disturbance) for those species which rely especially on interior forest conditions (Sections 6.11.7.2.3 and 6.11.7.4), where intact interior forest remains. The level of disturbance within the Beaver Dam Mine Site disproportionately affects uplands over wetlands. There exists large, natural, wetland habitats within the Beaver Dam Mine Site (e.g., Wetlands 2 and 29) that are not anticipated to be impacted by the Project. Section 6.10.7.1 presents the habitat types and areas, including anthropologic disturbances, that will be impacted by the Project.

Habitat descriptions for each observed avifauna functional group are described in Section 6.12.5.8. Habitat loss by functional groups based on the group's preferred habitat type(s) and PA habitat analysis described in Section 6.10.4.5 is presented in Table 6.12-11. Due to the diversity of species within the Passerine functional group, this group was further divided by habitat preference for this assessment. Specific habitat requirements (i.e., wetland type) were not distinguished and, conservatively, the broader habitat types from Section 6.10.3.5 were used to assess habitat loss by observed species. Based on the definitions of magnitude of impact, it is anticipated that all impacts to habitat types used by observed avifauna will be low, with the exception to anthropogenic disturbances (Table 6.10-6). Specific habitat requirements, loss and impacts to observed SOCI and SAR are further discussed in Section 6.8.7.2 and Section 6.13.

Table 6.12-11: Habitat Use and Loss within the Project Area and Magnitude of Impact

Functional Groups	Habitat Type Used	Area within the LAA (Ha)	Area within Project Area (BD Mine Site and HR) (Ha)	% of habitat type within the LAA directly impacted by the Project	Magnitude of Impacts to Habitat within LAA
Waterfowl	Lakes, Ponds, Beaver flowage Wetlands (includes all wetland classes)	1,052.9	12.8	1.2	Low
Shorebirds	Lakes, Ponds, Beaver flowage Wetlands (includes all wetland classes)	1,052.9	12.8	1.2	Low
Other Waterbirds	Lakes, Ponds, Beaver flowage Wetlands (includes all wetland classes)	1,052.9	12.8	1.2	Low
Diurnal Raptors	Hardwood Dominant Stands Softwood Dominant Stands Managed Forests[b] Lakes, Ponds, Beaver flowage Barrens (includes rock barrens)	4,631.0	148.5	3.2	Low
	Anthropogenic Disturbances[c]	20.3	13.4	66.0	N/A[d]

Table 6.12-11: Habitat Use and Loss within the Project Area and Magnitude of Impact (continued)

Functional Groups	Habitat Type Used	Area within the LAA (Ha)	Area within Project Area (BD Mine Site and HR) (Ha)	% of habitat type within the LAA directly impacted by the Project	Magnitude of Impacts to Habitat within LAA
Nocturnal Raptors	Hardwood Dominant Stands Softwood Dominant Stands Managed Forests[b] Lakes, Ponds, Beaver flowage Wetlands (includes all wetland classes)	5,440.1	156.7	2.9	Low
Passerines					
Stands of different maturity levels (including mature forests), wetlands (e.g., warblers, flycatchers)	Hardwood Dominant Stands Softwood Dominant Stands Other[a] Managed Forests[b] Wetlands (includes all wetland classes)	5,683.0	217.7	3.9	Low
Open canopy and regenerating stands, wetlands (e.g., sparrows, blackbirds)	Other[a] Managed Forests[b] Wetlands (includes all wetland classes)	1964.4	91.6	4.7	Low
Stands of different maturity levels, disturbed areas (e.g., American crow, common raven)	Hardwood Dominant Stands Softwood Dominant Stands Other[a] Managed Forests[b]	4,857.6	217.1	4.5	Low
	Anthropogenic Disturbances[c]	20.3	13.4	66.0	N/A[d]
Other Landbirds	Hardwood Dominant Stands Softwood Dominant Stands Other[a] Managed Forests[b] Barrens (includes rock barrens	4,873.9	217.1	4.5	Low
	Anthropogenic Disturbances[c]	20.3	13.4	66.0	N/A[d]

[a] Includes unmerchantable timber, often which is regenerative stands and stands which were not categorized as hardwood or softwood stands.

[b] Managed forests include plantations, cutblocks, selective cuts etc.

[c] Includes roads, railways, urban development, quarries, gravel pits, mining activity etc.

[d] Not carried forwarded into impact magnitude determination (Section 6.12.7.2).

Note: The Habitat and Flora LAA was used to determine habitat type and area, and resultant habitat loss for species (Section 6.10.7.1).

6.12.8.2 Habitat Fragmentation

Connectivity can be defined as the basic ecological requirement to be able to move freely within areas that provide critical functions for a species, and habitat fragmentation is the disturbance of this movement. Connectivity is critical for maintaining biodiversity and healthy species populations and interior forests are often an important feature that supports this movement (NSDNR, 2015). Interior forests are defined as an area within a forest that is sheltered from edge effects; interior and mature forest mapping is discussed in Section 6.10.3.6. As described in Section 6.10.3.6 there is a mapped Old Forest patch along the Haul Road and interior forest throughout the Beaver Dam Mine Site and Haul Road (Section 6.10, Figure 6.10-5).

The LAA is covered with a network of roads, historical mining and forestry activities, and forestry trails creating a largely disturbed forest landscape. The extent of the simulated existing disturbance and edge effect largely covering the majority of the LAA is presented in Figure 6.10-6. As presented in Section 6.10.4, the Project will affect 237 hectares (ha) of interior forest habitat, which accounts for 9% of the predicted interior forest area within the respective LAA. While Project activities are expected to result in increased habitat fragmentation and a decrease in habitat quality (e.g., sensory disturbance), the level of new fragmentation associated with the Beaver Dam Mine Site is anticipated to be low, given the current level of disturbance as discussed. The Beaver Dam Mine Site infrastructure footprint is situated primarily on an area of high existing disturbance and will only have fringe effects on the majority of available interior forest. There will be minimal isolation of habitat that is currently contiguous, limited to the patch of potential interior forest west of the NAG waste rock stockpile (Figure 6.10-6).

Construction of the Haul Road will involve a combination of new road construction (4.0 km) and upgrades to the existing logging road. The majority of the proposed Haul Road (99%) follows an existing road corridor, thereby limiting new habitat fragmentation. The existing Haul Road is used by lumber trucks, but the level of traffic varies seasonally and annually depending on which areas are undergoing timber harvesting. The 4 km section of new road immediately southwest of Highway 224 will add new habitat fragmentation to an area that has very little, if any, evidence of anthropogenic disturbance. Along this section of the Haul Road, 112 ha of potential interior forest will be impacted (Section 6.10.4, Figure 6.10-6), which will increase habitat fragmentation and decrease the habitat quality for those species that rely on interior forest.

Common migratory avifauna species that require old forest or interior forest habitats include; ovenbird, wood thrush, hermit thrush, magnolia warbler, black-throated blue warbler, black-throated green warbler, and white-throated sparrow. Additionally, avifauna species identified within the priority species list (Appendix K.1) that prefer mature or interior forest are outlined in Table 6.12-12.

Field observations have confirmed that some of the species listed in Table 6.12-12 (red-breasted nuthatch, black-backed woodpecker, ruby-crowned kinglet, boreal chickadee, yellow-bellied flycatcher, and Swainson's thrush) were observed at survey locations (Figures 6.12-1A to 6.12-1G) in close proximity to the Old Forest polygon. None of these species were reported exclusively within this Old Forest habitat.

6.12.8.3 Direct Mortality

Direct mortality of avifauna species could result from Project activities, particularly due to the increase in traffic during construction and operation of the facility (Section 6.1.4). Increased traffic poses a risk to avifauna along the length of the Haul Road between the Beaver Dam Mine Site and the Touquoy Mine Site. The Project expects a maximum of 190 round trips along the length of the Haul Road over 16 hours a day during the first two years of operation, decreasing in subsequent years. The increased level of traffic poses an increased risk to wildlife collisions, particularly along the Haul Road, where the speed limit is proposed to be 70 km/hr. The risk of collisions within the Beaver Dam Mine Site will be lower, as the speed limit will be reduced to 40 km/hr.

Indirect impacts or mortality could also result from exposure to contaminants or spills from incidents and accidents. Migratory avifauna may be indirectly impacted as a result of the surface water quality in the pit lake created in the Touquoy Mine Site open pit to store tailings from Beaver Dam Mine Site. if they were to land in the water. Mitigation measures, such as avifauna deterrents are currently in place at Touquoy Mine Site and they will be applied to reduce the potential environmental impacts of the Project on migratory avifauna at the Touquoy facility as per existing approvals.

Table 6.12-12: Bird Species within the Priority Species List that Rely on Mature and Interior Forest

Common Name	SARA	COSEWIC	NSESA	SRank	Habitat Requirements
Black-backed woodpecker				S3S4	Coniferous forest
Boreal chickadee				S3	Coniferous forest
Cape may warbler				S2B	Northern coniferous forest, mature spruce
Canada warbler	T	T	E	S3B	Dense understory vegetation of mature to mid-aged mixed forest
Eastern wood-pewee	SC	SC	V	S3S4B	Interior forests
Evening grosbeak				S3S4B, S3N	Breed in mature and second-growth coniferous forests
Canada jay				S3	Coniferous forest
Northern goshawk		NAR		S3S4	Nest in mature mixed hardwood forests
Pine grosbeak				S2S3B, SN5	Open coniferous forests.
Pine siskin				S2S3	Open coniferous forests, mixed forest and deciduous forests
Red-breasted nuthatch				S3	Deciduous and coniferous forests
Red crossbill				S3S4	Mature coniferous forests
Ruby-crowned kinglet				S3S4B	Coniferous and deciduous forests
Rusty blackbird	SC	SC	E	S2B	Wet coniferous and mixed wood forests
Swainson's thrush				S3S4B	Closed canopy forests, breeding habitat includes deciduous and coniferous forests
Yellow-bellied flycatcher				S3S4B	Conifer forests and peatlands. It nests in typically cool, moist conifer or mixed forests, bogs, swamps, and muskegs

6.12.8.4 Sensory Disturbance

The effect of the Project on avifauna can largely be attributed to sensory disturbance, specialty noise and light. Sensory disturbance would result from rock blasting, clearing and grubbing, infrastructure construction, lighting and operations, internal mine traffic and traffic along the Haul Road during operations. Blasting will occur within the Beaver Dam Mine Site during the operational phase. This along with other construction and operational activities will increase sensory disturbance above current conditions and will, as described above, reduce the habitat quality for some species.

Sensory disturbance will likely result in the localized wildlife avoidance of the PA, particularly in close proximity to the Beaver Dam Mine Site infrastructure footprint and Haul Road. Overall, Project activities will likely cause a change in usage of the PA by avifauna, with some species tending to avoid the area, while others may be attracted to the increased activity, including opportunistic species such as coyotes, raccoons, skunks, or black bears. Sensory disturbance related to Project activity will occur within the Beaver Dam Mine Site, Haul Road, and within the Touquoy Mine Site, as the addition of material from the Beaver Dam mine will extend the life of the Touquoy Mine Site by five years.

6.12.8.4.1 Noise

Changes to ambient noise levels and the presence of periodic vibrations from blasting have the potential to adversely affect fauna and avifauna by influencing migration and behavioral patterns. Noise and vibration are provincially regulated via the Workplace Health and Safety Regulations and the Pit and Quarry Guidelines, which protect the health of site workers and the general public at PA boundaries, respectively.

Existing noise (measured in 2014) around the Beaver Dam Mine Site had an average value of 33 decibels (dBA) ±. As such, in the noise model, baseline noise levels were assumed to be 33 dBA during the day and 27 dBA at night (Section 6.1.7, Table 6.1-8). The predicted noise levels at the property boundary of the Beaver Dam Mine Site are presented in the Noise Impact Assessment and expected to meet compliance at the Property Boundary (Appendix B.2). It should be noted that the findings within the Noise Impact Assessment are worst case (most conservative) predictions.

The Environment Code of Practice for Metal Mines (Environment Canada, 2012b) has established parameters for ambient noise levels for wildlife. These parameters indicate that ambient noise observed above 55 dBA during the day and 45 dBA at night can affect wildlife. The predicted noise levels presented in the Noise Impact Assessment (Appendix B.1 [Beaver Dam Mine Construction Noise Assessment] and Appendix B.2 [Updated Noise Impact Assessment Technical Report]) exceed the levels outlined by Environment Canada (2012b). Additionally, a literature review conducted by Shannon et al. (2016) found that avifauna have the potential to exhibit changes in song characteristics, reproduction, abundance, stress levels, and species richness at levels greater than 45 dBA, on average. Specially, studies showed biological responses commenced at 40 to 45 dBA, with a decline in species diversity (i.e., avoidance by sensitive species) and reproductive success at 43 to 58 dBA. Changes in song frequency and length were observed at 45 dBA. Francis et al (2009) notes noise pollution can lead to changes in avian communities and altered species interactions. However, a study of the impact of logging truck traffic on avifauna reports no observed effects on nesting at noise levels of 53 dbA (Grubb et al. 1998). It was also found that noise tolerant species had increased nest success through decreasing nest predation (Francis et al, 2009).

Impacts can also differ between acute and chronic noise sources. Chronic exposure may degrade auditory cues, feedback and vocal development over time, important for predator/prey detection, communication and orientation (Shannon et al, 2016; Bickley and Patricelli, 2010; Marler et al, 1973). A direct physiological impact causing a temporary decrease in auditory sensitivity can

occur at acute noise levels above 93 dBA, while permanent damage to avian auditory systems is not recorded until 125 to 140 dBA (Bickley and Patricelli, 2010). Routine Project operations are not predicated to reach these noise levels.

Elevated noise above background concentrations around the PA may cause avoidance within 400 m (S, W, E) to 1,000 m (N) of the Beaver Dam Mine Site, less than 500 m on either side of the Haul Road and within 850 m the Touquoy Mine Site property boundaries, based on the most conservative guideline (45 dBA) identified for potential broad wildlife effects (Environment Canada, 2012b). These ranges of noise distribution are due to changes in local topography. Avifauna within these approximate ranges of noise distribution surrounding the PA have the potential to be affected by noise during the day and overnight. However, it should be noted that noise effects are rarely isolated from other disturbances and impacts likely coincide with habitat suitability changes that accompany increased noise levels (Shannon et al, 2016).

6.12.8.4.2 Light

Light can impact avifauna by potentially causing disorientation or by causing attraction or avoidance (Langcore and Rich, 2004). Avifauna may be attracted to or disoriented by open pit lighting at night, particularly during migration periods, leading to mortality (Jones and Francis 2003). In turn, these behavioral changes can affect the success of foraging, reproduction, and communication of wildlife (Langcore and Rich, 2004) and can disrupt habitat connectivity (Bliss-Ketchum et al. 2016). Artificial lighting at night has been shown to influence the seasonal start of avifauna vocalizations, which could affect individual fitness and reproductive success (Da Silva et al. 2014).

While effects of light on wildlife are documented, it is still an emerging area of research and artificial lighting thresholds (e.g., duration, intensity, spectrum, etc.) for wildlife are not well defined. Currently there is no globally recognized or generally agreed upon standard for measuring biologically relevant light for wildlife or sky glow, which results in difficulty and inaccuracy when comparing between metrics and methods (DEE, 2020). Light is traditionally measured and quantified for human perception. However, this does not capture all light visible to wildlife. Furthermore, the visible spectrum and sensitivities differ by taxa and species (DEE, 2020).

Type of lighting may also impact fauna. Some lights can have increased effects on fauna due to the short wavelengths they emit (e.g., white or blue LEDs, metal halides). Wildlife is generally more sensitive to short, high energy UV/violet/blue wavelengths, particularly nocturnal species. Short wavelength light also scatters more in the atmosphere than long wavelength light, increasing the effects of sky glow (DEE, 2020; Pauwels, 2018). Yellow-orange light is typically associated with long wavelength lights (e.g., High Pressure Sodium, Low Pressure Sodium, Amber LED).

Light levels from the Project have been modeled in the Light Impact Assessment (Appendix D.1). While the calculated light levels at the residential receptors are below the limits recommended by the Institute of Lighting Engineers (ILE) guidelines, nighttime light prorogation from the Project may still cause sensory disturbance to avifauna. The Light Impact Assessment shows that the light levels from the Beaver Dam Mine Site reach background levels within 5 km of the source. While some Project-related light impacts will fall within natural variability (Appendix D.1), light sources from the Beaver Dam Mine site will have impacts to avifauna. These impacts will likely be experienced closer to the Beaver Dam Mine Site. The impact distance will also be dependent on the type of lighting used. As studies suggest (i.e., DEE, 2020; Pauwels, 2018), lights that emit more blue shortwave light (e.g., LEDs, metal halides) show greater impacts to fauna at night. These distances have been considered in the delineation of the LAA.

Light impacts from trucks on the Haul Road are expected to be insignificant compared to baseline daylight illuminance and will be blocked by the surrounding natural buffers and topography. In the evening, until 11 pm (when truck traffic ceases), light propagation from Haul Road traffic reaches background levels within 279 m. The impacts of Haul Road lighting on fauna is expected to be less than that of noise along the Haul Road. No permanent lighting will be installed on the Haul Road. Within the Beaver Dam Mine

Site, light impacts on avifauna will be reduced by installing lights facing downward and wherever practicable using motion-sensing lights.

6.12.8.5 Touquoy Mine Site

The potential interactions of the Project with avifauna within the Touquoy Mine Site is presented in Table 6.12-13.

Table 6.12-13: Potential Project Activities/Interactions with Avifauna at Touquoy Mine Site

Project Phase	Duration	Relevant Project Activity
Construction	1 year	• Tailings pipeline, make-up water pipeline alteration, and relocation of reclaim infrastructure
Operations and Maintenance	5 years	• Management of tailings produced from processing ore • Lighting of facilities and Mine Site roads • Waterfowl and other birds landing in pit lake
Active Closure	2 years	• Waterfowl and other birds landing in pit lake
Post-closure	+10 years (monitoring)	• N/A

N/A = not applicable.

The Project will have no new effects on Avifauna at the Touquoy Mine Site. Continued sensory disturbance caused by noise and light will occur within the Touquoy Mine Site as a result of the extended life of the Touquoy Mine Site associated with the Project. The continued interactions between fauna and the Touquoy Mine Site have been considered in the previous sections and within the Noise and Light Impact Assessments (Appendices B.1, B.2, and D.1).

6.12.9 Mitigation

In order to mitigate and reduce overall loss of function of habitat used by avifauna, and reduce direct impacts on avifauna, the actions provided in Table 6.12-14 will be implemented by AMNS where direct loss of habitat is expected to support development of the Project.

To verify the accuracy of the environmental assessment and the effectiveness of mitigation measures, a follow-up monitoring program is recommended. It is recommended that monitoring be conducted from the start of construction until the end of the active closure phase:

- conduct routine inspections as directed by regulators. Inspections are anticipated to be conducted daily by operators, and as required by qualified avian experts during construction, operation and active closure activities to identify and remove any trapped or injured avifauna; and
- notify Environment and Climate Change Canada within 24 hours in the event of the mortality or injury of ten or more migratory avifauna in a single event or in the event of the mortality or injury of a migratory avifauna SAR.

The mitigation measures outlined above are also applicable to the Touquoy Mine Site for the processing of Beaver Dam ore. Mitigation measures will be applied to reduce the potential environmental impacts of the Project on migratory avifauna at the Touquoy Mine Site as per existing operational approvals. Audio (Bird Gard Super Pro Amp:S4657) and visual deterrents (reflector tape) are currently being utilized at Touquoy Mine Site to dissuade avifauna from landing in the TMF. Each of the two audio deterrents employed has an effective range of 12 ha and is equipped with customizable calls from birds of prey. Due to the success of these deterrents, their use will continue when the tailings from Beaver Dam Mine Site are deposited in the Touquoy Mine Site open pit.

Regarding mature and interior forest; there is no significant impact expected from the Project to these habitat types, overall and in the greater adjacent area.

In instances where mature and interior forest cannot be avoided the following mitigation measures are proposed to identify and reduce indirect impacts to migratory avifauna that rely on this habitat throughout the PA:

- grubbing and clearing activities will be avoided during nesting season if possible;
- the Project will limit further disruptions to interior forests by utilizing existing roads and disturbed sites where possible;
- where possible, to avoid this habitat, adjustments will be made to infrastructure locations during detailed design phase; and
- monitoring of the effectiveness of mitigation is recommended as noted in Section 6.10.

Mitigations for SOCI and SAR avifauna will be discussed in Section 6.13. A comprehensive mitigation table for all VCs is provided in Section 9.

Table 6.12-14: Mitigation for Avifauna

Project Phase	Mitigation Measure
Construction	Avoid construction on native vegetation during the regional breeding season for migratory avifauna where practicable (beginning of April to end of August for migratory avifauna; ECCC 2015). Where this is not practicable, an avifauna nest mitigation plan will be developed
	If a raptor nest is found within the forested areas to be cleared, a buffer zone appropriate to the species (as determined in consultation with NSL&F) would be placed around the nest
Construction, Operation	Limit the amount of exposed soil during nesting season
	Discourage ground-nesting or burrow-nesting species (such as common nighthawk and bank swallows), by limiting large piles or patches of bare soil during the breeding season, wherever practicable
	Should any ground- or burrow-nesting species initiate breeding activities on stockpiles or exposed areas, AMNS will work with ECCC and NSE to develop buffer zones that incorporate adaptive management
	Maintain speed limits on mine roads (max. 40 km/hr. within Beaver Dam Mine Site, 70 km/hr. along Haul Road) to minimize collisions with avifauna
	Implement Dust Control Plan (Appendix C.3)
	Install downward-facing lights on site infrastructure and mine site haul roads. Wherever practicable, install motion-sensing lights to ensure lights are not turned on when they are not necessary
	Consider limiting use of lights that emit more blue shortwave light (e.g., LEDs, metal halides) which have greater impacts to wildlife at night, where practicable and considering operational safety.
	Conduct mobile refueling at least 30 m from any identified breeding locations
	Monitor known nests around stockpiles and exposed areas from a distance with a spotting scope or binoculars to verify the effectiveness of an identified buffer until the nests are inactive
	Conduct routine inspections of the open pit area to remove any trapped or injured avifauna. If identified, determine a plan for removal in consultation with an avian expert
	Notify ECCC within 24 hours in the event of the mortality or injury of ten or more migratory avifauna in a single event or in the event of the mortality or injury of a migratory avifauna SAR
Active Closure	Continued monitoring, as described in the above section.

NSL&F = Nova Scotia Lands and Forests; AMNS = Atlantic Mining NS Inc.;ECCC = Environment and Climate Change Canada; NSE = ; km/hr = kilometres per hour; m = metres; SAR = Species at risk.

6.12.10 Residual Effects and Significance

The predicted residual environmental effects of Project development and production on terrestrial fauna are assessed to be adverse, but not significant. The overall residual effect of the Project on terrestrial fauna is assessed as not significant after mitigation measures have been implemented and are summarized in Table 6.12-15.

A significant adverse environmental effect for avifauna has not been predicted for the Project for the following reasons, with consideration of the ecological and social context of the LAA surrounding the Project:

- During Construction:
  - Direct impacts to avifauna habitat is expected, however, impacts will be minimized through on-going Project design and micro-sighting of infrastructure footprints where ever practicable.
  - The baseline habitat of the Beaver Dam Mine Site and Haul Road is a network of existing fragmentation due to historical and present forestry activities, and the presence of the logging road that is proposed for upgrade.
  - Less than 5% of the suitable habitat in the LAA for observed species will be directly impacted by Project development. Habitat loss will be mitigated in the long term through reclamation planning.
  - The majority of Haul Road construction is road upgrades, minimizing the loss of habitat for avifauna.
  - Construction work will be considerate of the breeding bird season wherever practicable.
  - Construction noise and light will be limited to a 12-month window.
- During Operations:
  - Noise will be elevated above baseline during this period and may cause a displacement of avifauna in close proximity to the Haul Road and Mine Sites.
- During Closure:
  - Noise will be elevated above baseline during reclamation activities (2 years) involving mobile equipment and then drop to baseline for the post-closure period.
  - Appropriate mitigation such as wildlife deterrents will be implemented to deter wildlife species from entering the TMF and open pits during post-closure.

Table 6.12-15: Residual Effects for Avifauna

Project - VC Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction – Beaver Dam Mine Site and Haul Road (habitat loss from clearing and grubbing)	Limit habitat disturbance and minimize Project Area during detailed design, implement speed limits and minimize lighting.	L < 5% direct loss of habitat types used by observed species within the LAA Partial mitigation through restoration.	LAA Potential adverse effect to avifauna outside of the PA	A Although clearing and grubbing will occur outside of the sensitive period for avifauna, other activities will not.	MT (Beaver Dam Mine Site) Effects occur beyond 5 years when closure activities commence at Beaver Dam Mine Site. P (Haul Road) Closure of the Haul Road not expected.	O Effects occur once during the construction phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Loss	Not Significant
Construction – Beaver Dam Mine Site and Haul Road (sensory disturbance (noise, light, dust deposition) and wildlife vehicle collisions from construction activities)	Implement speed limits and minimize lighting.	M	LAA Potential adverse effect to avifauna outside of the PA	A VC interaction may affect seasonal aspects of avifauna.	ST Effects are limited to occur from as little as 1 day to 12 months	R Effects occur at regular intervals during the construction phase	R VC will recover to baseline conditions	Disturbance	Not Significant
Operational – Beaver Dam Mine Site, Haul Road and Touquoy Mine Site (disturbance (noise, light, dust deposition and wildlife vehicle collisions) from haul trucks, heavy machinery and mine operations)	Implement speed limits, install fences where necessary, and minimize lighting.	M Moderate changes relative to baseline conditions in remaining and surrounding habitat.	LAA Potential adverse effect to avifauna outside of the PA	A VC interaction may affect seasonal aspects of fauna.	MT Effects may occur up to 5 years.	R Effects occur at regular intervals.	R VC will recover to baseline conditions	Disturbance	Not Significant
Operations – Touquoy Mine Site Tailings deposition	Best management practices, Bird Deterrent Program implementation	L Change in habitat for avifauna	PA VC interaction is confined to the PA.	A VC interaction may occur during sensitive period for avifauna.	LT Effects may extend beyond 5 years	R VC interaction will occur at regular intervals	PR Mitigation cannot guarantee a return to baseline conditions	Creation of potential open water habitat; decreased water quality	Not Significant
Closure (Active) – Beaver Dam Mine Site (re-establishment of habitat for fauna)	N/A	L Minor change from baseline conditions.	LAA Potential effect to avifauna outside of the PA	A VC interaction may affect seasonal aspects of fauna.	LT Effects extend beyond active closure phase.	O Effects occur once during the closure phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Reclamation	Not Significant

Notes: For definitions of the below characteristics see Section 5.11, Table 5.11-1.

6.12.11 Proposed Compliance and Effects Monitoring Program Update

Monitoring of avifauna will be completed to verify the accuracy of the predicted environmental effects and the effectiveness of the mitigation measures specific to avifauna. Mitigations are outlined in Table 6.12-14. The Wildlife Mitigation and Monitoring Plan (WMMP, Appendix P.7) outlines protocols to minimize interactions between wildlife and Project activities. This document will evolve through the regulatory permitting process as well as public and Mi'kmaw engagement. In addition to the WMP, a Landbird SAR Mitigation and Monitoring Plan (Appendix A of Appendix P.7) has been developed to monitoring for avifauna SAR during Project development phases, assess the effectiveness of applied mitigation measures and propose adaptive management strategies as required. While this plan has been specifically developed for observed avifauna SAR, the mitigations and adaptive management strategies will be beneficial to many of the avifauna species present within the PA.

6.13 Species of Conservation Interest and Species at Risk

6.13.1 Introduction

6.13.1.1 Summary of Species of Conservation Interest and Species at Risk Before the Updates

Priority species were carried forward from all Valued Components (VCs) (fish, flora, fauna and avifauna) and assessed separately based on their elevated importance. Priority species or taxa specific baseline surveys were conducted within the Beaver Dam Mine Site and Haul Road based on findings from a detailed desktop study to examine potential for or historic presence of priority species within the Project Area (PA).

Two priority species of fish were identified during field surveys within and in proximity to the PA. American eel and brook trout were confirmed in watercourses and waterbodies within and downgradient of the PA. While Atlantic salmon have been documented within the West River Sheet Harbour and the Killag River, none were observed. No other fish Species of Conservation Interest (SOCI) were observed. No fish Species at Risk (SAR) were observed within or in proximity to the PA.

Mainland moose tracks were observed in three locations within the Beave Dam Mine Site. No other observations or evidence of mainland moose were observed. Dedicated wood turtle surveys were conducted within the Beaver Dam Mine Site or Haul Road; however, none were observed. No priority herpetofauna were observed during dedicated field surveys Snapping turtle had been previously observed near the Touquoy Mine Site outside field surveys. No bats, or evidence of, were observed during field surveys. Twenty-five priority avifauna species (17 SOCI, eight SAR) were observed within the Beaver Dam Mine Site and Haul Road.

A monarch butterfly was identified during the desktop review; however, no observations of milkweed were documented during field surveys. No other priority invertebrate species were observed during field surveys.

Five SOCI and no SAR vascular flora species were observed within the Beaver Dam Mine Site and Haul Road. Eleven priority lichen species were observed within the Lichen Study Area (LSA) and Haul Road. Of the eleven species observed, three are SAR (i.e., boreal felt lichen, blue felt lichen, frosted glass-whiskers lichen) and eight are SOCI.

Priority species identified within the PA represent a diversity of taxa, habitat preferences, and, represent a diversity of Project interactions, effects, mitigation, and monitoring and therefore are discussed in terms of each taxa, rather than individual species. A focus is placed on SAR, recognizing that an assessment of SAR impacts and mitigations will be generally appropriate for identified SOCI, and in consideration of assessments of broad taxonomic group in previous chapters. No SAR are assessed to be lost due to the Project and as a result of mitigations and detailed design planning, the predicted residual environmental effects of Project development and production on priority species are assessed to be adverse, but not significant.

6.13.1.2 Summary of Update to Species of Conservation Interest and Species at Risk

Supplementary field surveys were conducted for each taxa for the Updated 2021 EIS as a result of PA modifications and continued infrastructure micro-siting since the Revised 2019 EIS submission.

In 2020, four Atlantic salmon parr were identified in the Killag River, outside the PA, which was not previously sampled. Prior to 2020, Atlantic salmon was not observed during any Project fish sampling programs. In total three SOCI fish species were identified during field surveys within and in proximity to the PA.

In consideration of their breeding status qualifiers, it was determined that 32 priority avifauna species (23 SOCI, nine SAR) were observed within the Beaver Dam Mine Site and Haul Road, which includes an additional SAR due to status change in 2019 (evening grosbeak, SARA Special Concern).

An additional priority vascular flora species, Nova Scotia Agalinis (*Agalinis neoscotica*, S3S4), was observed during supplementary field surveys in 2019. A total of six SOCI flora species were observed within the Beaver Dam Mine Site and Haul Road. Additional targeted lichen surveys were completed in the western and southeastern expansions of the Beaver dam Mine Site in 2019. No new priority lichen species were observed.

Impacts to priority species were reassessed based on changes to the PA and Project infrastructure. The taxa specific effects assessments were updated based on improved understanding and evaluation of Project related impacts, as identified for the broad taxonomic group in previous chapters. Project mitigation measures have been reassessed based on the new design, additional baseline surveys and updated effects assessments, and include SAR specific monitoring plans (e.g., draft Landbird SAR Mitigation and Monitoring Plan and Preliminary Lichen Mitigation and Monitoring Plan), as per the Round 2, Information Requests (IR2) issued by the Impact Assessment Agency of Canada (IAAC, formerly the Canada Environmental Assessment Agency [CEAA 2019]) and Nova Scotia Environment (NSE 2019).

No new direct or indirect impacts to priority species are expected. Project effects to priority species remain adverse, but not significant.

Table 6.13-1: Updated Subsections from the 2019 Revised Environmental Impact Statement – Species of Conservation Interest and Species at Risk

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
-	-	6.13.1 Introduction	• New
6.13.1 Rationale for Valued Component Selection	No	6.13.2 Rationale for Valued Component Selection	• N/A
6.13.2 Baseline Program Methodology	Yes	6.13.3 Baseline Program Methodology	• Addition of 2019 field surveys: • Additional survey areas as a result of PA modification for infrastructure micro-sitting. • Review and update priority species (I2R NSE 2-184)
6.13.3 Baseline Conditions	Yes	6.13.4 Baseline Conditions	• Present results from 2019 field surveys: • Additional survey areas as a result of PA modification for infrastructure micro-sitting. • Review and update priority species (IR2 NSE 2-184)
6.13.4 Consideration of Consultation and Engagement Results	No	6.13.5 Consideration Engagement Results	• N/A
6.13.5 Effects Assessment Methodology – **Boundaries**	Yes	6.13.6 Effects Assessment Methodology – **Boundaries**	• PA modification for infrastructure micro-sitting. • Adjusted PA description. • LAA was enlarged due to the modified PA. • RAA was enlarged where necessary due to the modified PA. Fauna assessment area changed to the RAA.

Table 6.13-1: Updated Subsections from the 2019 Revised Environmental Impact Statement – Species of Conservation Interest and Species at Risk (continued)

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
6.13.5 Effects Assessment Methodology – **Thresholds for Determination of Significance**	Yes	6.13.6 Effects Assessment Methodology – **Thresholds for Determination of Significance**	• Updated significance threshold and magnitude assessment: • Reflect changes in VC baseline conditions and improve significance assessment criteria • Response to IR2 CEAA 2-02
6.13.6 Project Activities and Species of Conservation Interest and Species at Risk and Effects	Yes	6.13.7 Project Activities/Interactions with Species of Conservation Interest and Species at Risk	• Updated based on revised noise and light impact assessments. • Bolster discussion of direct and indirect impacts to priority species • Changes to project timelines.
6.13.7 Preferred Alternative Haul Road	Yes	Section Removed	• The Preferred Alternative Haul Road is no longer being considered and has been removed from the Project Description (Section 2) and EIS
6.13.8 Mitigation and Monitoring	Yes	6.13.9 Mitigation	• Updated based on field survey results and changes to effects assessment • Reflects improved understanding of impacts.
6.13.9 Residual Effects and Significance	Yes	6.13.10 Residual Effects and Significance	• Updated based on field survey results and changes to significance threshold determination. • Change to magnitude determination • Reflect changes to significance threshold and magnitude assessment.
6.13.10 Proposed Compliance and Effects Monitoring Program	No	6.11.11 Proposed Compliance and Effects Monitoring Program	• Updated monitoring programs • Response to IR2 NSE-2-02, NSE-2-13, CEAA-2-24 and CEAA-2-26

Notes: PA = Project Area; LAA = Local Assessment Area; RAA = Regional Assessment Area- = no update; IR2 = Round 2, Information Requests; CEAA = Canadian Environmental Assessment Agency; EIS = Environmental Impact Statement.

6.13.2 Rationale for Valued Component Selection

Species at Risk (SAR) are protected under federal or provincial endangered species legislation. These pieces of legislation outline protection of these species and their habitats in the form of species-specific recovery strategies and action plans, where available. The level of protection offered to a listed species varies depending on its designation. Species of conservation interest (SOCI) represent species whose populations are either currently or potentially threatened by natural or anthropogenic factors. These species are listed as S1-S3 (or any combination thereof, inclusive of S3S4) by the Atlantic Canada Conservation Data Centre (ACCDC) and are not designated by federal or provincial endangered species legislation. Natural systems and ecological processes often depend on healthy, diverse ecosystems. As such, understanding the distribution and diversity of rare species present within a PA is key to proper risk assessment, Project planning, and mitigation of risks posed to rare species.

6.13.3 Baseline Program Methodology

6.13.3.1 Desktop Priority Species List Methodology

A detailed desktop study to examine potential for presence of and effects on SAR within the vicinity of the PA was completed. This desktop evaluation for SOCI and SAR was completed in advance of field programs to advise the field methodologies described in the following section. Assessment of wildlife, vegetation, and habitat was completed based on the requirements outlined in the NSE Guide to Addressing Wildlife Species and Habitat in an EA Registration Document (NSE 2009b). The priority species list was used throughout the biophysical assessments to inform the field programs as it identified a broad list of priority species which have the potential to be present within the PA (Appendix K.1). The desktop priority list was based on general species habitat requirements and the broad geographic area in which individual species are known to occur.

Development of a priority list of species for each taxonomic group was completed based on a compilation of listed species from the following sources:

- Committee on the Status of Endangered Wildlife in Canada (COSEWIC) and the Federal *Species at Risk Act* (SARA 2002). All species listed as Endangered, Threatened, or of Special Concern.
- Nova Scotia *Endangered Species Act* (NSESA 1999). All species listed as Endangered, Threatened, or Vulnerable.
- Conservation Rank: All species with designated status ranks (S-Ranks) S1, S2 or S3 or any combination thereof (i.e., S3S4 is considered a Priority Species) as defined by the ACCDC.

Collectively, this group of species is known as priority species. This umbrella grouping includes SOCI that are not listed species under provincial or federal legislation (such as COSEWIC species and ACCDC S1, S2 and S3 species or any combination thereof), and SAR which are listed on SARA or NSESA. Additional guidance was provided by NSL&F SAR biologist, Mark Elderkin. As per conversations with Mr. Elderkin during the early spring of 2015, it was requested that all priority species lists be built using S-Ranks (S1, S2, S3, S3S4) rather than general S-Ranks (GS-Ranks Red and Yellow).

The priority species list is referenced across the various biophysical assessments and is provided in Appendix K.1. S-Rank definitions (ACCDC 2017) are provided in Table 6.13-2.

As outlined above, the compilation of a priority species list is habitat driven, rather than observation driven (based on information provided in reports from ACCDC or the MBBA, for example). This is based on the recognition that observation-based datasets are not comprehensive lists of species identified in any given area. A habitat-driven list forms a comprehensive list of all possible priority species that may be present on the landscape, based on habitat expectations for each species and presence of that habitat within the PA. As such, the information provided by observation-driven sources are supplementary to the priority species list, rather than forming the basis of the priority species list.

A list of all SOCI and SAR as defined above was compiled with habitat preferences and geographic distribution (if known) included. To complete the Project-specific priority species list, the province-wide list was narrowed based on:

- broad geographic area (for this Project, the broad geographic area considered is central mainland Nova Scotia);
- habitat preferences; and
- presence of preferred habitat within the PA based on habitat survey results.

Table 6.13-2: Provincial Status Ranks Definitions

S-rank	Definition
SX	**Presumed Extirpated** - Species or community is believed to be extirpated from the province. Not located despite intensive searches of historical sites and other appropriate habitat, and virtually no likelihood that it will be rediscovered.
S1	**Critically Imperiled** - Critically imperiled in the province because of extreme rarity (often 5 or fewer occurrences) or because of some factor(s) such as very steep declines making it especially vulnerable to extirpation from the state/province.
S2	**Imperiled** - Imperiled in the province because of rarity due to very restricted range, very few populations (often 20 or fewer), steep declines, or other factors making it very vulnerable to extirpation from the nation or state/province.
S3	**Vulnerable** - Vulnerable in the province due to a restricted range, relatively few populations (often 80 or fewer), recent and widespread declines, or other factors making it vulnerable to extirpation.
S4	**Apparently Secure** - Uncommon but not rare; some cause for long-term concern due to declines or other factors.
S5	**Secure** - Common, widespread, and abundant in the province.
SNR	**Unranked** - Nation or state/province conservation status not yet assessed.
SU	**Unrankable** - Currently unrankable due to lack of information or due to substantially conflicting information about status or trends.
SNA	**Not Applicable** - A conservation status rank is not applicable because the species is not a suitable target for conservation activities.
S#S#	**Range Rank** - A numeric range rank (e.g., S2S3) is used to indicate any range of uncertainty about the status of the species or community. Ranges cannot skip more than one rank (e.g., SU is used rather than S1S4).
Not Provided	Species is not known to occur in the province.
Breeding Status Qualifiers	
Qualifier	**Definition**
B	**Breeding** - Conservation status refers to the breeding population of the species in the province.
N	**Nonbreeding** - Conservation status refers to the non-breeding population of the species in the province.
M	**Migrant** - Migrant species occurring regularly on migration at particular staging areas or concentration spots where the species might warrant conservation attention. Conservation status refers to the aggregating transient population of the species in the province.

A single desktop priority species list is developed for all seasons for the Project using this methodology. The seasonality of mobile species is not used to screen species into, or out of, the desktop priority species list. The final priority list of species used for field assessments are highlighted in Appendix K.1.

Once the priority species list was completed, the Project Team reviewed a series of additional data sources. Sightings of priority species recorded within 5 km and 100 km by ACCDC were reviewed (reports included in Appendices I.1 and I.2). Original reports were prepared for the Beaver Dam Mine Site on September 8, 2014, for the Haul Road on June 3, 2016, and an additional report was prepared for the Touquoy Mine Site on September 10, 2015. An updated ACCDC report was attained and reviewed for the Beaver Dam Mine Site and Haul Road on January 4, 2021 in order to consider new species occurrences and potential impacts (IR2 NSE 2-184).

When the ACCDC prepares a rare species report, they provide the user with georeferenced shapefile points of rare species records within 5 km of the center of the study area. However, NSL&F has classified several species as 'location sensitive', meaning that ACCDC is not permitted to provide specific location data for these species in their reports. Concern about exploitation of location-sensitive species precludes inclusion of coordinates in the rare species reports. Location sensitive species in Nova Scotia include black ash (*Fraxinus nigra*), blandings turtle (*Emydoidea blandingii*), wood turtle (*Glyptemys insculpta*), peregrine falcon anatum/tundrius populations (*Falco peregrinus*, pop.1), and any bat hibernaculum. If any of these species are present within 5 km of the center of the study area, the ACCDC report will simply identify that they are present, but will not provide specific location data. No location sensitive species were documented within 5 km of the PA in any of the ACCDC reports.

The Nova Scotia Department of Communities, Culture and Heritage provided an Environmental Screening Report including a list of flora and fauna SAR and SOCI documented by their staff within the vicinity of the Beaver Dam Mine Site and Haul Road. The Nova Scotia Special Places Environmental Screening report is provided in Appendix I.3. Two additional datasets were reviewed for priority invertebrates. These include the Maritime Butterfly Atlas and Odonata Central. These datasets provide records of butterfly and odonate observations, respectively.

Additional SAR and SOCI lichen data were received from the Mersey Tobeatic Research Institute in 2019, and incorporated in the desktop evaluation. This data was used to advise field methodology and targeted lichen surveys for additional field programs completed, as well as inform Project impact assessments and mitigation approaches.

The compilation of the priority species list and the review of all other available desktop resources for priority species observations is done primarily to advise field methodology, and they inform field staff to the species they are likely to encounter during field surveys. The desktop review for priority species provided the study team with information that directly guided the methods and the timing of all field programs. All field staff reviewed the desktop evaluation for priority species prior to commencing field work. This allowed field staff to review field identification guides and ensured that they were familiar with priority species identification and their status ranks.

6.13.3.2 Field Program Methodologies

Field program methodologies for each taxonomic group are outlined in previous sections of this EIS (Section 6.9 Fish and Fish Habitat, Section 6.10 Flora and Habitat, Section 6.11 Terrestrial Fauna, and Section 6.12 Avifauna). This section describes the detailed and specific field program methods for SOCI and SAR, where applicable, within the Beaver Dam Mine Site and Haul Road. Specific biophysical field program methods are shown on Figures 6.13-1A to 6.13-1G.

In 2019, the PA was modified to allow for the micro-siting of infrastructure within the Beaver Dam Mine Site, as described in Section 2 (Project Description). As a result, additional targeted priority species surveys were conducted within the modified PA areas. to identify and record additional flora species and ecosystem habitats.

Methods and results from SAR/SOCI surveys at the Touquoy Mine Site are summarized in subheadings within the applicable sections of this EIS, however, the data is not being re-evaluated. For further information regarding Touquoy Mine Site, refer to the EARD (CRA 2007a) and Focus Report (CRA 2007b).

6.13.3.2.1 Priority Fish Survey Methodology

No targeted methods were employed specifically for priority fish species. The diversity of fish survey methods employed (eel pots, fyke nets, minnow traps, and electrofishing) were used with the goal of capturing the broadest diversity of fish species present within the PA. Detailed fish survey methods used in the PA is outlined in Section 6.9.3. The baseline fish and fish habitat survey methods have been updated, as reflected in Section 6.9.3 to reflect the revisions to the Fisheries Act; to increase the level of fish sampling effort, and to be able to quantify (in m^2) the impacts of the Project on fish habitat due to both direct and indirect project interactions. Evaluations for indirect impacts to fish habitat in Cameron Flowage/Killag River were selected to identify potential indirect effects of the Project to understand the extent of any indirect impacts on Atlantic salmon.

6.13.3.2.2 Priority Vascular Flora Survey Methodology

No specific targeted surveys for priority vascular plant species were completed. Botanical surveys were completed in all habitats throughout the Beaver Dam Mine Site and Haul Road to compile a comprehensive list of vascular flora species present. Botanists conducting vascular plant surveys thoroughly reviewed the results of the desktop evaluation for vascular flora priority species. This allowed the botanical surveys to focus on habitats with elevated potential for any priority vascular flora species. Vascular flora survey methods are outlined in Section 6.10.3.3.

Vascular plant assessments occurred early and late in the growing season to capture plant species with different phenology (IR2 NSE-2-185). Spring surveys to capture spring ephemerals and early developers were completed on June 22-23, 2015 at the Beaver Dam Mine Site and on June 22-23, 2016 along the Haul Road. Late season surveys to capture late developing species were completed on September 8, 12, and October 9, 2014 at the Beaver Dam Mine Site and on September 11-12, 2016 along the Haul Road. An additional vascular plant survey was conducted within the western expansion to the Beaver Dam Mine Site on September 18, 2018. Further vascular plant surveys were conducted in 2019 as a result of the PA modification, within the further western and southeastern expansions of the Beaver Dam Mine Site. Decorated surveys were conducted on August 22 and 23, 2019, as well as during habitat and wetland survey efforts from May to October 2019.

The following information was collected for any priority vegetation species identified during field surveys: site location, date, scientific name, count, size, habitat, location (UTM NAD83 CSRS), along with a photograph and any relevant comments. Any specimens that could not be identified in the field were photographed in order to aid in identification.

6.13.3.2.3 Priority Lichen Survey Methodology

Prior to undertaking the field assessment, a detailed desktop review of known lichen observations and potential habitat for rare lichens within and surrounding the PA was conducted. The desktop review involved a review of the following four components:

- the priority species list,
- predictive habitat mapping for boreal felt lichen (provided by NSL&F), a review of the extant populations of boreal felt lichen, vole ears (*Erioderma mollissimum*) and lichen datasets provided by ACCDC and MTRI;
- existing and proposed critical/core habitat mapping for vole ears and boreal felt lichen provided by ECCC-CWS and adopted by NSE; and
- results of wetland and habitat mapping.

To develop the predictive habitat maps for boreal felt lichen, NSL&F used an algorithm which identifies all forest stands in the provincial forestry database in which balsam fir (*Abies balsamea*) is listed as a primary or secondary species and which occur within 80 m of a mapped bog or fen. The model further confines the search to only those forest stands located within 30 km of the Atlantic Coast. This was used to predict areas with a higher potential of locating boreal felt lichen. This data set was reviewed in advance of field assessment and was uploaded onto the GPS units during field assessments. Other habitats identified by the Project Team as suitable for rare lichens were surveyed for lichens as well.

While the specific habitat requirements of each of priority lichen species varies slightly, they all require mature to over-mature forests. Stand age is one of the greatest determinants of lichen diversity (McMullin, Duinker, Cameron, Richardson, & Brodo, 2008). Within the PA, mature to over-mature stands are infrequent, with the majority of the PA having been harvested for timber production. Intact, natural, mature stands are more frequent within the Haul Road than within the Beaver Dam Mine Site. Lichen surveys throughout the Beaver Dam Mine Site and Haul Road were focused on undisturbed stands, particularly those located near mapped wetlands, as these habitats have elevated potential for identifying priority lichen species.

All suitable habitats within and surrounding the Beaver Dam Mine Site and within the Haul Road were originally surveyed in May 2015 and May 2016, respectively, for priority lichen species. The survey area was extended beyond the PA boundary in the vicinity of the Beaver Dam Mine Site and defined as the lichen study area (LSA; Figures 6.13-2A), so the Project Team could understand the distribution of rare lichens in a broader context. This broadened LSA allowed the Project Team to form conclusions based on lichen populations, rather than individual lichens. An additional priority lichen survey was conducted in conjunction with vascular plant surveys in the 2018 western extension to the Beaver Dam Mine Site on September 18, 2018 and in a small area directly north of the Beaver Dam Mine Site on October 29, 2018. As a result of continued PA modifications, in 2019, additional priority lichen surveys, were conducted within the further western and southeastern expansions of the Beaver Dam Mine Site. The LSA has been expanded to include these areas (Figure 6.13-2A).

Mature trees that are appropriate for hosting priority lichen species were visually inspected. The visual inspection focused on tree trunks, but included branches and twigs where it was determined to be safe and appropriate. The following information was collected for any priority lichen species identified during field surveys: site location, date, scientific name, count, size, habitat (host tree and general habitat), location (waypoint in UTM NAD83), height of the specimen, direction that the specimen was facing, along with a photograph and any relevant comments. Any specimens that could not be identified in the field were photographed in order to aid in identification.

6.13.3.2.4 Mainland Moose Survey Methodology

To determine the level of concern associated with mainland moose, the Project team commenced by consulting with the Endangered Mainland Moose Special Management Practices report (NSDNR, 2012) and the Status Report on the Eastern Moose (Parker, 2003). In addition, on January 5, 2015, the Project team consulted with Regional Wildlife Biologist, Shavonne Meyer, to request a record of all mainland moose sightings identified within a broad vicinity of the PA.

Tracking surveys were completed to determine if mainland moose are present within the Beaver Dam Mine Site. Six transects, totaling nine-kilometers in length, were established through representative habitat types. An observer capable of identifying moose and deer tracks, browse and scat completed the moose track surveys. Three winter tracking surveys were completed along these transects on January 14, February 18, and March 17, 2015. One moose pellet group inventory (PGI) survey was completed along these same transects on May 25, 2015.

Winter and spring moose surveys, consisting of eight one-kilometer transects, were completed within the Haul Road in March and April 2016. Typically, winter track surveys would be completed three times, following the same transects, in suitable winter tracking conditions, followed by a single round of spring PGI surveys. Winter track conditions and a lack of snow cover during the late winter of 2016 prevented the repetition of winter track surveys for Moose. On February 26, 2016, the Project team consulted with the Regional Wildlife Biologist, Shavonne Meyer, the provincial Large Mammal Biologist, Peter MacDonald, and with the provincial SAR Biologist, Mark Elderkin to discuss a change in methodology to reflect the lack of snow cover. Through this consultation, the Project team determined that one winter track survey would be complemented by repeated spring PGI surveys. Each PGI survey would be completed along a different series of transects, thereby increasing the coverage of the surveys, while still obtaining the data that would be necessary to make conclusions related to moose activity within the Haul Road. In total, 18 one-kilometer transects were established along the Haul Road. One winter track survey was completed on transects 1-8 on March 2, 2016. This was complemented by two sets of PGI surveys completed on March 16th, 2016 (Transects 9-18) and on April 26th, 2016 (Transects 1-8). Locations of moose and deer tracks, browse, and scat were recorded using a handheld GPS unit. Incidental observations of other wildlife species, tracks, and scat were also recorded. The placement of moose survey transects through the Beaver Dam Mine Site and Haul Road reflected a mixture of existing roads and intact forest, and were determined in consultation with NSL&F staff identified above. Mainland moose survey transects are identified in Section 6.11.4.1, Figure 6.11-3.

6.13.3.2.5 Bat Survey Methodology

A desktop analysis of potential bat habitat was conducted to determine level of concern associated with the Project and to determine whether field assessments were necessary. The desktop analysis started with a review of bat occurrences, as noted in the ACCDC reports. The Significant Species and Habitat Database was also searched for known potential bat hibernacula. According to NSL&F SAR Biologist, Mark Elderkin, bats are sensitive to activity up to 1 km away during hibernation. As such, a minimum of 1 km buffer is recommended when assessing risk to bat SAR. Provincial government records for Abandoned mine openings (AMOs) were reviewed (Hennick and Poole, 2016) within a 10 km radius of the site, as these AMOs potentially provide bat hibernacula. These records were reviewed for mine shaft type, access, original depth, and presence of water in the shaft to determine likelihood that the AMO is potential bat hibernacula. The records identified 18 AMOs within the Beaver Dam Mine Site. The 18 AMOs within the Beaver Dam Mine Site were evaluated in the field on September 18, 2014 for their potential to provide bat hibernacula. During all other surveys completed within the PA by the Project team, biologists were trained to evaluate landscapes for potential hibernacula including natural caves or anthropogenic mine openings or abandoned wells.

6.13.3.2.6 Priority Herpetofauna Survey Methodology

Wood turtles and snapping turtles have been identified as priority species with the potential to be present within the PA based on habitat preference and known distribution. The wood turtle is listed as threatened by COSEWIC, NSESA and SARA. This species prefers clear rivers, streams, or creeks with moderate current and sandy or gravelly substrate (ECCC, 2016c). The snapping turtle is listed as vulnerable in NS and is listed as a species of special concern by COSEWIC and SARA. This species occurs in almost any freshwater habitat, though it is most often found in slow-moving water with a soft mud or sand bottom and abundant vegetation (ECCC, 2016d).

Seven wood turtle surveys were conducted from May 17 to June 4, 2015 along the watercourse that runs between Crusher Lake and Mud Lake (part of watercourse 5) within the Beaver Dam Mine Site. No other suitable wood turtle habitat was identified across the Beaver Dam Mine Site and Haul Road that warranted a detailed survey for wood turtles. MEL biologists continued to look for signs of turtle usage during all other site surveys, particularly suitable nesting habitat along watercourse crossings throughout the Haul Road.

Wood turtles are often associated with some form of vegetative structure, therefore, MEL field staff searched for turtles at the base of woody shrubs, under or near deadfall, and amongst grasses or leaf litter. The ground and undergrowth was searched from the water's edge inland to 20 m along one side of the watercourse.

Wood turtles are active in temperatures over 9 °C, but best results are found when temperatures range from 15 to 20 °C. Wood turtle observations drop off significantly when temperatures exceed 25 °C. Ambient temperature appears to be as good an indicator of the probability of detection as sunlight so surveys can occur on cloudy days. As long as the air temperature is warmer than the water, there is a thermal advantage in basking on land (ECCC, 2016c). Surveys were completed between 10:00 and 18:00 hours.

Opportunistic observations for snapping turtle, painted turtle and their respective suitable habitat were documented through all field programs, particularly wetland and watercourse evaluations. Biologists conducting field assessments searched for turtles in aquatic ecosystems with slow moving water, mucky substrate, and dense vegetation. During June, particular attention was paid to identifying snapping turtles or signs thereof (i.e., scrapes, depredated nests) along exposed gravel including roadside shoulders, when snapping turtles move to these habitats to nest.

The PA was also surveyed for herpetofauna during other field programs, particularly wetland and watercourse assessments, with special attention paid towards identifying any signs of turtle usage. Signs such as animal sightings, vocalizations, amphibian egg masses, cast snake skins, turtle nest scrapes, or depredated nests were recorded during any field programs by biologists capable of recognizing these signs.

6.13.3.2.7 Priority Invertebrate Survey Methodology

A desktop review for rare invertebrates was completed. This included reviewing species records in the vicinity of the PA provided by Odonata Central, the Maritime Butterfly Atlas, and the ACCDC reports (Appendices I.1, I.2 and I.4) for Odonates, Lepidopterans and all other invertebrates, respectively. The PA falls within five 10 km^2 Maritime Butterfly Atlas survey squares (20NQ17, 20NQ18, 20NQ19, 20NQ28, 20NQ29), reports for which are provided in Appendix I.4. Incidental observations for priority invertebrates occurred during all field programs, particularly wetland and watercourse delineation, and fish habitat surveys. Incidental observations of odonates and lepidopterans include live adults or larvae, or cast skins. Signs of molluscs include live or dead individuals and shells.

6.13.3.2.8 Priority Avifauna Survey Methodology

The second atlas of the MBBA was reviewed to determine possible, probable, and confirmed records of breeding avian SAR and SOCI in proximity to the PA. The PA falls within five 10 km^2 MBBA survey squares (20NQ17, 20NQ18, 20NQ19, 20NQ28, 20NQ29). The results of MBBA surveys are presented in Section 6.12.3 and provided in Appendix L.2.

Targeted surveys for the common nighthawk were completed throughout the Beaver Dam Mine Site and Haul Road, as described in Section 6.12.4.6. Suitable habitat is available for this species within the PA, therefore, dedicated surveys for the common nighthawk were conducted within June (2015 and 2016) and July (2019) at either dawn (1 hour before sunrise to 30 minutes after sunrise) or dusk (30 minutes before sunset to an hour after sunset), as described in the Common Nighthawk Survey Protocol (Saskatchewan Ministry of Environment, 2015). Common nighthawk are crepuscular and were detectable at both dawn and dusk survey times. Stations were spaced at least 800 m apart and a point count survey with call playback was used to detect the presence of common nighthawk within the PA. A three-minute passive point count was conducted at each station, followed by a call playback which includes 30-seconds of the conspecific common nighthawk call followed by 30-seconds of silence (or passive surveying), repeated for three-minutes (i.e., three times). The total time spent at each survey point was a minimum of six-minutes. Three call playback stations were surveyed within the Beaver Dam Mine Site and 12 call playback stations were surveyed within the Haul Road, for a total of 15 call playback stations.

No other targeted surveys for priority bird species were conducted, as all other species are anticipated to be detectable during standard methods for bird surveys.

During data analysis, the Project Team uses breeding status qualifiers to identify which avian species are considered SOCI, based on the season in which they were observed. Breeding status qualifiers are defined by the Maritime Breeding Bird Atlas, and assigned to each species by the ACCDC. SAR are considered priority species, regardless of the seasonality of their observation. For instance, a bird with an S-Rank of S2S3B, S5N (such as the pine grosbeak) would not be considered a priority species if observed overwintering (the N qualifier represents a non-migratory, or overwintering population). Conversely, a species ranked S5B, S3N (such as the American robin) would not be considered a priority species if observed during migration or breeding season, and would only be considered a priority species if observed overwintering. Some species do not have a compound rank assigned with varying seasonal considerations, such as the turkey vulture (ranked S2S3B). This species has no alternate ranking status for migratory or overwintering populations, therefore this species, by default, would be considered apriority species regardless of its' observation date.

6.13.4 Baseline Conditions

Updates to priority species (total number, location etc.) reflected within this section are as a result of additional surveys required by changes to the PA in order to incorporate the micro-siting of Project infrastructure.

6.13.4.1 Priority Fish Species

A desktop evaluation for priority fish species revealed that four priority species have been identified within 5 km of the SA. These include Atlantic salmon (*Salmo salar*), American eel (*Anguilla rostrata*), alewife (*Alosa pseudoharengus*) and brook trout (*Salvelinus fontinalis*) (ACCDC, 2021). Priority fish species identified as having an elevated potential to be located within the PA, based on habitat preferences, and broad geographic range, include American eel, Atlantic salmon, brook trout, brook stickleback (*Culaea inconstans*), and landlocked rainbow smelt (*Osmerus mordax*). No location sensitive species of fish have been identified within 5 km of either the Beaver Dam Mine Site or the Haul Road, according to the ACCDC reports (Appendix I.1). The following priority

fish species are identified as having an elevated potential to be located within the PA, based on habitat preferences, and broad geographic area (Table 6.13-3).

Table 6.13-3: Priority Fish Species with Elevated Potential to Occur in the Project Area

Common Name	Scientific Name	SARA	COSEWIC	NSESA	S-Rank
Alewife	*Alosa pseudoharengus*	-	-	-	S3
American eel	*Anguilla rostrata*	-	Threatened	-	S2
Atlantic salmon – Southern Uplands Population	*Salmo salar pop. 6*	-	Endangered	-	S1
Brook stickleback	*Culaea inconstans*	-	-	-	S3
Landlocked Rainbow smelt	*Osmerus mordax (landlocked)*	-	-	-	S3
Brook trout	*Salvelinus fontinalis*	-	-	-	S3

As described in Section 6.9.3, all fish survey methods were designed to identify the diversity of species within the diversity of habitats present within the PA, including any priority species. Field survey locations for various fish programs are presented in Figures 6.9-2 to 6.9-4 and in Appendix J.4, Figure J.4-5. No species-specific targeted surveys were completed for priority fish species.

Within, or in proximity to, the Beaver Dam Mine Site, three priority species were identified – brook trout, Atlantic salmon, and American eel. Brook trout (S3), was identified within Watercourses 5, 12, 13, 23, the Killag River, Cameron Flowage, Crusher Lake, Mud Lake/WC27, and WL59. Atlantic salmon (COSEWIC, Endangered) was identified only within the Killag River. American eel (COSEWIC, Threatened) was identified in WC13, the Killag River, Cameron Flowage, and Mud Lake/WC27. Two priority species were identified within watercourses within the Haul Road. American eel and brook trout were both observed in Watercourses N, V, and AH.

According to the Nova Scotia Salmon Association (pers. comm. 2016), rainbow smelt and brook stickleback are not known to be present within the West River Sheet Harbour or Tangier River systems. Therefore, the likelihood of these species being present within the PA is very low.

Alewife (S3) are anadromous fish that spend most of its life in the marine environment, migrating into freshwater to spawn. In freshwater, alewife are found in open water habitats over all bottom types (Page and Burr, 2011). They spawn almost exclusively in lakes and large still waters and genetic differentiation between populations suggests that they typically return to their river of origin for spawning (DFO, 2016). Alewife do not migrate into fresh water until river temperatures start to warm and spawning usually occurs in June (NSSA 2005b; Gilhen 1974). Adults between their downstream migration back to the sea within a few days of spawning.

According to the Nova Scotia Freshwater Fish Species Distribution Records, alewife has been historically (1960s-1980s) within the Tangier River secondary watershed, specifically Bear, Forth, River, Third, and Tangier Lakes (NSFA, 2016). As such, it is anticipated that alewife may use watercourses within the Haul Road as migration corridors to upstream spawning areas (e.g., WC-AD). However, no lakes or large still waters fall within the Haul Road footprint. The ACCDC report (2021) provides one record of Alewife within the West River Sheet Harbour, approximately 1.7 km below the confluence of the Killag and West Rivers (no date provided). No other records of alewife within the West River Sheet Harbour secondary watershed could be identified through a desktop review (Alexander, Kerekes, & Sabean, 1986; Halfyard, 2007; NSAF, 2016), nor were any alefwife captured through extensive fishing efforts within and in proximity to the PA. Therefore, the likelihood of alewife being present within the Beaver Dam Mine Site and Haul Road watercourses within the West River Sheet Harbour watershed is considered low.

No fish SAR were documented during any fish surveys within the PA.

The Project Team received a letter from Lisa Poan, Fisheries Protection Biologist at Fisheries and Oceans Canada on April 20, 2015 (Entitled: DFO response to notification letter pursuant to subsection 79(1) of the *Species At Risk Act* for the Proposed Beaver Dam Mine Project). This letter indicated that the American eel and the Atlantic salmon (Southern Upland population) are under review for protection under SARA. If designated under Schedule 1 of SARA as proposed, prohibitions would immediately come into effect under Sections 32 and 33 of SARA. As such, the Project Team is moving forward with the Projects' effects assessment, with the assumption that these species may soon be protected under SARA. At the time of submission of this updated 2021 EIS, no change in status has been realized for either species.

6.13.4.1.1 Brook Trout

Across all survey years, a total of 191 brook trout (S3) were captured within the Beaver Dam Mine Site and a total of 8 were captured within the Haul Road during both electrofishing and trapping surveys.

Within the Beaver Dam Mine Site, brook trout were confirmed within the following watercourses:

- Watercourse 5 north of Crusher Lake between Crusher Lake and Mud Lake;
- Watercourse 12 between Wetlands 56 and 59;
- Watercourse 13 within the tributary between Cameron Flowage and Wetland 59;
- Watercourse 23 south of the western waste rock stockpile extension;
- Wetland 59;
- Killag River;
- Cameron Flowage;
- Crusher Lake; and
- Mud Lake and its Outlet (WC27).

Fish abundance and population estimates for watercourses and waterbodies within the PA are presented in the Baseline Fish and Fish Habitat 2020 Technical Report (Appendix J.3).

Based on the confirmed brook trout presence in Crusher Lake, it is expected that this species would be present and utilizing open water wetland habitat in Wetland 8 and Wetland 44 on the south side of Crusher Lake. Similarly, brook trout is expected to be present in open water habitat in Wetland 17 (brook trout confirmed in Mud Lake) and the open water portion of WL59, 61, Cameron Flowage and the Killag River. There is low potential for brook trout to access open water habitats within WL56 based on a 2015 observation of brook trout in WC12; however, during all sample events completed in 2020, water levels in WC12 were dry and are expected to seasonally limit passage of brook trout into WL56.

Along the Haul Road (2016), one individual brook trout was captured in a minnow trap within Watercourse V. Electrofishing surveys identified brook trout within Watercourses N (one individual), V (six individuals), and AH (one individual). There are no wetlands directly associated with any of these watercourses within the Haul Road.

Brook trout are known to inhabit a wide range of cool, freshwater environments, from small headwater streams to large lakes. If the river habitat is suitable for brook trout and they do not experience any stressors throughout the year, they tend not to travel large distances. Most of the populations existing in larger rivers act this way, not moving until the fall at the onset of spawning. Even then, if the river has adequate habitat diversity, they tend not to travel large distances. Other populations have adapted to various river conditions. They travel very large distances (greater than 120 km) in search of thermal refuge and/or spawning habitat. Some spawn in the main stem of rivers, while others utilize tributaries (NSDAF, 2005). Though typically not anadromous, brook trout require free passage along streams to move between areas of use, including spawning grounds, overwintering, summer rearing areas.

In Nova Scotia, mature brook trout migrate to spawn in lakes or streams in the fall of the year. Trout spawning sites are usually near groundwater upwelling or spring seeps and within a lake or stream with gravel substrate (NSDFA 2005). Optimal spawning conditions for brook trout include clear substrate 3 to 8 mm in size with limited fines (less than 5%), and velocities of 25 to 75 cm/s (Raleigh 1982).

Juvenile rearing areas require cold water, stable flow, and an abundance of cover. Optimal temperature for juvenile growth is 10 to 16°C, while cover in the form of deep water, overhanging and in-stream vegetation, undercut banks, woody debris, and rocky substrate should account for a minimum of 15% of total stream area (Raleigh 1982). In winter, brook trout aggregate in pools beneath silt-free rocky substrate and close to point sources of groundwater discharge (Raleigh 1982; Cunjak and Power 1986). Adult fish use both pools and riffles, with more than 25% in-stream cover being optimal (Raleigh 1982). Brook trout respond negatively to flashy or hydrologically dynamic systems and require stable flow for all life stages (Raleigh 1982). According to Scott and Crossman (1973), brook trout "will eat any living creature its mouth can accommodate", including prey items encompassing over 80 genera of aquatic insects, terrestrial insects, fishes (including other brook trout and eggs), amphibians, and even small reptiles and mammals. As such, they are generalized feeders which can take advantage of an available prey source.

Aquatic features within the Beaver Dam Mine Site and Haul Road are considered to provide suitable habitat for a variety of life stages of brook trout. Brook trout spawning habitat in the form of clean, gravel substrates or areas of possible groundwater upwelling were identified within Watercourses 5, 12, 13, and 14 within the Beaver Dam Mine Site. Along the Haul Road, potential brook trout spawning habitat was identified in Watercourses E, K, L, N, S, T, V, Z, AE, AF, and AH. Potential young of year and juvenile rearing areas in the form of complex habitat types, moderate velocities, and an abundance and variety of cover types were also identified within these watercourses, along with WC23 in the Beaver Dam Mine Site, and Watercourses I, H, P, Q, and AG within the Haul Road. However, the extents of these habitats are mostly intermittent, small-scale, and access through some watercourses is limited by seasonal dryness (in particular WC12, WC14, and WC23).

Low velocity, homogenous systems characterized by abundant in-stream vegetation and soft substrates (e.g., WC26 and WC27 within the Beaver Dam Mine Site) may support adult life stages brook trout, but lack the habitat complexity to support earlier life stages of this species. Similarly, wetland habitat with deeper, contiguous open water habitat (Wetlands 8, 17, 44, 56, 59, and 61) may provide areas of refuge and foraging for adult brook trout, but are not considered to provide suitable spawning or juvenile rearing habitats.

6.13.4.1.2 American Eel

Across all survey years, 17 American eel (COSEWIC, Threatened) were captured within the Beaver Dam Mine Site and a total of 36 were captured within the Haul Road through electrofishing and trapping surveys.

Within the Beaver Dam Mine Site, American eel were confirmed within WC13, the KIllag River, Cameron Flowage, and Mud Lake/WC27. Within the Haul Road, American eel were identified in WC-N (West River Sheet Harbour), WC-V (tributary to Lake Alma), and WC-AH (tributary to the Morgan River). These watercourses and waterbodies are located within both the West River Sheet Harbour (Watercourse 13, the Killag River, Cameron Flowage, Mud Lake/WC27, and Watercourses N and V) and Tangier River (Watercourse AH) secondary watersheds. Wetlands contiguous with watercourses and waterbodies which are confirmed to or potentially support American eel, may also support American eel. American eel (COSEWIC, Threatened) is not currently listed under SARA or NSESA, however, American eel have the Nova Scotia provincial S-Rank of S2, by ACCDC.

As a catadromous species, eels spend the majority of their lives in freshwater, moving to the Sargasso Sea to spawn. Their distribution includes marine waters of the western Atlantic Ocean and some freshwater systems connected to the Atlantic Ocean in South America, North America, and Greenland. Within freshwater environments, American eel are habitat generalists that can tolerate a wide range of water temperatures and pH levels. American eel are frequently found in watercourses that offer structural complexity and shade in the form of coarse woody debris, varied substrate, in-stream vegetation for daytime cover, and an available food source of forage fish, invertebrates, molluscs and vegetation.

American eel are widely distributed throughout the province. Eel densities in freshwater typically diminish with distance from the sea (COSEWIC 2006), but their presence in freshwater systems is also highly dependent on the eels' capacity to migrate upstream. Barriers, such as hydroelectric dams, can severely limit or impede the upstream passage of young eels. However, American eel, particularly immature adult yellow eels, are capable of climbing vertical surfaces, provided they are rough and wet (GOMC 2007). It has been documented that American eel are not restricted to contiguous watercourses as they possess the ability to traverse over land in wet, low lying grass habitats (MacGregor 2011). As such, all hydrologically connected watercourses within the PA are believed to be potentially accessible to the American eel, even if habitat provision in those watercourses is low.

Aside from watercourses and waterbodies with confirmed presence, American eel would likely find suitable areas to mature and overwinter within the open water features and streams within the Beaver Dam Mine Site and Haul Road, particularly those systems with dominant muck substrate, a diverse benthic food source, and cover in the form of large boulders, in-stream vegetation, and coarse woody-debris. This includes Watercourses 5, 14, 25, and 26, and open water features associated with Wetlands 59 and 61 within the Beaver Dam Mine Site, and Watercourses A, B, C, D, E, F, G, J, M, N, O, Q, R, S, T, U, V, W, X, Y, Z, AA, AB, AC, AC, AD, AE, AF, AG, AH, and AI within the Haul Road. However, habitat assessments, particularly along the Haul Road, are based in some cases on very short sections of watercourses evaluated within the PA only and, therefore, should be considered as preliminary summaries of fish habitat potential, with detailed evaluation necessary during the permitting stages of this Project to confirm fish habitat.

According to COSEWIC (COSEWIC, 2013), the Maritimes region falls within the American eel's Freshwater Ecological Area 3 (FEA3). This population has had some recorded population level fluctuations, lacking an overall trend between 1989 and 2002. The St. Lawrence River and Great Lakes (FEA1) population has experienced significant reduction in populations since the early 1980s. Given that the entire population spawns in the Sargasso Sea, the reduction of any individual population or reduction in range can affect the total abundance of the species, even if all populations are not experiencing the same decline.

Threats to the abundance and distribution of the American eel include a variety of natural and anthropogenic factors that result in direct mortality or indirect impacts to quality and access to habitat. Some hydroelectric dams can prevent or limit upstream migration of eels, while resulting in direct mortality to downstream migrants. Overfishing has contributed to population reduction, as well as the spread of an introduced parasite (*Anquillicola crassus*), changes to accessibility of habitat through installation of barriers, and potential impact to quality of habitat from land use practices and climate change (COSEWIC, 2013).

6.13.4.1.3 Atlantic Salmon

The Southern Uplands Population of Atlantic salmon (*Salmo salar*) is listed as endangered by COSEWIC (2010) and is provincially ranked as S1 by the ACCDC. This population is not currently protected under SARA or NSESA. Atlantic salmon are divided into unique populations, based on genetic distinction and range. For the purposes of this discussion, we are considering only the Southern Uplands (SU) Population, as outlined by DFO in the Recovery Potential Assessment for the Southern Uplands population of Atlantic salmon (Fisheries and Oceans Canada, 2013).

The SU Population of Atlantic Salmon has experienced significant reductions over the last few decades, with adult abundance declining from 88% to 99% from observed abundances in the 1980s (DFO, 2013). Current adult and juvenile abundance has been assessed as critically low in most rivers, and there is strong evidence for river-specific extirpations – only 54% of rivers in the SU region were found to contain salmon in 2000 (Amiro et al., 2000) and only 38% were found to contain salmon in 2008 (Gibson et al., 2010). The main contributing factors to these declines are considered to be degradation of freshwater habitat, acidification, and poor marine survival (Bowlby et al., 2014).

The WRSH watershed is one of 72 watersheds within the SU region. The main river channel, the West River, is approximately 30 km long and has two main tributaries – the Killag and Little Rivers. Of particular research interest has been the presence and provision of salmon and salmon habitat within these rivers. According to Ducharme (1972), the Killag River is the most important of the three rivers for Atlantic salmon production due to the presence of excellent spawning grounds. Ducharme (1972) also identified that most of the salmon spawning within the watershed takes place in the Killag River.

Atlantic salmon are considered extirpated from the Tangier River (DFO, 2009).

Southern Upland (SU) Atlantic salmon have been found along the entire coast of Nova Scotia, from the Bay of Fundy to Cape Breton. However, the full extent of the range of SU population is not fully known. The SU Atlantic salmon spawn in fresh water from October to November and spend one to four years as juveniles in the fresh water. The majority of the juveniles migrate to the sea after two years of being in fresh water. In spring, the salmon leave the rivers and by mid-summer migrate to the Atlantic Ocean by Newfoundland and Labrador. They spend one to three years in the Atlantic Ocean before returning as adults to fresh water to spawn. The majority of adults leave the rivers in spring after spawning and recondition out at sea before spawning in freshwater again. Within the freshwater environment, the SU Atlantic salmon is found in cool, clear, well-oxygenated waters which support a reliable food source of aquatic invertebrates. Gravel and cobble is the preferred substrate for spawning (Fisheries and Oceans Canada, 2013; Fisheries and Oceans Canada, 2016a).

Prior to 2020, Atlantic salmon was not observed during any fish sampling programs. In 2020, four Atlantic salmon parr ranging in size from 98 to 111 mm were identified during electrofishing surveys in the Killag River, which was not previously sampled. The observations were outside the PA, in a reach of the Killag River east of the Beaver Dam Mine Site downstream of the lime doser (Appendix J.4, Figure J.4-1). No Atlantic Salmon have been observed within the Beaver Dam Mine Site and Haul Road throughout extensive fishing surveys (2015-2020).

Atlantic salmon have been extensively documented within the West River Sheet Harbour, the Killag River, and the Little River by the Nova Scotia Salmon Association and is presumed to be present in several tributaries to these watercourses. Within the Beaver Dam Mine Site, Atlantic salmon may travel into the most downstream ends of direct tributaries to the Killag River and Cameron Flowage, which includes WC13 and 25. However, these small first- and second-order tributaries are not considered to provide valuable habitat for salmon life cycle requirements (i.e., spawning, juvenile rearing, overwintering). In proximity to the Beaver Dam Mine Site, Atlantic salmon may access the lower ends of WC26 and WC27 from the Killag River. Like WC13 and 25, though the species may access these systems, they are not considered to provide quality habitat. Detailed habitat descriptions for these systems are summarised in Section 6.9.4.2; and fully detailed in the Baseline Fish and Fish Habitat 2020 Technical Report (Appendix J.3).

Two higher order watercourses are likely to support habitat for Atlantic salmon within the Haul Road: the West River Sheet Harbour (WC-N), and Keef Brook (WC-H). The West River Sheet Harbour is considered to provide suitable habitat for all life stages of Atlantic salmon, with clean gravel and cobble substrate in well aerated areas, to deeper holding pools for adults. Keef Brook is considered to provide suitable habitat for older juveniles, but high velocities, limited water depths, and a lack of gravel substrate limits habitat suitability for spawning, young of year, and adults. It should be emphasized that the fish habitat characterizations described for Haul Road watercourses are only applicable to the length of watercourse surveyed.

Atlantic salmon are considered extirpated from the Tangier River and are therefore not considered to inhabit watercourses within the Haul Road that fall within the Tangier River secondary watershed.

Atlantic salmon are highly sensitive to fluctuations in habitat conditions, particularly pH and temperature. As such, many land use practices and impacts to the freshwater ecosystem can affect the abundance and distribution of salmon. Summer water temperatures were identified as a limiting factor within the Cameron Flowage/Killag River system for Atlantic salmon during baseline surveys. By mid-July, shoreline temperatures within Cameron Flowage were above the optimal range for cold-water fishes, and temperatures were observed to exceed 20°C in the Killag River by late August. The pH range for many aquatic features sampled during baseline surveys are also considered limiting to Atlantic salmon habitat. However, aquatic features within the Killag River tertiary watershed were generally less acidic than those sampled in other tertiary watersheds, for example Cope Brook.

The Nova Scotia Salmon Association, recognizing the impact low pH on salmon in the West River Sheet Harbour, has been operating an acid mitigation project on the West River for over 15 years. This involves two lime dosing stations, and terrestrial (helicopter based) liming, which increase the pH of the water to a suitable range for juvenile salmon. This project has resulted in significant increase in smolt populations and improved overall habitat quality within the West River Sheet Harbour.

The Nova Scotia Salmon Association is currently using lime dosers in order to offset the acidity of watercourses and improve water quality for Atlantic salmon. Two lime dosers are currently in use, they are located within the West River Sheet Harbour and the Killag River (Appendix J.4, Figure J.4-1). Terrestrial liming programs have been implemented in the Paul Brook, Tent Brook and Keef Brook watersheds as well. Maintenance of surface water quality and quantity is imperative to the continued success of ongoing salmon restoration efforts in the West River Sheet Harbour, Killag River and their tributaries. For more information regarding The Nova Scotia Salmon Associations acid rain mitigation project refer to Section 6.9.4.1.4.

6.13.4.1.4 Priority Fish Summary

No fish SAR were observed within or in proximity to the PA. Three priority species of fish were identified during field surveys within and in proximity to the PA. American eel and brook trout were confirmed in watercourses and waterbodies within and downgradient of the PA, while Atlantic salmon was confirmed only in the Killag River, east of the Beaver Dam Mine Site and downstream of the lime doser. No other fish SOCI were observed. Alewife, while not identified during fish surveys, may use watercourses within the Haul Road (specifically the Tangier River secondary watershed) as migration corridors. No other priority species are expected based on habitat, species distribution, and survey effort completed within the PA.

6.13.4.1.5 Touquoy Mine Site

Moose River, within the Touquoy Mine Site, provides habitat for Atlantic salmon and brook trout. Good juvenile and rearing habitat and potential spawning habitat is available for Atlantic salmon. Several juvenile Atlantic salmon were observed; however, these species were believed to be from the landlocked population known to Scraggy Lake. Good adult and juvenile brook trout feeding habitat, fair rearing habitat, and potential spawning habitat is available within Moose River (CRA 2007a,b).

The Nova Scotia Department of Agriculture and Fisheries conducted a fisheries resource study in Scraggy Lake in July of 1975. Fish captured included; brook trout and American eel. Atlantic salmon smolts were recorded during creel census in 1979. Fingerling landlocked Atlantic salmon and brook trout were stocked in Scraggy Lake between 1998-2000 and 1994-1996, respectively (CRA 2007a,b).

6.13.4.2 Priority Vascular Flora Species

The desktop evaluation for priority species of vascular flora revealed that none were identified within 5 km of the PA by ACCDC reports. NSL&F has classified several species as 'location sensitive', meaning their exact locations cannot be provided to proponents in ACCDC reports. Instead, ACCDC will simply indicate whether a location sensitive species is documented within 5 km of the PA. Black ash (*Fraxinus nigra*), a location sensitive vascular flora species, was not documented within 5 km of the PA in any of the three ACCDC reports (Beaver Dam Mine Site, Haul Road, and Touquoy Mine Site).

A list of vascular plant priority species which have elevated potential to be located within the PA based on habitat preferences and known distribution is provided in Table 6.13-4. Species which have been documented within the vicinity of the PA by the Nova Scotia Department of Communities, Culture and Heritage Environmental Screening Report (Appendix I.3) are highlighted in bold text.

Table 6.13-4: List of Priority Vascular Flora Species with Elevated Potential to Occur in the Project Area

Latin Name	Common Name	SARA, COSEWIC, NSESA Status	S Rank
Lachnanthes caroliniana	Redroot	SARA & COSEWIC Special Concern, NSESA Vulnerable	S2
Potamogeton pulcher	Spotted pondweed	NSESA Vulnerable	S2S3
Fraxinus nigra	Black ash	NSESA Threatened	S1S2
Agalinis neoscotica	Nova Scotia Agalinis		S3S4
Agalinis paupercula	Small-flowered agalinis		S1
Allium burdickii	Narrow-leaved wild leek		S1?
Allium schoenoprasum	Wild chives		S2

Table 6.13-4: List of Priority Vascular Flora Species with Elevated Potential to Occur in the Project Area (continued)

Latin Name	Common Name	SARA, COSEWIC, NSESA Status	S Rank
Allium tricoccum	Wild leek		S1
Amelanchier nantucketensis	Nantucket serviceberry		S1
Anemone Canadensis	Canada anemone		S2
Arabis drummondii	Drummond's rockcress		S2
Asclepias incarnata ssp. Pulchra	Swamp milkweed		S3?
Barbarea orthoceras	American yellow rocket		S1
Bartonia virginica	Yellow bartonia		S3
Betula borealis	Northern birch		S2
Betula pumila var. pumila	Bog birch		S2S3
Betula pumila var. renifolia	Bog birch		S1?
Betula michauxii	**Michaux's dwarf birch**		**S2**
Botrychium lanceolatum var. angustisegmentum	Lance-leaf grape-fern		S2S3
Botrychium lunaria	Common moonwort		S1
Bromus latiglumis	Broad-glumed brome		S1
Cardamine pratensis var. angustifolia	Cuckoo flower		S1
Carex adusta	Lesser brown sedge		S2S3
Carex alopecoidea	Foxtail sedge		S1
Carex foenea	Fernald's hay sedge		S3?
Carex granularis	Limestone meadow sedge		S1
Carex grisea	Inflated narrow-leaved sedge		S1
Carex haydenii	Hayden's sedge		S1
Carex lapponica	Lapland sedge		S1?
Carex peckii	White-tinged sedge		S2?
Carex plantaginea	Plantain-leaved sedge		S1
Carex rosea	Rosy sedge		S3
Carex tribuloides	Blunt broom sedge		S3?
Carex tribuloides var. tribuloides	Blunt broom sedge		S3?
Carex vacillans	Estuarine sedge		S1S3
Carex viridula var. elatior	Greenish sedge		S1
Caulophyllum thalictroides	Blue cohosh		S2
Crataegus robinsonii	Robinson's hawthorn		S1?
Crataegus submollis	Quebec hawthorn		S1?
Cyperus lupulinus	Hop flatsedge		S1
Cyperus lupulinus ssp. Macilentus	Hop flatsedge		S1
Cypripedium parviflorum	Yellow lady's-slipper		S2S3
Cypripedium reginae	**Showy lady's-slipper**		**S2**
Dichanthelium acuminatum var. lindheimeri	Woolly panic grass		S1?
Eleocharis erythropoda	Red-stemmed spikerush		S1

Table 6.13-4: List of Priority Vascular Flora Species with Elevated Potential to Occur in the Project Area (continued)

Latin Name	Common Name	SARA, COSEWIC, NSESA Status	S Rank
Eleocharis ovata	Ovate spikerush		S2?
Empetrum eamesii	Pink crowberry		S3
Empetrum eamesii ssp. Atropurpureum	Pink crowberry		S2S3
Empetrum eamesii ssp. Eamesii	Pink crowberry		S2S3
Epilobium strictum	Downy willowherb		S3
Equisetum hyemale	Common scouring-rush		S3S4
Equisetum hyemale var. affine	Common scouring-rush		S3S4
Equisetum palustre	Marsh horsetail		S1
Equisetum variegatum	Variegated horsetail		S3
Erigeron philadelphicus	Philadelphia fleabane		S2
Eriophorum gracile	Slender cottongrass		S2
Eupatorium dubium	Coastal plain joe-pye-weed		S2
Festuca prolifera	Proliferous fescue		S1S2
Fraxinus pennsylvanica	Red ash		S1
Galium aparine	Common bedstraw		S2S3
Galium obtusum ssp. Obtusum	Blunt-leaved bedstraw		S2S3
Geocaulon lividum	Northern comandra		S3
Geranium bicknellii	Bicknell's crane's-bill		S3
Goodyera pubescens	Downy rattlesnake-plantain		S2
Halenia deflexa ssp. brentoniana	Spurred gentian		S1?
Hieracium paniculatum	Panicled hawkweed		S3
Hieracium scabrum var. leucocaule	Rough hawkweed		S1
Hordeum brachyantherum	Meadow barley		S1
Humulus lupulus var. lupuloides	Common hop		S1?
Hypericum dissimulatum	Disguised St John's-wort		S2S3
Hypericum majus	Large St John's-wort		S2
Impatiens pallida	Pale jewelweed		S2
Isoetes acadiensis	Acadian quillwort		S3
Juncus dudleyi	Dudley's rush		S3
Juncus subcaudatus	Woods-rush		S3
Juncus subcaudatus var. planisepalus	Woods-rush		S3
Limosella australis	Southern mudwort		S3
Liparis loeselii	Loesel's twayblade		S3S4
Listera australis (syn. Neottia bifolia)	Southern twayblade		S3
Lycopodium complanatum	Northern clubmoss		S3S4
Lycopodium sabinifolium	Ground-fir		S3?
Lysimachia quadrifolia	Whorled yellow loosestrife		S1
Minuartia groenlandica	Greenland stitchwort		S3

Table 6.13-4: List of Priority Vascular Flora Species with Elevated Potential to Occur in the Project Area (continued)

Latin Name	Common Name	SARA, COSEWIC, NSESA Status	S Rank
Myriophyllum farwellii	Farwell's water milfoil		S2
Ophioglossum pusillum	Northern adder's-tongue		S2S3
Panicum dichotomiflorum var. puritanorum	Fall panic grass		S1?
Panicum tuckermanii	Tuckerman's panic grass		S3S4
Pilea pumila	Dwarf clearweed		S1
Pilea pumila var. pumila	Dwarf clearweed		S1
Piptatherum canadense	Canada rice grass		S2
Plantago rugelii	Rugel's plantain		S2S3
Plantago rugelii var. rugelii	Rugel's plantain		S2S3
Platanthera flava var. herbiola	Pale green orchid		S2
Platanthera grandiflora	Large purple fringed orchid		S3
Polygala sanguinea	Blood milkwort		S2S3
Polygonum careyi	Carey's smartweed		S1
Polypodium appalachianum	Appalachian polypody		S3?
Potamogeton obtusifolius	Blunt-leaved pondweed		S3
Potamogeton zosteriformis	Flat-stemmed pondweed		S2S3
Potentilla Canadensis	Canada cinquefoil		S2S3
Potentilla canadensis var. Canadensis	Canada cinquefoil		S2S3
Proserpinaca palustris	Marsh mermaidweed		S3
Pyrola asarifolia	Pink pyrola		S3
Pyrola asarifolia ssp. Asarifolia	Pink pyrola		S3
Ranunculus gmelinii+	Gmelin's water buttercup		S3
Ranunculus pensylvanicus	Pennsylvania buttercup		S1
Ranunculus sceleratus	Cursed buttercup		S1S2
Ranunculus sceleratus var. sceleratus	Cursed buttercup		S1S2
Rhamnus alnifolia	**Alder-leaved buckthorn**		**S3**
Rhinanthus minor ssp. groenlandicus	Little yellow rattle		S1
Rosa acicularis	Prickly rose		S1
Rosa acicularis ssp. Sayi	Prickly rose		S1
Rudbeckia laciniata	Cut-leaved coneflower		S1S2
Rudbeckia laciniata var. gaspereauensis	Cut-Leaved coneflower		S1S2
Rumex persicarioides	Peach-leaved dock		S2?
Salix pedicellaris	Bog willow		S2
Salix sericea	Silky willow		S2
Salix serissima	Autumn willow		S1
Saxifraga cernua	Nodding saxifrage		S1
Schizaea pusilla	Little curlygrass fern		S3
Sisyrinchium atlanticum	Eastern blue-eyed-grass		S3S4

Table 6.13-4: List of Priority Vascular Flora Species with Elevated Potential to Occur in the Project Area (continued)

Latin Name	Common Name	SARA, COSEWIC, NSESA Status	S Rank
Sisyrinchium fuscatum	Coastal plain blue-eyed-grass		S1
Solidago latissimifolia	Elliott's goldenrod		S3S4
Spiraea septentrionalis	Northern meadowsweet		S1?
Stellaria crassifolia	Fleshy stitchwort		S1
Stellaria crassifolia var. crassifolia	Fleshy stitchwort		S1
Stellaria longifolia	Long-leaved starwort		S2
Stellaria longifolia var. longifolia	Long-leaved starwort		S2
Symphyotrichum boreale	Boreal aster		S2?
Symphyotrichum undulatum	Wavy-leaved aster		S2
Thalictrum venulosum	Northern meadow-rue		S1
Torreyochloa pallida var. pallida	Pale false manna grass		S1
Trichostema dichotomum	Forked bluecurls		S1
Trisetum spicatum	Narrow false oats		S3S4
Utricularia ochroleuca	Yellowish-white bladderwort		S1
Vaccinium caespitosum	Dwarf bilberry		S3
Vaccinium ovalifolium	Oval-leaved bilberry		S1
Vaccinium uliginosum	Alpine bilberry		S3
Vallisneria Americana	Wild celery		S2
Veratrum viride	Green false hellebore		S1
Veronica serpyllifolia ssp. Humifusa	Thyme-leaved speedwell		S2S3
Viola nephrophylla	**Northern bog violet**		**S2**
Viola sagittata	Arrow-leaved violet		S3S4
Viola sagittata var. ovata	Arrow-leaved violet		S3S4
Zizia aurea	**Golden alexanders**		**S1**

6.13.4.2.1 Priority Vascular Flora Observed within the Beaver Dam Mine Site and Haul Road

A total of 295 species of vascular flora have been identified in field assessments within the Beaver Dam Mine Site and Haul Road. A comprehensive list of species identified is provided in Appendix K.1 and discussed in Section 6.10.4. No SAR vascular plant species were observed. A total of six flora are SOCI species, based on provincial status ranks (S3 and S3S4), including an additional vascular plant species, Nova Scotia Agalinis (*Agalinis neoscotica*, S3S4), observed during additional field surveys in 2019. These SOCI identified within the Beaver Dam Mine Site and Haul Road are outlined in Table 6.13-5.

Table 6.13-5: Priority Vascular Flora Observed within the Beaver Dam Mine Site and Haul Road

Common Name	Scientific Name	COSEWIC/ SARA/NSESA	S-Rank	Habitat in Project Area
Wiegand's sedge	*Carex wiegandii*	-	S3	Observed in three locations, all within the Beaver Dam Mine Site. Within Wetlands 12 and 33, and in one upland location between Wetlands 48 and 13.
Lesser rattlesnake plantain	*Goodyera repens*	-	S3	Observed in one location on the upland margin of Wetland 29, within the Beaver Dam Mine Site.
Southern twayblade	*Listera australis (syn. Neottia bifolia)*	-	S3	Observed along the Haul Road in Wetlands 80, 115, 129, 135, 137, 147, 161 and within the upland between 137 and 136. Twayblade was typically observed in clumps of 1-5 individuals.
Appalachian polypody	*Polypodium appalachianum*	-	S3	Observed in one location immediately adjacent to Wetland 137 growing on a boulder within the Haul Road.
Highbush blueberry	*Vaccinium corymbosum*	-	S3S4	Observed in one location within Wetland 157 within the Haul Road.
Nova Scotia Agalinis	*Agalinis neoscotica*	-	S3S4	Observed in two locations along existing access roads in the southeast expansion of the Beaver Dam Mine Site.

6.13.4.2.2 Wiegand's Sedge

Wiegand's sedge (*Carex wiegandii*) was identified in three locations within Beaver Dam Mine Site. This species is a member of the Stellulatae section of the genus Carex. This species grows in a tuft formation in acidic peatlands, black spruce and larch bogs, and conifer and alder thickets. Within the PA, it was located in two wetlands and one nearby upland area. Wetland 12 is an open treed swamp with mixed canopy coverage and organic soils up to 35 cm deep. The wetland has some disturbance from timber harvesting, resulting in an open canopy. Wetland 33 is a coniferous treed swamp with organic soils exceeding 40 cm depth. This wetland has also experienced some timber harvesting yet has a relatively diverse vegetation community including *Carex Wiegandii*. The upland habitat in which Wiegand's sedge was identified is a disturbed habitat as well, adjacent to a watercourse which connects wetlands 48 and 13. In Nova Scotia, Wiegand's sedge is considered vulnerable by ACCDC (S3). Wiegand's sedge grows in clumps or clusters of many individual plants. Where *C. wiegandii* was observed, the population consisted of one to five clumps of individuals, covering approximately 0.5 to 1 m^2.

6.13.4.2.3 Lesser Rattlesnake Plantain

Lesser rattlesnake plantain (*Goodyera repens*) is a small, inconspicuous member of the orchid family (*Orchidaceae*), found in coniferous forests throughout Nova Scotia. Within the PA, two individuals were identified on the upland edge of wetland 29, in a coniferous forest, adjacent to recent timber harvesting. Ground cover was sparse, which is typical habitat for this species. Within Nova Scotia, it is infrequent, but can be numerous where found based on its rhizomatous grown pattern. In Nova Scotia, lesser rattlesnake plantain is considered vulnerable by ACCDC (S3).

6.13.4.2.4 Southern Twayblade

Southern twayblade *(Listera australis, syn. Neottia bifolia*) is a small inconspicuous member of the orchid family (Orchidaceae), which has been found in eight locations within the Haul Road: Wetlands 80, 115, 129, 135, 137, 147, and 161, and in upland habitat between Wetland 136 and 137. This species belongs to the Atlantic Coastal Plain Flora community and its primary habitat is shaded sphagnum mosses in bogs or coniferous treed swamps. Within the PA, it was typically found in clusters of 5-10 individual plants at the base of small sphagnum hummocks in treed swamps. Its distribution is scattered throughout Nova Scotia and it is considered vulnerable by the ACCDC (S3).

6.13.4.2.5 Appalachian Polypody

Appalachian polypody (*Polypodium appalachianum*) is a member of the Polypody fern family (Polypodiaceae). Its habitat is restricted to cliffs, rocky slopes, bedrock outcrops, and boulders. A population of approximately seven individuals was identified in upland habitat adjacent to wetland 137 (a mixed wood treed swamp) within the Haul Road. The distribution throughout the province is unclear and it is considered vulnerable by the ACCDC (S3).

6.13.4.2.6 Highbush Blueberry

Highbush blueberry (*Vaccinium corymbosum*) is an ericaceous shrub (family Ericaceae) in the Atlantic Coastal Plain Flora community. This species is usually limited to bogs, rock barrens, and lakeshores around Digby and Queens Counties, but it can be found in other locations with remnant populations of Atlantic Coastal Plain Flora. Within the Haul Road, two individuals were identified in wetland 157. This wetland is a treed swamp which is immediately adjacent to Upper Kidney Lake. This species is considered vulnerable to apparently secure by the ACCDC (S3S4).

6.13.4.2.7 Nova Scotia Agalinis

Nova Scotia Agalinis (*Agalinis neoscotica*) is a flowering plant part of the figwort family (Scrophulariaceae) within the Atlantic Coastal Plain Flora community. This species is typically found on saturated sandy or peaty soils, commonly within freshwater (bogs) and saline wetland and along lake and seashores. Two individuals were observed along existing access roads in the southeast expansion of the Beaver Dam Mine Site. This species is considered vulnerable to apparently secure by the ACCDC (S3S4).

6.13.4.2.8 Priority Vascular Flora Summary

Six vascular flora SOCI were identified within the Beaver Dam Mine Site and Haul Road. Three vascular flora SAR were identified as having elevated potential to be located within the Beaver Dam Mine Site and Haul Road based on habitat preference and known distribution, however no vascular flora SAR were identified. These species, listed in Table 6.13-5, are redroot (*Lachnanthes caroliniana*, SARA & COSEWIC Special Concern, NSESA Vulnerable), spotted pondweed (*Potamogeton pulcher*, NSESA

Vulnerable), and black ash *(Fraxinus nigra*, NSESA Threatened). The preferred habitats for each of these species were focused on during all vegetation, habitat, and wetland delineation surveys. All priority vascular plant species identified in the Beaver Dam Mine Site and Haul Road are shown on Figures 6.13-2A to 6.13-2E.

6.13.4.2.9 Touquoy Mine Site

No SOCI plants were observed during vascular plant surveys conducted in August 2004, May and June 2005, and September 2006 as part of the EARD process (CRA 2007a).

One black ash (Fraxinus nigra) was discovered within the Touquoy Mine Site incidentally during wetland surveys in September 2015. The permitted loss of the Black Ash as part of Touquoy Mine Site development occurred in the Spring of 2016, after the Mi'kmaq of Nova Scotia were consulted.

6.13.4.3 Priority Lichen Species

The desktop evaluation for priority lichen species revealed that boreal felt lichen (*Erioderma pedicellatum*) has been documented within 5 km of the PA in both the Beaver Dam Mine Site/Haul Road and Touquoy Mine Site ACCDC reports (Appendices I.1 and I.2). Boreal felt lichen is listed as Endangered by COSEWIC, SARA, and NSESA, and ranked S1 by the ACCDC. NSL&F has not determined any lichen species to be 'location sensitive'. A list of lichen priority species which have elevated potential to be located within the PA, based on habitat preferences and known distribution is provided in Table 6.13-6. No lichen species were documented by the Nova Scotia Department of Communities, Culture and Heritage Environmental Screening Report (Appendix I.3). Species provided by MTRI are bolded.

Table 6.13-6: Priority Lichen Species with Elevated Potential to Occur in the Project Area

Common Name	Scientific Name	SARA	COSEWIC	NSESA	S-Rank
Boreal felt lichen - Atlantic pop.	***Erioderma pedicellatum (Atlantic pop.)***	**Endangered**	**Endangered**	**Endangered**	**S1**
Graceful felt lichen (Vole ears lichen)	*Erioderma mollissimum*	Endangered	Endangered	Endangered	S1S2
Blue felt lichen	***Pectania plumbea***	**Special Concern**	**Special Concern**	**Vulnerable**	**S3**
Black-foam lichen	*Anzia colpodes*	Threatened	Threatened	Threatened	S3
Frosted glass-whiskers	*Sclerophora peronella*	Special Concern	Special Concern		S1?
Black-footed reindeer lichen	*Cladina stygia*	-	-	-	S3?
Blistered tarpaper lichen	*Collema furfuraceum*	-	-	-	S3
White-rimmed shingles lichen	*Fuscopannaria leucosticte*	-	Threatened	-	S2S3

Surveys for lichen were completed on February 19, May 2-5, May 8, and 23, 2015 as well as September 18, 2018 and October 29, 2018 within the Beaver Dam Mine Site and surrounding Lichen Study Area (LSA) and May 25th and 26th, 2016 within the Haul Road. Additional targeted surveys were completed in the western and southeastern expansions of the Beaver dam Mine Site on July 10 and August 26, 2019. Eleven priority lichen species occurrences were observed within the LSA and Haul Road. Of the eleven species observed, three are SAR and eight are SOCI, as provided in Table 6.13-7. Of the three SAR identified, two are located within the PA. Blue felt lichen was observed in the Beaver Dam Mine Site and Haul Road and in the broader LSA, while frosted glass whiskers was identified within the Beaver Dam Mine Site. Boreal felt lichen was identified in the LSA originally by the Project Team, but not within the PA. However, upon return in 2016 and 2017, the three observed locations of the boreal felt lichen were no longer present. Locations where lichen SAR and SOCI species were observed are shown on Figures 6.13-2A to 6.13-2E.

Table 6.13-7: Priority Lichen Observed within the Beaver Dam Mine Site, Haul Road and Lichen Study Area

Common Name	Scientific Name	SARA/COSEWIC/ NSESA	S-Rank	Location in the Project Area
Blistered jellyskin lichen	*Leptogium corticola*	-	S3	Six locations observed within the Beaver Dam Mine Site, east of Wetland 29, upland island in Wetland 2, adjacent to Wetland 61, within Wetland 4 and two within/adjacent to Wetland 205. One individual observed north of the PA, in the LSA.
Blistered tarpaper lichen	*Collema nigrescens*	-	S3	Identified in one location northeast of Cameron Flowage, outside the PA, in the LSA.
Blue felt lichen	*Pectania plumbea*	SARA/COSEWIC Special Concern NSESA Vulnerable	S3	Identified in 33 locations within the Beaver Dam Mine Site (17), broader LSA (12), and along the Haul Road (4).
Boreal felt lichen	*Erioderma pedicellatum*	Endangered	S1	Historically identified by the Project Team in three locations to the southwest of Beaver Dam Mine Site, in the LSA, within an un-delineated portion of Wetland 29. Follow up surveys in 2016 and 2017 confirmed its absence.
Frosted glass-whiskers lichen	*Sclerophora peronella*	SARA/COSEWIC Special Concern	S1?	Identified in eight locations within the Beaver Dam Mine Site, adjacent to Wetlands 2 and 29 and one individual east of Wetland 216.
Peppered moon lichen	*Sticta fuliginosa*	-	S3	Identified in four locations within the Beaver Dam Mine Site: two north of Wetland 2, one within Wetland 17 and one north of Crusher Lake. One individual was observed southwest of the PA, in the LSA.
Eastern candlewax lichen	*Ahtiana aurescnes*	-	S2S3	Two locations of three individuals were identified within Wetlands 10 and 14 within the Beaver Dam Mine Site.
Slender monk's hood lichen	*Hypogymnia vittata*	-	S3S4	Identified in four locations within the Beaver Dam Mine Site: one within Wetland 222, one within Wetland 64 and two locations (five individuals) within Wetland 212.
Salted shell lichen	*Coccocarpia palmicola*	-	S3S4	Fifteen locations were identified within the Beaver Dam Mine Site. Seven other observations were made outside the PA, in the LSA.
Powdered fringe lichen	*Heterodermia speciosa*	-	S3	One individual located east of Wetland 216 within the Beaver Dam Mine Site.
Fringe lichen	*Heterodermia neglecta*	-	S3S4	One individual located northeast of Wetland 216 within the Beaver Dam Mine Site.

6.13.4.3.1 Blistered Jellyskin Lichen

Blistered jellyskin lichen (*Leptogium corticola*) was observed in seven locations growing on red maple along the edges of wetlands and lacustrine habitats. This species is a foliose lichen belonging to the Collemataceae family. This lichen is found primarily on the base of hardwood trees in moist environments, but occasionally can be found growing on rocks and boulders. Six observations occurred within the Beaver Dam Mine Site while one was observed outside the PA in the broader LSA. Of the six found in the Beaver Dam Mine Site, two occurrences were observed in Wetlands 4 and 205, both mixed-wood swamps or swamp-fen complexes. Four occurrences were directly adjacent to Wetlands 2, 29, 61 and 205, also mixed-wood wetland complexes. In Nova Scotia, blistered jellyskin lichen is considered uncommon in the province by the ACCDC (S3). All observations were associated with the Beaver Dam Mine Site and broader LSA; none were observed within the Haul Road.

6.13.4.3.2 Blistered Tarpaper Lichen

Blistered tarpaper lichen (*Collema nigrescens*) was observed at one location spreading over a length of 4 m over a red maple on a slope leading to a lake/clear-cut, approximately 200 m northeast of the northern extent of Cameron Flowage, outside of the PA within the broader LSA. This species is a foliose lichen belonging to the Collemataceae family. This species is typically found growing on the bark of poplar trees and other hardwood trees in mature forests. None were observed within the Haul Road. In Nova Scotia, blistered tarpaper lichen is considered uncommon in the province by the ACCDC (S3).

6.13.4.3.3 Blue Felt Lichen

Blue felt lichen (*Pectania plumbea*) was observed in 33 locations on mature red maple trees in a variety of habitats, including wetland edges, edges of clear-cut, and lacustrine habitat, which were within and in proximity to the PA. This species is typically found in mature hardwood forests in varying moisture regimes. This species is a foliose lichen and a member of the Pannariaceae family.

Of the 33 observations, 17 were located within the Beaver Dam Mine Site and 12 observations were in the broader LSA surrounding the Beaver Dam Mine Site. Four occurrences were located along the section of Haul Road where new road construction will be required. Within the Beaver Dam Mine Site, seven observations were documented on the edge of and within Wetland 14 (swamp-bog-fen complex), three within the delineated portion of Wetland 17 (tall-shrub swamp-treed bog complex), one within Wetland 4 (treed swamp-fen complex) and one within Wetland 205 (mixed-wood swamp). Additional occurrences were observed in wetland-adjacent upland habitat 17 m southwest of Wetland 61 (shrub-fen complex), 9 m north of Wetland 2 (bog), 4 m south of Wetland 1 (bog) and 5 m south of Wetland 29 (swamp-fen-bog complex). The four occurrences found along the Haul Road were found on mature red maple trees in a mature mixed wood forest or treed swamps (i.e., Wetland 112). Three occurrences were just beyond the Haul Road, 350 and 170 m northwest of Wetland 126 and 90 m south of Wetland 116. This species is listed as special concern by COSEWIC and SARA and vulnerable by NSESA and S3 by the ACCDC.

An At-Risk-Lichens Special Management Practices (SMP) was released by NSL&F on May 23, 2018. The At-Risk-Lichens SMP lists blue felt lichen as a rare and sensitive species (NSRNR, 2018).

6.13.4.3.4 Boreal Felt Lichen

Boreal felt lichen (*Erioderma pedicellatum*) was observed in three locations on mature balsam fir stands on the edges of the undelineated portion of Wetland 29, outside of the Beaver Dam Mine Site but within the broader LSA, on May 8, 2015. Typically, this species is found on mature balsam fir stands, but it has been documented on spruce, red maple and birch. Habitat within portions of the PA appeared to be suitable for this species as indicated by two foliose lichen species commonly found in boreal felt lichen habitat which were present throughout the LSA and within the PA. These two foliose lichens were salted shell lichen (*Coccocarpia palmicola*) and textured lungwort (*Lobaria scrobiculata*). However, boreal felt lichen was not observed with the PA. Additionally, a follow up survey conducted in the fall of 2016 determined that all three observed thalli in wetland 29 were no longer present. Their absence was reconfirmed on December 4, 2017. ACCDC has noted an additional eight occurrences of boreal felt lichen within the defined critical/core habitat in the LAA.

Boreal felt lichen is a red-listed, critically endangered species worldwide. It is listed as endangered by COSEWIC, SARA, NSESA, and S1 by the ACCDC. The Amended Recovery Strategy for the Boreal Felt lichen (*Erioderma pedicellatum*) Atlantic population, in Canada (ECCC, 2018) was released in 2018. Micro-siting of Project infrastructure was completed based on the identification of the species' updated critical/core habitat as outlined within the Amended Recovery Strategy (ECCC, 2018) and the NSE adopted Recovery Plan for Boreal Felt Lichen (NSE, 2020). Boreal felt lichen is also listed within the NSL&F At-Risk-Lichens SMP (NSDNR, 2018). This SMP updated and replaced the previous SMP (2012).

6.13.4.3.5 Frosted Glass-whickers Lichen

Frosted glass-whiskers lichen (*Sclerophora peronella*) was observed in eight locations on red maple trees primarily in upland habitat, adjacent to wetlands 2, 29 and 216 within the Beaver Dam Mine Site. This species belongs to the Coniocybaceae family and is a very small (1 mm) fruticose lichen and typically grows in old growth forests with relatively stable humidity levels and usually on the heartwood of hardwood trees. It very rarely grows on bark. Four separate populations were found scattered along the edge of the central inland inclusion within wetland 2. Populations ranged from approximately 10 individual lichens covering less than 0.5 cm^2 to an excess of 200 individuals over an area measuring 240 cm^2. This species was also found west of wetland 2 in upland forests. An additional two observations were documented 20 m east of wetland 29 and 20 m north of the southern wetland/upland boundary of the central upland inclusion in wetland 29. Areas within the Beaver Dam Mine Site and Haul Road contained moderately suitable habitat for this species, primarily along the proposed new section of the Haul Road (Section 2, Figure 2.3-1) where more mature hard wood stands with exposed heartwood were found. Despite the presence of suitable habitat within the Haul Road, no specimens were observed. This species is listed as special concern by COSEWIC and SARA.

This species was not identified as having a high likelihood to be present within the PA during the desktop evaluation for rare lichens. This is because it is outside of the previously documented range of this species. According to the Identification and Information Guide to Species at Risk in Nova Scotia (Mersey Tobeatic Research Institute, 2008), Frosted glass whiskers had only been documented in two locations in northwestern Cape Breton Island (Inverness County). This presumed range of this species meant it was excluded from the priority species list, based on known distribution at the time of the desktop review. Since the publication of this Guide, the number of records of this species in Nova Scotia has increased. According to the ACCDC (J. Churchill, Pers. Comm., 2016), this species currently has 30 confirmed records in the database, throughout the province. The Project Team confirmed with the lichen specialist that completed the Beaver Dam surveys that he has submitted another 35 records to ACCDC for inclusion into their database. He also confirmed that this species is largely over looked and under-reported, because of the very small size and cryptic nature of the species.

Similarly, to blue felt lichen, The At-Risk-Lichens SMP (NSDNR, 2018) lists frosted glass-whiskers lichen as a rare and sensitive species.

6.13.4.3.6 Peppered Moon Lichen

Peppered moon lichen (*Sticta Fuliginosa*) was observed primarily on mature red maples near the boundary and within wetland habitat. Four populations were observed within the Beaver Dam Mine Site and one was observed outside the PA within the broader LSA. Within the PA, *S. fuliginosa* was observed in two locations north of Wetland 2, north of Wetland 10, and inside wetland 17. Wetland 2 is a large complex consisting of a treed-bog, graminoid bog, and low shrub bog, Wetland 10 is a low shrub fen, and Wetland 17 is a complex consisting of a tallshrub swamp and coniferous treed bog. In Nova Scotia, peppered moon lichen is considered vulnerable by ACCDC (S3). No observations of this species were documented within the Haul Road.

6.13.4.3.7 Eastern Candlewax Lichen

Eastern candlewax lichen (*Ahtiana aurescnes*) was observed on balsam fir along the edge habitat of Wetlands 10 and 14, both within the Beaver Dam Mine Site. Wetland 10 is a low shrub fen and Wetland 14 is a complex comprised of shrub bog, mixed wood treed swamp, and low shrub fen. The observation of eastern candlewax lichen in Wetland 14 occurred in the shrub bog portion of this complex. The ACCDC identifies eastern candlewax lichen as S2S3. No observations of this species were documented within the Haul Road.

6.13.4.3.8 Slender Monk's Hood Lichen

Four locations of slender monk's hood lichen (*Hypogymnia vittata*) were within Wetlands 64, 222 and 212 (two locations of five individuals) within the Beaver Dam Mine Site. Occurrences were found on black spruce within mixed-wood tree and shrub dominated swamps. Slender monk's hood lichen is a foliose lichen ranked as S3S4 by the ACCDC. This lichen was not observed incidentally or during dedicated surveys along the Haul Road.

6.13.4.3.9 Salted Shell Lichen

Salted shell lichen (*Coccocarpia palmicola*) was observed within the Beaver Dam Mine Site and beyond the PA, within the LSA. No observations of this species were documented within the Haul Road. Within the Beaver Dam Mine Site fifteen locations of salted shell lichen were identified; three within Wetland 220, three west of Wetland 231, two within Wetland 205, two within Wetland 212, one within Wetland 4, one within Wetland 64, one west of Wetland 236, one adjacent to Wetland 219 and one on an upland island within Wetland 29. One of the two populations within Wetland 212 appeared to be unhealthy and was observed on a dying black spruce. Seven additional occurrences were observed within the broader LSA. According to Nash et al. (2002), salted shell lichen inhabit rocks and soil in moist habitats as well as trees. Salted shell lichen is listed as S3S4 by the ACCDC.

6.13.4.3.10 Powdered Fringe Lichen

According to Nash et al. (2002), powdered fringe lichen *(Heterodermia speciosa*) are primarily found on moist rocks or on tree trucks in humid climates. Within Beaver Dam Mine Site, this lichen was found on a mature red maple, east of Wetland 216. No observations of this species were documented within the Haul Road. Powdered fringe lichen is ranked as S3 by the ACCDC.

6.13.4.3.11 Fringe Lichen

An individual fringe lichen (*Heterodermia neglecta*) was found northeast of Wetland 216, 13 m south of the Killag River on a red maple. No observations of this species were documented within the Haul Road. Fringe lichen is ranked as S3S4 by the ACCDC.

6.13.4.3.12 Priority Lichen Summary

While the specific habitat requirements of each of these priority species varies slightly, the common thread between each of these species' habitat requirements is mature to over-mature forests. Stand age is one of the greatest determinants of lichen diversity (McMullin, Duinker, Cameron, Richardson, & Brodo, 2008). Within the Beaver Dam Mine Site, mature to over-mature stands are infrequent, with the majority of the PA having been harvested for timber production. Mature to over-mature forests within the Beaver Dam Mine Site that remain are typically associated with large wetland complexes, which are often avoided during timber harvesting. Mature to over-mature forest suitable for rare lichens is present within the Haul Road, primarily where the proposed route involves new construction. No other species of priority non-vascular flora were identified within the PA.

In total, 11 priority lichen species were observed during lichen surveys, three SAR and eight SOCI. Of the three SAR identified, two are located within the PA. Blue felt lichen was observed in the Beaver Dam Mine Site, Haul Road and in the broader LSA, while Frosted Glass Whiskers was only identified within the Beaver Dam Mine Site. Boreal felt lichen was identified beyond the PA, in the LSA. As discussed, the three occurrences observed by the Project Team may no longer be extant and their status will be verified through the Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6). The locations of all priority lichen species documented within and adjacent to the PA are provided on Figures 6.13-2A to 6.13-2E.

6.13.4.3.13 Touquoy Mine Site

Lichen surveys conducted in the Touquoy Mine Site in 2004 and 2005 as part of the EARD process found the presence of blue felt lichen (*Degelia plumbea*). An additional lichen survey in 2007 found seven additional SOCI including; salted shell lichen (*Coccocarpia palmicola*), corrugated shingles lichen (*Fuscopannaria ahlneri*), powdered fringe lichen (*Heterodermia speciosa*), blistered jellyskin lichen (*Leptogium corticola*), blue-gray moss shingle lichen (*Moelleropsis nebulosa*), naked kidney lichen (Nephroma bellum), and peppered moon lichen (*Sticta fuliginosa*) (CRA 2007a).

6.13.4.4 Priority Terrestrial Mammal Species

The desktop evaluation for priority species of terrestrial fauna revealed that mainland moose (*Alces americanus*) has been documented within 5 km of the PA by the ACCDC reports (Appendices I.1 and I.2). Three records were available for moose within 5 km of the Beaver Dam Mine Site, while the mainland moose was not documented within 5 km of the Haul Road or Touquoy Mine Site. Mainland moose are listed as Endangered under the NSESA and is provincially ranked as rare by ACCDC (S1).

NSL&F has determined that bat hibernacula sites are 'location sensitive', meaning that their exact locations cannot be provided to proponents in ACCDC reports. No bat hibernaculum were documented within 5 km of the PA by the ACCDC reports. The Project Team reviewed the Recovery Strategy for Little Brown Myotis, Northern Myotis, and Tri-colored Bat in Canada (2015), which confirmed that no known critical habitat (hibernacula) is located in the vicinity of the PA.

A list priority mammal species which have elevated potential to be located within the PA, based on habitat preferences and known distribution is provided in Table 6.13-8. No mammal species were documented by the Nova Scotia Department of Communities, Culture and Heritage Environmental Screening Report (Appendix I.3).

Table 6.13-8: Priority Terrestrial Fauna Species with Elevated Potential to Occur in the Project Area

Common Name	Scientific Name	SARA	COSEWIC	NSESA	S-Rank
Eastern pipistrelle (Tri-coloured bat)	*Perimyotis subflavus*	Endangered	Endangered	Endangered	S1
Eastern red bat	*Lasiurus borealis*	-	-	-	S1S2B, S1M
Hoary bat	*Lasiurus cinereus*	-	-	-	S1S2B, S1M
Little brown myotis	*Myotis lucifugus*	Endangered	Endangered	Endangered	S1
Maritime shrew	*Sorex maritimensis*	-	-	-	S3
Mainland moose	*Alces alces americanus*	-	-	Endangered	S1
Northern long-eared myotis	*Myotis septentrionalis*	Endangered	Endangered	Endangered	S1
Rock vole	*Microtus chrotorrhinus*	-	-	-	S2
Silver-haired bat	*Lasionycteris noctivagans*	-	-	-	SUB, S1M

6.13.4.4.1 Mainland Moose

The mainland moose (*Alces alces americana*) is listed as endangered under NSESA and considered S1, or critically imperiled, by the ACCDC. The moose is the largest member of the deer family (Cervidae), which prefers boreal forest and mixed wood habitats with an abundant food source of young twigs and stems from deciduous trees and shrubs. As a large mammal, they are prone to thermal stress in the summer, often seeking refuge in coniferous forests with full canopy cover. As adept swimmers, they often forage for submerged aquatic vegetation during the summer as well, which provide minerals critical for antler growth. During winter, their long legs and large bodies allow them to move through deep snow, relatively unhindered by cold weather, which may be restrictive to smaller Cervids such as white-tailed deer.

While moose habitat preferences can change as the abundance of available habitat changes (Osko, Hiltz, Hudson, & Wasel, 2004), and habitat selection shows a high degree of variability among individuals (McLaren, Taylor, & Luke, 2009), moose generally require large areas with diverse habitat types (Snaith & Beazley, 2004). Moose habitat preferences are correlated with forage and cover requirements, as well as breeding behaviours (Peek, Urich, & Mackie, 1976). Early successional deciduous vegetation is the main source of moose forage, food types often associated with open or disturbed areas (Snaith, Beazley, MacKinnon, & Duinker, 2002; Snaith & Beazley, 2004; Parker, 2003). The presence of such early successional trees and shrubs is particularly important during the winter months (Parker, 2003). Regenerating vegetation provides good moose browse for 5 to 40 years following disturbances, such as fire, disease, timber harvest, and wind-throw (Snaith, Beazley, MacKinnon, & Duinker, 2002; Snaith & Beazley, 2004). Fire appears to be the most important disturbance in terms of providing quality moose habitat (Parker, 2003 and references therein). Critical habitat for moose in Alberta was described as open lowlands providing high quality food early in the spring (Hauge & Keith, 1981).

In Nova Scotia, the most important food species are red, sugar, and mountain maple, as well as yellow and white birch (Snaith & Beazley, 2004). In the summer months, particularly in June, aquatic vegetation can be an important component of the diet of moose (Peek, Urich, & Mackie, 1976; Fraser, Arthur, Morton, & Thompson, 1980), but the fact that moose have persisted in areas containing infrequent or unsuitable wetlands suggests that these areas are not essential foraging grounds for moose in Nova Scotia (Snaith & Beazley, 2004). This is supported by the findings of Telfer (1967a) who observed no feeding of moose on aquatic vegetation in the Cobequid region. Water bodies such as streams, ponds, and lake shorelines can be important for relief from heat stress in the summer months (Parker, 2003) because moose are not well adapted for temperatures above 14 to 20°C (Snaith & Beazley, 2004). Moose have also been shown to preferentially select dense, mature forests with a closed canopy in the summer

months (Schwab and Pitt 1991) because the canopy provides shade and heat relief. Dussault et al. (2004) determined that moose showed behavioural adaptations to avoid heat stress in the summer, including using thermal shelters during the day and increasing nocturnal activity.

When female moose give birth to their calves in the spring of the year, they often select islands or peninsulas because of the protection from predators they afford, or areas of high elevation because of visibility in availability of escape routes (Wilton & Garner, 1991). In mountainous regions of British Columbia, however, only 52% of 31 GPS-collared female moose climbed to higher elevations to calve, while the other 48% changed little in elevation (Poole, Serrouya, & Stuart-Smith, 2007). These researchers found that those females that remained at lower elevations preferentially selected areas with increased forage, decreased slope, and in closer proximity to water. Langley & Pletscher (1994) characterized calving areas in Montana and British Columbia as having dense hiding cover and open patches with bare ground. Cederlund, Sandegren, & Larsson (1987) found that all cows returned to the same summer range each spring, and Bogomolova and Kurochkin (2002) determined that cows returned to the same area of the forest every year before giving birth.

Although not considered critical habitat (Balsom, Ballard, & Whitlaw, 1996), mature, conifer forests are extremely important for moose in Nova Scotia during the late winter months (Telfer, 1967a; Peek, Urich, & Mackie, 1976; Parker, 2003) because they provide protection from extreme weather and the canopy prevents snow from accumulating to depths hindering moose movement (Snaith & Beazley, 2004). Travelling in areas where they sink into the snow can cause moose to expend a significant amount of energy (Lundmark and Ball, 2008) at a time when adequate forage may be scarce. Ideal winter habitat also includes regenerating mixed woods that provide both hardwood and softwood browse (Parker, 2003). In the winter months, moose in northern Nova Scotia concentrate in small areas known as "yards" and move very little (winter range of 2.6 km^2), particularly when the yard is contains good browse as in the Cobequid region (Telfer, 1967a,b). In Quebec, the vast majority of these winter yards were less than 0.5 km^2 in area (Guertin, Doucet, & Weary, 1984). Prescott (1968) determined that the use of winter yards by moose in northeastern Nova Scotia was influenced most heavily by having a variety of vegetation types and that food availability was more important than cover in determining the attractiveness of winter habitat to moose (summarized from Parker, 2003). Moose yards in Quebec were characterized by gentle slopes with southern exposure, with pure or mixed stands of black spruce and adjacent patches of white birch, young balsam fir, and alder (Guertin, Doucet, & Weary, 1984). Other important winter food items include willow, which accounted for 35% of the winter diet of moose in northern British Columbia (Goulet, 1985).

A similarly restricted winter range of moose was determined from studies in Minnesota (Van Ballenberghe and Peek, 1971; Phillips, Berg, & Siniff, 1973). Phillips, Berg, & Siniff (1973) that found that the late winter ranges of all tracked moose were distinct in habitat from the areas used at other time of year and that the summer-fall and early winter ranges were much larger. Furthermore, they determined that most moose returned to the same wintering area each year and that they used similar travel routes each year between seasonal habitats. Geist (1963) suggested that moose return every year to their accustomed summer range. Seasonal movements between winter and summer ranges were reported in moose in Alberta, with individual movement of up to 20 km observed (Hauge & Keith, 1981). Even greater migrations between winter and non-winter ranges of up to 75 km were observed in British Columbia, with non-winter ranges being twice as large as winter ranges (Demarchi, 2003). If the habitat in an area is diverse and provides the necessary interspersion of open areas for foraging and dense, mature forests for cover and relief from snow, seasonal ranges need not be widely separated (Snaith & Beazley, 2004). For example, only 22% and 38% of adult moose in Michigan migrated between distinct summer and winter ranges in 1999 and 2000, respectively. In Alaska, 43% of bulls and cows had distinct winter and summer ranges and distance between ranges were up to 17 km (Bangs, Bailey, & Portner, 1984). In southwestern Nova Scotia, however, the mean home range of moose was found to be large (55.2 km^2) because the rocky, barren conditions mean the moose must range farther to obtain resources (see Snaith & Beazley, 2004). When moving between seasonal ranges, moose use well established routes and travel corridors (Neumann, 2009). In terms of activity within seasons, daily movement rates of moose are higher in the summer than in the winter (McLaren, Taylor, & Luke, 2009).

Two sub-species of moose are present within Nova Scotia. The Cape Breton population (*Alces andersoni*) is an introduced species from Alberta and their population is abundant and stable. According to NSL&F (2007), the mainland moose (Alces americana) population has been reduced to approximately 1200 individuals, restricted to small, isolated sub-populations. The Recovery Plan for Moose in Mainland Nova Scotia (NSDNR, 2007) identifies several limiting factors to moose abundance and distribution. These include disease and parasites, poaching, access to habitat, development, forest practices, acid rain, and climate change. Of highest concern are threats related to disease and parasites, poaching, access to moose habitat, and development.

The primary parasite threatening survival of mainland moose is a parasitic worm *(Parelaphostrongylus tenuis*), known as brainworm. Approximately 65% of white-tailed deer in Nova Scotia are carriers of this parasite; however, it is not lethal to deer. According to NSL&F (2007, p.14), "Where moose and deer range overlap, brainworm is a significant mortality factor". Because the abundance of white-tailed deer can have an influence on the health of mainland moose, signs of white-tailed deer are documented during mainland moose surveys.

The threats of poaching and access to moose habitat are correlated, as increased access to moose habitat can ultimately increase the level of poaching. These threats can result in lowered viability of individual populations of moose by direct mortality and reduction in range. Similarly, land development of various types can result in increased access to moose habitat, fragmentation of habitat, and direct loss of habitat, while (potentially) further isolating sub-populations from one another.

According to the Recovery Plan for Mainland Moose in Nova Scotia (NSDNR, 2007, p. 30), core habitat means "specific areas of habitat essential for the long-term survivability and recovery of endangered or threatened species and that are designated as core habitat" under the Nova Scotia Endangered Species Act. Mainland moose use a wide variety of habitat types, over relatively large home ranges. The specific spatial and temporal use of the landscape and habitat is not well known in Nova Scotia. As such, 'core habitat' has not been defined or designated under the Endangered Species Act. The PA lies within a significant Mainland Moose Concentration Area, as identified in Endangered Mainland Moose Special Management Practices (NSDNR, 2012).

Within the PA, mainland moose tracks were observed within the Beaver Dam Mine Site in disturbed, roadside habitat north of Wetland 56 on May 24th, 2015 during a targeted PGI survey. Moose tracks were observed incidentally in two locations on September 9th, 2014, in Wetland 210 and just beyond the Beaver Dam Mine Site, adjacent to Wetland 206. No signs of mainland moose were observed during any survey within Haul Road.

6.13.4.4.2 Bats

A single abandoned mine opening (AMO) (BED-1-003) was identified as a potential bat hibernaculum. The remaining AMOs when surveyed were either infilled, contained a concrete cap, or were flooded with water, which all limit the potential for bat hibernacula. The Beaver Dam Gold Mining Company J.H. Austin Main Shaft (BED-1-003) (Hennick et al 2016) is located on the Beaver Dam Road, Halifax County at UTM Zone 20, 522256 east, and 4990298 north. It is located just east of the Beaver Dam Road at the western end of an open historical settling pond (wetland 59) southwest of Cameron Flowage.

The J.H. Austin Main Shaft was originally 67 m deep. It has a concrete collar and cap. The installation date of the collar and concrete cap are unknown, but they have since collapsed and the AMO appears to be filled with rocks. The opening appeared to be less than 5 m deep, with no water observed. The potential for usage of the opening by bats was determined to be very low; however, it could not be visually confirmed because the Project Team could not safely inspect the opening for any internal complexities. A second abandoned mine opening was observed 9 m west of BED-1-003. This opening is described in the NSL&F database as BED-1-002 as an air shaft for the main J.H. Austin Shaft (BED-1-003). This mine opening was clear of debris and backfill and groundwater was observed in BED-1-002 approximately four meters below the ground surface and one-meter below the top of the mine shaft infrastructure.

As a result of the observed groundwater in the opening nine meters away (BED-1-002), it was hypothesized that groundwater was likely quite close to the surface within BED-1-003 even though it was not observed due to debris and backfill. LiDAR data collected by GHD was used to evaluate the potential of BED-1-003 as a bat hibernaculum. Results derived from LiDAR data (provided on Figure 6.13-5 shows the grade elevation at BED-1-002 (open AMO) to be 134.38 m while the elevation of the BED-1-002 mine shaft opening is 131.43 m. The data also shows the elevation of a pond 40 m downslope of BED-1-002 to be 130.43 m (all elevations are of ±0.15 m accuracy). Based on these elevations and the distance to the pond, the percent grade of the slope on which BED-1-002 and BED-1-003 are located is 9.88%. At this percent slope, the maximum elevation level of the grade at BED-1-003 (located nine-meters from BED-1-002) would be 135.27 m. This would infer that the water is present in BED-1-003 five-meters below (135.27 m minus 130.43 m) the surface, which places it at or just below the location of the debris in the mine shaft. The inferred proximity of water to the top of the mine shaft (approximately five-meters) reduces the potential of BED-1-003 as a bat hibernaculum.

No AMOs were identified along the Haul Road, although a cluster of 99 AMOs is present approximately 6.4 km southeast of the Haul Road, along the Mooseland Road, within the Mooseland Gold District. A desktop evaluation for potential bat hibernacula was completed within this cluster of AMOs. The Project Team screened out AMOs with opening types of trench and pit, and stope, flooded, infilled, and capped AMOs, and those with an original depth of less than 10 m. According to this desktop review, none of the AMOs reviewed (in the cluster of 99) have the potential to support bat hibernacula. As a result, no bat hibernacula were identified along the Haul Road. Additionally, no potential bat hibernacula were identified through desktop evaluation within 10 km of the PA.

6.13.4.5 Priority Terrestrial Mammal Summary

Through all targeted surveys and incidental observations, evidence of a single mammalian priority species was observed. One set of moose tracks observed within the Beaver Dam Mine Site on May 24th, 2015 during a targeted PGI survey. Two sets of mainland moose tracks were observed incidentally within and directly adjacent to the Beaver Dam Mine Site on September 9, 2014. No other moose signs (tracks, scat, browse) were observed during targeted moose surveys (tracks or PGI) completed within the Beaver Dam Mine Site or the Haul Road. Suitable habitat for mainland moose is present within, and adjacent to the PA. Although no core habitat has been defined for mainland moose in Nova Scotia, the PA is located within a Significant Mainland Moose Concentration Area.

Determination of the presence of several bat SAR was completed and included both desktop and field components. This evaluation for bat SAR determined that the PA does not contain suitable habitat for bat hibernacula, and no evidence was found that indicates any usage of the PA by priority bat species. No bat hibernaculum are known to be present within a 10 km radius of the PA. No bats, or evidence thereof, were observed incidentally during biophysical surveys, particularly bird surveys which are conducted when bats are more active.

Incidental sightings of mammals were completed during all field programs throughout the PA during all seasons. Aside from mainland moose tracks, no priority mammals or signs thereof were observed. Given the mobility of mammal species, the absence of observation does not confirm absence of the species within the PA. The size of a species and a species' behavior can result in a bias against detection. For instance, very small species such as the maritime shrew (S3) and the rock vole (S2) have been documented within 5 km of the PA, but were not observed by the Project Team within the PA. As another example, the fisher (Martes pennanti, S2) is a largely nocturnal hunter, with large home ranges and elusive behavior. They prefer dense, mature to over-mature coniferous stands with large hollow snags for den sites. Their preferred habitat and prey items (porcupine, rabbits, squirrels and other small mammals) are present within the PA. The lack of observed evidence of fisher does not confirm absence of the species.

6.13.4.5.1 Touquoy Mine Site

Mainland moose tracks were observed within the Touquoy Mine Site in a bog during field surveys to support the Touquoy Environmental Assessment in 2006. Moose are known to the Tangier Grand Lake Wilderness Area, and evidence of moose is reported every year by NSL&F in the Moose River Gold Mines area during deer pellet surveys (CRA, 2007a).

No suitable bat hibernating areas were found within the Touquoy Mine Site during environmental screening to support the Touquoy Environmental Assessment (CRA, 2007a).

6.13.4.6 Priority Herpetofauna Species

The desktop evaluation for priority herpetofauna species revealed that no priority species were documented within 5 km of the Beaver Dam Mine Site or Haul Road by the ACCDC report (Appendix I.1). Wood turtle (SARA/COSEWIC/NSESA Threatened; S2) has been classified as 'location sensitive'. The ACCDC reports a wood turtle observation more than 20 km from the Project. While wood turtle may be present within the watershed, it was confirmed that this observation was located outside the West River Sheet Harbour watershed, in which the Project is located (NSLF, pers. comm. 2021).

The following priority herpetofauna species are identified as having an elevated potential to be located within the PA, based on habitat preferences, and broad geographic area (Table 6.13-9). No amphibians or reptiles were documented by the Nova Scotia Department of Communities, Culture and Heritage Environmental Screening Report (Appendix I.3).

Table 6.13-9: Priority Herpetofauna Species with Elevated Potential to Occur in the Project Area

Common Name	Scientific Name	SARA/COSEWIC/NSESA	S-Rank	Habitat Preference
Snapping turtle	*Chelydra serpentina*	SARA/COSEWIC Special Concern NSESA Vulnerable	S3	Southern New Brunswick and parts of mainland Nova Scotia in ponds, lakes, slow-moving streams, and sometimes in brackish water if these water bodies have soft mud bottoms and abundant aquatic vegetation
Wood turtle	*Glyptemys insculpta*	SARA/COSEWIC/NSESA Threatened	S2	Lives along permanent streams during much of each year, but in summer may roam widely overland and can be found in a variety of terrestrial habitats adjacent to streams, from deciduous woods, cultivated fields, and woodland bogs, to marshy pastures. Use of woodland bogs and marshy fields is most common in the northern part of the range
Eastern painted turtle	*Chrysemys picta picta*	COSEWIC Special Concern	S4S5	Occupies slow moving, relatively shallow and well-vegetated wetlands and waterbodies, particularly with organic substrates. Semi-tolerant of anthropogenic landscapes.

Targeted turtle surveys within the Beaver Dam Mine Site did not reveal any sightings of wood turtles, painted turtle or suitable nesting habitat. No opportunistic observations of wood turtles, painted turtle or suitable nesting habitat were documented during any wetland or watercourse surveys throughout the PA.

One female snapping turtle (SARA/COSEWIC, Special Concern; NSESA, Vulnerable; S3) and nest was observed by DFO within the Beaver Dam Mine Site on June 27, 2019. The observation was on a rocky, man-made berm east of Wetland 59 (historic settling pond; Figure 6.13-1A. Previously, there were only incidental observations of this species, one on June 26, 2016 where the Mooseland Road section of the Haul Road crosses Fish River (during bird surveys, near PC45), and two adjacent to the Touquoy Mine Site (see following section; Figure 6.13-1G). Similar to the wood turtle, snapping turtle populations are threatened by low juvenile recruitment and high juvenile mortality. Snapping turtles have a life span of approximately 50 years, however, sexual maturity it not reached until the age of 15 to 20 years, and survival rates (form embryo through to sexual maturity) are estimated to be as low as 0.1%. According to Environment and Climate Change Canada (2016), the very low juvenile recruitment means that high adult survivability is required to maintain a viable population. As such, a single adult mortality due to natural or anthropogenic factors can be significant to the population.

Snapping turtles can be found in a variety of freshwater ecosystems, such as slow-moving rivers, wetlands, lakes, streams and ponds. Hibernation occurs in freshwater systems deep enough to prevent freezing through during the winter, with a mucky or muddy substrate. They are the most aquatic of freshwater turtles in Nova Scotia, but they do travel through upland habitat and use gravelly areas to nest. The preference for gravelly substrate during nesting is a threat to turtles, as gravid females are attracted to roadsides to nest in the gravelly shoulders of roads. This can result in direct mortality of reproductive females and emerging hatchlings from vehicular collisions. This type of direct mortality, along with direct loss of freshwater and riparian habitats, poses significant threats to the viability of snapping turtle populations in Nova Scotia. Additional threats include an increase in human-subsidized predators such as foxes, coyotes, raccoons, and skunks (Environment and Climate Change Canada, 2016).

Suitable habitat for snapping turtles has been observed in Wetlands 8, 10, 14, 17, 29, 44, 56, 59, 61, 64, 66, 68, 69, 159, 168, 171, and 207. These wetlands provide standing water to a depth exceeding 0.5 m and muddy substrate (e.g., lentic and lotic wetlands and wetlands with open water features), which provide potential overwintering habitat.

6.13.4.6.1 Touquoy Mine Site

No wood turtle, painted turtle or suitable habitat were observed within the Touquoy Mine Site during wood turtle habitat surveys conducted in 2004 (CRA 2007a). No snapping turtles were recorded within the Touquoy Mine Site during the EARD process, however, two snapping turtles were observed in the vicinity, within the LAA. One observation was north of the Touquoy Mine Site on Moose River Road (20T 504304E, 4981602N), and the second was on Higgins Mines Road (20T 504380E, 4980699N) west of the Touquoy Mine Site. Snapping turtles were frequently observed (16 observations) by AMNS between June 19, 2017 and July 2, 2020, primarily on roadsides near Moose River and Scraggy Lake.

6.13.4.7 Priority Invertebrate Species

The desktop evaluation for priority invertebrate species revealed that one monarch butterfly was identified within 5 km of the PA by the ACCDC reports. NSL&F has not identified any invertebrate species as 'location sensitive' species and no invertebrate species were documented by the Nova Scotia Department of Communities, Culture and Heritage Environmental Screening Report (Appendix I.3). The Maritime Butterfly Atlas was reviewed (20NQ17, 20NQ18, 20NQ19, 20NQ28, 20NQ29) for observations of priority Lepidopterans (Appendix I.4). Additionally, Odonata Central (n.d.) was reviewed for records of priority odonates within the vicinity of the PA. A list of priority invertebrate species which have elevated potential to be located within the PA, based on habitat preferences and known distribution is provided in Table 6.13-10.

Table 6.13-10: Priority Invertebrate Species with Elevated Potential to Occur in the Project Area

Common Name	Scientific Name	SARA/COSEWIC/ NSESA	S-Rank	Habitat Preference
Monarch	*Danaus plexippus*	SARA Special Concern COSEWIC Endangered NSESA Endangered	S2B	Almost anywhere during the spring (northward) migration; near the larval food plants during the breeding season; in the fall commonly near the coast, often in large numbers, all heading south. Larvae are found feeding on the following milkweed species: common milkweed and swamp milkweed, neither of which are abundant plants in Nova Scotia. Common milkweed: very common in lower Saint John river valley and possibly north central Nova Scotia.
Skillet clubtail	*Gomphus ventricosus*	SARA/COSEWIC Endangered	S1	The larvae inhabit large rivers where they burrow in the soft mud of deep pools.
Triangle floater	*Alasmidonta undulata*	-	S2S3	Frequently found in stream and rivers in sand and gravel substrates.
Pepper and salt skipper	*Amblyscirtes hegon*	-	S2S3	Found on the edges of forests and streams. Larvae found feeding on a variety of grass species.
Common roadside-skipper	*Amblyscirtes vialis*	-	S3S4	Found in trails, roads in wooded areas, and often near streams. Larvae are found feeding off of a variety of grass species.
Baltimore checkerspot	*Euphydryas phaeton*	-	S2S3	Found in fresh-water marshes, wet roadsides and meadows. Larvae found feeding on turtlehead and has been reported to feed on beardtongue.
Grey comma	*Polygonia progne*	-	S3S4	Found in woods and aspen parklands. Larvae found feeding on currants and gooseberries and sometimes elm.
Striped hairstreak	*Satyrium liparops*	-	S2S3	Found in deciduous forest edges, gardens and roadsides. Larvae found feeding off of members of the Rose family such as plum and cherries. Occurrences with oak, willow, and blueberry.

Surveys for benthic invertebrates were completed as part of the fish habitat assessment, following CABIN protocol methodologies. No priority invertebrate species were identified through sampling for benthic invertebrates (as described in Section 6.9.3.2). Field staff searched for signs of aquatic invertebrates, such as freshwater mussels during all wetland and watercourse related programs. None were observed. According to Fisheries and Oceans Canada (2016b), the brook floater (*Alasmidonta varicosa*) has not been documented in any watersheds within the PA.

The desktop review of damselflies and dragonflies through Odonata Central did not confirm presence of any priority species in the vicinity of the PA nor were any priority species observed during surveys completed within the PA.

A review of data provided by the Maritime Butterfly Atlas and ACCDC confirmed that one monarch butterfly was observed within the Beaver Dam Mine Site, adjacent to Wetland 59 (square 20NQ29). Monarch butterflies rely on milkweed as a host plant for their larvae; as such, it is a key indicator for presence of the monarch. Surveys for vascular plants were conducted throughout the PA, and staff were instructed to identify any suitable habitat for monarchs based on presence of milkweed. No milkweed was documented during surveys for vascular flora, or opportunistically during any other surveys. It is possible that the monarch uses the Beaver Dam Mine Site, at least periodically, during migration.

No other targeted surveys were completed for invertebrates; however, no opportunistic observations of priority invertebrate species were recorded. No other priority invertebrate species were identified during the desktop review.

6.13.4.8 Priority Avifauna Species

A desktop review for priority species revealed that 33 priority bird species were identified as having the potential to occur within the Beaver Dam Mine Site and Haul Road based on habitat availability and geographic distribution. Eighteen species have been documented within 5 km of the Beaver Dam Mine Site and Haul Road by the ACCDC reports. These species are underlined in Table 6.13-11.

NSL&F has classified one species, the peregrine falcon, as 'location sensitive', meaning that their exact locations cannot be provided to proponents in ACCDC reports. Instead, ACCDC indicates whether a location sensitive species is documented within 5 km of the PA. The peregrine falcon (*Anatum/tundrius pop.*) has not been documented within 5 km of the PA in the ACCDC reports.

The Nova Scotia Department of Communities, Culture and Heritage Environmental Screening Report (Appendix I.3) reported nesting records or probable nesting records for 16 priority species within the vicinity of the PA. These species are bolded in Table 6.13-11.

A list of priority avifauna species which have elevated potential to be located within the PA, based on habitat preferences and known distribution is provided in Table 6.13-11.

6.13.4.8.1 Priority Avifauna Observed within the Beaver Dam Mine Site and Haul Road

During field assessments within the Beaver Dam Mine Site and Haul Road, a total of 32 priority bird species, 23 SOCI and nine SAR, were observed, in consideration of their breeding status qualifiers. These species are presented in Table 6.13-12. These results include species observed during the additional 2019 surveys within the Beaver Dam Mine Site.

Table 6.13-12: Priority Avifauna Observed within the Beaver Dam Mine Site and Haul Road

Common name	SARA	COSEWIC	NSESA	S-Rank*	Season observed	Number in the Beaver Dam Mine Site								Number in Haul Road						All PA

Notes: SC=Special Concern, T=Threatened, E= Endangered and V=Vulnerable. SM=Spring Migration, B=Breeding, FM=Fall Migration, I-B= Observed incidentally during breeding, I-FM= Observed incidentally during fall migration and I-SM=Observed incidentally during spring migration.

The ACCDC works with provincial and federal experts to develop rarity ranks (i.e., S-ranks) for species in Nova Scotia, as well as the other maritime provinces, see http://www.accdc.com/en/rank-definitions.html for more information.

Crusher Point Counts (CPC) waypoints were part of the Beaver Dan Mine Site in Fall 2014, but that area of the Beaver Dam Mine was removed following that season due to changes in the design of the Project footprint. Therefore, data from these point counts were not included in analyses of results for the dedicated surveys, but priority species are included here as incidental observations.

NPS Indicates that the species was observed in that season but based on breeding status; it is not a priority species during that season. Inc. indicates that the species was observed incidentally, i.e., outside of a designated point count location.

HR-PC12-PC17 were located along an alternate Haul Road design, which is no longer being consider. These point count stations have been removed from this assessment.

Observed avifauna species with a single S-rank (i.e., ACCDC only provides a breeding status rank), which have no alternate seasonal ranking status, are considered, by default, a priority species regardless of its' observation date. Furthermore, if an avifauna species with compound ranks, but no migratory rank, has a priority status during breeding season (e.g., S3B, S4N), this species would be considered a priority species if observed during migration (spring or fall). Conversely, American robin (S5B, S3N) and purple finch (S4S5B, S3S4N) were only observed during breeding and migration seasons. These species are only considered a priority species if observed overwintering and are therefore not classified as a priority species herein.

Given the abundance of priority bird species observed, SOCI are only described in tabular form above, which identifies the location, abundance, and seasonality of observations. The nine avifauna SAR observed in the Beaver Dam Mine Site and Haul Road are described in further detail below.

6.13.4.8.2 Common Nighthawk

The common nighthawk is a medium-sized bird, with large eyes, a small bill, and a large mouth on its large flattened head. They have long slender pointed wings and a long slightly notched tail. Preferred breeding habitats include areas devoid of vegetation, such as sand dunes, beaches, logged areas, burned-over areas, forest clearings, peat bogs, and pastures. Common nighthawks were not detected during the dedicated species surveys completed within the Beaver Dam Mine Site in 2015; however, preferred breeding habitat, specifically logged areas, peat bogs and forest clearings, were observed within the Beaver Dam Mine Site.

Suitable breeding habitats were observed within the Haul Road and four common nighthawks were observed during both breeding bird (n=1) and dedicated species surveys (n=3) in 2016. Common nighthawks were observed within the Haul Road, in habitats with expansive gravelly areas adjacent to clear cuts or disturbed areas (Haul Road PC26, CONI1, and CONI9). There were no signs of breeding evidence (e.g., booming display) observed, but breeding is still possible as these birds were observed near suitable nesting habitat, specifically clear cuts and gravel on expanded roadsides. Common nighthawk populations have been on the decline; however, the reasons for the decline have not been determined. Large-scale pesticide use, which has reduced the numbers of insect prey, is a likely factor for the decline in common nighthawk populations (COSEWIC, 2007a). Habitat loss and alteration, including fire suppression and intensive agriculture, may also have contributed to these declines (COSEWIC, 2007a). The common nighthawk is federally listed as threatened by COSEWIC and SARA, provincially listed as threatened by NSESA, and the breeding population in Nova Scotia is ranked as Imperiled (i.e., S-rank S2B) by ACCDC.

6.13.4.8.3 Peregrine Falcon

The peregrine falcon is a medium to large falcon with long, pointed wings. Peregrine falcons use a wide variety of habitats, including Arctic tundra, sea coasts, prairies, and urban centers. They nest on cliff ledges, in crevices, and near bridges. Suitable breeding habitat was not present within the Beaver Dam Mine Site and Haul Road. Two peregrine falcons were observed incidentally (n=1) and during the dedicated fall migration surveys (n=1) adjacent to the Beaver Dam Mine Site, in 2014. Both observations were documented immediately north of the Beaver Dam Mine Site, between Mud Lake and Cameron Flowage. The peregrine falcon populations have seen a decline due to exposure to organochlorine pesticides, particularly DDT, causing reproductive failure (these compounds continue to be used in parts of the wintering range of Anatum and Tundrius peregrine falcons; COSEWIC, 2007b). Human disturbance at nest sites, including illegal harvest of eggs and nestlings also contribute to a decline in the populations (COSEWIC, 2007b). The peregrine falcon is federally listed as special concern under COSEWIC and SARA, provincially listed as vulnerable under NSESA, and the breeding population in Nova Scotia is ranked as critically imperiled (i.e., S-rank S1B) by the ACCDC.

6.13.4.8.4 Chimney Swift

The chimney swift is often mistaken for a swallow; however, it is easily distinguished by its cigar-shaped body, short tail, and long narrow pointed wings. Chimney swifts mainly use chimneys for nesting and roosting, since hollow trees in old growth forests have become rare, however, they will also nest in other artificial sites with vertical surfaces and low light (including air vents, old wells, abandoned cisterns, outhouses, boathouses, garages, silos, barns, lighthouses, and firewood sheds; Cornell Lab of Ornithology, n.d.). They are aerial foragers and are often found near water where insects are abundant. No suitable chimneys for roosting and nesting were observed within the PA; however, waterbodies used for foraging are present within the Beaver Dam Mine Site and Haul Road. Two chimney swifts were observed incidentally during the breeding season in 2015, within the Beaver Dam Mine Site (Figure 6.13-1A). They were observed from wetland 53, which is in the center of the Beaver Dam Mine Site, south of Crusher Lake. There were no signs observed of chimney swifts breeding.

The main cause for the decline of the chimney swift is unknown; however, factors such as a decrease in insect prey due to pesticides and habitat loss are likely involved in the decline (COSEWIC, 2007c). The chimney swift is federally listed as threatened under COSEWIC and SARA, provincially listed as endangered under NSESA, and the breeding population in Nova Scotia is ranked as imperiled (i.e., S2B), whereas the aggregating transient population is ranked as critically imperiled by the ACCDC (i.e., S-rank SM1).

6.13.4.8.5 Olive-sided Flycatcher

The olive-sided flycatcher is a medium-sized songbird, with deep brown olive-gray on the sides and flanks. Suitable habitat for the olive-sided flycatcher includes open areas with tall trees or snags, forest openings, forest edges near natural openings, or human-made openings. Suitable habitat also includes coniferous or mixed coniferous forests, likely near wetland areas. Suitable habitat, including logged areas.

and forest edges near natural and human-made openings, are present within the Beaver Dam Mine Site and Haul Road. No evidence of breeding was observed; however, 10 males were heard singing within the Beaver Dam Mine Site during the 2015 breeding bird surveys, and incidentally within Haul Road in 2016, suggesting possible breeding within the associated habitats (Figure 6.13-2A). Olive-sided flycatcher observations were sparse, yet scattered across the Beaver Dam Mine Site and Haul Road. This species was documented near wetland boundaries, typically with disturbed habitats nearby.

The decrease in the population of olive-sided flycatchers is puzzling due to its preference for sparse canopy cover; it may respond positively to forest management practices, such as timber harvesting. A contributing factor to the population declines may be due to habitat alteration and loss in migration stopover and wintering grounds (Cornell Lab of Ornithology, n.d). The olive-sided flycatcher is federally listed as threatened under COSEWIC and SARA, provincially listed as threatened under NSESA, and the breeding population in Nova Scotia is ranked as imperiled (i.e., S-rank S2B) by ACCDC.

6.13.4.8.6 Canada Warbler

The Canada warbler is a small brightly coloured songbird; the males have blue-gray upperparts and tail with a contrasting yellow throat and breast. The Canada warbler has a wide range of suitable habitats, including deciduous, coniferous, and mixed forests and wetlands with a well-developed shrub layer. Their preferred habitat is moist mixed forests (COSEWIC, 2008). They also use regenerating stands after natural and human-caused disturbances (COSEWIC, 2008). The Canada warbler's preferred habitat, was observed within the Beaver Dam Mine Site and Haul Road. Regenerating forest stands, mixed forests and shrub dominated wetlands are predominant on the landscape within the PA. Eighteen Canada warblers were observed during the 2015, 2016 and 2019 breeding bird surveys within the Beaver Dam Mine Site and Haul Road. Within the Beaver Dam Mine Site, probable breeding

behavior (i.e., agitated behavior and anxiety calls of an adult) was observed by one Canada warbler and possible breeding was exhibited by singing males during breeding season. Along the Haul Road, an observation of this species in the same location in two subsequent breeding bird surveys indicates that an individual may have established a territory, which is evidence of probable breeding.

The factors for population decline of the Canada Warbler are unknown. One likely reason is habitat degradation and loss of wintering ranges. Habitat loss includes agricultural activities and road development and conversion of swamp forests (COSEWIC, 2008). The Canada warbler is federally listed as Threatened under COSEWIC and SARA, provincially listed as Endangered under NSESA, and the breeding population in Nova Scotia is ranked as Vulnerable (S3B) by ACCDC.

6.13.4.8.7 Rusty Blackbird

The rusty blackbird is a medium-sized songbird with pale yellow eyes, a black slightly curved bill, and a slightly rounded tail. Rusty blackbird breeding habitat is forested wetlands, including peat bogs, sedge meadows, marshes, swamp, beaver ponds, slow moving streams, and pasture edges. One rusty blackbird was observed incidentally within Beaver Dam Mine Site during the 2014 fall migration survey in a large wetland complex to the northwest of Beaver Dam Mine Site (PC15). Breeding habitat, including forested wetlands, swamps, and peat bogs are present within the Beaver Dam Mine Site and Haul Road, however, no evidence of breeding was observed (no birds were observed in Haul Road).

The biggest threat to the rusty blackbird is degradation of the primary wintering range in the Mississippi Valley (i.e., conversion of flood plain forests to agricultural land and urban zones; COSEWIC, 2006). The rusty blackbird is federally listed as special concern under COSEWIC and SARA, provincially listed as endangered under NSESA, and the breeding population in Nova Scotia is ranked as imperiled (i.e., S2B) by ACCDC.

6.13.4.8.8 Barn Swallow

The barn swallow is a medium-sized songbird, which is easily distinguishable by the steely-blue upperparts and cinnamon underparts, chestnut throat and forehead, and the deeply forked tail. Caves, holes, crevices, and ledges in cliff faces were the most common nesting habitats of barn swallows prior to European colonization; however, they have since shifted to nesting in and on artificial structures (e.g., barns and other outbuildings, garages, houses, bridges and road culverts; COSEWIC, 2011). Nesting habitat is available within the Beaver Dam Mine Site and Haul Road, particularly artificial structures including a cabin, bridges, and road culverts. One barn swallow was observed within the Haul Road during the 2016 spring migration surveys, near wetland 159, between Highway 224 and the Beaver Dam Mine Site, shown on Figures 6.13-1A to 6.13-1G. None were observed during the breeding bird surveys completed in the Beaver Dam Mine Site.

6.13.4.8.9 Eastern Wood-pewee

The eastern wood-pewee is a small insectivore belonging to the “tyrant flycatchers” (Tyrannidae) family. Visually, this species can often be confused by other fly catchers and male and females are not sexually dimorphic. Despite this species looking very similar to its cousin species, it can often be distinguished by its “pee-ah-wee” song (COSEWIC 2012). The breeding range of this species covers the majority of south-central and eastern North America and in the winter months, this species is found primarily in South America.

This species, like many other avifauna insectivores have been experiencing a decline in populations despite being resilient to many habitat changes (COSEWIC 2012). According to the data, declines in the eastern-wood pewee have been occurring over the past

40 years in both Canada and the United States (COSEWIC 2012). Over the past ten years, there has been an observed population decline by 25% (COSEWIC 2012).

In Canada, the eastern wood-pewee is often associated with forested edge habitats often surrounding cut blocks, wetlands, lakes and rivers or in close proximity to these features. The eastern wood-pewee is listed as special concern by COSEWIC and SARA, vulnerable by NSESA and vulnerable/apparently secure (S3S4B) by the ACCDC.

Two individuals were incidentally observed during the breading season, one at the outlet of Cameron Flowage, to the east of the Beaver Dam Mine Site, and one along the Haul Road, east of Wetland 114. Suitable breeding habitat is present within the PA.

6.13.4.8.10 Evening Grosbeak

Evening grosbeaks are a member of the true finch family (Fringillidae), are a short stocky, vibrant coloured and equipped with a large yellowish-green bill (COSEWIC 2016). This species breeds in Mexico, Canada and the United States. In the winter months, their range can vary widely depending on the food source available and is often found in backyards feeding off feeders. Breeding habitat is typically in open, mature mixedwood upland forests often dominated by balsam fir and white spruce and where their main food source, the spruce budworm (*Choristoneura spp.)* is present (COSEWIC 2016).

Since the 1970's, a significant long-term decline in the Evening Grosbeak population as occurred. According to some reports, a decline of nearly 40% has occurred since the 1970's (COSEWIC 2016). Leading factors which may be contributing to the decline of this species include: fluctuations in spruce budworm populations, mortalities by window strike and road collisions, ingestion of sodium chloride from road sides and the effects of climate change. The evening grosbeak is listed as special concern by SARA and COSEWIC, vulnerable by NSESA and vulnerable/apparently secure (S3S4B) in the breeding season and vulnerable (S3N) in the winter months.

Two individuals were observed during the spring along the Haul Road, in upland habitat, adjacent to cut blocks. No breeding evidence was observed. Suitable breeding habitat is present within the PA.

6.13.4.8.11 Priority Avifauna Summary

Across all survey seasons, a total of 26 priority species, 18 SOCI and eight SAR, were observed either during dedicated survey periods or incidentally within the Beaver Dam Mine Site and Haul Road. The presence of wetlands, forested uplands, watercourses, clearings and fragmented habitats (resulting in edge habitats) provided suitable habitat for many of the priority bird species in Nova Scotia.

During all breeding bird surveys, evidence of breeding behavior was recorded for all species, with particular attention towards SAR and SOCI. Breeding evidence was recorded in accordance with guidance provided by Bird Studies Canada (2016), which defines behavior in terms of possible, probable, and confirmed breeders. Any species observed during breeding season singing in suitable habitat is identified as a possible breeder. Signs of probable breeding observed are agitation and established territories. Evidence of confirmed breeders observed includes distraction displays, feeding young or carrying food, nests with young, or recently fledged young. Breeding evidence was observed for 18 priority avifauna species. The highest evidence of breeding status recorded for all priority bird species observed during breeding season is presented in Table 6.13-13 (SAR are bolded). Two SAR are identified as possible breeders (olive-sided flycatcher and common nighthawk), and one as probable (Canada warbler). Nine SOCI are identified as possible breeders, while five show evidence of probable breeding and one was confirmed breeding (Swainson's thrush).

Table 6.13-13: Breeding Evidence for Priority Avifauna within the Beaver Dam Mne Site and Haul Road

Code	Common Name	2015 Breeding Evidence	2016 Breeding Evidence	2019 Breeding Evidence

6.13.4.8.12 Touquoy Mine Site

The 2005 breeding bird surveys of the Touquoy Mine Site found ten priority species. They are as follows; pine grosbeak (*Pinicola enucleator*), willow flycatcher (*Empidonax traillii*), yellow-bellied flycatcher, barn swallow, boreal chickadee, ruby-crowned kinglet, rusty blackbird, bay-breasted warbler, Swainson's thrush, and pine siskin.

6.13.5 Consideration of Engagement Results

Key issues raised during public and Mi'kmaq engagement relating to SOCI and SAR include potential direct effects on rare flora and fauna associated with construction of the Beaver Dam Mine Site and Haul Road and potential indirect effects associated with changes to other VCs, such as wetlands, surface water and groundwater. Potential effects on traditional uses of land and resources by the Mi'kmaq were noted, including SOCI / SAR species of significance to the Mi'kmaq such as moose and American Eel.

The results of the public and Mi'kmaq engagement have been considered in the environmental effects assessment, including AMNS's commitments on mitigation and monitoring measures and proposed compliance and effects monitoring programs, as well as the AMNS's broader commitment to ongoing public and Mi'kmaq engagement. Specific to evaluating the effect on SOCI and SAR, these are found within the following environmental effects assessment.

6.13.6 Effects Assessment Methodology

6.13.6.1 Boundaries

6.13.6.1.1 Spatial Boundaries

The spatial boundaries used for the assessment of Project effects to SAR and SOCI are described below.

The PA (Section 5.5, Figure 5.5-1) consists of the three project components; Beaver Dam Mine Site, Touquoy Mine Site, and the Haul Road and extends from Marinette to Moose River Gold Mines, Halifax County, NS. The Beaver Dam Mine Site is located at the eastern end of the Beaver Dam Mines Road. The Haul Road spans from the Beaver Dam Mine Site to Moose River Gold Mines, where the Touquoy Mine Site [processing and exhausted pit (to be used to dispose Beaver Dam tailings)] is located. The PA has changed as a result of the expansion of the Beaver Dam Mine Site to accommodate micro-sitting of mine infrastructure and ongoing modifications to the Haul Road design, as described in Section 2 (Project Description). These changes have been captured under the existing and additional desktop and field evaluations.

The LAA and RAA are specific to each taxa and are provided herein:

- Fish:
  - The LAA (Section 6.7, Figures 6.7-4 and 6.7-11) consists of portions of downstream aquatic habitats and headwaters where appropriate, depending on project activities, up to the maximum size of the tertiary watershed(s). The LAA boundaries were defined considering the maximum expected extent of direct and indirect impacts to the aquatic environment as well as the location of Project activities across all PA components.
  - The RAA (Section 6.7, Figures 6.7-4 and 6.7-11) encompasses the three secondary watersheds that the PA is located within. These watersheds are the West River Sheet Harbour secondary watershed, the Tangier River secondary watershed, and the Fish River secondary watershed. The RAA is broader than the expected Project impacts and considers other Project boundaries as per the cumulative effects methodology.
- Vascular Flora and Lichens:
  - The LAA (Section 6.10, Figure 6.10-7) consists of a 2 km buffer surrounding the Beaver Dam Mine Site and a 500 m buffer surrounding the Haul Road (excluding Mooseland Road). The LAA includes the focused LSA surrounding the Beaver Dam Mine Site. This area encompasses the maximum expected extent of Project direct and indirect impacts to habitat and flora. The LAA has been modified to reflect the changes in the PA. The Touquoy Mine Site and the Mooseland Road portion of the Haul Road were not included in the LAA because there is not expected to be a change to habitat and flora from current conditions.
  - The RAA (Section 6.10, Figure 6.10-7) encompasses NSL&F's Ecological Land Classification Ecodistrict 440 (Eastern Interior) within Halifax Regional Municipality (HRM), east and north of Lake Charlotte. Where the Ecodistrict boundary approached the northern extent of the Beaver Dam Mine Site, the RAA was enlarged to include a 5 km buffer around the PA. This Ecodistrict spans an area broader than the expected Project impacts and considers other project boundaries as per cumulative effects methodology.

- Terrestrial Fauna:
  - The LAA (Section 6.11, Figure 6.11-1) consists of a 5 km buffer surrounding the Beaver Dam Mine Site and a 500 m buffer surrounding the Haul Road and Touquoy Mine Site components of the PA. The LAA boundaries were defined considering the expected extent of most direct and indirect impacts to terrestrial fauna. The LAA has been modified to reflect the changes to the PA.
  - The RAA (Section 6.11-1, Figure 6.11-1) encompasses NSL&F's Ecological Land Classification Ecodistrict 440 (Eastern Interior) within Halifax Regional Municipality (HRM), east and north of Lake Charlotte. Where the Ecodistrict boundary approached the northern extent of the Beaver Dam Mine Site, the RAA was enlarged to include a minimum 5 km buffer around the PA. This Ecodistrict spans an area broader than the expected Project impacts and considers other project boundaries as per cumulative effects methodology. Due to larger home ranges of terrestrial fauna, the RAA will be used to help identify the direct or indirect impacts to terrestrial fauna species and habitats that extend beyond the LAA.
- Avifauna:
  - The LAA (Section 6.12, Figure 6.12-1) consists of a 5 km buffer surrounding the Beaver Dam Mine Site and a 500 m buffer surrounding the Haul Road and Touquoy Mine Site components of the PA. The LAA boundaries were defined considering the maximum expected extent of direct and indirect impacts to avifauna. The LAA has been modified to reflect the changes to the PA.
  - The RAA (Section 6.12, Figure 6.12-1) encompasses NSL&F's Ecological Land Classification Ecodistrict 440 (Eastern Interior) within Halifax Regional Municipality (HRM), east and north of Lake Charlotte. Where the Ecodistrict boundary approached the northern extent of the Beaver Dam Mine Site, the RAA was enlarged to include a minimum 5 km buffer around the PA. This Ecodistrict spans an area broader than the expected Project impacts and considers other project boundaries as per cumulative effects methodology.

Assessment of SAR/SOCI will be completed in consideration of the LAA as the primary spatial boundary. All spatial boundaries will help to identify the direct or indirect impacts to priority species and the effects of the Project on distribution and abundance of these species.

6.13.6.1.2 Temporal Boundaries

The temporal boundaries used for the assessment of effects to SOCI and SAR are the construction phase, operations phase, active closure and post-closure.

6.13.6.1.3 Technical Boundaries

No technical boundaries were identified for the effects assessment of SOCI and SAR.

6.13.6.1.4 Administrative Boundaries

The primary administrative boundaries for SOCI and SAR are outlined in the federal SARA and provincial NSESA. Terrestrial fauna are provided protection under the provincial *Wildlife Act* and the federal *Canada Wildlife Act*. Fish species are further regulated under the federal *Fisheries Act*, while migratory bird species are regulated under the *Migratory Birds Convention Act*.

6.13.6.2 Thresholds for Determination of Significance

A significant adverse effect from the Project on SOCI and SAR is defined as an effect that is likely to cause a permanent, unmitigated, alteration to habitat that supports a species' distribution, or alteration of critical habitat. An adverse effect that does not cause a permanent alteration to habitat of SOCI and SAR species is not considered to be significant. Sedentary species such as vascular and non-vascular flora do not have the opportunity to move to avoid direct or indirect impact. For these species, the loss of an individual or individuals of a SAR species that is important in the context of the province, or that species' overall abundance or distribution, may be considered significant, if appropriate mitigation measures are not implemented. Mortality of a single SAR could, under some circumstances, be considered a significant effect. The loss of an individual SAR due to an accident or malfunction (i.e., wildlife collision) is not incorporated into the magnitude threshold or overall significance of Project activities.

Magnitude of effects has been defined separately for each VC and is dependent on loss of habitat. The same logic was applied to assess the magnitude of a predicted change in SOCI and SAR for each VC, in consideration of specific habitat use of the priority species and the loss of SAR as described above. Specific magnitude definitions are presented in the following sections.

The timing of residual effects for SOCI and SAR considers when the residual environmental effect is expected to occur, considering seasonal aspects. The duration of residual effects considers the time frame over which the effects are likely to last, ranging from short-term to permanent. Long term reflects the commencement of reclamation activities, relating to habitat, flora, fauna and avifauna. The frequency of residual effects considers the rate of recurrence of the effects, ranging from once to continuous. The reversibility of residual effects considers the time required for habitat to recover to naturalized conditions, or whether the changes to habitat, if identified, are permanent.

6.13.6.2.1 Priority Fish Species

The following logic was applied to assess the magnitude of a predicted direct change in SOCI and SAR fish and fish habitat and was determined by the habitat analysis results described in Section 6.9.6.2.

- **Negligible**: no measurable change in fish habitat quantity or quality for priority fish species described as one or more of the following (and/or):
  - less than one percent change in surface flow;
  - no direct loss of fish habitat; and
  - predicted change of surface water quality indicator is less than 10% of background conditions, (i.e., no measurable change of state of indicator from background conditions).
- **Low**: a measurable change in priority fish species habitat area or quality, but within the range of natural variation described as one or more of the following (and/or):
  - less than 10% flow reduction and not affecting the ability of documented fish species to use the habitat to carry out one or more life processes;
  - direct loss of to up to 20 m^2 of fish habitat in any individual fish-bearing wetland or watercourse; and
  - water quality in the receiving environment is predicted to be greater than guidelines and increase by greater than 10% over baseline levels but remains well within the observed range of natural variation (defined as 25th to 75th percentile baseline water quality).

- **Moderate**: a measurable change in priority fish habitat area or quality, above the range of natural variation, which partially limits the ability of fish to use the habitat to carry out one or more life processes described as one or more of the following (and/or):
  - less than 10% flow reduction but greater than a 10% net increase in the duration (number) of days below the 30% MAD (based on daily flows), which partially limits the ability of fish to use the habitat to carry out one or more life processes;
  - direct loss of fish habitat, greater than 20 m^2, up to 100 m^2 in any individual fish bearing wetland or watercourse; and
  - water quality in the receiving environment is predicted to be greater than guidelines and differ substantially from baseline levels and approaches upper observed limits of natural variation (defined as percentile baseline water quality).
- **High**: a measurable change in priority fish habitat area or quality to an extent which limits the ability of fish to use the habitat to carry out one or more life processes described as one or more of the following (and/or):
  - greater than a 10% flow reduction and a greater than 10% increase in number of days below the 30% MAD (based on daily flows), which limits the ability of fish to use the habitat to carry out one or more life processes;
  - direct loss of fish habitat greater than 100 m^2 in any individual fish-bearing wetland or watercourse; and
  - water quality in the receiving environment is predicted to be greater than guidelines and differ substantially from baseline water quality (outside of 75th to 95th baseline water quality), resulting in a detectable change beyond the range of natural variation.

6.13.6.2.2 Priority Flora Species

The following logic was applied to assess the magnitude of a predicted direct change in SOCI and SAR flora and habitat and was determined by the habitat analysis results described in Section 6.10.4.5.

- **Negligible** – the Project is predicted to result in less than 1% direct loss of habitat types within the LAA;
- **Low** – the Project is predicted to result in 1 to 5% direct loss of a habitat type within the LAA, and the loss of habitat is mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present;
- **Moderate** – the Project is predicted to result in 5 to 25% direct loss of a habitat type within the LAA and the loss of habitat is mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present; and,
- **High** – the Project is predicted to result in greater than 25% direct loss of a habitat type within the LAA and the loss of flora SAR. The loss of SAR and habitat is not mitigated in the long term through translocation, compensation or reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.

6.13.6.2.3 Priority Terrestrial Fauna Species

The following logic was applied to assess the magnitude of a predicted change in observed priority terrestrial fauna, based on the habitat analysis results described in Section 6.11.6.2:

- **Negligible** – the Project is predicted to result in less than 1% direct loss of habitat types used by observed SAR fauna within the LAA.
- **Low** – the Project is predicted to result in 1 to 5% direct loss of habitat types used by observed SAR fauna within the LAA, and the loss of habitat is mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.
- **Moderate** – the Project is predicted to result in 5 to 25% direct loss of habitat types used by observed SAR fauna within the LAA and the loss of habitat is mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.
- **High** – the Project is predicted to result in greater than 25% direct loss of habitat types used by observed SAR fauna within the LAA and the loss of habitat is not mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.

The Habitat and Flora LAA was used to determine habitat type and area, and resultant habitat loss for species (Section 6.10.7.1).

6.13.6.2.4 Priority Avifauna Species

The following logic was applied to assess the magnitude of a predicted change in priority avifauna, based on the habitat analysis results described in Section 6.12.7.2:

- **Negligible** – the Project is predicted to result in less than 1% direct loss of habitat types used by observed SAR avifauna within the LAA.
- **Low** – the Project is predicted to result in 1 to 5% direct loss of habitat types used by observed SAR avifauna within the LAA, and the loss of habitat is mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.
- **Moderate** – the Project is predicted to result in 5 to 25% direct loss of habitat types used by observed SAR avifauna within the LAA and the loss of habitat is mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.
- **High** – the Project is predicted to result in greater than 25% direct loss of habitat types used by observed SAR avifauna within the LAA and the loss of habitat is not mitigated in the long term through reclamation planning and other mitigation measures as determined to be necessary based on flora species and communities present.

The Habitat and Flora LAA was used to determine habitat type and area, and resultant habitat loss for species (Section 6.10.7.1).

6.13.7 Project Activities/Interactions with Species of Conservation Interest and Species at Risk

Priority species identified within the PA represent a diversity of taxa, habitat preferences, and, therefore, represent a diversity of potential and confirmed Project interactions, effects, mitigation, and monitoring. As such, Project effects, mitigation, and monitoring are discussed in terms of each taxa, rather than individual species, with a focus on SAR, recognizing that mitigation measures for SAR will generally provide appropriate mitigation for identified SOCI in the same taxonomic group. Where this is not the case, it will be stated. Project interactions, mitigation, and monitoring for each broad taxonomic group are outlined in previous chapters as well, and these mitigation measures are appropriate and should be applied for all SOCI and SAR within the same taxonomic group.

6.13.7.1.1 Priority Fish Species

Three priority fish species have been identified to reside in watercourses within or in proximity to the PA (American eel, Atlantic salmon, and brook trout). American eel and Atlantic Salmon have been included in the effects assessment section of this EIS. Although these species are not listed under provincial or federal endangered species legislation, DFO has indicated that they are currently being reviewed for protection under SARA, and it would be prudent for the Project Team to plan for these species as if they were protected under this legislation. Atlantic salmon and brook trout are sensitive to changes in their aquatic ecosystem, and they have specific habitat requirements, while American eel are considered to be habitat generalists. As such, standard mitigation and monitoring for fish and fish habitat (Sections 6.9.8 and 6.9.10) will address direct and indirect effects to Atlantic salmon, brook trout and American eel.

Atlantic salmon was identified in the Killag River east of the Beaver Dam Mine Site in 2020 during electrofishing surveys. No Atlantic Salmon have been observed within the Beaver Dam Mine Site and Haul Road throughout extensive fishing surveys (2015-2020). The species has been extensively documented within the West River Sheet Harbour, the Killag River, and the Little River by the Nova Scotia Salmon Association and is presumed to be present in several tributaries to these watercourses. Within and in proximity to the Beaver Dam Mine Site, Atlantic salmon may travel into the most downstream extents of direct tributaries to the Killag River and Cameron Flowage based on documented presence within the Killag River, which includes WC13, WC25, WC27, and WC27. Though the species may access these systems, no quality Atlantic salmon habitat provisions are expected to be provided by these watercourses. Preferred Atlantic Salmon habitat within and in proximity to the Beaver Dam Mine Site is confined to the main bodies of the Killag River/Cameron Flowage. Two watercourses are likely to support habitat for Atlantic salmon within the Haul Road: the West River Sheet Harbour (WC-N) and Keef Brook (WC-H). The West River Sheet Harbour is considered to provide suitable habitat for all life stages of Atlantic salmon, while Keef Brook is considered to provide suitable habitat for older juveniles.

American eel were confirmed within WC13, the Killag River, Cameron Flowage, and Mud Lake/WC27 within the Beaver Dam Mine Site, and in WC-N, WC-V, and WC-AH within the Haul Road. Wetlands contiguous with watercourses and waterbodies which are confirmed to or potentially support American eel, may also support American eel. Suitable freshwater habitat for juvenile and adult American eel was also identified in Watercourses 5, 14, 25, and 26, and open water features associated with Wetlands 59 and 61 within the Beaver Dam Mine Site, and Watercourses A, B, C, D, E, F, G, J, M, N, O, Q, R, S, T, U, V, W, X, Y, Z, AA, AB, AC, AC, AD, AE, AF, AG, AH, and AI within the Haul Road. However, all hydrologically connected watercourses within the PA are believed to be potentially accessible to the American eel, even if habitat provision in those watercourses is low.

Based on the results of extensive fishing surveys and fish habitat assessments, no Atlantic salmon have been confirmed or are anticipated to frequent any of the fish-bearing aquatic features proposed for direct alteration to support Project development within the Beaver Dam Mine Site. No direct impacts to Atlantic salmon are anticipated as a result of the Project. In addition, none of the proposed direct effects to fish habitat along the Haul Road are expected to occur in suitable habitat for Atlantic salmon.

Direct loss of American eel habitat within the Beaver Dam Mine Site is anticipated based on confirmed or potential presence of the species in WC5, WC13, WC14, WC25, and open water areas of Wetland 59 and Wetland 61. Direct effects to potential American eel habitat along the Haul Road include WC-C, WC-D, WC-J, WC-M, WC-O, WC-X, WC-AC, WC-AF, and WC-AG. Eight wetlands that are expected or confirmed to support fish habitat, including potential American eel habitat, will also be partially altered within the Haul Road to support road upgrades, widening and re-alignment as required. Project interactions along the Haul Road are expected to be minimized with the implementation of standard mitigation practices for installation of culverts in fish bearing streams (Nova Scotia Environment, 2015b) and in many cases are expected to result in improved fish passage based on condition of current crossing along the existing logging road. Standard approvals and mitigation will be required for all watercourse crossings, including those in involving new road construction.

Additional information pertaining to the direct loss of fish habitat within the Beaver Dam Mine Site and Haul Road are presented in Sections 6.9.7.2 and 6.9.7.3. Through reconfiguring the Beaver Dam Mine Site layout, AMNS has been able to achieve avoidance of direct impacts in several tributaries to Crusher Lake and Mud Lake. The mitigation sequence (avoid, mitigate, offset) is presented in Section 6.9.8.

Expected and potential indirect fish and fish habitat impacts to surface water features (wetlands, watercourses, and waterbodies) in the immediate vicinity of the PA as a result of the Project construction and development within the Beaver Dam Mine Site and Haul Road are fully described and tabulated Sections 6.9.7.2.2., 6.9.7.2.3, and 6.9.7.2.4. These indirect effects of Project activities are expected to be similar in nature between priority fish species and all other fish species. Maintaining water quality and quantity downstream in the LAA is paramount for limiting broader fish and fish habitat impacts within each affected watershed associated with the Beaver Dam Mine, particularly those known to support priority fish species. Given the proximity of the Project to the Killag River, and the importance of the Killag River on Atlantic salmon, a thorough description of potential indirect effects of the Project on fish habitat quality in Cameron Flowage/Killag River is presented in Sections 6.9.7.2.2 and 6.9.7.2.4. All direct and indirect effects to fish and fish habitat, including water quantity (baseflow reduction, hydrological and hydraulic alteration) and water quality effects have been fully assessed and quantified in Section 6.9.7, and included in the draft Fish Habitat Offset Plan (Appendix J.3).

The Touquoy Mine Site is currently operational. Potential impacts to surface water quality and quantity as a result of the storage of Beaver Dam tailings in the exhausted Touquoy open pit mine were examined in Section 6.7.8.4. There are no direct or indirect effects to priority fish or fish habitat anticipated to be caused by the processing of ore and the management of tailings (exhausted pit) from the Beaver Dam Mine Project (Section 6.9.7.7).

6.13.7.1.2 Priority Vascular Flora and Lichen Species

Development of the Beaver Dam Mine Site and upgrading and construction of new sections of the Haul Road (Section 2, Figure 2.3-1) will result in direct impacts to vascular and non-vascular individuals and to flora communities at the full or partial forest stand level. The effects of the Project on flora encompass vascular and non-vascular priority flora species in aquatic, wetland, and upland habitats. As such, many of the effects described in Section 6.8 and Section 6.10, specific to wetland and flora habitat respectively, will directly relate to effects on priority flora species. The majority of direct impacts to flora will occur during site preparation and construction.

Micro-siting of infrastructure has been completed to avoid priority flora and lichen species, wherever practicable, and has reduced the direct impact of the Project on flora and lichens. The division and micro-siting of the waste rock stockpiles has relocated infrastructure out of two defined boreal felt lichen critical habitat areas that interact with the PA (NSLF, 2020), to the west of the NAG waste rock stockpile and south of the Beaver Dam Mine Site. The critical habitat area includes the lichen substrata, the wetland in which the substrata is found and the surrounding critical function zone, which maintains the necessary biophysical

functions (e.g., hydrology, microclimate) for the persistence of boreal felt lichen (NSLF, 2020). The boreal felt lichen critical habitat in relation to Project development is presented in Figure 6.13-2.

Micro-siting and PA modifications of the Beaver Dam Mine Site has allowed for avoidance of all eight of the known locations of frosted glass-whiskers and reduced the number of individuals of blue felt lichen directly impacted from three to two, which are proposed for translocation (Appendix P.6 Preliminary Lichen Mitigation and Monitoring Plan). These two occurrences are located within the proposed NAG waste rock stockpile and Crusher area. Ten SOOCI lichen will be directly impacted by Beaver Dam Mine Site infrastructure: six occurrences of salted shell lichen, three occurrences of slender monk's hood lichen and one eastern candlewax lichen. No priority vascular flora are anticipated to be directly impacted within the Beaver Dam Mine Site. The most recent Project design changes avoided two clusters of Wiegand's sedge by relocating the eastern waste rock stockpile.

Within the Haul Road, no priority lichen are anticipated to be directly impacted. One occurrence of southern twayblade within Wetland 161, is found withing the proposed alignment and is expected to be directly impacted. While detailed design of the Haul Road is not yet complete, it is not anticipated that other vascular or non-vascular flora priority species will be directly impacted by upgrading the existing road or by the construction of the new 4 km section of the Haul Road. As is possible, AMNS will work to avoid priority flora species during detailed Project design of the Haul Road upgrades.

Indirect effects to habitat and flora described in Section 6.10 are relevant to priority flora species as well. As such, Project activities may indirectly affect priority lichen species which have been avoided, but exist in close proximity to Project infrastructure. Project related traffic, crushing operations and raw material handling (e.g., loading, transport) during site preparation, operation, and maintenance can result in increased emissions and deposition of dust on vegetation within proximity of contributing Project activities (Appendix C.1 Air Emissions Assessment). Modeled air quality does not report a consequential increase or exceedance of assessment criteria for NO_2, SO_2 and volatile organic compounds (Appendix C.1). Deposition of dust on flora can temporarily reduce evapotranspiration, photosynthesis and can bioaccumulate within tissue, which may reduce overall growth rates, especially for non-vascular flora such as lichen (Degtjarenko, 2016; Naeth and Wilkinson 2008; Farmer, 1993).

Due to their non-vascular physiology, lichens are especially sensitive to changing environmental conditions, particularly air quality and edge effects (Boudreault et al. 2008; COSEWIC 2002). Studies, such as Neitlich et al. (2017), Naeth and Wilkinson (2008), Loppi and Frati (2005) and Farmer (1993), present the primary drivers of atmospheric contamination to lichen from mine operations: sulfur dioxide and nitrous oxide emissions, metal mobilization and dust generation. The Project is predicted to result in localized particulate and metal mobilization through dust generation during construction and operations (i.e., mining and hauling ore). Dust deposition may result in increased alkalinity in substrate pH composition (e.g., bark of host tree) and bioaccumulation in lichen tissue which can impact lichen health and species richness (Degtjarenko, 2016; Naeth and Wilkinson 2008; Farmer, 1993). Farmer (1993) present that bryophytes and lichens along a gravel road (traffic and distance unknown) were unaffected within 2 years of operation. Significant changes to the communities were noted at 10 years. Species decline was noted at dust deposition levels of 1.0-2.5 g/m^2/day. Effects to lichens were still observed at levels 0.07 g/m^2/day. Effects of fugitive dust, and resultant mobilized elements, on lichens have been observed up to 1 to 2 km from mine haul roads (Neitlich et al. 2017; ECCC, 2018). However, the emission rates and lifespan of the operations which resulted in these findings are substantially higher than those of the Project, when calculated at the most conservative rates. Other comparable mining operations (i.e., diamond mines) have reported that deposition rates reached background levels 100 m from haul roads (Dominion Diamonds 2018).

Along the Haul Road, the modeled particulate deposition rate at worst-case point of impingement drops below 0.07 g/m^2/day, the threshold where Farmer (1993) noted species decline or other impacts, within 500 m of the road. Therefore, effects of dust deception on lichen are not expected beyond 500 m of the Haul Road. The Haul Road is expected to the be largest source of particulate emissions within the PA.

Edge effects, which are a result of fragmented habitats, typically through conventional forestry practices, are viewed as a major factor for change in lichen diversity and health (Rheault et al. 2002). Microclimates of forested edges which adjoin clearcuts are different than those of interior forests. Edge effects include alteration of humidity, higher wind velocity, increase solar radiation often resulting in vegetation, and community structure changes (Rheault et al. 2002). Poikilohydric organisms (such as lichens) which have the inability to regulate and maintain their water content are often sensitive to these effects (Rheault et al. 2002).

The distance in which lichen individuals and populations are affected by edge effects (referred to as depth of edge-influence) have been well studied (Moen & Jonsson, 2002). Studies have shown that the depth of influence on pendent fruticose lichens (Esseen and Renhorn 1997) and diversity of cyanolichens (Haughian and Harper 2020) range from 60 to 80 m, respectively. However, studies by Gauslaa et al. (2018) recommend setbacks of greater than 240 m for three Lobaria species studied in temperate rainforests of British Columbia. These results show edge effects, and the depth of influence, is species and context-dependent (e.g., dependent on size of the clearings, substrate, type of climate etc.). Additionally, changes in vegetation communities that support lichen species could affect lichen community, health and abundance (Cornelission et al. 2001).

Potential indirect impacts to vascular plants and lichens surrounding Project infrastructure will be reduced through best management strategies and mitigation measures. The Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6) considers the impacts of edge effects and dust/particulate deposition and is further discussed in Section 6.13.9.

The Touquoy Mine Site is currently in operation. There are no direct or indirect effects to priority vascular flora and lichen species anticipated to be caused by the processing of ore and the management of tailings (exhausted pit) from the Beaver Dam Mine Project. Effects to habitat and flora related to the Project are described in Section 6.10.

6.13.7.1.3 Priority Terrestrial Fauna Species

The assessment of potential adverse interactions and effects of the Project on this VC takes into account the potential for the Project to result in changes to:

- permanent and temporary habitat alteration and fragmentation;
- disturbance and/or displacement;
- potential for direct and indirect mortality to individuals; and
- sensory disturbance.

Priority terrestrial fauna observed during field surveys within the PA includes the mainland moose and the snapping turtle. Each of these species has variable habitat preferences, depending on the time of year. Mainland moose are found in habitat mosaics of uneven age stands with abundant twigs and foliage for foraging. These uneven-aged mosaic forests that moose prefer can be formed from natural disturbance such as fire or wind throw, or anthropogenic disturbance such as timber harvesting. During the summer months, they are reliant upon aquatic systems (lakes, rivers, and wetlands) for submergent and emergent vegetation, and cover from thermal stress (NSDNR, 2007). Mainland moose are not particularly affected by habitat fragmentation based on habitat preference; however, increased access into a site (construction of new roads) may increase poaching levels. As such, low-level habitat fragmentation can indirectly affect mainland moose.

The snapping turtle can be found in a variety of freshwater ecosystems, such as slow-moving rivers, wetlands, lakes, streams, and ponds. Hibernation occurs in freshwater systems deep enough to prevent freezing through during the winter, with a mucky or muddy substrate. They are the most aquatic of freshwater turtles in Nova Scotia, but they do travel through upland habitat and use gravelly areas to nest. The preference for gravelly substrate during nesting is a threat to turtles, as gravid females are attracted to

the gravelly shoulders of roads for nesting. The potential for direct mortality of reproductive females is highest where roads intersect or are adjacent to aquatic ecosystems. This risk is highest in June when females are nesting, particularly given the proposed increase in traffic along the Haul Road.

Development of the Beaver Dam Mine Site and associated upgrades to the Haul Road will cause direct impacts to habitat used by terrestrial fauna, including wetlands with suitable hibernacula for snapping turtles, and those with abundant submergent and emergent vegetation for mainland moose. Moose tracks were observed adjacent to Wetland 56 which has habitat for foraging and thermal regulation (i.e., open water features). Wetland 56 will be directly impacted by the open pit. Wetlands 206 and 210 which contained, or were in proximity to, evidence of mainland moose will be avoided by Project development.

Wetlands 8, 10, 14, 17, 29, 44, 56, 59, 61, 64, 66, 68, 69, 159, 168, 171, and 207. are identified as potentially providing hibernacula for snapping turtles where open water is present. Wetland 10 is expected to be directly impacted by the western waste rock stockpile and Wetlands 59 and 61 are expected to be impacted by construction of the open pit. All other wetlands with hibernacula potential within the Beaver Dam Mine Site will be avoided. All other wetlands with potential to support snapping turtles within the Haul Road (Wetlands 66, 68, 69, 159, 168, and 171) will have minimal impact proposed, associated with upgrade or construction of the Haul Road. Either these wetlands will be avoided, or where interactions may occur with proposed alignment, impacts to snapping turtle habitat are expected to be minimal, with proper mitigation. Impacts to wetland habitats will occur mostly within the construction phase of the Project during clearing, grubbing, and development of the Beaver Dam Mine Site and its associated infrastructure, and upgrading of the Haul Road (widening). Habitat within the PA currently exhibits fragmented conditions based on historic mine operations and current and historic timber harvesting activity within and adjacent to the PA. Refer to the wetland cumulative effects modelling (Section 6.8.7.2) which determined the extent of predicted habitat loss for mainland moose and snapping turtle within the Beaver Dam Mine Site.

How wildlife species such as mainland moose and snapping turtle are affected by habitat availability, use, or fragmentation is determined by species habitat requirements (e.g., thermal, cover, security) and rates of movement through various habitats (With & Crist, 1995). Fragmentation of a particular species' habitat implies a loss of habitat, reduced patch size, and/or increasing distance between patches. However, fragmentation may also suggest an increase of new habitat (Andren, 1994). Therefore, the effect of habitat fragmentation on a species (population) would be primarily through not only habitat loss, but also habitat changes. Habitat patches are parts of the landscape mosaic and the presence of a species in a patch may be a function not only of patch size and isolation, but also of the neighboring habitat. In landscapes with more than 30% of suitable habitat, fragmentation is primarily habitat loss (With & Crist, 1995). Habitat generalists may survive in very small patches because they can also use resources in the surroundings. Furthermore, the total species diversity across habitats in a given landscape may increase when new patches of habitat are created within the continuous habitat, since new species may be found in these new habitats, even if they are human-made (Andren, 1994).

Habitat selection by wildlife is primarily a response to security, thermal comfort, and forage needs. Wildlife must balance these conflicting requirements. Habitat selection is species-specific and choices will depend on physiological constraints and social needs of the species. Literature in conservation biology indicates that maintenance of movement corridors of suitable habitat between population centers is fundamental to wildlife health (Bentz, Saxena, & O'Leary, 1994).

Although security and thermal cover are important, habitat selection is strongly influenced by relative foraging opportunities (Renecker and Hudson 1999). Requirements for security vary seasonally and are greatest when animals feel threatened. Wildlife is vulnerable at parturition and when accompanied by neonates, a condition that is exacerbated when the mother is in poor condition. To off-set this disadvantage, wildlife select habitats consistent with their physical attributes and cryptic coloration. For example, white-tailed deer escape cover in forests (Renecker & Hudson, 1999).

Ungulate species, such as mainland moose, use upland forests and shrub areas for cover and foraging, including early-successional and previously harvested stands. Dense conifer stands are preferred in the winter, which provide reduced snow depth and thermal protection (Timmermann and McNicol 1988). Moose also require aquatic and wetland habitat for summer thermoregulation, calving and foraging (Timmermann and McNicol 1988). Snapping turtle is generally more aquatic than other turtle species, and require shallow aquatic environments for overwintering/hibernations, breeding and cover. Snapping turtle can tolerate and utilize disturbed areas, such as systems with poor water quality and anthropogenic features for nesting (e.g., berms, roadsides; ECCC 2020). A habitat loss by observed fauna species (or species group) based on the habitat analysis described in Section 6.11.7.1 and presented in Table 6.11-7. Based on the definitions of magnitude of impact, it is anticipated that all impacts to habitat types used by observed SAR and SOCI terrestrial fauna (i.e., mainland moose and snapping turtle) will be low, in comparison to habitat availability within the LAA.

Sensory disturbance to terrestrial fauna would result from rock blasting, clearing and grubbing, infrastructure construction during the construction phase and, overall increased traffic, blasting, mining activities and trucking during operations within the PA. This would likely result in localized wildlife avoidance of the PA, including moose and snapping turtle. Increased human activity could result in increased usage of the PA by opportunistic species such as coyotes, raccoons, skunks, or black bears. Overall, Project activities could cause a change in usage of the PA by wildlife, with some species tending to avoid the area, while others may be attracted to the increased activity. Studies completed by Buckmaster et al. (1999) indicate that wildlife populations may be expected to disperse from the area during periods of construction. However, this displacement is generally of short temporal disturbance as most cases reveal that wildlife have returned rapidly after human activity has ceased (Shank, 1979).

Changes to ambient noise and light levels and the presence of periodic vibrations have the potential to adversely affect fauna by influencing circadian patterns, seasonal patterns, movement and distribution, and community interactions and composition (Pauwels, 2018). Refer to Section 6.11.7.4 for a discussion on predicted sensory disturbance impacts to terrestrial fauna as a result of the Project.

Mainland moose are likely to be less significantly affected by sensory disturbance, due to their ability to easily travel to avoid this disturbance. Hibernating snapping turtles, on the other hand, are unable to easily escape sensory disturbance easily during hibernation. As such, practices should be implemented to reduce blasting near wetlands with suitable snapping turtle hibernacula during hibernation. Hibernation generally occurs from October through March, depending on seasonal temperatures (i.e., hibernation can start later in a warm fall and end sooner in an early spring, and vice versa).

Direct mortality of priority fauna species could result from Project activities, particularly due to the increase in traffic during construction and operation of the facility. Increased traffic poses a risk to wildlife such as the mainland moose and snapping turtle along the entire length of the Haul Road between the Beaver Dam Mine Site and the Touquoy Mine Site. Indirect mortality to these species could also occur from exposure to contaminants or spills from unplanned incidents.

The Touquoy Mine Site is currently operational. There are no direct or indirect effects to priority fauna species anticipated to be caused by the processing of ore and the management of tailings (exhausted pit) from the Beaver Dam Mine Project. Effects to terrestrial fauna species related to the Project are described in Section 6.11.

6.13.7.1.4 Priority Avifauna Species

The assessment of potential adverse interactions and effects of the Project on this VC takes into account the potential for the Project to result in changes to:

- Permanent and temporary habitat alteration and fragmentation;
- Disturbance and/or displacement;
- Potential for direct and indirect mortality to individuals; and
- Sensory disturbance.

With appropriate mitigation and monitoring, no direct mortality of priority bird species is anticipated, with the exception of the low potential for a bird strike with a haul truck. Avian usage of the PA during construction and operation of the Beaver Dam Mine will largely be driven by changes to habitat, resulting in localized avoidance of the PA by some species. Noise and light generated during all Project phases also has the potential to affect avifauna. Artificial noise and light, especially at night, have been shown to influence avian migration and behavior pattens, which could affect individual fitness and reproductive success (Da Silva et al. 2014). Refer to Section 6.11.7.4 for a discussion on predicted sensory disturbance impacts to terrestrial fauna as a result of the Project.

A habitat loss by observed avifauna functional groups based on the group's preferred habitat type(s) present in Section 6.12.8.1 and the habitat analysis described in Section 6.12.8.1 is presented in Table 6.12-11. Consideration was given to the specific avifauna SAR habitat preferences as described in Section 6.13.5.5. Seven of the nine observed SAR are Passerines (i.e., chimney swift, olive-side flycatcher, Canada warbler, rusty blackbird, barn swallow, eastern wood-pewee and evening grosbeak). Generally, these species inhabit forested areas, of varying stand ages, with access to wetlands and water features. Based on the definitions of magnitude of impact, it is anticipated that all impacts to habitat types used by observed SAR avifauna will be low, in comparison to habitat availability within the LAA. Refer to the wetland cumulative effects modelling (Section 6.8.7.2) which determined the extent of predicted habitat loss for Canada warbler, olive-sided flycatcher, and rusty blackbird within the Beaver Dam Mine Site.

Some priority species may avoid the PA in favor of undisturbed habitat in the surrounding landscape. Other priority species are anticipated to be attracted to the mine infrastructure and newly created habitat. The common nighthawk, for instance, is a crepuscular insectivore which nests on exposed gravel and disturbed areas. Lighting of buildings at dawn and dusk can create a foraging opportunity where insects are attracted to the lights. Barn swallows commonly nest in the eaves of built structures and bank swallows can nest in vertical slopes in sandy or silty soil, even in areas with high activity levels. These species of swallows have similar feeding habits as the common nighthawk. As such, Project activities may increase habitat suitability for both these species.

The placement of the open pit cannot be micro-sited as its location is dependent on the ore location. A single greater yellowlegs was observed during breeding bird surveys within Wetland 59 (Beaver Dam Mine Site PC1). Single observations of greater yellowlegs were also made during breeding bird surveys within the Beaver Dam Mine Site at PC3 and PC10, located along a road that connects the eastern and the western stockpiles and north of the PA, respectively. The road where PC3 is located was micro-sited to minimize impact to wetlands.

Detailed designs of the Haul Road will minimize impact to wetlands which may offer suitable nesting habitat for greater yellowlegs (such as that observed at Haul Road PC3). Wetland 64, the area of highest evidence of possible nesting (Haul Road PC1) will be impacted by upgrades to Beaver Dam Mines Road and increased traffic. This will occur during the construction and operation phases. As a result of PA and infrastructure modifications, a waterline has been rerouted and will no longer discharge into Wetland

64, avoiding resultant changes in hydrology and greater yellowlegs habitat. Detailed design planning for these upgrades will take into consideration the location of Wetland 64, and others along the Haul Road to reduce the impact to these locations if possible (such as Haul Road PC 3, near Wetland 121) while maintaining safe road conditions for haul activities.

The current habitat in the Beaver Dam Mine Site displays a high level of disturbance and has been fragmented by historical mine operations, forestry operations, and roads. As a result, the Beaver Dam Mine Site does not offer high quality breeding habitat for the greater yellow legs. Suitable nesting habitat for greater yellowlegs is present within the LAA surrounding the Beaver Dam Mine Site and Haul Road, which will remain unaltered. Specific mitigation and monitoring commitments related to the greater yellowlegs are provided in Section 6.13.8.4.

The Touquoy Mine Site is currently in operation. There are no direct or indirect effects to priority avifauna species anticipated to be caused by the processing of ore and the management of tailings (exhausted pit) from the Beaver Dam Mine Project. Effects to avifauna species related to the Project are described in Section 6.12.

6.13.8 Mitigation

The potential effects related to species and that are associated with the different phases of the Beaver Dam Mine Project are outlined in Tables 6.13-14 to 6.13-17, for each taxonomic group of species. Specific mitigation measures related to priority species are outlined in the following sections. A comprehensive mitigation table for all VCs is provided in Section 9.

6.13.8.1 Priority Fish Species

Standard mitigation for fish and fish habitat is expected to appropriately mitigate effects on priority fish species. Watercourse alteration permitting will also be required, at which time detailed fish habitat quantification and potential effects on priority fish species will be addressed. The following mitigation efforts (Table 6.13-14) are considered in addition to those general fish and fish habitat mitigation measures outlined in Section 6.9.8.

- AMNS has achieved avoidance of direct impacts and reduction in indirect impacts to fish and fish habitat through redesigning the site layout, as described in Section 6.9.8.1.
- Direct and indirect effects to fish and fish habitat, including priority fish species, has been fully assessed, quantified and incorporated into the draft Fish Habitat Offset Plan (Appendix J.3).
- A Mine Water Management Plan has been developed and will be implemented. This Plan describes water collection and treatment plans within the Beaver Dam Mine Site, which will avoid and minimize direct or indirect effects to fish and fish habitat. Specific provisions to prevent impacts to important habitat in Cameron Flowage/Killag River includes discharging water from the North Settling Pond to supplement baseflow.
- Site specific terms and conditions for alteration of watercourses which support priority fish species will be communicated to all site personnel and strictly adhered to; fish rescue will be completed within the Beaver Dam Mine Site prior to commencement of mine development;
- Culverts to be installed will be done in accordance with the NSE Watercourse Standard (2015) or as updated at time of construction to ensure fish passage through new culverts, and improving access by upgrading or removing improperly installed culverts, where possible; and,
- The location of all watercourses known to support priority species will be communicated to site personnel along with recommended mitigation measures.

Table 6.13-14: Mitigation for Priority Fish

Species and Rank	Observations	Direct Impacts from Proposed Infrastructure	Potential Adverse Effects	Mitigation	Effectiveness of Mitigation
Atlantic salmon (Nova Scotia Southern Upland Population) COSEWIC – E ACCDC – S1	Atlantic Salmon were observed in the Killag River, beyond the PA. Atlantic salmon have been documented within the West River Sheet Harbour watershed, including the West River Sheet Harbour (WC-N), Killag River, and Little River. No Atlantic salmon were observed within the Beaver Dam Mine Site and Haul Road throughout extensive fishing surveys (2015-2020).	No direct impacts to Atlantic salmon or Atlantic salmon habitat are anticipated as a result of the Project.	Harmful alteration, destruction, or disruption to habitat as a result of indirect impacts to watercourses downgradient of the PA.	Implement Offsetting Plan Complete fish rescue and relocation within all fish habitat where direct impact is proposed Limit access to the PA and prohibit staff fishing within the PA to avoid increased fishing pressures Blasting activities will adhere to setback recommendations and other mitigation strategies advised by DFO for measures to avoid causing harm to fish and fish habitat Develop and follow a detailed explosive management plan as part of the permitting process Use an emulsion-type explosive that will minimize nitrogen release to surface water and groundwater Implement AEMP to monitor Project effects on fish and fish habitat Install groundwater pumps to supplement baseflow in Cameron Flowage, if necessary Implement the Mine Water Management Plan Collect and treat all contact water, as required Implement Erosion and Sediment Management Plan Replace crushed, hung, or improperly installed culverts along the Haul Road that are impeding fish passage Replacement of crushed, hung, or improperly installed culverts along the Haul Road that are impeding fish passage	Avoidance and mitigation results in no harmful alteration, destruction or disruption to Atlantic salmon or its habitat within the PA Potential indirect impacts to Atlantic salmon to be monitored as part of Aquatic Effects Monitoring Plan (AEMP) Include monitoring of mitigation effectiveness in development of AEMP
American eel COSEWIC – TH ACCDC – S2	American eel were confirmed in WC13, the KIllag River, Cameron Flowage, and Mud Lake/WC27 within the Beaver Dam Mine SIte. American eel were confirmed in Watercourse N, V and AH along the Haul Road Potential American eel habitat includes Watercourses 5, 14, 25, and 26, and open water features associated with Wetlands 59 and 61 within the Beaver Dam Mine Site, and Watercourses A, B, C, D, E, F, G, J, M, N, O, Q, R, S, T, U, V, W, X, Y, Z, AA, AB, AC, AC, AD, AE, AF, AG, AH, and AI within the Haul Road All hydrologically connected watercourses within the PA are believed to be potentially accessible to the American eel, even if habitat provision in those watercourses is low.	The development of the open pit is expected to impact confirmed and potential American eel habitat in Wetlands 59, 61 and WC12, WC13, WC14, and WC25. Potential American eel habitat in WC5 to be directly impacted by internal haul road. No change in impact along the Haul Road Direct impacts from the Haul Road to potential American eel habitat in WC-C, WC-D, WC-J, WC-L, WC-M, WC-O, WC-X, WC-AC, WC-AF, WC-AG, and potential fish habitat in WL64, WL66, WL73, WL77, WL76, WL146, WL154, WL159, and WL160.	Harmful alteration, destruction, or disruption to habitat as a result of direct and indirect impacts to watercourses within and downgradient of the PA		Avoidance and mitigation results in no harmful alteration, destruction or disruption to fish or fish habitat for the majority of the PA. Any Harmful Alteration, Disruption, or Destruction (HADD) of fish habitat through direct or indirect project impacts will require authorization under Section 35 of the Fisheries Act. A draft Fish Habitat Offset Plan (Appendix J.3) has been prepared to provide quantification of aquatic habitat both directly and indirectly affected by the Project and to outline the offset measures proposed to compensate for any HADD determination Potential indirect impacts to American eel to be monitored as part of Aquatic Effects Monitoring Plan (AEMP) Include monitoring of mitigation effectiveness in development of AEMP

Notes: No monitoring plan, action plan, or recovery strategy the species listed.

PA = Project Area; DFO = Department of Fisheries and Ocean; AEMP = Aquatic Effects Monitoring Plan; HADD = Harmful Alteration, Disruption, or Destruction.

6.13.8.2 Priority Vascular Flora and Lichen Species

No vascular flora SAR has been observed within the PA. Five priority species of vascular flora were identified across the Beaver Dam Mine Site and within the Haul Road. Two SAR lichens and seven SOCI lichens were identified within the PA. The following mitigation efforts for SAR lichen (Table 6.13-15) are considered in addition to standard mitigation measures outlined previously in Sections 6.10.8.

- Avoid SOCI wherever possible, particularly during micro-siting and detailed engineering of the Haul Road upgrades and new construction. Clearly identifying locations of SOCI where they will be avoided, and instruct personnel of their whereabouts.
- A map of all priority vascular and non-vascular flora will be provided to site personnel during site orientation, and the locations of all priority flora species that will be avoided during Project construction will be clearly flagged in the field.
- AMNS will transplant priority vascular species, where deemed reasonable and appropriate in consultation with regulators, that are located within the direct footprint of the Beaver Dam Mine Site infrastructure or Haul Road to nearby areas where suitable habitat is present. Where avoidance or transplanting is not possible, the Project Team will collect vascular flora SOCI form areas proposed for direct impact for herbarium records or for preservation of seeds in a seed bank through Acadia University.
- Wherever avoidance of lichen SAR is not possible, the Project Team will implement the Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6), developed in consultation with lichen specialists and regulators.
- Where avoidance and transplantation is not possible, the Project Team will collect specimens for submission to Frances Anderson or equivalent contact at time of construction (Lichen Specialist, Research Associate, and Nova Scotia Museum).
- Lichens are particularly sensitive to changing environmental conditions, particularly air quality and edge effects. The Project Team will implement the Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6) for those lichen SAR identified beyond the Project infrastructure footprint but in close proximity to the proposed development to determine the extent of indirect effects on those species.

Table 6.13-15: Mitigation for SAR Lichen

Species and Rank	Observations	Direct Impacts from Proposed Infrastructure and Micro-siting	Potential Adverse Effects	Monitoring Plan, Action Plan, or Recovery Strategy	Mitigation	Effectiveness of Mitigation
Blue felt lichen SARA - SC COSEWIC - SC NSESA – V ACCDC – S3	33 observed locations in the Beaver Dam Mine Site, Haul Road, and in the broader LSA Observations within the Beaver Dam Mine Site (17 individuals): Seven occurrences in Wetland 14 Three occurrences in Wetland 17 One occurrence in Wetland 4 One occurrence in Wetland 205 Occurrences adjacent to Wetlands 1, 2, 29, and 61. Observations along the Haul Road (four occurrences): One occurrence adjacent to Wetland 112 Two occurrences 350 and 170 m northwest of Wetland 126 (beyond PA) One occurrence 90 m south of Wetland 116 (beyond PA)	Two occurrences will be directly impacted (NAG waste rock stockpile and Crusher area) No direct impact along Haul Road, within 30 m buffer of centerline Water line north of the open pit has been micro-sited to avoid lichen occurrences. Infrastructure interacts with the 100 m buffer of five individuals within the Beaver Dam Mine Site and four individuals along the Haul Road.	Sensitive to changing environmental conditions, particularly air quality and edge effects. Edge effects – e.g.: increased light, wind, temp; decrease in moisture due to nearby disturbance. Accidental cutting of host tree or too close to host tree	NSLF At-Risk-Lichen SMP, 2018	Complete further detailed design of Haul Road and micro siting of mine infrastructure to avoid priority lichen species. Reduce disturbance through buffering of habitat - maintain 100m buffer, wherever practicable Implement air quality monitoring and dust suppression plans Flag host trees and setback areas Implement dust suppression plan Provide map of all priority vascular and non-vascular flora, and their setbacks, to site personnel during site orientation Implement the Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6), developed in consultation with lichen specialists and regulators, for observations within and in close proximity to the PA Wherever avoidance of SAR lichen species is not possible, the Project Team will implement the Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6), developed in consultation with lichen specialists and regulators. The two directly impacted blue felt lichen occurrences are proposed for translocation. Where avoidance and translocation are not possible, the Project Team will collect specimens for submission to Frances Anderson or equivalent contact at time of construction (Lichen Specialist, Research Associate, and Nova Scotia Museum)	Monitoring transplants and other monitoring sites, as per the Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6) Observed populations are of similar extent or exhibit similar abundance/distribution to baseline data (considering loss from external environmental factors) Implement mitigations and adaptive management proposed in the Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6)as required
Boreal felt lichen SARA - E COSEWIC - E NSESA – E ACCDC – S1	Habitat identified as potential Boreal Felt Lichen habitat by NSL&F was surveyed – BFL was identified in the LSA. Three thalli were found south of the PA. Follow up surveys conducted in the fall of 2016 determined that all three thalli were no longer present. Their absence was reconfirmed on December 4, 2017	No direct Project interaction with Boreal Felt Lichen Critical Habitat Areas Closest Project infrastructure to the three historic observations is 975 m, 1014 m, and 940 m, respectively. Micro-siting of Project infrastructure moved development from the Boreal Felt Lichen Critical Habitat Areas and increased distance from observations.	Sensitive to changing environmental conditions, particularly air quality and edge effects. Edge effects – e.g.: increased light, wind, temp; decrease in moisture due to nearby disturbance. Accidental cutting of host tree or too close to host tree Adverse effects are not anticipated due to Project distance from the occurrences and critical habitat.	Amended Recovery Strategy, 2018 NSLF At-Risk-Lichen SMP, 2018 NSLF Adopted Boreal Felt Lichen Recovery Plan, 2020	Micro-siting of Project infrastructure has been completed to avoid observations and Boreal Felt Lichen Critical Habitat Areas Continued detailed Project design to ensure no development occurs within the Boreal Felt Lichen Critical Habitat Areas Implement air quality monitoring and dust suppression plans Flag host tree and setback areas Implement dust suppression plan Provide map of all priority vascular and non-vascular flora, and their setbacks, to site personnel during site orientation Implement the Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6), developed in consultation with lichen specialists and regulators.	Monitoring transplants and other monitoring sites, as per Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6) Observed populations are of similar extent or exhibit similar abundance/distribution over the study area to baseline data (considering loss from external environmental factors) Implement mitigations and adaptive management proposed in the Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6) as required

Table 6.13-15: Mitigation for SAR Lichen (continued)

Species and Rank	Observations	Direct Impacts from Proposed Infrastructure and Micro-siting	Potential Adverse Effects	Monitoring Plan, Action Plan, or Recovery Strategy	Mitigation	Effectiveness of Mitigation
Frosted glass-whiskers SARA - SC COSEWIC – SC ACCDC – S1?	Observations within the Beaver Dam Mine Site (eight individuals): One occurrence east of Wetland 29 One occurrence on an upland island within Wetland 29 One occurrence west Wetland 2 Four occurrences on an upland island within Wetland 2 One individual north of the open pit No occurrences observed along the Haul Road	No occurrences are expected to be directly impacted within the Beaver Dam Mine Site or Haul Road Water line north of the open pit has been micro-sited to avoid lichen occurrences. Micro-siting of Project infrastructure avoided previous direct impact to three occurrences	Sensitive to changing environmental conditions, particularly air quality and edge effects. Edge effects – e.g.: increased light, wind, temp; decrease in moisture due to nearby disturbance. Accidental cutting of host tree or too close to host tree	Management Plan 2011 NSLF At-Risk-Lichen SMP, 2018	Complete further detailed design of Haul Road and micro siting of mine infrastructure to avoid priority lichen species Complete further detailed design of Haul Road and micro siting of mine infrastructure to avoid priority lichen species. Reduce disturbance through buffering of habitat - maintain 100m buffer, wherever practicable Implement air quality monitoring and dust suppression plans Flag host trees and setback areas Implement dust suppression plan Provide map of all priority vascular and non-vascular flora, and their setbacks, to site personnel during site orientation Implement the Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6), developed in consultation with lichen specialists and regulators, for observations within and in close proximity to the PA Wherever avoidance of SAR lichen species is not possible, the Project Team will implement the Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6), developed in consultation with lichen specialists and regulators. Where avoidance and transplantation are not possible, the Project Team will collect specimens for submission to Frances Anderson or equivalent contact at time of construction (Lichen Specialist, Research Associate, and Nova Scotia Museum)	Monitoring transplants and other monitoring sites, as per Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6) Observed populations are of similar extent or exhibit similar abundance/distribution over the study area to baseline data (considering loss from external environmental factors) Implement mitigations and adaptive management proposed in the Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6) as required

6.13.8.3 Priority Terrestrial Fauna Species

Standard mitigation for terrestrial fauna is expected to appropriately mitigate effects on priority fauna species. The following mitigation efforts (Table 6.13-16) are considered in addition to those outlined in Section 6.12.8.

- Wildlife observation reporting to appropriate site personnel during construction, operation and decommissioning of Project.
- AMNS encourages the public to report mainland moose sightings to the province at https://novascotia.ca/natr/wildlife/sustainable/msform.asp.
- Development and implementation of a draft Wildlife Management and Mitigation Plan (Appendix P.7).
- Limit use of lights to the amount necessary to ensure safe Project operations. Install lights facing downward and wherever practicable using motion-sensing lights.
- Impacts to snapping turtles will be reduced by implementing a 30 m buffer on aquatic habitat deemed suitable for snapping turtles, wherever practicable.
- Where avoidance of potential turtle hibernation habitat is not possible, construction in these habitats should be limited to the growing season when hibernating turtles are not likely to be impacted (October through April).
- Culverts will be installed in wetlands and watercourses under provincial permits as required. Culverts can encourage reptiles and amphibians to cross through those, rather than crossing roads, particularly if approach to the road prevents access. This can be especially important for turtles during nesting season (June) when they are more attracted to gravelly roadsides.
- Wetland and watercourse alterations will be completed under approval from NSE, with associated mitigation, monitoring and compensation measures employed.
- Implement signage on the Haul Road during operations adjacent to major stream crossings or waterbodies, preferably signage that is installed only seasonally during turtles' active period as drivers are more likely to pay attention to new signs when they are erected prior to nesting season, for example, than if signs remain all year.
- Increase dust suppression on roads to improve visibility during nesting season and hatchling emergence.

Table 3.16-16: Mitigation for Priority Terrestrial Fauna

Species and Ranks	Observations	Direct Impacts from Proposed Infrastructure and Micro-siting	Potential Adverse Effects	Monitoring Plan, Action Plan, or Recovery Strategy	Mitigation	Effectiveness of Mitigation
Snapping turtle SARA - SC COSEWIC - SC NSESA – V ACCDC – S3	One snapping turtle and nest was observed on the berm of WL59 One snapping turtle was observed within the Haul Road. Two snapping turtles were opportunistically observed adjacent the Touquoy Mine Site, within the LAA. Snapping turtles were frequently observed at the Touquoy Mine Site between June 19, 2017 and July 2, 2020. Suitable habitat for Snapping Turtles has been observed in Wetlands 8, 10, 14, 17, 29, 44, 56, 59, 61, 64, 66, 68, 69, 159, 168, 171, and 207.	Wetland 56 and 59 directly impacted by open pit The southern portion of Wetland 17 and western portions of Wetland 61 fall within the open pit Small portions of Wetlands 10 is directly impacted (in area away from water features) Potential use of Haul Road (e.g., nesting) Infrastructure was micro-sited out of Wetland 8 and 29, no direct impacts. The open water portions of Wetlands 8, 10, 11, and 29 within the Beaver Dam Mine Site are not proposed for direct impact Bypass roads have been micro-sited to avoid Wetland 64. A waterline has been rerouted and will no longer discharge into Wetland 64, avoiding resultant changes in hydrology.	Habitat alteration, fragmentation, or loss Unintentional destruction of nests, eggs, hatchlings or adults Accidental mortality from vehicle strike Potential chemical contamination Sensory disturbance (noise, light)	Draft Wildlife Mitigation and Monitoring Plan (Appendix P.7)	Include in the development and implementation of the Draft Wildlife Mitigation and Monitoring Plan (Appendix P.7) Implement wildlife observation reporting to appropriate site personnel during construction, operation, and decommissioning of Project Safety and Environment orientation and training will include information on turtles and nesting season awareness training, particularly along the Haul Road. If snapping turtle activity is occurring within and/or adjacent to the Beaver Dam Mine Site or Haul Road, additional turtle awareness and management program will be implemented to ensure all staff are well informed regarding the increased turtle activity, especially during breeding season Complete further detailed design of Haul Road and micro siting of Beaver Dam Mine Site infrastructure to avoid aquatic habitat Upgrade existing roads, wherever practicable, instead of building new roads Replace crushed, hung, or improperly installed culverts, wherever practicable, to improve habitat connectivity (while maintaining existing hydrological conditions) Reduce disturbance through buffering of habitat - a 30 m buffer on aquatic habitat deemed suitable for snapping turtles, wherever practicable Where avoidance of potential turtle hibernation habitat is not possible, construction in these habitats will be limited to the growing season when hibernating turtles are not likely to be impacted (Overwintering period - October through April), wherever practicable Implement surface water quality monitoring program Install turtle crossing signs near major watercourse crossings, or in areas where snapping turtles have been observed, in an effort to increase awareness and reduce vehicular collisions - preferably only seasonally when turtles are active Vehicles will yield to wildlife on roads Dust suppression to improve visibility during nesting and hatchling emergence Vehicles will adhere to safe speed limits, particularly around blind corners An un-vegetated buffer along roadsides will be maintained, where possible, to improve visibility along roadsides and reduce the potential for collisions with wildlife If a turtle is found, report immediately to site Environmental Technician; if found on road, move away provided not actively nesting using proper moving technique Use predator excluders on identified nests Install fencing, where practicable, to prevent wildlife from accessing areas with increased risk of injuries to wild species - appropriate dimensions to address and eliminate accidental falls of species of varying size including turtles into the open pit	No increase in mortalities due to mine related activities. If mortalities are occurring, AMNS will consult with regulatory agencies to determine the necessary action to be taken Assess findings from the Draft Wildlife Mitigation and Monitoring Plan (Appendix P.7), and implement adaptive management measure as needed
Mainland moose NSESA – E ACCDC – S1	PA is within a Mainland Moose Concentration Area Mainland moose tracks were observed within the Beaver Dam Mine Site north of Wetland 56, within Wetland 210, and observed incidentally outside of the PA north of Wetland 206 No signs of mainland moose were observed incidentally or during dedicated surveys within the Haul Road	Potential habitat within the Beaver Dam Mine Site and Haul Road – use of disturbed roadside habitat	Increased access into a site (construction of new roads) may increase poaching levels Lowered viability of individual populations of moose by direct mortality and reduction in range Habitat alteration, fragmentation, or loss Sensory disturbance (noise, light)	Recovery Plan for Mainland Moose in Nova Scotia (NSDNR, 2007)	Include in the development and implementation of the Draft Wildlife Mitigation and Monitoring Plan (Appendix P.7). Implement Moose Management and Monitoring Program - including activities such as repeated winter track surveys and pellet group inventories, and collaboration with the Mi'kmaq of Nova Scotia to study Mainland Moose in a broader context Implement wildlife observation reporting to appropriate site personnel during construction, operation, and decommissioning of Project Vehicles will yield to wildlife on roads Vehicles will adhere to safe speed limits, particularly around blind corners. An un-vegetated buffer along roadsides will be maintained, where possible, to improve visibility along roadsides and reduce the potential for collisions with wildlife Install fencing, where practicable, to prevent wildlife from accessing areas with increased risk of injuries to wild species - appropriate dimensions to address and eliminate accidental falls of species of varying size including deer and moose into the open pit	No increase in mortalities due to mine related activities. If mortalities are occurring, the Proponent will consult with regulatory agencies to determine the necessary action to be taken If monitoring of Mainland Moose to verify the efficacy of mitigation strategies show signs of disturbance due to mine related activities, the Proponent will consult with regulatory agencies to develop an adaptive management plan or other appropriate mitigation as deemed necessary by regulators Assess findings from the Draft Wildlife Mitigation and Monitoring Plan (Appendix P.7) and implement adaptive management measure as needed

6.13.8.4 Priority Avifauna Species

The potential effects related to migratory birds and the different phases of the Beaver Dam Mine Project are outlined in Section 6.12.7. Most direct and indirect impacts on birds, including SAR, are accounted for in general mitigation/monitoring for all birds, since many have legislated protection under the *Migratory Birds Convention Act* (primarily through avoiding clearing/grubbing during nesting season if possible, and conducting detailed pre-construction nest searches if clearing or grubbing must occur during nesting season). These pre-construction nest searches are particularly important in wetlands which provide suitable breeding habitat for the Olive-sided Flycatcher, Canada Warbler and Rusty Blackbird.

A draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]) has been developed to verify the accuracy of the environmental assessment and the effectiveness of mitigation measures. Mitigations presented in this plan are described below and further outlined in Table 6.13-17:

- Avoiding clearing, grubbing and construction on native vegetation during the regional breeding season for migratory avifauna where practicable (beginning of April to end of August; ECCC 2015).
- Where this is not practicable, nesting bird surveys will be conducted Environmental personnel.
- Discourage ground- or burrow-nesting species (particularly common nighthawk and bank swallows, as directly requested by IR2 CEAA 2-24), by limiting the amount of exposed soil and stockpile slopes (less than 70°) during the breeding season, where practicable.
- Should any avifauna species initiate breeding or a nest be discovered in areas impacted by mine operations within the PA, the following actions will be taken:
  - The appropriate AMNS site personnel will be noticed immediately. Regulatory agencies (ECCC and NSL&F) will be contacted to review appropriate mitigation measures and buffer zones.
  - Spatial setbacks and temporal restrictions will be applied to the nest until chicks have fledged.
  - Monitoring will occur by qualified personnel (e.g., Environmental Technician) to determine if the chicks have fledged and if operations can re-commence.
- If a raptor nest is found within the forested areas to be cleared, a buffer zone appropriate to the species (as determined in consultation with NSL&F) would be placed around the nest.
- Monitor identified nests from a distance with a spotting scope or binoculars to verify the effectiveness of an identified buffer until the nests are inactive.
- Conduct routine inspections of the open pit area to remove any trapped or injured avifauna. If identified, determine a plan for removal in consultation with an avian specialist.
- Minimize on-site lighting while still allowing for safe operation and by installing downward-facing lights on site infrastructure and haul roads. Wherever practicable, install motion-sensing lights to ensure lights are not turned on when they are not necessary.
- Maintain speed limits on mine roads (max. 40 km/hr. within Beaver Dam Mine Site, 70 km/hr. along Haul Road) to minimize collisions with avifauna, implement dust suppression mitigations and conduct mobile refueling at least 30 m from any known breeding locations.

Table 6.13-17: Mitigations for Species at Risk Avifauna and Greater Yellowlegs (SOCI)

Species and Ranks	Observations	Direct Impacts from Proposed Infrastructure and Micro-siting	Potential Adverse Effects	Monitoring Plan, Action Plan, or Recovery Strategy	Mitigation	Effectiveness of Mitigation
Common nighthawk SARA - Th COSEWIC - SC NSESA – Th ACCDC – S2B	Observed along the Haul Road Four Common Nighthawks were observed during both breeding bird (n=1) and dedicated species surveys (n=3) in 2016	Possible breeding habitat within the PA - commonly associated with expansive gravelly areas adjacent to clear cuts or disturbed areas such as roadsides	Collisions with anthropogenic structures and vehicles Habitat alteration, fragmentation, or loss Sensory disturbance (noise, light) Unintentional destruction of nests, eggs, nestlings or adults Breeding disruption or functional habitat loss due to sensory disturbance (noise or light)	Recovery Strategy 2016	Avoid clearing/grubbing activities during nesting season If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation Discourage ground- or burrow-nesting species by limiting the amount of exposed soil Limit light use to direct and focused light when needed for worker safety Implement noise management including use of mufflers on equipment and regular maintenance Implement dust suppression plan Implement the draft Landbird Mitigation and Monitoring Plan (Appendix A of draft Wildlife Mitigation and Monitoring Plan) and Appendix P.7 draft Wildlife Mitigation and Monitoring Plan. All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	Assess findings from the Landbird SAR Mitigation and Monitoring Plan and Wildlife Management Plan, and implement adaptive management measure as needed If monitoring to verify the efficacy of mitigation strategies and any executed setbacks show signs of disturbance despite the setback, consultation with Environment and Climate Change Canada's Canadian Wildlife Service and other appropriate regulatory authorities will take place to develop a proposed adaptive management plan Monitor known nests around stockpiles and exposed areas from a distance with a spotting scope or binoculars to verify the effectiveness of the buffer until the nests are inactive Notify Environment and Climate Change Canada within 24 hours in the event of the mortality or injury of ten or more migratory birds in a single event or in the event of the mortality or injury of a migratory bird SAR
Canada warbler SARA - Th COSEWIC - Th NSESA – E ACCDC – S3B	Preferred habitat (moist mixed forests) was observed within the Beaver Dam Mine Site and Haul Road Eighteen Canada warblers were observed during the 2015, 2016 and 2019 breeding bird surveys within the Beaver Dam Mine Site and Haul Road.	Possible breeding habitat within the PA - moist mixed forests	Collisions with anthropogenic structures and vehicles Habitat alteration, fragmentation, or loss Sensory disturbance (noise, light) Unintentional destruction of nests, eggs, nestlings or adults Breeding disruption or functional habitat loss due to sensory disturbance (noise or light)	Recovery Strategy 2016	Avoid clearing/grubbing activities during nesting season If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation Limit light use to direct and focused light when needed for worker safety Implement noise management including use of mufflers on equipment and regular maintenance Implement dust suppression plan Implement the draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]) All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	Assess findings from the draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]), and implement adaptive management measure as needed If monitoring to verify the efficacy of mitigation strategies and any executed setbacks show signs of disturbance despite the setback, consultation with Environment and Climate Change Canada's Canadian Wildlife Service and other appropriate regulatory authorities will take place to develop a proposed adaptive management plan Notify Environment and Climate Change Canada within 24 hours in the event of the mortality or injury of ten or more migratory birds in a single event or in the event of the mortality or injury of a migratory bird SAR
Olive-sided flycatcher SARA - Th COSEWIC - SC NSESA – Th ACCDC – S2B	Observations were sparse, yet scattered across the Beaver Dam Mine Site (n=5) and Haul Road (n=5)	Possible breeding habitat within PA - commonly associated with edge habitat	Collisions with anthropogenic structures and vehicles Habitat alteration, fragmentation, or loss Sensory disturbance (noise, light) Unintentional destruction of nests, eggs, nestlings or adults Breeding disruption or functional habitat loss due to sensory disturbance (noise or light)	Recovery Strategy 2016	Avoid clearing/grubbing activities during nesting season If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation Limit light use to direct and focused light when needed for worker safety Implement noise management including use of mufflers on equipment and regular maintenance Implement dust suppression plan Implement surface water quality monitoring program Implement the draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]) All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	Assess findings from the draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]), and implement adaptive management measure as needed If monitoring to verify the efficacy of mitigation strategies and any executed setbacks show signs of disturbance despite the setback, consultation with Environment and Climate Change Canada's Canadian Wildlife Service and other appropriate regulatory authorities will take place to develop a proposed adaptive management plan Notify Environment and Climate Change Canada within 24 hours in the event of the mortality or injury of ten or more migratory birds in a single event or in the event of the mortality or injury of a migratory bird SAR

Table 6.13-17: Mitigations for SAR Avifauna and Greater Yellowlegs (SOCI) (continued)

Species and Ranks	Observations	Direct Impacts from Proposed Infrastructure and Micro-siting	Potential Adverse Effects	Monitoring Plan, Action Plan, or Recovery Strategy	Mitigation	Effectiveness of Mitigation
Eastern wood-pewee SARA - SC COSEWIC - SC NSESA – V ACCDC – S3S4B	Two observed: one identified at the outlet of Cameron Flowage, to the east of the Beaver Dam Mine Site, while the second was observed incidentally along the Haul Road, east of Wetland 114	Possible breeding habitat within PA – mature and intermediate mixed wood forest with open understory No expected direct impact to the two observation locations	Collisions with anthropogenic structures and vehicles Habitat alteration, fragmentation, or loss Sensory disturbance (noise, light) Unintentional destruction of nests, eggs, nestlings, or adults Breeding disruption or functional habitat loss due to sensory disturbance (noise or light) Impacts from dust along Haul Road	No current monitoring plan, action plan or recovery strategy for this species in this area	Avoid clearing/grubbing activities during nesting season If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation Limit light use to direct and focused light when needed for worker safety Implement noise management including use of mufflers on equipment and regular maintenance Implement dust suppression plan Implement draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]) All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	Assess findings from the draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]), and implement adaptive management measure as needed If monitoring to verify the efficacy of mitigation strategies and any executed setbacks show signs of disturbance despite the setback, consultation with Environment and Climate Change Canada's Canadian Wildlife Service and other appropriate regulatory authorities will take place to develop a proposed adaptive management plan Notify Environment and Climate Change Canada within 24 hours in the event of the mortality or injury of ten or more migratory birds in a single event or in the event of the mortality or injury of a migratory bird SAR
Peregrine falcon SARA - SC COSEWIC - NAR NSESA – V ACCDC – S1B	Two peregrine falcons were observed incidentally (n=1) and during the dedicated fall migration surveys (n=1) adjacent to the Beaver Dam Mine Site, in 2014. Both observations were documented immediately north of the Beaver Dam Mine Site, between Mud Lake and Cameron Flowage.	Suitable breeding habitat was not present within the Beaver Dam Mine Site or Haul Road No direct impact to two observation locations	Habitat alteration, fragmentation, or loss Sensory disturbance (noise, light) Unintentional destruction of nests, eggs, nestlings, or adults Breeding disruption or functional habitat loss due to sensory disturbance (noise or light)	Management Plan 2017	Avoid clearing/grubbing activities during nesting season If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation Limit light use to direct and focused light when needed for worker safety Implement dust suppression plan Implement noise management including use of mufflers on equipment and regular maintenance Implement the draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]) All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	Assess findings from the draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]), and implement adaptive management measure as needed If a raptor nest is found within the forested areas to be cleared, a buffer zone appropriate to the species (as determined in consultation with NSL&F) would be placed around the nest If monitoring to verify the efficacy of mitigation strategies and any executed setbacks show signs of disturbance despite the setback, consultation with Environment and Climate Change Canada's Canadian Wildlife Service and other appropriate regulatory authorities will take place to develop a proposed adaptive management plan Notify Environment and Climate Change Canada within 24 hours in the event of the mortality or injury of ten or more migratory birds in a single event or in the event of the mortality or injury of a migratory bird SAR
Chimney swift SARA - Th COSEWIC - Th NSESA – E ACCDC – S2B, S1M	Two chimney swifts were observed incidentally during the breeding season in 2015, within the Beaver Dam Mine Site. They were observed from Wetland 53, which is in the center of the Beaver Dam Mine Site, south of Crusher Lake There were no signs observed of chimney swift breeding	No suitable chimneys for roosting and nesting were observed within the PA; however, waterbodies used for foraging are present within the Beaver Dam Mine Site and Haul Road. Wetland 53 is no longer impacted by Project infrastructure.	Collisions with anthropogenic structures and vehicles Habitat alteration, fragmentation, or loss Sensory disturbance (noise, light) Unintentional destruction of nests, eggs, nestlings, or adults Breeding disruption or functional habitat loss due to sensory disturbance (noise or light)	No current monitoring plan, action plan or recovery strategy for this species in this area	Avoid clearing/grubbing activities during nesting season If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation Limit light use to direct and focused light when needed for worker safety Implement dust suppression plan Implement noise management including use of mufflers on equipment and regular maintenance Implement the draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]. All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	Assess findings from the draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]), and implement adaptive management measure as needed If monitoring to verify the efficacy of mitigation strategies and any executed setbacks show signs of disturbance despite the setback, consultation with Environment and Climate Change Canada's Canadian Wildlife Service and other appropriate regulatory authorities will take place to develop a proposed adaptive management plan Notify Environment and Climate Change Canada within 24 hours in the event of the mortality or injury of ten or more migratory birds in a single event or in the event of the mortality or injury of a migratory bird SAR

Table 6.13-17: Mitigations for SAR Avifauna and Greater Yellowlegs (SOCI) (continued)

Species and Ranks	Observations	Direct Impacts from Proposed Infrastructure and Micro-siting	Potential Adverse Effects	Monitoring Plan, Action Plan, or Recovery Strategy	Mitigation	Effectiveness of Mitigation
Rusty blackbird SARA - SC COSEWIC - SC NSESA - E	One rusty blackbird was observed incidentally during the 2014 fall migration survey in a large wetland complex to the north of the Beaver Dam Mine Site (PC15).	Breeding habitat, including forested wetlands, swamps, and peat bogs are present within the Beaver Dam Mine Site and Haul Road, however, no evidence of breeding was observed (no birds were observed within PA). No direct impact to observation location (beyond the PA)	Collisions with anthropogenic structures and vehicles Habitat alteration, fragmentation, or loss - particularly wetland loss Sensory disturbance (noise, light) Unintentional destruction of nests, eggs, nestlings, or adults Breeding disruption or functional habitat loss due to sensory disturbance (noise or light)	Management Plan 2015	Avoid clearing/grubbing activities during nesting season Complete further detailed design of Haul Road and micro siting of mine infrastructure to avoid major wetlands. Where wetlands cannot be avoided, total Project footprint within the wetland will be minimized to the extent practicable. Implement wetland monitoring programs If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation Limit light use to direct and focused light when needed for worker safety Implement dust suppression plans Implement noise management including use of mufflers on equipment and regular maintenance Implement the Landbird SAR Mitigation and Monitoring Plan and Wildlife Management Plan All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	Assess findings from the draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]), and implement adaptive management measure as needed Assess impacts to habitat through Wetland Monitoring Program If monitoring to verify the efficacy of mitigation strategies and any executed setbacks show signs of disturbance despite the setback, consultation with Environment and Climate Change Canada's Canadian Wildlife Service and other appropriate regulatory authorities will take place to develop a proposed adaptive management plan Notify Environment and Climate Change Canada within 24 hours in the event of the mortality or injury of ten or more migratory birds in a single event or in the event of the mortality or injury of a migratory bird SAR
Barn swallow SARA - Th COSEWIC - Th NSESA - E	One barn swallow was observed along the Haul Road during the 2016 spring migration surveys, near Wetland 159. None were observed during the breeding bird surveys completed in the Beaver Dam Mine Site. Potential nesting habitat is available within the Beaver Dam Mine Site and Haul Road, particularly artificial structures including a cabin, bridges, and road culverts.	Possible breeding habitat within PA – artificial structures No expected direct impact to observation location along the Haul Road.	Habitat alteration, fragmentation, or loss Collisions with anthropogenic structures and vehicles Attraction to manmade structures for nesting Unintentional destruction of nests, eggs, nestlings or adults Breeding disruption or functional habitat loss due to sensory disturbance (noise or light)	No current monitoring plan, action plan or recovery strategy for this species in this area	Avoid clearing/grubbing activities during nesting season If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation Check abandoned structures on site for nests prior to any demolition Limit light use to direct and focused light when needed for worker safety Implement dust suppression plans Implement noise management including use of mufflers on equipment and regular maintenance Implement the Landbird SAR Mitigation and Monitoring Plan and Wildlife Management Plan All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	Assess findings from the draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]), and implement adaptive management measure as needed If monitoring to verify the efficacy of mitigation strategies and any executed setbacks show signs of disturbance despite the setback, consultation with Environment and Climate Change Canada's Canadian Wildlife Service and other appropriate regulatory authorities will take place to develop a proposed adaptive management plan Notify Environment and Climate Change Canada within 24 hours in the event of the mortality or injury of ten or more migratory birds in a single event or in the event of the mortality or injury of a migratory bird SAR
Greater yellowlegs ACCDC – S3B,S3S4M	A total of 25 observations within the Beaver Dam Mine Site and eight observations along the Haul Road	Possible breeding habitat within the Beaver Dam Mine Site in close proximity or directly impacted by infrastructure Probable breeding habitat within Wetland 64 in close proximity to Haul Road upgrades. Bypass roads have been micro-sited to avoid Wetland 64. A waterline has been rerouted and will no longer discharge into Wetland 64, avoiding resultant changes in hydrology.	Collisions with anthropogenic structures and vehicles Habitat alteration, fragmentation, or loss Sensory disturbance (noise, light) Unintentional destruction of nests, eggs, nestlings or adults Breeding disruption or functional habitat loss due to sensory disturbance (noise or light) Impacts from dust along Haul Road	No current monitoring plan, action plan or recovery strategy for this species in this area	Avoid clearing/grubbing activities during nesting season Complete construction and upgrades of Haul Road within Wetland 64 outside of the active nesting season for Greater Yellowlegs, if practicable If construction is required during the active nesting season, an avian specialist will monitor for nesting activity within Wetland 64 and adjacent undisturbed habitat. If evidence of nesting is observed, AMNS will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation. Implement dust suppression plans Limit light use to direct and focused light when needed for worker safety Implement noise management including use of mufflers on equipment and regular maintenance Implement the draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]) All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	Assess findings from the draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]), and implement adaptive management measure as needed If monitoring of Greater Yellowlegs to verify the efficacy of mitigation strategies and any executed setbacks show signs of disturbance despite the setback, consultation with Environment and Climate Change Canada's Canadian Wildlife Service and other appropriate regulatory authorities will take place to develop a proposed adaptive management plan Implement bird deterrents in Wetland 64 as necessary Notify Environment and Climate Change Canada within 24 hours in the event of the mortality or injury of ten or more migratory birds in a single event or in the event of the mortality or injury of a migratory bird SAR

Table 6.13-17: Mitigations for SAR Avifauna and Greater Yellowlegs (SOCI) (continued)

Species and Ranks	Observations	Direct Impacts from Proposed Infrastructure and Micro-siting	Potential Adverse Effects	Monitoring Plan, Action Plan, or Recovery Strategy	Mitigation	Effectiveness of Mitigation
Evening grosbeak SARA – SC COSEWIC – SC NSESA – Th ACCDC – S3S4B, S3N	Two individuals were observed during the breeding season in 2016, at PC7 along the Haul Road, in upland habitat. There were no signs observed of breeding	Possible breeding habitat within PA –open, mature mixedwood upland forests Observed location is directly adjacent to prosed Haul Road alignment.	Collisions with anthropogenic structures and vehicles Habitat alteration, fragmentation, or loss Sensory disturbance (noise, light) Unintentional destruction of nests, eggs, nestlings or adults Breeding disruption or functional habitat loss due to sensory disturbance (noise or light)	No current monitoring plan, action plan or recovery strategy for this species in this area	Avoid clearing/grubbing activities during nesting season If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation Limit light use to direct and focused light when needed for worker safety Implement dust suppression plans Implement noise management including use of mufflers on equipment and regular maintenance Implement the draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]) All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	Assess findings from the draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]), and implement adaptive management measure as needed If monitoring to verify the efficacy of mitigation strategies and any executed setbacks show signs of disturbance despite the setback, consultation with Environment and Climate Change Canada's Canadian Wildlife Service and other appropriate regulatory authorities will take place to develop a proposed adaptive management plan Notify Environment and Climate Change Canada within 24 hours in the event of the mortality or injury of ten or more migratory birds in a single event or in the event of the mortality or injury of a migratory bird SAR

- While no significant impacts are expected from the Project to mature and interior forests, overall and in the greater adjacent area, in instances where these habitat types cannot be avoided specific mitigations are proposed in Section 6.10 of the Updated 2021 EIS (AMNS 2021a).
- A draft Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]), will be implemented during Project development.
- Wetland monitoring will occur within the PA, in wetland habitat that will be avoided by the Project, to ensure that wetland integrity is maintained, as these are the locations which have the highest potential to support landbird SAR.
- Implement surface water quality monitoring program, as many landbird SAR are reliant on wetlands and sources of open water for critical life functions.
- Communicate regulations related to nesting birds to all site personnel, particularly focused on those priority bird species which may be attracted to Project activities.
- Notify Environment and Climate Change Canada within 24 hours in the event of the mortality or injury of ten or more migratory birds in a single event or in the event of the mortality or injury of a bird SAR.

Additional mitigation measures specific to greater yellowlegs include:

- Wherever possible, clearing/grubbing and construction within and near wetland habitat will be limited during the nesting season;
- If construction is required within Wetland 64 during the active nesting season, an avian specialist will monitor for nesting activity within the wetland and adjacent undisturbed habitat. The proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation.
- An AMNS and contractor awareness program will be implemented to inform staff of greater yellowlegs identification and signs of nesting behavior. Contractors will be informed of their responsibility to remain inside approved work areas, and to report signs of nesting behavior of the greater yellowlegs to the Proponent's staff.
- To avoid nesting activity, bird deterrents will be implemented within Wetland 64, as this is the only location where probably breading was observed, following best-management-practices used in the mining industry.
- If new breeding evidence or nests are observed within 300 m of Project activities, a site mitigation plan will be developed in consultation with regulators. Nests will be monitored from a distance using binoculars or a spotting scope to avoid further human disturbance from monitoring. An acceptable setback (to be established in consultation with regulatory authorities) will be established.
- New bypass roads have been micro-sited to avoid Wetland 64 and, as a result of PA and infrastructure modifications, a waterline has been rerouted and will no longer discharge into Wetland 64, avoiding resultant changes in hydrology.

6.13.9 Residual Effects and Significance

Based on avoidance, mitigation and monitoring proposed for all priority species listed above, the following residual effects are anticipated. Project VC interactions of a priority taxa (e.g., priority fish species) that have the same residual environmental effects characteristic rankings of their related non-priority specific VC (e.g., fish and fish habitat) are not carried forward in the tables below. Rationales for differences in residual effect rankings are described following sections and tables.

The ecological and social context of each priority species taxa was included throughout the evaluation as was completed for all VCs. In general, the ecological and social context specific to priority species are more significant than non-listed species in each taxa. Ecological (species abundance, habitat, food source etc.) and social factors (recreational, commercial and Indigenous) for priority species are typically more specific and sensitive than for non-priority species. For example, rusty blackbirds have very specific ecological requirements for foraging and nesting and brook trout is of great social importance recreationally as one of Nova Scotia's most important sports fish and is also an important fish for the Mi'kmaq of Nova Scotia. SAR/SOCI species are less abundant than common species (e.g., mainland moose vs. snowshoe hare).

6.13.9.1 Priority Fish Species

Two VC interactions presented in Table 6.9-25 have been carried forward to Table 6.13-18 for priority fish species. In general, the residual effects to fish and fish habitat presented in Section 6.9.9 is consistent with the residual effects to priority fish species. No direct impacts are proposed in watercourses, waterbodies or wetlands known or expected to provide habitat for Atlantic salmon. Direct impacts are proposed in several habitats known to support brook trout and American eel; however, the residual effects to these species is reflected in Section 6.9.9. Given implementation of appropriate avoidance, mitigation and offsetting, significant adverse residual impacts to brook trout and American eel are not anticipated. Along the Haul Road, it is expected that fish habitat direct impact can be minimized through proper planning, micro-sighting of the upgraded road footprint, and installation of culverts in accordance with the Nova Scotia Watercourse Alteration Standard (2015). The two VC interactions which have been carried forward to the table below include indirect impacts during operations and post-closure, where the potential impact to sensitive Atlantic salmon habitat within the Killag River is the most elevated. The geographic extent, timing, duration, frequency, reversibility and magnitude of indirect impacts to Atlantic salmon remains the same as is with non-priority specific fish and fish habitat for these VC interactions. However, the scrutiny and analysis undertaken in determining the magnitude of each effect was substantially higher for priority species, particularly Atlantic salmon in Cameron Flowage/Killag River.

6.13.9.2 Priority Vascular Plant and Lichen Species

There are no differences between the residual environmental effects for non-priority specific flora and lichens compared to priority flora and lichens. Refer to Table 6.10-13 for residual environmental effects of habitat and flora.

No SAR vascular flora will be directly impacted by the Project. Mitigation of the two blue felt lichen occurrences that are expected to be directly impacted is proposed through the Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6).

6.13.9.3 Priority Terrestrial Fauna Species

All four VC interactions presented in Table 6.11-10 have been carried forward to Table 6.13-19 for priority terrestrial fauna species.

Project activities are expected to result in increased habitat fragmentation and a decrease in habitat quantity and quality for those species, including mainland moose, which rely especially on interior forest conditions. Clearing and grubbing during construction can reduce cover for priority turtle species (e.g., snapping turtle), indirectly affect water quality, and isolate populations (ECCC, 2016). For species relying on interior forest condition, the decrease in habitat quantity and quality is based on increased activity and sensory disturbance, along with increased physical habitat loss and fragmentation, which interferes with the long-term population viability and is a serious threat to the mainland moose in particular (NSDNR, 2007).

Table 6.13-18: Residual Effects for Priority Fish and Fish Habitat

Project VC Interactions	Parameter	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
			Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Operations –Beaver Dam Mine Site Indirect impacts including groundwater drawdown, groundwater seepage, altered surface water quality Cameron Flowage/Killag River Tent Lake Cope Brook	Indirect	Interceptor trench west of PAG stockpile Water treatment (as required) Discharge point location at northern end of Cameron Flowage Vegetative buffers to provide shade to on-site ponds Install groundwater pumps to supplement baseflow in Cameron Flowage Explosives Management Best Management Practices	L Interaction likely to cause indirect impacts to fish habitat	LAA Potential adverse effect to fish habitat outside of the PA	A Seasonal habitat provisions may affect VC	P Effect is expected to be permanent	R Effects occur at regular intervals throughout the Project	PR Groundwater drawdown effects will cease once the pit lake has filled. Surface water interactions are partially reversible	Habitat alteration	Not significant
Post Closure – Beaver Dam Mine Site and Touquoy Mine site Surface water quality Cameron Flowage/Killag River Moose River	Indirect	Water treatment (as required)	N VC interaction will remain below appropriate guidelines	LAA VC interaction will extend beyond PA	A Seasonal aspects will affect VC	P Effect is expected to be permanent	R Effects are expected to occur over a regular interval	PR VC will partially recover to baseline conditions	Change in water quality	Not significant

Notes: See Section 6.9Table 6.9-7 for definitions of the below characteristics.

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	I	Intermittent	IR	Irreversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	PR	Partially Reversible
H	High					P	Permanent	C	Continuous		

Table 6.13-19: Residual Effects for Priority Terrestrial Fauna

Project - VC Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction – Beaver Dam Mine Site and Haul Road (habitat loss and fragmentation from clearing and grubbing)	Limit habitat disturbance and minimize Project footprint during detailed design, implement speed limits, install fences where necessary, and minimize lighting.	L < 5% direct loss of habitat types used by observed SAR and SOCI within the LAA Partial mitigation through restoration.	RAA Potential adverse effect to fauna outside of the LAA (fragmentation)	A VC interaction may affect seasonal aspects of fauna.	MT (Beaver Dam Mine Site) Effects occur beyond 5 years when closure activities commence at Beaver Dam Mine Site. P (Haul Road) Closure of the Haul Road not expected.	O Effects occur once during the construction phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Loss	Not Significant
Construction – Beaver Dam Mine Site and Haul Road (sensory disturbance (noise, light, dust deposition) and wildlife vehicle collisions from construction activities)	Implement speed limits, install fences where necessary, and minimize lighting.	M	LAA Potential adverse effect to fauna outside of the PA	A VC interaction may affect seasonal aspects of fauna.	ST Effects are limited to occur from as little as 1 day to 12 months	R Effects occur at regular intervals during the construction phase	R VC will recover to baseline conditions	Disturbance	Not Significant
Operational – Beaver Dam Mine Site, Haul Road and Touquoy Mine Site (disturbance (noise, light, dust deposition and wildlife vehicle collisions) from haul trucks, heavy machinery and mine operations)	Implement speed limits, install fences where necessary, and minimize lighting.	M Moderate changes relative to baseline conditions in remaining and surrounding habitat.	LAA Potential adverse effect to fauna beyond the PA.	A VC interaction may affect seasonal aspects of fauna.	MT Effects may occur up to 5 years.	R Effects occur at regular intervals.	R VC will recover to baseline conditions	Disturbance	Not Significant
Closure (Active) – Beaver Dam Mine Site (re-establishment of habitat for fauna)	N/A	L Minor change from baseline conditions.	LAA Potential effect to fauna outside of the PA	A VC interaction may affect seasonal aspects of fauna.	LT Effects extend beyond active closure phase.	O Effects occur once during the closure phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Reclamation	Not Significant

Notes: See Section 5.11, Table 5.11-1 for definitions of the below characteristics.

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	IR	Irreversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	PR	Partially Reversible
H	High					P	Permanent	C	Continuous		

However, physical habitat loss for observed priority terrestrial fauna species is expected to be low, as presented in Section 6.11, in comparison to available habitat in the LAA. Based on the current high level of disturbed habitat and the limited Project edge effect impact to predicted interior forest patches, habitat fragmentation is also assessed to be low. Undisturbed, unfragmented habitat is present in the RAA, and the larger tracts are maintained around the PA, particularly on the north and southwest. Baseline conditions within the Beaver Dam Mine Site and the majority of the Haul Road (between logging roads and forestry activity) already demonstrate fragmentation as a result of a high level of forestry activity, especially within the Beaver Dam Mine Site where habitat loss will be greatest. The Beaver Dam Mine Site infrastructure footprint is situated primarily on an area of high existing disturbance and will only have fringe effects on the interior forest availability. There will be minimal isolation of habitat that is currently contiguous, limited to the portion of potential interior forest west of the NAG waste rock stockpile. However, broadly speaking, accessible routes to provide movement through and across the larger region at the LAA and RAA level still exist for wildlife and are un-impacted by the development of the Project. The RAA is generally remote, with a total of 72,663 ha of predicted interior forest. The maximum Project edge effect as discussed in Section 6.10.7.1, will affect 237 ha of interior forest habitat, which accounts for 0.3% of predicted interior forest in the RAA.

Vehicle and haul truck activity will occur throughout the PA during the construction, operations, and and closure phases. Vehicle and haul truck activity can cause impacts to priority fauna from wildlife vehicle collisions, dust, noise, and accidents (e.g., spills). Wildlife vehicle collisions can directly affect priority fauna and noise can indirectly affect priority fauna by encouraging avoidance behaviour.

Blasting and drilling of in-situ rock will occur at the Beaver Dam Mine Site during the operational phase of the Project. Blasting could negatively affect priority fauna from the noise associated with the activity. Although blasting is restricted to the PA the sound disturbance to terrestrial fauna has the potential to extend into the LAA. For example, a noise disturbance can cause flight behaviour in all terrestrial fauna but the impact to the energy balance of a mainland moose may have more severe consequences compared to a non-priority fauna species because stress on an already endangered (NSESA) population may impede its biological success in turn having a greater impact on the species.

6.13.9.4 Priority Avifauna Species

All four VC interactions presented in Table 6.12-15 have been carried forward to Table 6.13-20 for priority avifauna species.

Project activities (i.e., clearing and grubbing) are expected to result in increased habitat fragmentation and a decrease in habitat quantity and quality for those avifauna species, which rely especially on interior forest conditions. For species relying on interior forest condition, such as those presented in Table 6.12-11, the decrease in habitat quantity and quality is primarily based on increased activity and sensory disturbance, along with increased physical habitat loss and fragmentation.

However, physical habitat loss for observed SAR avifauna species is expected to be low, as presented in Section 6.12, in comparison to available habitat in the LAA. Based on the current high level of disturbed habitat and the limited Project edge effect impact to predicted interior forest patches, habitat fragmentation is also assessed to be low. Undisturbed, unfragmented habitat is present in the LAA and RAA, and the larger tracts are maintained around the PA, particularly on the north and southwest. Baseline conditions within the Beaver Dam Mine Site and the majority of the Haul Road (between logging roads and forestry activity) already demonstrate fragmentation as a result of a high level of forestry activity, especially within the Beaver Dam Mine Site where habitat loss will be greatest. The Beaver Dam Mine Site infrastructure footprint is situated primarily on an area of high existing disturbance and will only have fringe effects on the interior forest availability. The LAA is generally remote, with a total of 2,660 ha of predicted interior forest. The maximum Project edge effect as discussed in Section 6.10.7.1.2, will affect 237 ha of interior forest habitat, which accounts for which accounts for 9% of predicted interior forest in the LAA and 0.3% within the RAA.

Table 6.13-20: Residual Effects for Priority Avifauna

Project - VC Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction – Beaver Dam Mine Site and Haul Road (habitat loss from clearing and grubbing)	Limit habitat disturbance and minimize Project footprint during detailed design, implement speed limits and minimize lighting.	L < 5% direct loss of habitat types used by observed species within the LAA Partial mitigation through restoration.	LAA Potential adverse effect to avifauna outside of the PA	A Although clearing and grubbing will occur outside of the sensitive period for avifauna, other activities will not.	MT (Beaver Dam Mine Site) Effects occur beyond 5 years when closure activities commence at Beaver Dam Mine Site. P (Haul Road) Closure of the Haul Road not expected.	O Effects occur once during the construction phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Loss	Not Significant
Construction – Beaver Dam Mine Site and Haul Road (sensory disturbance (noise, light, dust deposition) and wildlife vehicle collisions from construction activities)	Implement speed limits and minimize lighting.	M	LAA Potential adverse effect to avifauna outside of the PA	A VC interaction may affect seasonal aspects of avifauna.	ST Effects are limited to occur from as little as 1 day to 12 months	R Effects occur at regular intervals during the construction phase	R VC will recover to baseline conditions	Disturbance	Not Significant
Operational – Beaver Dam Mine Site, Haul Road and Touquoy Mine Site (disturbance (noise, light, dust deposition and wildlife vehicle collisions) from haul trucks, heavy machinery and mine operations)	Implement speed limits, install fences where necessary, and minimize lighting.	M Moderate changes relative to baseline conditions in remaining and surrounding habitat.	LAA Potential adverse effect to avifauna outside of the PA	A VC interaction may affect seasonal aspects of fauna.	MT Effects may occur up to 5 years.	R Effects occur at regular intervals.	R VC will recover to baseline conditions	Disturbance	Not Significant
Operations – Touquoy Mine Site Tailings deposition	Best management practices, Bird Deterrent Program implementation	L Change in habitat for avifauna	PA VC interaction is confined to the PA.	A VC interaction may occur during sensitive period for avifauna.	LT Effects may extend beyond 5 years	R VC interaction will occur at regular intervals	PR Mitigation cannot guarantee a return to baseline conditions	Creation of potential open water habitat; decreased water quality	Not Significant
Closure (Active) – Beaver Dam Mine Site (re-establishment of habitat for fauna)	N/A	L Minor change from baseline conditions.	LAA Potential effect to avifauna outside of the PA	A VC interaction may affect seasonal aspects of fauna.	LT Effects extend beyond active closure phase.	O Effects occur once during the closure phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Reclamation	Not Significant

Notes: See Section 5.11, Table 5.11-1 for definitions of the below characteristics.

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	IR	Irreversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	PR	Partially Reversible
H	High					P	Permanent	C	Continuous		

There will be minimal isolation of habitat that is currently contiguous, limited to the patch of potential interior forest west of the NAG waste rock stockpile (Figure 6.10-6). However, broadly speaking, accessible routes to provide movement through and across the larger region at the LAA and RAA level still exist for wildlife and are un-impacted by the development of the Project.

Mitigation measures such as bird awareness and best management practices will be used. Best management practices include the avoidance of clearing and grubbing during the breeding season for migratory birds where practical (beginning of April to end of August for migratory birds; ECCC 2015).

Disturbances (e.g., wildlife vehicle collisions, light etc.) have the potential to pose a greater impact on priority bird species in comparison to non-priority specific bird species. This can be attributed to the rarity of priority bird species.

6.13.10 Proposed Compliance and Effects Monitoring Programs

Monitoring for specific priority species will be completed to verify the accuracy of the predicted environmental effects and the effectiveness of the mitigation measures outlined in Section 6.13.8. Preliminary monitoring programs have been prepared and will be established and adapted through the permitting process, as well as public and Mi'kmaw engagement. The following plans have been prepared or will be developed as part of the Project's commitments to monitoring and mitigating adverse effects to priority species:

- draft Mine Water Management Plan (Appendix P.4), describes surface water management mitigation measures and monitoring including sediment and erosion. Surface Water Monitoring Program is included in this Management Plan and may be updated based on regulatory review during the permitting phase (i.e., before submission of the Industrial Approval application);
- Fugitive Dust Control Plan (Appendix C.3);
- Preliminary Wetland Monitoring Program (Section 6.8.10);
- Preliminary Wetland Compensation Plan (Appendix H.3);
- draft Wildlife Mitigation and Monitoring Plan (Appendix P.7), including a specific Mainland Moose Management Plan for submission of the Industrial Approval submission for the Project;
- draft Lichen Mitigation and Monitoring Plan (Appendix P.6);
- draft Landbird SAR Mitigation and Monitoring Plan (included as Appendix A of the draft Wildlife Mitigation and Monitoring Plan [Appendix P.7]); and
- Conceptual Aquatic Effects Monitoring Program (AEMP) to be developed as part of the permitting process (i.e., included as part of the Industrial Approval application).

The monitoring of priority fish species will be captured under the conceptual AEMP, as well as general fish monitoring within the Surface Water Monitoring Plan. The AEMP is planned to be a comprehensive monitoring program designed to detect changes in the aquatic environment that may be mine-related. The AEMP includes study areas (watercourses and waterbodies) anticipated to be potentially influenced by predicted Project-related activities. The program will also include reference areas outside of the immediate zone of influence of the mine within the same or nearby watersheds. Monitoring components broadly include surface water quality and quantity, sediment quality, and fish and fish habitat.

The draft Wildlife Mitigation and Monitoring Plan has been developed to describe mitigation measures including protocols to minimize interactions between wildlife and Project activities. This Plan includes but is not limited to the following:

- Breeding birds and nesting protocols during construction and operations;
- Preliminary Landbird SAR Mitigation and Monitoring Plan, developed to address IR2 CEAA-2-24 (Appendix A of Appendix P.7); and
- Mainland Moose Monitoring and Management – will includes commitment for additional baseline data collection as well as monitoring potential for additional monitoring during construction and operations.

The draft Wildlife Management Plan will be finalized during the permitting process (i.e., final submitted as part of the Industrial Approval application) and will address regulatory, pubic and Mi'kmaq comments.

A draft Lichen Mitigation and Monitoring Plan has been prepared, as per IR2 CEAA-2-26, to evaluate the predicted Project related effects on lichen SAR and the success of the proposed translocation mitigations. The monitoring of vascular plants is encompassed within the Wetland Monitoring Plan may include priority vascular and non-vascular flora.

AMNS will look to support research opportunities to help inform priority species management and their protection. These initiatives may be incorporated into the above listed mitigation and monitoring plans.

6.14 Mi'kmaq of Nova Scotia

6.14.1 Introduction

6.14.1.1 Summary of Mi'kmaq of Nova Scotia Before the Updates

The Millbrook First Nation Traditional Land and Resource Use Study (TLRUS) was shared with AMNS just prior to submission of the Round 1, Information Request and revised EIS in February 2019 (AMNS 2019). As a result, detailed analysis of this TRLUS conclusions was not included in this 2019 submission package. The analysis of Project impacts and recommended mitigation measures was broad in nature.

6.14.1.2 Summary of Updates to Mi'kmaq of Nova Scotia

The EIS has been updated to reflect specific information provided by Millbrook First Nation regarding traditional land use and information received through on-going engagement efforts with the Mi'kmaq of Nova Scotia. Proposed mitigation measures have been updated to reflect changes in the Project Description (Section 2) and based on traditional land use within and surrounding the Project Area (PA). The TLRUS has been shared under confidential cover and as a result of this confidential arrangement with Millbrook First Nation, the TLRUS is not appended to this Updated EIS and information relating to Millbrook traditional land use has only been provided in a general format and not documented on supporting figures.

Residual impacts and significance thresholds have been refined. The human health risk assessment (HHRA) has been updated (Round 2, Information Request [IR2] response CEAA 2-38 and included in Appendix C.2) along with the visual zone of influence (IR2 response CEAA 2-01 and included in Appendix M.2).

Notes: - = no update; IR2 = Round 2, Information Requests; CEAA = Canadian Environmental Assessment Agency; TLURS = Traditional Land and Resources Use Study; HHRA = Human Health Risk Assessment; EIS = environmental impact statement; N/A = Not Applicable.

6.14.2 Rationale for Valued Component Selection

Assessment of the potential for the Project to interact with and affect the Mi'kmaq of Nova Scotia is included in consideration of its socio-economic, socio-cultural, and/or traditional importance; in recognition of potential or established Indigenous and Treaty rights; and due to the nature of potential Project-Valued Component (VC) interactions. The Impact Assessment Agency of Canada (formerly Canadian Environmental Assessment Agency [CEAA]) Environmental Impact Statement (EIS) Guidelines (CEAA 2016) for the Beaver Dam Mine Project (the Project) references *Canadian Environmental Assessment Act*, (2012) 5(1)(c) that states:

> *5 (1) For the purposes of this Act, the environmental effects that are to be taken into account in relation to an act or thing, a physical activity, a designated project or a project are*
>
> *(c) with respect to aboriginal peoples, an effect occurring in Canada of any change that may be caused to the environment on*
>
> *(i) health and socio-economic conditions,*
>
> *(ii) physical and cultural heritage,*
>
> *(iii) the current use of lands and resources for traditional purposes, or*
>
> *(iv) any structure, site or thing that is of historical, archaeological, paleontological or architectural significance.*

As per Nova Scotia's Environmental Assessment Regulations, proponents are required to identify concerns of the Mi'kmaq of Nova Scotia regarding potential adverse effects and clarify the steps taken or proposed to be taken by Atlantic Mining NS Inc. (AMNS) to address concerns.

The Mi'kmaq in the provinces of Nova Scotia, New Brunswick, PEI, and the Gaspé Peninsula in Quebec are founded on land historically occupied by the ancestors of the Mi'kmaq. The earliest evidence of the Mi'kmaq of Nova Scotia in the Maritimes Region indicates that the ancestors of the Mi'kmaq have existed on the land for more than 11,000 years (NSOAA 2017). The Mi'kmaq generally lived in semi-permanent and permanent settlements at resource-rich locations (Appendix M.1). The lives of the Mi'kmaq of Nova Scotia, in what are today referred to as the Maritime Provinces, considered the seasonal cycles of the local vegetation, animals, and fish, living a traditional life as fishers, hunters, and gatherers throughout their territory (Appendix M.1). In the summer months, summer villages along the Eastern Shore provided fish, shellfish, fowl, and eggs, while during the colder months, the Mi'kmaq did most of their game hunting, moving inland from their summer camps (Hoffman 1955 in Appendix M.1).

The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights, including the right to fish for a "moderate livelihood" which flows from the Peace and Friendship Treaties, and Aboriginal rights to hunt, fish and gather for food, social and ceremonial (FSC) purposes – more broadly referred to as "traditional" purposes. The EIS Guidelines (CEAA 2016) for the Project states:

> *The proponent is expected to engage with Aboriginal groups that may be affected by the project, beginning as early as possible in the project planning process. The proponent will provide Aboriginal groups with opportunities to learn about the project and its potential effects make their concerns known about the project's potential effects and discuss measures to mitigate those effects. The proponent is strongly encouraged to work with Aboriginal groups in establishing an engagement approach. The proponent will make reasonable efforts to integrate Aboriginal traditional knowledge into the assessment of environmental impacts.*

The Crown has a duty to consult with the Mi'kmaq of Nova Scotia, which is achieved in accordance with the Mi'kmaq-Canada-Nova Scotia Consultation TOR. As per Supreme Court of Canada instruction and subsequent guidance from governments, such as the Updated Guidelines for Federal Officials to Fulfill the Duty to Consult (Government of Canada, 2011) and the Proponents' Guide: Engagement with the Mi'kmaq of Nova Scotia (Province of Nova Scotia, 2012), the Crown may delegate procedural aspects of consultation to proponents. However, the duty to consult, and constitutional obligation remains with the Crown. As noted in the EIS Guidelines (CEAA 2016) the results of the AMNS's Mi'kmaq of Nova Scotia engagement program *"helps to contribute to the Crown's understanding of any potential adverse impacts of the project on potential or established Aboriginal or treaty rights, title and related interests, and the effectiveness of measures proposed to avoid or minimise those impacts"*.

For the purposes of consultation, 11 of the 13 Mi'kmaq communities are represented in consultation by the Kwilmu'k Maw-klusuaqn Negotiation Office (KMKNO), which reports to the Assembly of Nova Scotia Mi'kmaq Chiefs (ANSMC). Millbrook and Sipekne'katik First Nations represent their own communities in consultation through their elected Chiefs and Councils.

In summary, the historical presence of the Mi'kmaq in Nova Scotia, their proven Indigenous and treaty rights and title claim, the duty of the Crown to consult with the Mi'kmaq of Nova Scotia when contemplating decisions that could potentially adversely affect their rights form the rationale for the selection of the Mi'kmaq of Nova Scotia as a VC. The Mi'kmaq of Nova Scotia continue to rely on their traditional lands for cultural and economic survival. Broadly speaking, the Project has the potential to impact the Mi'kmaq's ability to access lands during the temporal life of the Project; and, to potentially alter the presence or availability of animals or plants that the Mi'kmaq rely on. Details relating to the specific nature of the potential impacts of the Project on the Mi'kmaq of Nova Scotia are described herein.

6.14.3 Baseline Program Methodology

6.14.3.1 Beaver Dam Mine Site and Haul Road Baseline Program Methodology

Five main components were used to define the baseline information for the Mi'kmaq of Nova Scotia:

- Information obtained during on-going engagement with the Mi'kmaq of Nova Scotia;
- Completion of a Mi'kmaq Ecological Knowledge Study (MEKS) (2016);
- Information shared with AMNS by Millbrook First Nation from a completed Traditional Land and Resource Use Study (TLRUS; MFC 2019) (Under Confidential Agreement);
- Publicly available Indigenous knowledge related to the Mi'kmaq of Nova Scotia; and
- Completion of archaeological screening and reconnaissance.

The on-going engagement activities and issues raised during the engagement are described in Section 4 of this EIS. The archaeological screening is described in Section 6.15 of this EIS, with findings relevant to the Mi'kmaq noted in this section. Issues raised during the Mi'kmaq engagement activities were considered in Project design and the overall development of this EIS, as described in Section 4.

6.14.3.1.1 Mi'kmaq Ecological Knowledge Study

The Confederacy of Mainland Mi'kmaq (CMM) was retained in 2009 by GHD Limited on behalf of the AMNS to complete an MEKS for the proposed Beaver Dam Mine Project at the Beaver Dam Mine Site. In 2015, CMM was retained to update the MEKS, due to changes in the Haul Road to include approximately 4 km of new construction. CMM was then retained again in 2016 to finalize the MEKS to include the revised PA and any additional information. This MEKS is attached as Appendix M.1.

The purpose of the MEKS is to foster the integration of Mi'kmaw traditional ecological knowledge into the environmental assessment process and development decisions. It also aims to identify and report any ecological concerns regarding the Project's impact on Mi'kmaw use of land, resources and special places within the Project Study Area.

The MEKS includes:

- a study of historic and current Mi'kmaq land and resource use;
- an evaluation of the potential impacts of the Project on Mi'kmaq use and occupation and constitutionally protected rights;
- an evaluation of the significance of the potential impacts of the Project on Mi'kmaq use and occupation; and
- recommendations to proponents and regulators that may include recommendations for mitigation measures, further study, or consultation with the Mi'kmaq of Nova Scotia.

The MEKS baseline information includes both historic and available current Mi'kmaq land and resource use. As defined in the MEKS, the MEKS Study Area for the evaluation of traditional practices is the Project Area with a 5-km radius while the historic use may include a wider surrounding area.

In addition, a MEKS was undertaken by Mi'kma'ki All Points Services for the Fifteen Mile Stream Gold Project at Fifteen Mile Stream, Nova Scotia. Aspects of this study, predominately the historical use sections and broad information, provides insight and relevance for the Beaver Dam Mine Project.

Figure 6.14-1 shows the Mi'kmaq LAA which is the equivalent to the MEKS Study Area. Relevant details from the MEKS relating to historical and available current Mi'kmaq land and resource use are included in this section and support the analysis of potential Project impacts to the Mi'kmaq of Nova Scotia. As the conclusions and recommendations as they are portrayed in the study are broad in nature, AMNS sought further refinement and detail of traditional and current Mi'kmaq land and resource use from CMM and other potential researchers. In 2018, Millbrook First Nation commenced a Traditional Land and Resource Use Study, described below, which supplements the conclusions of the MEKS.

6.14.3.1.2 Traditional Land and Resource Use Study

In addition to the MEKS cited above, in 2018, a Traditional Land and Resource Use Study (TLRUS; MFC 2019) was undertaken by Millbrook First Nation to document historical and current use of the Project Area and surrounding areas by the Millbrook First Nation. This document was shared with AMNS under a confidentiality agreement/confidential cover. AMNS has integrated information obtained from the TLRUS in a general format in appropriate sections of the EIS.

For the purposes of the TLRUS, a Local Study Area (LSA) and a Regional Study Area (RSA) were used. The RSA is based on the territorial boundaries of the Eskikewa'kik and captures some of the areas of greatest intensity of land and resource use by the Eskikewa'kik currently and within recent memory. The LSA includes the Beaver Dam Mine Site, Haul Road and the Touquoy Mine Site, plus a 5 km buffer. This TLRUS LSA is the same as the defined local assessment area (LAA) for the Mi'kmaq of Nova Scotia in this EIS (Section 6.14.6.1.1).

Direct engagement with the Mi'kmaq of Nova Scotia through the KMKNO, Sipekne'katik First Nation and the ANSMC for this Project in the past seven years has demonstrated that there is general agreement that Millbrook First Nation, with the Beaver Lake and Sheet Harbour Indian Reserves (IRS) in close proximity to the Project, are the Mi'kmaq community that will be most affected by the Project. Millbrook First Nation took the initiative to undertake the TLRUS which provides detail on historical and current use of their community in this local area that that supports the analysis of impacts, with additional valuable information also provided through the MEKS. As a result of the proximity of this community to the Project, and the data available through the TLRUS, the analysis of Project impacts is tailored to a discussion of impacts to the Millbrook First Nation specifically, acknowledging that conclusions formed relating to Project effects and mitigation measures proposed are relevant to all Mi'kmaq communities. This approach, and Project conclusions and mitigation measures have been reviewed and validated with both Millbrook First Nation, the KMKNO and the broader Mi'kmaq of Nova Scotia through direct engagement efforts.

6.14.3.2 Touquoy Baseline Program Methodology

Four main components were used to define the baseline information for the Mi'kmaq of Nova Scotia:

- Information obtained during ongoing engagement with the Mi'kmaq of Nova Scotia since 2005;
- Completion of a Mi'kmaq Ecological Knowledge Study (MEKS) for the Touquoy Golf Project (CRA 2007a);
- Publicly-available Indigenous knowledge related to the Mi'kmaq of Nova Scotia;
- Information shared with AMNS by Millbrook First Nation from a completed Traditional Land and Resource Use Study (TLRUS; MFC 2019); and,
- Completion of archaeological screening and reconnaissance at the Touquoy Mine Site.

The MEKS was completed for the Touquoy Gold Project in December 2005 [prior to the development of the Mi'kmaq of Nova Scotia's MEKS Protocol (ANSMC 2007)]. Mi'kmaq involvement and the results of the MEKS for Touquoy Gold Project were documented in the EARD for this project that can be found on the NSE Environmental Assessment website. (http://novascotia.ca/nse/ea/MooseRiver.asp)

6.14.4 Baseline Conditions

6.14.4.1 Regional Baseline Conditions and General Information Relating to Mi'kmaq Communities

There are 13 Mi'kmaq communities in Nova Scotia, with two First Nation (Mi'kmaq) reserves in the vicinity of the Project: Beaver Lake IR 17 (49.4 ha) is located approximately 5 km southwest from the Beaver Dam Mine Site, and Sheet Harbour IR 36 (32.7 ha) is located 20 km south of the Project. Both these reserves belong to the Millbrook First Nation which is located in Truro, Nova Scotia, 54 km northwest of the Beaver Dam Mine Site. The 2017 Census reports 21 and 25 Mi'kmaw residents at Beaver Lake and Sheet Harbour, respectively (Statistics Canada 2017, 2017a).

- Beaver Lake: established in 1867 and approximately 49.4 ha in size is situated along Hwy 224. The estimated population on reserve is 21 with a total of five homes and four small cottages/camps.
- Sheet Harbour: set aside under Millbrook administration in 1960 and approximately 32.7 ha along Hwy 7, the estimated population on reserve is 25 with a total of nine homes, two trailers, a community hall and a convenience/gas bar.

The Sipekne'katik First Nation, located in Indian Brook, Nova Scotia, is located approximately 61 km west of the Project. The Pictou Landing First Nation (PLFN), located north of the town of New Glasgow, is located 66 km north of the Project.

Mi'kmaq rights are communal rights and therefore shared amongst all members of the Mi'kmaq Nation in Nova Scotia. Community profiles of the 13 Mi'kmaw First Nations in Nova Scotia have been included in Table 6.14-2 (Stantec 2018c, CBU 2020).

The locations of First Nations reserve lands in Nova Scotia are also depicted below on Figure 6.14-2.

Figure 6.14-2: First nations Reserve Lands in Nova Scotia

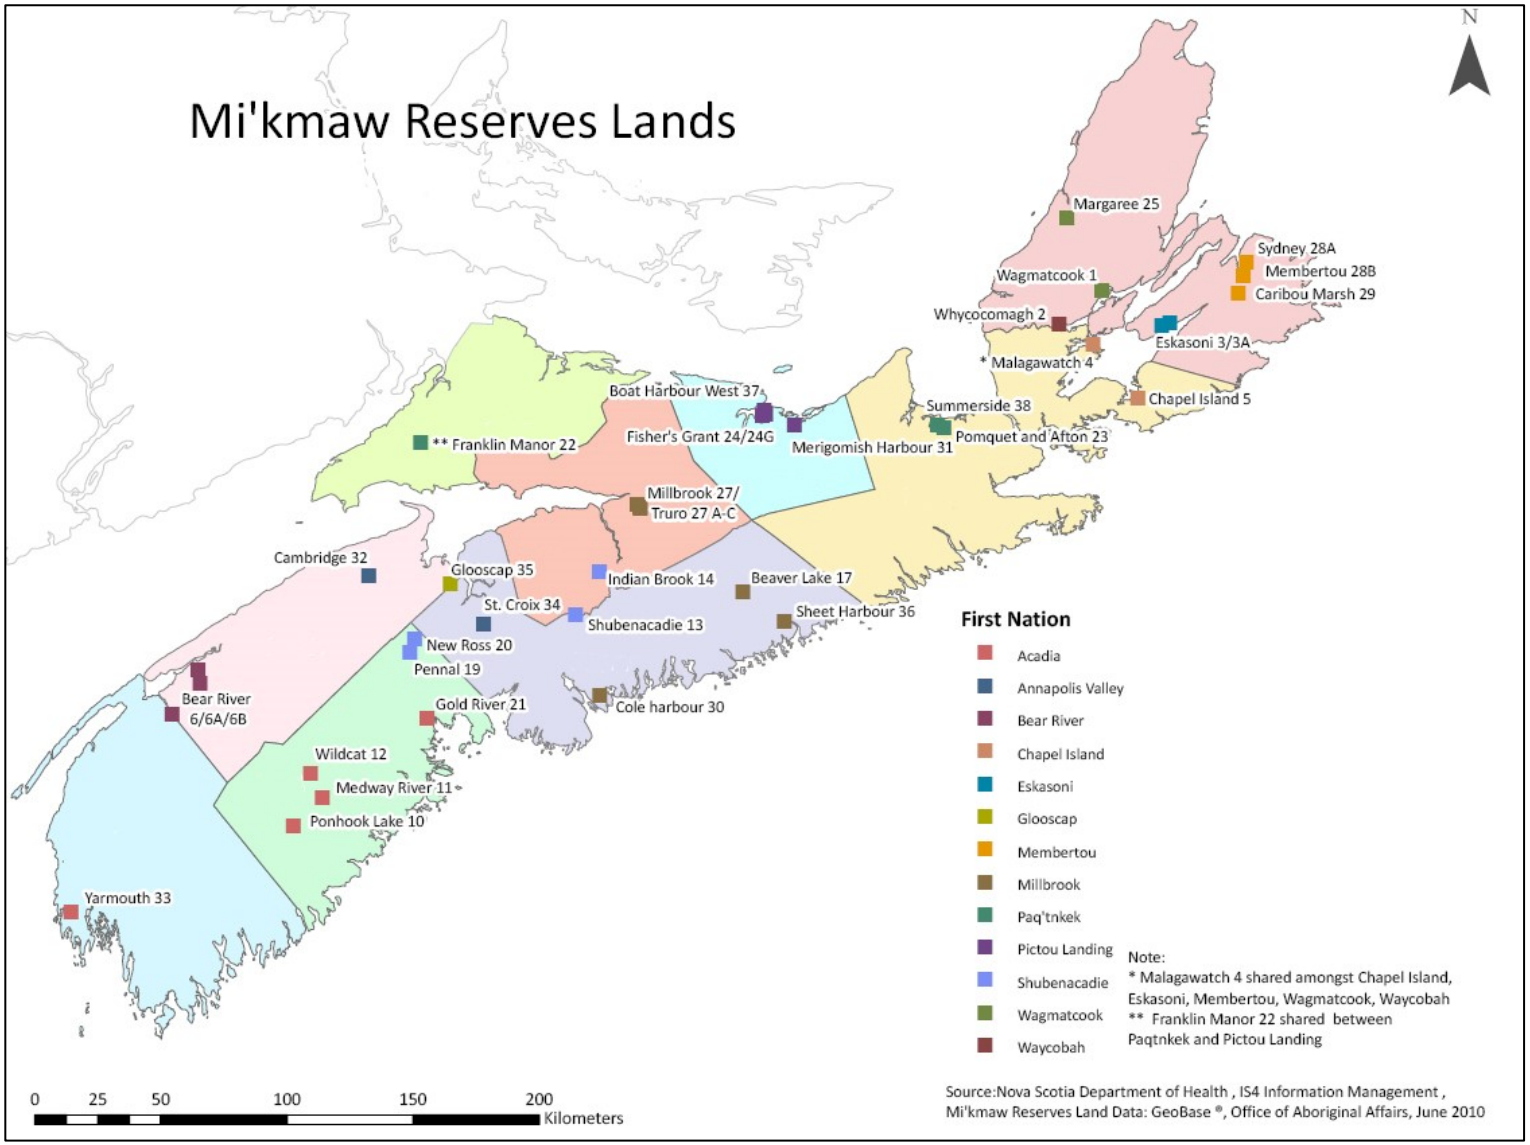

Table 6.14-2: Community profiles of the 13 Mi'kmaw First Nations in Nova Scotia

Mi'kmaw First Nation	Description
Acadia First Nation	
Location	Acadia First Nation in southwestern Nova Scotia is comprised of five reserves, in five counties from Yarmouth to Halifax.
Reserves	Gold River IR 21; Medway River IR 11; Ponhook Lake IR 10; Wildcat IR 12; Yarmouth IR 33
General Overview	Acadia First Nation encompasses five reserves: Yarmouth 33 (3.2 km east of Yarmouth with an area of 27.7 ha), Ponhook Lake 10 (115.2 km southwest of Halifax with an area of 101.8 ha), Medway River 11 (108.8 km southwest of Halifax with an area of 4.7 ha), Wildcat 12 (11 km southwest of Halifax with an area of 465.4 ha) and Gold River 21 (60.8 km west of Halifax with an area of 270.2 ha) (INAC undated, as citied in Stantec 2018c). Acadia First Nation also has separate land holdings in Gardner's Mill and Hammonds Plains. Acadia First Nation is represented by the ANSMC. According to 2017 census data, the registered population was 1,519 (approx. 230 on and 1,289 off reserve). As of February 2020 the total population was 1,664: Registered Males on Own Reserve – 112 Registered Females on Own Reserve – 127 Registered Males on Other Reserves – 2 Registered Females on Other Reserves – 0 Registered Males on No Band Crown Land – 1 Registered Females on No Band Crown Land – 2 Registered Males Living Off-Reserve – 697 Registered Females Living Off-Reserve – 723 (CBU, 2020) No data was available related to age of population.
Health and Socio-economic Conditions	The availability of infrastructure within each community varies, however Acadia First Nation has experienced infrastructure growth over the past decade, including the development of housing and roads (Acadia First Nation undated, as citied in Stantec 2018c). An after-school program exists within Yarmouth for children ages 5-12 attending elementary school. Health centers are in Yarmouth and Gold River. The Yarmouth Health Centre includes a dentist, Victorian Order of Nurses (VON), clinic nursing, foot care clinics and wellness and health promotion clinics (Acadia First Nation undated, as citied in Stantec 2018c). The Gold River Health Centre provides a VON, clinic nursing, wellness and health-promotion clinics, afterschool program and parent and tot groups (Acadia First Nation undated, as citied in Stantec 2018c). In Wildcat, a VON is available once a month (Acadia First Nation undated, as citied in Stantec 2018c). Recent economic developments for the Nation include administrative buildings, gaming facilities, and offices in Halifax and Milton to serve the off-reserve population.
Physical and Cultural Heritage (including archaeological, paleontological, historical or architectural sites)	The Acadia First Nation were once based in what is today's Queen's County with artifacts found along the Mersey River (KMKNO undated, as citied in Stantec 2018c). Proposed PA does not overlap with any known physical and cultural heritage sites related specifically to Acadia First Nation.
Historical and Current Use of Lands and Waters	All Mi'kmaq in Nova Scotia would have a right to trap, hunt and harvest fish, animals and plants in the PA, as part of their Aboriginal and Treaty rights to hunt, fish, and gather. In particular, Mi'kmaq community members likely use the area within and surrounding the PA to hunt deer, bear, porcupine and foul; trap rabbits, fox and other small fur-bearing animals; fish for trout and other freshwater species; gather berries and plants for food and medicinal purposes; harvest plants, birchbark and fallen wood for handicrafts and cultural items. Mi'kmaq families also enjoy camps in the area for recreational purposes. All Nova Scotia Mi'kmaq communities hold FSC and commercial communal fishing licenses to harvest a variety of marine and freshwater species in tidal and non-tidal waters of Nova Scotia. Specific details and information relating to how subpopulations within a Mi'kmaq community (women, youth, elders, families) engage in traditional practices, other than the general information provided above, has not been shared with AMNS through direct engagement and the MEKS, but AMNS understands additional information may be available during the EIS review process from Mi'kmaq communities, and will continue to work with communities to integrate that information into project planning.
Asserted or Established Aboriginal and / or Treaty Rights	The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights. This includes traditional rights to hunt, gather and fish, as well as treaty-protected rights to hunt and gather, and to fish for a "moderate livelihood". Those activities are related to sustenance, cultural and socio-economic practice.
Annapolis Valley First Nation	
Location	Annapolis Valley First Nation is comprised of two reserves within Kings County in southwestern Nova Scotia.
General Overview	Annapolis Valley First Nation encompasses two reserve lands: Annapolis Valley (Cambridge) (88 km northwest of Halifax with an area of 59 ha) and St. Croix 34 (46.6 km northwest of Halifax with an area of 126.2 ha) (INAC undated, as citied in Stantec 2018c). Annapolis Valley First Nation is represented by the ANSMC. According to 2017 census data, the registered population was 290 (approx. 117 on and 173 off reserve). As of February 2020, the population was 302: Registered Males on Own Reserve – 68 Registered Females on Own Reserve – 55 Registered Males Living Off-Reserve – 73 Registered Females Living Off-Reserve – 106 (CBU, 2020) No data was available related to age of population.
Health and Socio-economic Conditions	Established in 1998, the Three Wishes Learning Centre provides a nursery school program, after school program, and culture programs (Annapolis Valley First Nation undated). The Annapolis Valley First Nation Health Centre has a registered community health nurse, access to prevention and weight control programs, foot care clinics, prenatal programs, massage therapy, physical activity programs, drug and alcohol abuse prevention, suicide prevention, injury / illness prevention and health and wellness promotion (Annapolis Valley First Nation undated). A dental hygienist is available twice a month at the health center. Annapolis Valley First Nation's economic initiatives include Annapolis Valley First Nation Gaming, Annapolis Valley First Nation Smoke Shop, and Annapolis Valley First Nation Gas Bar (Annapolis Valley First Nation undated, as citied in Stantec 2018c).

Table 6.14-2: Community profiles of the 13 Mi'kmaw First Nations in Nova Scotia (continued)

Mi'kmaw First Nation	Description
Physical and Cultural Heritage (including archaeological, paleontological, historical or architectural sites)	There is a long history of Mi'kmaq presence in Annapolis Royal and the surrounding areas; archeologists have identified several settlement patterns (Statoil 2017, as citied in Stantec 2018c). The Mi'kmaq lived in Annapolis Valley when the Europeans arrived in the area, with lifestyles heavily influenced by the land and ecosystems and a strong tradition of innovation connected to the homelands. Proposed PA does not overlap with any known physical and cultural heritage sites related specifically to Annapolis First Nation.
Historical and Current Use of Lands and Waters	All Mi'kmaq in Nova Scotia would have a right to trap, hunt and harvest fish, animals and plants in the PA, as part of their Aboriginal and Treaty rights to hunt, fish, and gather. In particular, Mi'kmaq community members use the area within and surrounding the PA to hunt deer, bear, porcupine and foul; trap rabbits, fox and other small fur-bearing animals; fish for trout and other freshwater species; gather berries and plants for food and medicinal purposes; harvest plants, birchbark and fallen wood for handicrafts and cultural items. Mi'kmaq families also enjoy camps in the area for recreational purposes. All Nova Scotia Mi'kmaq communities hold FSC and commercial communal fishing licenses to harvest a variety of marine and freshwater species in tidal and non-tidal waters of Nova Scotia. Specific details and information relating to how subpopulations within a Mi'kmaq community (women, youth, elders, families) engage in traditional practices, other than the general information provided above, has not been shared with AMNS through direct engagement and the MEKS, but AMNS understands additional information may be available during the EIS review process from Mi'kmaq communities, and will continue to work with communities to integrate that information into project planning.
Asserted or Established Aboriginal and / or Treaty Rights	The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights. This includes traditional rights to hunt, gather and fish, as well as treaty-protected rights to hunt and gather, and to fish for a "moderate livelihood". Those activities are related to sustenance, cultural and socio-economic practice.
Bear River First Nation	
Location	Bear River First Nation is comprised of three reserves, within the Annapolis Valley between the towns of Annapolis Royal and Digby (KMKNO undated).
General Overview	Bear River First Nation encompasses three reserve lands: Bear River 6 (17.7 km southeast of Digby with an area of 633.8 ha), Bear River 6A (9.6 km southeast of Annapolis Valley with an area of 31.2 ha), and Bear River 6B (6.4 km southeast of Annapolis Valley with an area of 24.3 ha) (INAC undated). Bear River First Nation is represented by the ANSMC. According to 2017 census data, the registered population was 338 (approx. 110 on and 228 off reserve). As of February 2020, the population was 357: Registered Males on Own Reserve – 50 Registered Females on Own Reserve – 63 Registered Males on Other Reserves – 0 Registered Females on Other Reserves – 1 Registered Males Living Off-Reserve – 119 registered Females Living Off-Reserve – 124 (CBU, 2020) No data was available related to age of population.
Health and Socio-economic Conditions	The majority of community members live on the Bear River 6, also known as L'sitkuk Mainland (Mainland Mi'kmaq Development Inc. 2016, as citied in Stantec 2018c). In Bear River, a learning center provides space for educational activities. There is a health center in Bear River, offering healing services and workshops (Bear River First Nation 2016, as citied in Stantec 2018c). A doctor visits the health center monthly (Bear River First Nation 2016, as citied in Stantec 2018c). Recently, an RCMP satellite office opened in the community. Bear River First Nation enterprises include a Treaty Gas bar, L'sitkuk Gas Bar Limited, and a seasonal Heritage and Cultural Centre.
Physical and Cultural Heritage (including archaeological, paleontological, historical or architectural sites)	There is a long history of Bear River Mi'kmaq presence in Digby and Annapolis Counties (Mainland Mi'kmaq Development Inc. 2016, as citied in Stantec 2018c). As early as 1612, the Mi'kmaq have been recorded as harvesting resources in the Annapolis River and French Bay (Bay of Fundy) (Mainland Mi'kmaq Development Inc. 2016, as citied in Stantec 2018c). Traditionally, during the fall and winter, families would travel to hunt big game such as moose, deer, caribou and bear, and smaller game such as beaver, bird species, and rabbit. In the spring, families typically settled along the coast and in the summer, they harvested shellfish such as clam, mussels, and scallops as well as several fish species including cod, salmon, trout, eel, herring, and bass (Mainland Mi'kmaq Development Inc. 2016, as citied in Stantec 2018c). Seals, walrus, porpoises and berries and plants were also harvested. Bear River First Nation was traditionally, and continues to be, well known for their artwork, specializing in embroidering porcupine quills on birchbark, leatherwork, and basketry (Mainland Mi'kmaq Development Inc. 2016, as citied in Stantec 2018c). Proposed PA does not overlap with any known physical and cultural heritage sites related specifically to Bear River First Nation.
Historical and Current Use of Lands and Waters	All Mi'kmaq in Nova Scotia would have a right to trap, hunt and harvest fish, animals and plants in the PA, as part of their Aboriginal and Treaty rights to hunt, fish, and gather. In particular Mi'kmaq community members use the area within and surrounding the PA to hunt deer, bear, porcupine and foul; trap rabbits, fox and other small fur-bearing animals; fish for trout and other freshwater species; gather berries and plants for food and medicinal purposes; harvest plants, birchbark and fallen wood for handicrafts and cultural items. Mi'kmaq families also enjoy camps in the area for recreational purposes. All Nova Scotia Mi'kmaq communities hold FSC and commercial communal fishing licenses to harvest a variety of marine and freshwater species in tidal and non-tidal waters of Nova Scotia. Specific details and information relating to how subpopulations within a Mi'kmaq community (women, youth, elders, families) engage in traditional practices, other than the general information provided above, has not been shared with AMNS through direct engagement and the MEKS, but AMNS understands additional information may be available during the EIS review process from Mi'kmaq communities, and will continue to work with communities to integrate that information into project planning.
Asserted or Established Aboriginal and / or Treaty Rights	The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights. This includes traditional rights to hunt, gather and fish, as well as treaty-protected rights to hunt and gather, and to fish for a "moderate livelihood". Those activities are related to sustenance, cultural and socio-economic practice.

Table 6.14-2: Community profiles of the 13 Mi'kmaw First Nations in Nova Scotia (continued)

Mi'kmaw First Nation	Description
Eskasoni First Nation	
Location	Eskasoni First Nation is comprised of three reserves, along the shore of the Bras d'Or Lakes.
General Overview	Eskasoni First Nation encompasses three reserves: Eskasoni 3 (40 km southwest of Sydney with an area of 3,504.6 ha), Eskasoni 3A (40 km southwest of Sydney with an area of 28.5 ha), and Malagawatch 4 (62 km southwest of Sydney with an area of 661.3 ha) (INAC undated, as citied in Stantec 2018c). Eskasoni First Nation is the largest Indigenous community in Atlantic Canada (KMKNO undated, as citied in Stantec 2018c). According to 2017 census data, the registered population was 4,443 (approx. 3,780 on and 631 off reserve). As of February 2020, the population was 4,642: Registered Males on Own Reserve – 1,953 Registered Females on Own Reserve – 1,998 Registered Males on Other Reserves – 16 Registered Females on Other Reserves – 18 Registered Males on Other Band Crown Land – 1 Registered Females on Other Band Crown Land – 0 Registered Males Living Off-Reserve – 303 Registered Females Living Off-Reserve – 353 (CBU, 2020) No data was available related to age of population.
Health and Socio-economic Conditions	Eskasoni First Nation has community-owned infrastructure such as a community-operated school, accommodating students from kindergarten to grade 12, a supermarket, a community rink and a cultural center. The Eskasoni Community Health Centre provides a wide range of primary care services as well as several health programs and services such as blood collection, community health nursing, maternal child health, medical transportation, and diabetic services (Eskasoni Community Health Centre 2004, as citied in Stantec 2018c). The Eskasoni Pharmacy is in the Health Centre. The pharmacy provides information to the community on drug use, Native Alcohol and Drug Addiction Counseling Association, and Mi'kmaq Family and Children's Services. The Health Centre is staffed with a nurse, medical transcriptionist, and several physicians (Eskasoni Community Health Centre 2004, as citied in Stantec 2018c). Community Health Representatives are also on-site and act as a liaison between health care providers and community members, assisting with translation and administration of health care services and programs (Eskasoni Community Health Centre 2004, as citied in Stantec 2018c). Within the community there is also a fire department, with four career firefighters and 20 volunteer firefighters (Eskasoni First Nation undated, as citied in Stantec 2018c). As described in more detail below, Eskasoni First Nation hold several commercial communal licenses for a variety of fish and marine species. The community operates Crane Cove Seafoods. Crane Cove Seafoods owns 13 vessels ranging from 30 – 65 feet and employs over 100 community members, with an additional 35 community members employed at the associated processing plant (Eskasoni First Nation undated, as citied in Stantec 2018c). Fish harvesting takes place throughout Nova Scotia from Ingonish to Yarmouth.
Physical and Cultural Heritage (including archaeological, paleontological, historical or architectural sites)	Chartered in 1832, Eskasoni First Nation became an official reserve in 1834. From 1845 to 1851, much of Cape Breton suffered from famine (MGS 2012, as citied in Stantec 2018c). During this time, the Mi'kmaq transitioned into a more stationary lifestyle and found opportunities to provide labour, typically traveling to Sydney to work and sell wares (MGS 2012, as citied in Stantec 2018c). The population of Eskasoni grew in the 1940s as the Department of Indian Affairs implemented a new policy to centralize Indigenous peoples (Eskasoni First Nation undated, as citied in Stantec 2018c). In the 1950s, Eskasoni First Nation began controlling their own affairs and a Band Council was established in 1958 (Eskasoni First Nation undated, as citied in Stantec 2018c). Proposed PA does not overlap with any known physical and cultural heritage sites related specifically to Eskasoni First Nation.
Historical and Current Use of Lands and Waters	All Mi'kmaq in Nova Scotia would have a right to trap, hunt and harvest fish, animals and plants in the PA, as part of their Aboriginal and Treaty rights to hunt, fish, and gather. In particular, Mi'kmaq community members use the area within and surrounding the PA to hunt deer, bear, porcupine and foul; trap rabbits, fox and other small fur-bearing animals; fish for trout and other freshwater species; gather berries and plants for food and medicinal purposes; harvest plants, birchbark and fallen wood for handicrafts and cultural items. Mi'kmaq families also enjoy camps in the area for recreational purposes. All Nova Scotia Mi'kmaq communities hold FSC and commercial communal fishing licenses to harvest a variety of marine and freshwater species in tidal and non-tidal waters of Nova Scotia. Specific details and information relating to how subpopulations within a Mi'kmaq community (women, youth, elders, families) engage in traditional practices, other than the general information provided above, has not been shared with AMNS through direct engagement and the MEKS, but AMNS understands additional information may be available during the EIS review process from Mi'kmaq communities, and will continue to work with communities to integrate that information into project planning.
Asserted or Established Aboriginal and / or Treaty Rights	The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights. This includes traditional rights to hunt, gather and fish, as well as treaty-protected rights to hunt and gather, and to fish for a "moderate livelihood". Those activities are related to sustenance, cultural and socio-economic practice.
Glooscap First Nation	
Location	Glooscap First Nation is comprised of one reserve (Glooscap 35), northwest of Halifax.
General Overview	Glooscap 35 is 68.8 km northwest of Halifax with an area of 171.1 ha (INAC undated). Glooscap First Nation is represented by the ANSMC. According to 2017 census data, the registered population was 374 (approx. 94 on and 280 off reserve). As of February 2020, the population was 393: Registered Males on Own Reserve – 32 Registered Females on Own Reserve – 65 Registered Females on Other Reserves – 1 Registered Males Living Off-Reserve – 143 Registered Females Living Off-Reserve – 152 (CBU, 2020) No data was available related to age of population.
Health and Socio-economic Conditions	Glooscap First Nation does not have any schools within the community; however, the Nation has an appointed education director who oversees primary and secondary education for on-reserve members (Glooscap First Nation 2018, as citied in Stantec 2018c). There is a Health Centre in the community, offering health and healing services that focus on six components: education, health promotion, culture and language, nutrition, social support, and parent / family involvement (Glooscap First Nation 2018, as citied in Stantec 2018c). Established in 2014, Glooscap Ventures was created as the economic department for the community and is owned and operated by Glooscap First Nation. Glooscap Ventures manages on-reserve businesses including the variety store / gas bar, gaming facility, and commercial fisheries. Currently, Glooscap Ventures is developing a 27-acre parcel of land, Glooscap Landing, along Highway 101 for retail purposes (Glooscap First Nation 2018, as citied in Stantec 2018c). Other initiatives include the expansion of the commercial fisheries and pursuing opportunities in renewable energy (Glooscap First Nation 2018, as citied in Stantec 2018c).

Table 6.14-2: Community profiles of the 13 Mi'kmaw First Nations in Nova Scotia (continued)

Mi'kmaw First Nation	Description
Physical and Cultural Heritage (including archaeological, paleontological, historical or architectural sites)	Established in 1984, Glooscap First Nation became the thirteenth Mi'kmaq band in NS (KMKNO undated). Originally, Glooscap First Nation was created following the separation of two communities, Annapolis Valley and Glooscap, that were 30 km apart (KMKNO undated, as citied in Stantec 2018c). Glooscap First Nation was originally known as Horton but was renamed in 2001 (KMKNO undated, as citied in Stantec 2018c). Proposed PA does not overlap with any known physical and cultural heritage sites related specifically to Glooscap First Nation.
Historical and Current Use of Lands and Waters	All Mi'kmaq in Nova Scotia would have a right to trap, hunt and harvest fish, animals and plants in the PA, as part of their Aboriginal and Treaty rights to hunt, fish, and gather. In particular, Mi'kmaq community members use the area within and surrounding the PA to hunt deer, bear, porcupine and foul; trap rabbits, fox and other small fur-bearing animals; fish for trout and other freshwater species; gather berries and plants for food and medicinal purposes; harvest plants, birchbark and fallen wood for handicrafts and cultural items. Mi'kmaq families also enjoy camps in the area for recreational purposes. All Nova Scotia Mi'kmaq communities hold FSC and commercial communal fishing licenses to harvest a variety of marine and freshwater species in tidal and non-tidal waters of Nova Scotia. Specific details and information relating to how subpopulations within a Mi'kmaq community (women, youth, elders, families) engage in traditional practices, other than the general information provided above, has not been shared with AMNS through direct engagement and the MEKS, but AMNS understands additional information may be available during the EIS review process from Mi'kmaq communities, and will continue to work with communities to integrate that information into project planning.
Asserted or Established Aboriginal and / or Treaty Rights	The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights. This includes traditional rights to hunt, gather and fish, as well as treaty-protected rights to hunt and gather, and to fish for a "moderate livelihood". Those activities are related to sustenance, cultural and socio-economic practice.
Membertou First Nation	
Location	Membertou First Nation is comprised of four reserves, in northeastern and southwestern Sydney.
General Overview	Membertou First Nation encompasses four reserves: Membertou 28B (1.6 km south of Sydney with an area of 100.1 ha), Sydney 28A (1.6 km northeast of Sydney with an area of 5.1 ha), Caribou Marsh 29 (8 km southwest of Sydney with an area of 219 ha) and Malagawatch 4 (62 km southwest of Sydney with an area of 661.3 ha) (INAC undated, as citied in Stantec 2018c). Membertou First Nation is represented by the ANSMC. According to 2017 census data, the registered population was 1,500 (approx. 904 on and 552 off reserve). As of February 2020, the population was 1,573: Registered Males on Own Reserve – 482 Registered Females on Own Reserve – 454 Registered Males on Other Reserves – 19 Registered Females on Other Reserves – 25 Registered Males on No Band Crown Land – 1 Registered Females on No Band Crown Land – 2 Registered Males Living Off-Reserve – 299 Registered Females Living Off-Reserve – 291 (CBU, 2020) No data was available related to age of population.
Health and Socio-economic Conditions	Membertou First Nation has one school, Maupeltuewey Kina'matno'kuom, accommodating students from kindergarten to grade 6 (Membertou First Nation undated). A local Cape Breton Regional Police detachment is in Membertou. The Membertou Wellness Centre delivers programs to the community that address prominent health issues such as smoking cessation, crisis prevention / intervention, addictions services, and home and community care (Membertou First Nation undated, as citied in Stantec 2018c). The Membertou Wellness Centre also provides a family practice medical clinic with a doctor available Monday through Friday (Membertou First Nation undated, as citied in Stantec 2018c). Membertou First Nation has made considerable investments in infrastructure and providing services to community members over the last decade such as a gas station, church, community center, band office and boxing gym. Membertou First Nation also recently built the Membertou Sports and Wellness Centre, with two ice surfaces, an indoor walking track, a YMCA gym and multi-purpose meeting and event rooms (Membertou Sports and Wellness Centre undated, as citied in Stantec 2018c). Within Membertou, there is a business park including the Membertou Trade and Convention Centre, Membertou Heritage Park and Petroglyphs Gift Shop, a hotel, Kiju's Restaurant, Membertou Entertainment Centre, and private businesses. In 2002, Membertou First Nation became the first Indigenous government in the world to be ISO-certified (CANDO 2018, as citied in Stantec 2018c). The Nation owns and operates a seafood company, First Fishermen Seafoods. The company has six fleet vessels and harvests a variety of groundfish, shellfish, tuna, and swordfish (Membertou First Nation undated, as citied in Stantec 2018c). Membertou First Nation is part of a Mi'kmaq coalition that, in Fall 2020, acquired Clearwater Seafoods. This coalition includes a business partner, Premium Brands. Clearwater is one of the largest fully integrated seafood companies in North America, and is as of Fall 2020, owned by the Mi'kmaq. The details of this commercial acquisition include Membertou and a coalition of participating Mi'kmaq communities from across Nova Scotia and Newfoundland, owning 50% of Clearwater Seafoods, and 100% of all Canadian Clearwater licenses.
Physical and Cultural Heritage (including archaeological, paleontological, historical or architectural sites)	Once known as Kings Road, Membertou was situated along the banks of Sydney Harbour. In 1926, Membertou was officially moved to its present location (Membertou First Nation undated). As an urban Indigenous community, few members relied solely on traditional hunting, fishing, and gathering to earn their living; instead, both men and women worked in various industries (Membertou First Nation undated, as citied in Stantec 2018c). Proposed PA does not overlap with any known physical and cultural heritage sites related specifically to Membertou First Nation.
Historical and Current Use of Lands and Waters	All Mi'kmaq in Nova Scotia would have a right to trap, hunt and harvest fish, animals and plants in the PA, as part of their Aboriginal and Treaty rights to hunt, fish, and gather. In particular, Mi'kmaq community members use the area within and surrounding the PA to hunt deer, bear, porcupine and foul; trap rabbits, fox and other small fur-bearing animals; fish for trout and other freshwater species; gather berries and plants for food and medicinal purposes; harvest plants, birchbark and fallen wood for handicrafts and cultural items. Mi'kmaq families also enjoy camps in the area for recreational purposes. All Nova Scotia Mi'kmaq communities hold FSC and commercial communal fishing licenses to harvest a variety of marine and freshwater species in tidal and non-tidal waters of Nova Scotia. Specific details and information relating to how subpopulations within a Mi'kmaq community (women, youth, elders, families) engage in traditional practices, other than the general information provided above, has not been shared with AMNS through direct engagement and the MEKS, but AMNS understands additional information may be available during the EIS review process from Mi'kmaq communities, and will continue to work with communities to integrate that information into project planning.
Asserted or Established Aboriginal and / or Treaty Rights	The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights. This includes traditional rights to hunt, gather and fish, as well as treaty-protected rights to hunt and gather, and to fish for a "moderate livelihood". Those activities are related to sustenance, cultural and socio-economic practice.

Table 6.14-2: Community profiles of the 13 Mi'kmaw First Nations in Nova Scotia (continued)

Mi'kmaw First Nation	Description
Paq'tnkek Mi'kmaw Nation	
Location	Paq'tnkek Mi'kmaw Nation is comprised of three reserves, southeast of Amherst and east of Antigonish.
General Overview	Paq'tnkek Mi'kmaw Nation encompasses three reserves: Franklin Manor 22 (32 km southeast of Amherst with an area of 212.5 ha), Paq'tnkek-Niktuek 23 (24 km east of Antigonish with an area of 218.1 ha), and Welnek 38 (18 km east of Antigonish with an area of 43.4 ha) (INAC undated, as citied in Stantec 2018c). Paq'tnkek is represented by the ANSMC. According to 2017 census data, the registered population was 573 (approx. 404 on and 141 off reserve). As of February 2020, the population was 599: Registered Males on Own Reserve – 197 Registered Females on Own Reserve – 229 Registered Males on Other Reserves – 10 Registered Females on Other Reserves – 20 Registered Males Living Off-Reserve – 62 Registered Females Living Off-Reserve – 81 (CBU, 2020) No data was available related to age of population.
Health and Socio-economic Conditions	Since 1980, the Paq'tnkek Pre-School has been in operation in Afton, NS. The nearest RCMP detachment is in Antigonish. The Paq'tnkek Health Centre provides a variety of programs and services to community members, including community health promotion, education, and prevention programming (Paq'tnkek Mi'kmaw Nation 2018, as citied in Stantec 2018c). Paq'tnkek Mi'kmaw Nation has an Economic Development Department which manages all development projects within the community, including recent infrastructure development projects related to highway development and commercial opportunities. The First Nation also operates the Paq'tnkek Entertainment Centre, Gas Bar, and Smoke Shop (Paq'tnkek Mi'kmaw Nation 2018, as citied in Stantec 2018c). The First Nation owns and operates the Paq'tnkek Fisheries Enterprise, employing 20 community members. The enterprise has a fleet of five communal vessels and harvests lobster, snow crab, and herring (Paq'tnkek Mi'kmaw Nation 2018, as citied in Stantec 2018c).
Physical and Cultural Heritage (including archaeological, paleontological, historical or architectural sites)	Established in 1820, Paq'tnkek, meaning "by the bay", has been a traditional stopping point for Mi'kmaq travelling to and from Unama'ki, and a central meeting point for Chiefs across the province. Cultural and traditional practices such as spearing eel and salmon and snaring rabbits are still practiced within the community (Paq'tnkek Mi'kmaw Nation 2018, as citied in Stantec 2018c). Proposed PA does not overlap with any known physical and cultural heritage sites related specifically to Paq'tnkek First Nation.
Historical and Current Use of Lands and Waters	All Mi'kmaq in Nova Scotia would have a right to trap, hunt and harvest fish, animals and plants in the PA, as part of their Aboriginal and Treaty rights to hunt, fish, and gather. In particular, Mi'kmaq community members use the area within and surrounding the PA to hunt deer, bear, porcupine and foul; trap rabbits, fox and other small fur-bearing animals; fish for trout and other freshwater species; gather berries and plants for food and medicinal purposes; harvest plants, birchbark and fallen wood for handicrafts and cultural items. Mi'kmaq families also enjoy camps in the area for recreational purposes. All Nova Scotia Mi'kmaq communities hold FSC and commercial communal fishing licenses to harvest a variety of marine and freshwater species in tidal and non-tidal waters of Nova Scotia. Specific details and information relating to how subpopulations within a Mi'kmaq community (women, youth, elders, families) engage in traditional practices, other than the general information provided above, has not been shared with AMNS through direct engagement and the MEKS, but AMNS understands additional information may be available during the EIS review process from Mi'kmaq communities, and will continue to work with communities to integrate that information into project planning.
Asserted or Established Aboriginal and / or Treaty Right	The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights. This includes traditional rights to hunt, gather and fish, as well as treaty-protected rights to hunt and gather, and to fish for a "moderate livelihood". Those activities are related to sustenance, cultural and socio-economic practice.
Pictou Landing First Nation	
Location	Pictou Landing First Nation is comprised of five reserves on the south shore of the Northumberland Strait in Pictou County.
General Overview	Pictou Landing First Nation encompasses five reserves: Franklin Manor 22 (32 km southeast of Amherst with an area of 212.5 ha), Fisher's Grant (10 km north of New Glasgow with an area of 142.7 ha), Boat Harbour West 37 (8 km north of New Glasgow with an area of 98.2 ha), Fisher's Grant 24G (3.2 km southeast of Pictou Landing with an area of 60.0 ha) and Merigomish Harbour 31 (12.8 km east of New Glasgow with an area of 14.2 ha) (INAC undated). Pictou Landing First Nation is represented by the ANSMC. According to 2017 census data, the registered population was 663 (approx. 483 on and 157 off reserve). As of February 2020, the population was 672: Registered Males on Own Reserve – 241 Registered Females on Own Reserve – 250 Registered Males on Other Reserves – 10 Registered Females on Other Reserves – 12 Registered Males Living Off-Reserve – 83 Registered Females Living Off-Reserve – 76 (CBU, 2020) No data was available related to age of population.
Health and Socio-economic Conditions	Pictou Landing First Nation School accommodates students from primary to grade 6. There are no police detachments or fire halls within the community. The Nation has a church, gas bar, and health center (KMKNO undated, as citied in Stantec 2018c). As described in more detail below Pictou Landing First Nation holds several commercial communal licenses for a variety of fish and marine species. The Pictou Landing First Nation fishery is the Nation's main industry, with a fleet of 12 vessels and employing approximately 100 people (full and part time) a year (KMKNO undated, as citied in Stantec 2018c).
Physical and Cultural Heritage (including archaeological, paleontological, historical or architectural sites)	Pictou Landing First Nation have lived on a seasonal basis in and around a small tidal estuary connected by a narrow channel to the Northumberland Strait (Statoil 2017, as citied in Stantec 2018c). The area provided an abundance of resources such as fish, eel, crustaceans, and shellfish as well as hunting and trapping near shore (Statoil 2017, as citied in Stantec 2018c). Proposed PA does not overlap with any known physical and cultural heritage sites related specifically to Pictou Landing First Nation.

Table 6.14-2: Community profiles of the 13 Mi'kmaw First Nations in Nova Scotia (continued)

Mi'kmaw First Nation	Description
Historical and Current Use of Lands and Waters	All Mi'kmaq in Nova Scotia would have a right to trap, hunt and harvest fish, animals and plants in the PA, as part of their Aboriginal and Treaty rights to hunt, fish, and gather. In particular, Mi'kmaq community members use the area within and surrounding the PA to hunt deer, bear, porcupine and foul; trap rabbits, fox and other small fur-bearing animals; fish for trout and other freshwater species; gather berries and plants for food and medicinal purposes; harvest plants, birchbark and fallen wood for handicrafts and cultural items. Mi'kmaq families also enjoy camps in the area for recreational purposes. All Nova Scotia Mi'kmaq communities hold FSC and commercial communal fishing licenses to harvest a variety of marine and freshwater species in tidal and non-tidal waters of Nova Scotia. Specific details and information relating to how subpopulations within a Mi'kmaq community (women, youth, elders, families) engage in traditional practices, other than the general information provided above, has not been shared with AMNS through direct engagement and the MEKS, but AMNS understands additional information may be available during the EIS review process from Mi'kmaq communities, and will continue to work with communities to integrate that information into project planning.
Asserted or Established Aboriginal and / or Treaty Rights	The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights. This includes traditional rights to hunt, gather and fish, as well as treaty-protected rights to hunt and gather, and to fish for a "moderate livelihood". Those activities are related to sustenance, cultural and socio-economic practice.
Potlotek First Nation	
Location	Potlotek First Nation is comprised of two reserves, southwest of Sydney.
General Overview	Potlotek First Nation encompasses two reserves: Chapel Island 5 (69 km southwest of Sydney with an area of 595.5 ha) and Malagawatch 4 (62 km southwest of Sydney with an area of 661.3 ha (INAC undated, as citied in Stantec 2018c). Potlotek First Nation is represented by the ANSMC. According to 2017 census data, the registered population was 727 (approx. 552 on and 140 off reserve). As of February 2020, the population was 773: Registered Males on Own Reserve – 297 Registered Females on Own Reserve – 290 Registered Males on Other Reserves – 19 Registered Females on Other Reserves – 19 Registered Males Living Off-Reserve – 66 Registered Females Living Off-Reserve – 82 (CBU, 2020) No data was available related to age of population.
Health and Socio-economic Conditions	Within the community, there is a day care and elementary school, the Mi'kmawey School. Established in 1998, it accommodates students from primary to grade 6 (Potlotek First Nation 2016, as citied in Stantec 2018c). An RCMP building and fire hall exist within the community. The Potlotek Volunteer Fire Department has 14 active members (KMKNO undated, as citied in Stantec 2018c). A Health Centre is in the community, providing a variety of services and programs such as addiction services, maternal care, home care, advanced and diabetic foot care, healing programs and wellness programs (Potlotek First Nation 2016, as citied in Stantec 2018c). A doctor visits the Health Centre on a weekly basis (Potlotek First Nation 2016, as citied in Stantec 2018c). Additional infrastructure within the community includes the Chapel Island Community Hall / Kateri Chapel and a Youth Centre. Recently, economic developments such as the construction of a store-gas bar which includes Robins Donuts, a Rite Stop, Esso and video lottery terminals have provided employment opportunities for community members (KMKNO undated). The fisheries industry plays a dominant role in the First Nation's economy, particularly in oyster cultivation. Formed in 1995, the Apaqtukewaq Fisheries Co-op includes four members and employs seven people during peak season (May to September) (Potlotek First Nation 2016, as citied in Stantec 2018c). An oyster plant operates within the community and the Co-op operates two fishing vessels used for harvesting of lobster and snow crab (Potlotek First Nation 2016, as citied in Stantec 2018c).
Physical and Cultural Heritage (including archaeological, paleontological, historical or architectural sites)	Established in 1834, Potlotek First Nation, also known as Chapel Island, is the home of the Saint Anne's Mission where each year Mi'kmaw people gather to celebrate the Feast of Saint Anne (Potlotek First Nation 2016, as citied in Stantec 2018c). Chapel Island is considered a sacred ground to the Mi'kmaq (Potlotek First Nation 2016, as citied in Stantec 2018c). Proposed PA does not overlap with any known physical and cultural heritage sites related specifically to Potletek First Nation.
Historical and Current Use of Lands and Waters	All Mi'kmaq in Nova Scotia would have a right to trap, hunt and harvest fish, animals and plants in the PA, as part of their Aboriginal and Treaty rights to hunt, fish, and gather. In particular, Mi'kmaq community members use the area within and surrounding the PA to hunt deer, bear, porcupine and foul; trap rabbits, fox and other small fur-bearing animals; fish for trout and other freshwater species; gather berries and plants for food and medicinal purposes; harvest plants, birchbark and fallen wood for handicrafts and cultural items. Mi'kmaq families also enjoy camps in the area for recreational purposes. All Nova Scotia Mi'kmaq communities hold FSC and commercial communal fishing licenses to harvest a variety of marine and freshwater species in tidal and non-tidal waters of Nova Scotia. Specific details and information relating to how subpopulations within a Mi'kmaq community (women, youth, elders, families) engage in traditional practices, other than the general information provided above, has not been shared with AMNS through direct engagement and the MEKS, but AMNS understands additional information may be available during the EIS review process from Mi'kmaq communities, and will continue to work with communities to integrate that information into project planning.
Asserted or Established Aboriginal and / or Treaty Rights	The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights. This includes traditional rights to hunt, gather and fish, as well as treaty-protected rights to hunt and gather, and to fish for a "moderate livelihood". Those activities are related to sustenance, cultural and socio-economic practice.
Wagmatcook First Nation	
Location	Wagmatcook First Nation is comprised of three reserves, within the Bras d'Or Lakes region of Cape Breton.

Table 6.14-2: Community profiles of the 13 Mi'kmaw First Nations in Nova Scotia (continued)

Mi'kmaw First Nation	Description
General Overview	Wagmatcook encompasses three reserves: Malagawatch 4 (62 km southwest of Sydney with an area of 661.3 ha), Margaree 25 (68.8 km northwest of Sydney with an area of 0.8 ha), and Wagmatcook 1 (51 km west of Sydney with an area of 385.0 ha) (INAC undated). Wagmatcook First Nation is represented by the ANSMC. According to 2017 census data, the registered population was 852 (approx. 626 on and 184 off reserve). As of February 2020 the population was 900: Registered Males on Own Reserve – 334 Registered Females on Own Reserve – 328 Registered Males on Other Reserves – 19 Registered Females on Other Reserves – 25 Registered Males Living Off-Reserve – 83 Registered Females Living Off-Reserve – 111 (CBU, 2020) No data was available related to age of population.
Health and Socio-economic Conditions	In 1986, Wagmatcook First Nation initiated the first Indigenous secondary school in the Atlantic Region and established the first Nova Scotia Mi'kmaq Day Care Centre (Statoil 2017, as citied in Stantec 2018c). A new elementary-secondary education school, Wamgatcookewey School, is the first kindergarten to grade 12 Mi'kmaq First Nation school in Nova Scotia (Wagmatcook First Nation 2016, as citied in Stantec 2018c). There is no police detachment within the community, but there is a fire hall. The cultural center, the Wagmatcook Enterprise and Cultural Centre, provides a variety of services to community members including an Alternate School for Youth, cultural demonstration projects, and a Fitness Centre (Wagmatcook First Nation 2016, as citied in Stantec 2018c). The cultural center also houses the TD Canada Trust Agency bank, a Canada Post office, and the Clean Wave Restaurant (Wagmatcook First Nation 2016, as citied in Stantec 2018c). The band also operates a gas bar, grocery store, wharf, and warehouse. The Wagmatcook commercial fishery has been in operation since 1990 and is communally owned by registered members of Wagmatcook First Nation (Wagmatcook First Nation 2016). The Wagmatcook Commercial Fishery employs 35 fishers and one shore-based manager (Wagmatcook First Nation 2016). It utilizes a total of eleven fishing vessels and primarily harvests groundfish, palegics, shellfish and is a producer / wholesaler of shell ice products (Wagmatcook First Nation 2016). The fishery has six Cape Islander-style lobster vessels, one groundfish vessel, two storage facilities and an ice processing facility (Wagmatcook First Nation 2016, as citied in Stantec 2018c). The fishery generates the highest projected returns to the community (Wagmatcook First Nation 2016, as citied in Stantec 2018c).
Physical and Cultural Heritage (including archaeological, paleontological, historical or architectural sites)	Proposed PA does not overlap with any known physical and cultural heritage sites related specifically to Wagmatcook First Nation.
Historical and Current Use of Lands and Waters	All Mi'kmaq in Nova Scotia would have a right to trap, hunt and harvest fish, animals and plants in the PA, as part of their Aboriginal and Treaty rights to hunt, fish, and gather. In particular, Mi'kmaq community members use the area within and surrounding the PA to hunt deer, bear, porcupine and foul; trap rabbits, fox and other small fur-bearing animals; fish for trout and other freshwater species; gather berries and plants for food and medicinal purposes; harvest plants, birchbark and fallen wood for handicrafts and cultural items. Mi'kmaq families also enjoy camps in the area for recreational purposes. All Nova Scotia Mi'kmaq communities hold FSC and commercial communal fishing licenses to harvest a variety of marine and freshwater species in tidal and non-tidal waters of Nova Scotia. Specific details and information relating to how subpopulations within a Mi'kmaq community (women, youth, elders, families) engage in traditional practices, other than the general information provided above, has not been shared with AMNS through direct engagement and the MEKS, but AMNS understands additional information may be available during the EIS review process from Mi'kmaq communities, and will continue to work with communities to integrate that information into project planning.
Asserted or Established Aboriginal and / or Treaty Rights	The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights. This includes traditional rights to hunt, gather and fish, as well as treaty-protected rights to hunt and gather, and to fish for a "moderate livelihood". Those activities are related to sustenance, cultural and socio-economic practice.
We'koqma'q First Nation	
Location	We'ko'kmaq (Waycobah) First Nation is comprised of two reserves within the village of Whycocomagh in Cape Breton.
General Overview	Waycobah First Nation encompasses two reserves: Malagawatch 4 (62 km southwest of Sydney with an area of 661.3 ha) and Whycocomagh 2 (70 km west of Sydney with an area of 908 ha) (INAC undated, as citied in Stantec 2018c). Waycobah First Nation is represented by the ANSMC. According to 2017 census data, the registered population was 999 (approx. 883 on and 81 off reserve). As of February 2020 the population was 1031: Registered Males on Own Reserve – 454 Registered Females on Own Reserve – 458 Registered Males on Other Reserves – 15 Registered Females on Other Reserves – 18 Registered Males on Own Band Crown Land – 1 Registered Females on Own Band Crown Land – 1 Registered Males Living Off-Reserve – 36 Registered Females Living Off-Reserve – 48 (CBU, 2020) No data was available related to age of population.
Health and Socio-economic Conditions	In 2008, a new elementary-secondary school was opened within the community (Waycobah First Nation undated). A daycare facility also exists within the community as well as a RCMP station and volunteer fire department. In 2010, the Theresa Cremo Memorial Health Centre was opened, offering a variety of programs and services such as a full time Nurse Practitioner, full time clinical therapist, prenatal classes, lab collection, Reiki treatments, an Alcohol and Drug counselor, midwifery clinics, well women and men clinics, a dietician, teen health clinic and a variety of activities for members of the community of all ages (Waycobah First Nation undated). A doctor is available at the Health Centre twice a week. The Nation also owns and operates a convenience store and gas bar and a gaming center (Waycobah First Nation undated, as citied in Stantec 2018c). The First Nation has two lobster licenses, shrimp trap and trawl licenses, groundfish quotas and an active elver fishery (Waycobah First Nation undated). The Waycobah Fisheries employs approximately 35 community members (Waycobah First Nation undated, as citied in Stantec 2018c). In 2011, a trout fish farm was re-established within the community. Although owned by Cold Water Fisheries, employees are largely Waycobah community members (Waycobah First Nation undated, as citied in Stantec 2018c).

Table 6.14-2: Community profiles of the 13 Mi'kmaw First Nations in Nova Scotia (continued)

Mi'kmaw First Nation	Description
Physical and Cultural Heritage (including archaeological, paleontological, historical or architectural sites)	Established in the early 1800s, Waycobah First Nation was originally known as We'ko'kmaq. In the 1940s, the community experienced a decline in population because of the federal government's centralization policy, where many individuals were relocated to the community of Eskasoni (Waycobah First Nation undated, as citied in Stantec 2018c). Proposed PA does not overlap with any known physical and cultural heritage sites related specifically to We'ko'kmaq First Nation.
Historical and Current Use of Lands and Waters	All Mi'kmaq in Nova Scotia would have a right to trap, hunt and harvest fish, animals and plants in the PA, as part of their Aboriginal and Treaty rights to hunt, fish, and gather. In particular, Mi'kmaq community members use the area within and surrounding the PA to hunt deer, bear, porcupine and foul; trap rabbits, fox and other small fur-bearing animals; fish for trout and other freshwater species; gather berries and plants for food and medicinal purposes; harvest plants, birchbark and fallen wood for handicrafts and cultural items. Mi'kmaq families also enjoy camps in the area for recreational purposes. All Nova Scotia Mi'kmaq communities hold FSC and commercial communal fishing licenses to harvest a variety of marine and freshwater species in tidal and non-tidal waters of Nova Scotia. Specific details and information relating to how subpopulations within a Mi'kmaq community (women, youth, elders, families) engage in traditional practices, other than the general information provided above, has not been shared with AMNS through direct engagement and the MEKS, but AMNS understands additional information may be available during the EIS review process from Mi'kmaq communities, and will continue to work with communities to integrate that information into project planning.
Asserted or Established Aboriginal and / or Treaty Rights	The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights. This includes traditional rights to hunt, gather and fish, as well as treaty-protected rights to hunt and gather, and to fish for a "moderate livelihood". Those activities are related to sustenance, cultural and socio-economic practice.
Millbrook First Nation	
Location	Millbrook First Nation is comprised of seven reserves, near the communities of Truro and Halifax. It is the Mi'kmaq First Nation that is located in closest geographic proximity to the proposed Project.
General Overview	Millbrook First Nation encompasses seven reserves. Four reserve lands: Truro 27A, Truro 27B, Truro 27C and Millbrook 27, are near the town of Truro with a total area of 344.9 ha (INAC undated, as citied in Stantec 2018c). The remaining three are: Beaver Lake 17 (78.4 km southeast of Halifax with an area of 49.4 ha), Sheet Harbour 36 (91.2 km northeast of Halifax with an area of 32.7 ha), and Cole Harbour 30 (9.6 km east of Halifax with an area of 18.6 ha (INAC undated). The Beaver Lake and Sheet Harbour reserves are the two Millbrook communities in closest geographic proximity to the proposed Project. Millbrook First Nation is currently not represented in consultation by the ANSMC. According to 2017 census data, the registered population was 1,831 (approx. 872 on and 916 off reserve). As of February 2020, the population was 1,995: Registered Males on Own Reserve – 452 Registered Females on Own Reserve – 460 Registered Males on Other Reserves – 22 Registered Females on Other Reserves – 15 Registered Females on Own Crown Land – 1 Registered Males on Other Band Crown Land – 1 Registered Females on Other Band Crown Land – 1 Registered Males on No Band Crown Land – 1 Registered Males Living Off-Reserve – 507 Registered Females Living Off-Reserve – 535 (CBU, 2020) No data was available related to age of population.
Health and Socio-economic Conditions	Infrastructure and services available in the community of Millbrook are the Millbrook Band Office, Millbrook Community Hall, Millbrook Ballfield, Millbrook Gym, Millbrook Early Education Centre, Millbrook Senior's Centre, and Sacred Heart Mission Church (Millbrook First Nation 2018, as citied in Stantec 2018c). The Millbrook Health Centre is also in the community, providing a variety of programs and services such as home and community care and assisted living programs, youth support, addiction services, wellness programs and community support and family enrichment programs. Millbrook First Nation owns, develops, and manages the retail park, Millbrook Power Centre, in Truro, NS. This park encompasses 68 acres of commercial land on the most traveled stretch of highway in Nova Scotia, outside of Halifax (Millbrook First Nation 2018, as citied in Stantec 2018c). Since opening in 2001, the Millbrook Power Centre has approximately a dozen tenants including a multiplex theatre, several restaurants, two hotels, a recreational vehicle retailer, a service station, an aquaculture facility, a furniture store, and the Glooscap Heritage Centre (Millbrook First Nation 2018, as citied in Stantec 2018c). There have also been recent developments in the Cole Harbour community, including apartment buildings, General Dynamics Building, and a gaming center. Millbrook Fisheries is an important part of the local economy, controlling eight vessels and employing over 40 staff members throughout the year. In recent years, Millbrook First Nation has opened several cannabis dispensaries in the community of Millbrook.
Physical and Cultural Heritage (including archaeological, paleontological, historical or architectural sites)	From the late 1700s to the early 1800s, the Mi'kmaq near Truro were settled along the banks of the Salmon River. The Mi'kmaq then relocated to their current community at Millbrook (Millbrook First Nation 2018, as citied in Stantec 2018c). Both the MEKS and the Archaeological studies completed for the Touquoy Gold Project and the Fifteen Mile Stream Gold Project were considered in this EIS, and archaeological studies appended to this EIS. The proposed PA does not overlap with any known physical and cultural heritage sites related specifically to Millbrook First Nation.
Historical and Current Use of Lands and Waters	All Mi'kmaq in Nova Scotia would have a right to trap, hunt and harvest fish, animals and plants in the PA, as part of their Aboriginal and Treaty rights to hunt, fish, and gather. As described in the TLRUS, the LSA is a significant area for Millbrook occupancy including permament residences at the Beaver Dam IR, as well as camps within and directly adjacent to the LSA used to support harvesting activities and that provide restorative peace and solitude to Millbrook citizens. The LSA is also a significant harvesting location for many species such as big game (deer and bear), small game (rabbits and grouse), furbearers (beaver and coyotes), fish (trout), berries, wood and medicine. All Nova Scotia Mi'kmaq communities hold FSC and commercial communal fishing licenses to harvest a variety of marine and freshwater species in tidal and non-tidal waters of Nova Scotia. Specific details and information relating to how subpopulations within a Mi'kmaq community (women, youth, elders, families) engage in traditional practices, has been shared with AMNS through direct engagement and through the generation of the TLRUS. Overall, the TLRUS concludes that all subpopulations of the Millbrook First Nation engage in traditional practices throughout the LSA. A detailed description of historical and current use of lands and waters is provided in Section 1.1.2.2.
Asserted or Established Aboriginal and / or Treaty Rights	The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights. This includes traditional rights to hunt, gather and fish, as well as treaty-protected rights to hunt and gather, and to fish for a "moderate livelihood". Those activities are related to sustenance, cultural and socio-economic practice

Table 6.14-2: Community profiles of the 13 Mi'kmaw First Nations in Nova Scotia (continued)

Mi'kmaw First Nation	Description
Sipekne'katik First Nation	
Location	Sipekne'katik First Nation (also known as Indian Brook or Shubenacadie) is comprised of five reserves in Hants County, near the town of Shubenacadie. It is the second most proximate Mi'kmaw community to the proposed Project.
General Overview	Sipekne'katik First Nation encompasses five reserves: Indian Brook 14 (29 km southwest of Truro with an area of 1,234.2 ha), Wallace Hills 14A (with an area of 54.8 ha), Shubenacadie 13 (32 km north of Halifax with an area of 412.0 ha), Pennal 19 (67.2 km northwest of Halifax with an area of 43.5 ha) and New Ross 20 (64 km northwest of Halifax with an area of 408.3 ha) (INAC undated, as citied in Stantec 2018c).The Indian Brook and Shubenacadie reserves would be the two most proximate Sipekne'katik communities to the proposed Project. Sipekne'katik First Nation is currently not represented by the ANSMC. According to 2017 census data, the registered population was 2,645 (approx. 1,268 on and 1,298 off reserve). As of February 2020, the population was 2,771: Registered Males on Own Reserve – 617 Registered Females on Own Reserve – 699 Registered Males on Other Reserves – 34 Registered Females on Other Reserves – 31 Registered Males on Other Band Crown Land – 2 Registered Females on Other Band Crown Land – 1 Registered Males on No Band Crown Land – 8 Registered Females on No Band Crown Land – 7 Registered Males Living Off-Reserve – 655 Registered Females Living Off-Reserve – 717 (CBU, 2020) No data was available related to age of population.
Health and Socio-economic Conditions	In 2008, the L'nu Sipuk Kina'muokum (LSK) school opened in the community, accommodating students from primary to grade 12. The school specializes in Mi'kmaq studies and Mi'kmaq language courses (Sipekne'katik First Nation 2016, as citied in Stantec 2018c). Little Eagles Daycare Centre provides care to children ages 1-4 years old (Sipekne'katik First Nation 2016, as citied in Stantec 2018c). The community also has the Sipekne'katik Multipurpose Centre, used for community meetings, events, and social gatherings. Local businesses within the community include a community gas-bar, tobacco shop, gaming room and convenience store. The Sipekne'katik First Nation Fisheries Department is an economic enterprise, managing 33 fishing licenses for various species including lobster, crab, and groundfish (BP 2017, as citied in Stantec 2018c).
Physical and Cultural Heritage (including archaeological, paleontological, historical or architectural sites)	Established in 1820, Sipekne'katik was originally named "Indian Brook". The area was traditionally used as a sacred site to prepare for ceremonies and hunting and fishing trips (Sipekn'katik First Nation undated). In 1752, one of the most significant Peace and Friendship Treaties was signed at Shubenacadie District (Sipekn'katik First Nation 2016, as citied in Stantec 2018c). This treaty dealt with lands, hunting, fishing, trapping, gathering, and trading. In 2002, a memorial was erected in honor of Chief Jean Baptiste Cope and the Treaty of 1752 (Sipekn'katik First Nation 2016, as citied in Stantec 2018c). Proposed PA does not overlap with any known physical and cultural heritage sites related specifically to Sipekne'katik First Nation.
Historical and Current Use of Lands and Waters	All Mi'kmaq in Nova Scotia would have a right to trap, hunt and harvest fish, animals and plants in the PA, as part of their Aboriginal and Treaty rights to hunt, fish, and gather. In particular, Mi'kmaq community members use the area within and surrounding the PA to hunt deer, bear, porcupine and foul; trap rabbits, fox and other small fur-bearing animals; fish for trout and other freshwater species; gather berries and plants for food and medicinal purposes; harvest plants, birchbark and fallen wood for handicrafts and cultural items. Mi'kmaq families also enjoy camps in the area for recreational purposes. All Nova Scotia Mi'kmaq communities hold FSC and commercial communal fishing licenses to harvest a variety of marine and freshwater species in tidal and non-tidal waters of Nova Scotia. Specific details and information relating to how subpopulations within a Mi'kmaq community (women, youth, elders, families) engage in traditional practices, other than the general information provided above, has not been shared with AMNS through direct engagement and the MEKS, but AMNS understands additional information may be available during the EIS review process from Mi'kmaq communities, and will continue to work with communities to integrate that information into project planning.
Asserted or Established Aboriginal and / or Treaty Rights	The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights. This includes traditional rights to hunt, gather and fish, as well as treaty-protected rights to hunt and gather, and to fish for a "moderate livelihood". Those activities are related to sustenance, cultural and socio-economic practice.

6.14.4.2 Beaver Dam Mine Site and Haul Road Baseline Conditions

This section describes the historical and current traditional Mi'kmaq use of the PA, LAA and RAA (Section 6.14.6.1), as described through regional research, direct engagement, the TLRUS (MFC 2019), and the conclusions from the MEKS (Appendix M.1). The Project LAA is consistent with the Local Study Area (LSA) defined in the TLRUS (MFC 2019) and for ease of review, the term LAA is used in this section. Historical use has been informed by the MEKS, and the TLRUS also relies on the MEKS for the description of Mi'kmaq historical use of the area and describes this description as robust (MFC 2019). As a result, the historical Mi'kmaq land and resource use section is written in consideration of the collective Mi'kmaq of Nova Scotia and is directly referenced from the MEKS.

AMNS acknowledges the collective rights for all Mi'kmaq of Nova Scotia. Given the proximity of the Project to the Millbrook First Nation Beaver Lake IR and Sheet Harbour IR and, given the documented Millbrook First Nation traditional and current use presented in the TLRUS (MFC 2019), the EIS has tailored the description and analysis of the Project and current Mi'kmaq land and resource use, health and socio-economic conditions, physical and cultural heritage to the Millbrook First Nation community and its members. This approach has been validated through engagement with Millbrook First Nation, the KMKNO, and the broader Mi'kmaq of Nova Scotia community.

6.14.4.2.1 Historic Mi'kmaq Land and Resource Use

Historical Mi'kmaq Land and Resource Use is described in detail in the MEKS and is summarized within this section. For the detailed description, please reference the MEKS (CMM 2016) in Appendix M.1.

Pre-Contact

Mi'kmaq traditional use of the land in Nova Scotia involved semi-permanent and permanent settlements. Summer villages of the Mi'kmaq were usually located on the banks of streams or rivers. The most important factor in the choice of a site was the proximity of the site to a navigable body of water. Sites around the mouths of rivers with heavy spawning runs were highly favourable for use, as well as smaller rivers running back into a system of lakes (Appendix M.1).

Beaver Dam lies within Eskikewa'kik or the "skin dressing territory". This particular district spans from Halifax County across to Guysborough County. Various authors and historians have differed in their description of how far this territory expands, but all have agreed that Beaver Dam lies within this district (Appendix M.1).

Although little historical information has been written about Mi'kmaq inhabiting these areas in large numbers, there is some documentation that suggests that they mainly inhabited Halifax and Port Mulgrave. Bernard Hoffman has noted that there were seven main sites within Eskikewa'kik; including sites at Ship Harbour, Spry Bay Harbour and Liscomb Harbour near the study area (Appendix M.1).

Mi'kmaq cultures hunted land and marine mammals and fish for sustenance and some trading until the late sixteenth century, when traditional activities began to change in response to contact with the Europeans. Settlements, although not permanent, were located near major waterways and harbours, providing accessibility to trade with the Europeans. The Mi'kmaq traveled inland through minor streams and rivers, either by canoe or on foot (Appendix M.1).

Post-Contact

Nicholas Denys gives a brief description of the area "Bay de Toutes Isles" which would cover the area along the Eastern Shore known as the Bay of Islands running from Ship Harbour along the coast to Liscomb Harbour. "This bay has nearly four leagues of depth, and there are several rivers which discharge into it. These are small and are only, as it were, large brooks, [though] by them the Indians come and go." He stated that there *seems to be a large number of Indians living in that area in order to hunt the moose* (Appendix M.1).

Mi'kmaq at Beaver Dam

The Mi'kmaq referred to this area as Kopitewey Kwimuti literally meaning Beaver Harbour. In 1852, 100 acres had been set-aside for Simon Francis on the Sheet Harbour Road at the head of Beaver Lake. There is little written prior to the setting aside of this reserve under Samuel Fairbanks' Return of Land report in 1866 (Appendix M.1).

The reference plan from Natural Resources Canada shows a parcel of ten acres adjacent to the Beaver Dam reserve as being allotted to Peter Paul in 1930. The original letters patent and grant was not located, but Peter Paul's name again comes up in lands held by himself and his brother adjacent to the Sheet Harbour Reserve (Appendix M.1).

In the Old Man Told Us by Ruth Holmes Whitehead, reference is made to John Cope killing 18 moose at Beaver Dam and selling them to the men at Fifteen Mile Stream Goldmine in 1918 (Appendix M.1).

In 1973, John Covert conducted another survey at Beaver Lake and found that the reserve contained 122 acres instead of the initial one hundred acres granted to Simon. The reserve was formally set-aside to Millbrook Band in 1960 (Appendix M.1).

Mi'kmaq at Sheet Harbour

Around the seventeen hundreds, the Mi'kmaq lived along the eastern coast, at Spry Bay Harbour, Ship Harbour and Sheet Harbour. In 1762, Jonathan Belcher issued a proclamation protecting the traditional hunting and fishing territories of the Indians. This area included all that portion of Canso and running westerly as far as Musquodoboit (Appendix M.1).

Following the American Revolution in 1776, an influx of loyalists induced on settling in Nova Scotia, were given gratuitous land grants and most of the land laid out for the Indians was encroached upon. In 1783 a license of occupation was issued to the Indians for 11,520 acres in order to protect their fishing and hunting rights. James E. Rutledge mentioned in his book History of Sheet Harbour that when a number of soldiers had moved to the area in 1784, "there was an encampment of Indians in the maple grove now the property of the heirs of Robert Rutledge at Watt Section".8 This in all likelihood was the section of land included within the license of occupation (Appendix M.1).

A large portion of the areas given under these licenses, were encroached upon by European settlers but Mi'kmaq occupation continued at Sheet Harbour prior to the establishment of the formal reserve in 1915. The white settlers, angered by Belcher's proclamation for protecting Mi'kmaq hunting territories, ignored his rule, and continued to settle there. The lands set aside for the Indians were eventually abandoned, but some continued to return there to hunt and fish (Appendix M.1).

In Frank Speck's work, Beothuk and Micmacs, he describes the hunting territories. "The Micmac, like the rest of the northern and eastern Algonkian, whose subsistence was gained by hunting and fishing, had their country subdivided into more or less well recognized districts in which certain individual proprietors or families enjoyed the inherited privileges of hunting" (Appendix M.1).

Contained within Speck's list of territories, predominantly Cope surnames continued to hunt and fish at Ship Harbour, Jeddore, Ten and Fifteen Mile Lake, Sheet Harbour and Liscomb (Appendix M.1).

Mi'kmaq at Ship Harbour

The Mi'kmaq referred to the area at Ship Harbour as Tetmnipukwek10 meaning "where Indian men are bludgeoned to death". In 1813, a petition came from Francis Coop for land at Ship Harbour for himself, his wife and seven children as outlined in document RG 20 A – Coop Francis. The petition stated that 200 acres of land be laid out for him, as he was sober and industrious, on the provison that it could only be passed on to his children at the head of the Ship Harbour River (CMM 2016).

In 1848, John Spry Morris laid out 500 acres of land in 100-acre lots, with a small lot measuring 47 acres being reserved for fishing. The five lots were laid off to Francis Paul, Joseph Paul, Lewis Paul, Lewis Newal and Lewis Brooks. Two additional lots were allotted to Francis Paul's sons, James Paul and Joseph Paul. A survey of the area in 1853 had referred to 700 acres of land but did not mention the 47 acres reserved for fishing (CMM 2016).

After 1855 little correspondence is written about the Mi'kmaq living at Ship Harbour. There are a few bills for provisions and aid given to them in 1856 (MG 15 Volume 6 no. 14). Various requests for blankets had dropped from 1861 onward, as they believed that an outbreak of smallpox had serious effect on the numbers living at Musquodoboit, Sheet Harbour and Ship Harbour. Joseph Browner had requested that four dollars worth of blankets be sent to him for Indians living at Tangier, but no mention of Ship Harbour. (Journal of Assembly: 1863, No. 16, p.5.) (CMM 2016).

In 1893, J. Lewis & Sons inquired into the possibility of purchasing land at Ship Harbour Reserve in order to locate a factory and use the timber on the land. The Superintendent General then wrote to the Indian agent to inquire any Indians lived there, and would be willing to surrender the reserve. Joseph Cope's letter to the Superintendent General stated: "the said or supposed Reserve has been abandoned by the Indians thirty or forty years ago. Although a good number of us are there every summer for the [?] work pur- poses..." (CMM 2016).

In 1919, the government wanted to centralize the Mi'kmaq on two main reserves at Shubenacadie and Indian Brook. They had made several attempts with the Halifax County Indians to either settle permanently on Ship Harbour, or to dispose of the land. The property was eventually surrendered along with Sambro and Ingram River, but the Mi'kmaq continued to use that area as shown in Frank Speck's Beothuks and Micmac. He pointed out that Andrew Francis was allotted hunting territory #29 in 1922, which covered land at the Great Ship Harbour: whether or not that fell into the lands originally set aside as an Indian Reserve is unknown (CMM 2016).

Historic land loss and displacement of the Mi'kmaq as a result of the taking up of lands by settlers and their industries has had a profound impact on current land use patterns. Although there was continuous Mi'kmaq resistance and resilience in the face of this, this process has immensely shaped what Mi'kmaq land use looks like today (MFC 2019).

The 1876 Indian Act was another major factor in the alternation of Mi'kmaq land use patterns. Under this Act was the failed Centralization Policy of 1942 that attempted to cut Indian administration costs by forcing Mi'kmaq families onto two central reserves - Eskasoni and Shubencadie. Further to this, assimilation was the ultimate goal of the residential school system and from 1930 to 1966 one thousand Mi'kmaq children attended the Shubencadie Indian Residential School. Attendance at residential school led to a loss of language, culture, and identity and disrupted intergenerational knowledge transfer of Mi'kmaq cultural values and norms (MFC 2019).

Beginning in the late 1970s a series of legal milestones occurred that led to a recognition of Mi'kmaq Aboriginal and treaty rights in the courts. This again began to re-shape Mi'kmaq land use patterns through greater access to traditional resources. However, by this time multi-generational alienation from lands had already led to a significant loss of place-based traditional knowledge that was irreplaceable (MFC 2019).

6.14.4.2.2 Known Mi'kmaq Archaeological Sites near the Beaver Dam Mine Site and Haul Road

The vast majority of archaeological discoveries in Nova Scotia have been incidental rather than the result of targeted archaeological surveys. More often than not they have been made in the context of some sort of development – agricultural development or residential, industrial or infrastructural construction. The Beaver Dam Mine Site and Haul Road have to date not had significant development activities. The archaeological record for most of Eskikewa'kik is very sparse and consists mostly of sporadic surface finds.

It is obvious therefore, and important to note, that the relative lack of archaeological evidence in the Beaver Dam Mine Site and the Haul Road cannot be construed as proof of a lack of pre-contact Mi'kmaw occupancy. Nova Scotia Museum records did not contain any archaeological sites within the MEKS Study Area. The adjoining areas have had some activity recorded in the Maritime Archaeological Resource Inventory. The information collected from that research has shown that Mi'kmaq presence is documented surrounding the study area (Appendix M.1).

AMNS has shared the archaeological reports directly with KMKNO (October 5, 2020).

6.14.4.2.3 Current Mi'kmaq Land and Resource Use

Drawing from information provided through the MEKS, the TLRUS (MFC 2019), direct information gathered from engagement activities between AMNS and the Millbrook First Nation and Sipekne'katik First Nation, and the KMKNO, and the Project team's knowledge of the Beaver Dam Mine Site and the Haul Road, the following summary of current Mi'kmaq land and resource use has been prepared as a basis from which to understand and evaluate Project interactions and potential effects of the Project on the Mi'kmaq of Nova Scotia. As described in Section 1.1.2.2, the description and analysis in this section has been tailored to Millbrook First Nation, unless specific mention of information relating to a different Mi'kmaq community is noted. Information was requested from all Mi'kmaq communities in Nova Scotia through the MEKS and direct engagement with KMKNO and Sipekne'katik First Nation; however, the TLRUS (MFC 2019) prepared for Millbrook First Nation and information received directly from the Millbrook First Nation community informs AMNS's specific understanding of traditional and current use. Some generalized information, especially relating to traditional use, was available through the MEKS and is presented herein. The baseline information provided in the MEKS is generally consistent with that baseline data collected by the Millbrook First Nation through the TLRUS (MFC 2019).

The following key aspects were considered and requested from the Mi'kmaw communities during collection of baseline data (either through direct engagement or the completion of the MEKS and TLRUS):

- General information about Mi'kmaq of Nova Scotia populations;
- General description of baseline conditions within the Beaver Dam Mine Site and Haul Road and surrounding landscape to support an understanding of the current experience of the traditional practice for the Mi'kmaq of Nova Scotia;
- Sites or areas that are used by the Mi'kmaq of Nova Scotia either for permanent residences or on a seasonal/temporary basis and the number of people that use each site/area identified;
- Drinking water sources (permanent, seasonal, periodic, or occasional);

- Consumption of country foods (also known as traditional foods) including food that is trapped, fished, hunted, harvested, or grown for subsistence or medicinal purposes, outside of the commercial food chain;
- Which country foods are consumed by which groups, how frequently, and where these country foods are harvested;
- How are different subpopulations of the Mi'kmaq communities using the land;
- How often is the right practiced or exercised and timing/seasonality of the practice; the context in which the right is practiced;
- Commercial activities (e.g. fishing, trapping, hunting, forestry, outfitting) and the frequency, duration and timing of these activities including maps and data sets; and
- Recreational uses and the frequency, duration and timing of these activities.

Baseline information that was shared and available for the Project is described in this section. This summary of current use is specific to the Millbrook First Nation, through the completion of the TLRUS (MFC 2019), supported by conclusion of the MEKS. This report describes Millbrook traditional land and resource use in the regional and local study areas through careful documentation of harvesting and occupancy locations, as well as the presentation of qualitative information relating to participants' relationships with these locations (MFC 2019).

It is important to note that some limitations relating to baseline information are present and thus, evaluation of Project interactions and potential effects to the Millbrook First Nation and more broadly the Mi'kmaq of Nova Scotia, are provided with some limitations on specific analysis:

- **Drinking Water Sources:** No surface drinking water sources were identified through the MEKS or TLRUS, and direct engagement activities with the communities. As a result, no analysis of specific surface water drinking water sources is completed. However, a discussion of impact to drinking water at the Cameron Flowage/Killag River (the discharge location from the Project) is included as it is considered the reasonable worst case predicted water quality conditions stemming from the Project.
- **Residences (Permanent or Seasonal):** No specific detail relating to location of seasonal or temporary camps/cottages/residences were provided to AMNS. The MEKS did not provide any information relating to seasonal or permanent residences, with the exception of the Beaver Lake IR 17. The TLRUS identified several Millbrook camp locations, but no specific locations were provided. Thus, no analysis of specific Millbrook residential receptors has been included in this Project EIS. Conclusions relating to Project impacts at the Beaver Dam Mine Site and Haul Road property boundaries have been provided for each VC in Table 6.14-5 and these conclusions can support analysis of camps/cottages that have been identified in a more generalized way surrounding, and in close proximity to, the Beaver Dam Mine Site and Haul Road.
- **Ceremonial/Spiritual Activities and Sites:** General or specific information about sacred sites was not provided in the MEKS or TLRUS.

Additional information relating to strengthening AMNS understanding of current Millbrook and more broadly, Mi'kmaq, land use was requested as documented in detail in Section 4 and summarized herein. AMNS will continue to work with the Millbrook First Nation and the Mi'kmaq of Nova Scotia to identify any outstanding traditional and current use information related to the Project.

Baseline Current Millbrook First Nation Land Use

Cultural continuity through practice is of great importance to the Mi'kmaq – and the connection of that continued practice for their cultural survival.

The TLRUS describes current primary impacts on Millbrook traditional land and resource use (harvesting and occupancy) in the RAA and then provides a high-level description of current harvesting and occupancy values within the RAA. Then, the TLRUS provides a detailed description of harvesting and occupancy within the LAA. This description at the LAA level, along with supplemental information documented in the MEKS and through direct engagement with Millbrook First Nation, the KMKNO, and the Mi'kmaq of Nova Scotia forms the basis of the baseline current Mi'kmaq use for the purposes of evaluation of impacts to the Millbrook First Nation, and, by extension, the Mi'kmaq of Nova Scotia, from the Project.

Current Primary Impacts and Harvesting and Occupancy Values within the RAA

Within the RAA, the primary impacts can be described in four main impact categories: direct physical disturbance; sensory disturbance; access considerations; and the quality and quantity of resources (MFC 2019).

The RAA has experienced direct physical disturbance and changes in access for baseline Millbrook First Nation and Mi'kmaq practices. The main disturbances in close proximity to the Beaver Dam Mine Site and the Haul Road stem from forestry activities (cut blocks, logging roads and mills), the existing operating Touquoy mine, the tourism industry, and the Port of Sheet Harbour (MFC 2019). Sensory disturbance in the RAA is linked largely to forestry activities (noise and lights from logging and haul trucks and noise, light and odours from mill sites). The Touquoy Gold Project and the Port of Sheet Harbour also contribute to baseline noise and light levels. The TLRUS estimates that only one third of the RAA is available for the Mi'kmaq for harvesting and occupancy (MFC 2019), which is then further limited by designated protected areas (provincial) which don't allow hunting and camping within their boundaries. Finally, there has been a documented decline in the quantity and quality of the traditional resources as demonstrated by designated species at risk and reduction in baseline water quality throughout the RAA as a result of herbicides and insecticides used by forestry and agricultural industries (MFC 2019).

The TLRUS describes a high-level description of harvesting and occupancy in the RAA. Occupancy is defined by the presence of indicators - camps, cabins and overnight sites, place names and burial sites. Although specific locations were not shared with the AMNS, this occupancy is documented within the TLRUS and includes a detailed list of Mi'kmaq place names, and is described in general ways for the purposes of AMNS evaluation of Project impacts. Harvesting locations are also described in a general format within the RAA (MFC 2019) and can be summarized by documenting that many Millbrook members, particularly local members of the Beaver Lake and Sheet Harbour IRS, are sustenance harvesters, with hunting, fishing, and trapping practices as important contributions to their household income (MFC 2019). Harvesting includes big game, fish and shellfish and medicinal and ceremonial plant and tree species. The MEKS also documents Mi'kmaq place names, demonstrating occupancy within the RAA.

Current Primary Impacts within the LAA

The majority of documented primary impacts within the LAA relating to physical disturbance is as a result of forestry activities including cut blocks and associated forestry roads (MFC 2019). Millbrook members also provided comment on the changed landscape at the Touquoy Gold Project, at the western extent of the LAA. Sensory disturbance is also documented at the western extent of the LAA from the Touquoy Gold Project, and from forestry activities throughout the LAA which are described as limited and primarily short term in nature (MFC 2019). The forestry industry also resulted in changed access within the eastern portions of the LAA, and the Touquoy Gold Project has changed access to the adjacent areas for Milbrook hunters, as they are concerned about discharging their firearms in close proximity to the mine and possibly hurting someone. Overall, the TLRUS describes a

general reduction in quantity of resources such as deer, trout, medicines and berries within the LAA, and describes a reduction in water quality as a result of logging activities in close proximity to streams and resulting reduction in riparian zones causing an increase in water temperatures.

Harvesting and Occupancy Values with the LAA

The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights. This includes traditional rights to hunt, gather and fish, as well as treaty-protected rights to hunt and gather, and to fish for a "moderate livelihood", which may take place throughout the year. According to the TLRUS (MFC 2019), the LAA is used by the Millbrook First Nation for the following purposes:

- Hunting deer, bear, rabbit and grouse for sustenance;
- Trapping rabbits, bobcat, beaver, coyotes, musrat, mink, otter, weasel and other small fur bearing animals for pelts and food;
- Gathering/harvesting various plants for medicinal and sustenance purposes;
- Gathering/harvesting fallen wood and birchbark for handicrafts and cultural items;
- Fishing for trout and other freshwater species; and
- Modern-day camps for recreational purposes.

The TLRUS (MFC 2019) states that local residents of the Beaver Dam, Sheet Harbour and Millbrook IRs frequently use the area (range of use from weekly to yearly, depending on availability of species) for hunting (deer, bear, rabbit, grouse, porcupine) and rely on the wild harvest as an important food and dietary source. Equally, community members harvest berries when in season, and a number of plants that are also used for sustenance, as well as traditional medicines. The seasonal and recreational use of animals and plants important to the Millbrook community members supports the continuity of traditional practices and is very important to the maintenance of their culture and the practice of their rights. Millbrook harvesting activities and practices are culturally important as they ensure the sharing and maintenance of cultural values and their practice. Millbrook First Nation community members use plants and animals harvested in the area for traditional sustenance purposes, health-related medicinal purposes, and spiritual and cultural purposes.

Additionally, the MEKS (CCM 2016) provided the following information related to current Mi'kmaq land and resource use sites, species of significance to Mi'kmaq, and Mi'kmaw communities, with the current Mi'kmaq land and resource uses categorized and identified as:

- Kill/hunting: trout, eel, bear, rabbit, deer, porcupine, partridge, coyote, mink, muskrat, weasels, raccoon, fox, otter and beaver;
- Burial/birth: potential burial sites recorded within the MEKS study area on the western side of the Beaver Dam Mine Road but not within the PA;
- Ceremonial: none identified;
- Gathering: wild fruit, berries, water, food plant, specialty wood, logs, feathers, quills; and
- Habitation: anchored boat, travel route, overnight site.

Species of significance to the Mi'kmaq are associated with three categories; these are listed below with the number of occurrences in the study area based on field work completed by CMM in summer 2016:

- Medicinal: 49 species present;
- Food/beverage: 27 species present; and
- Craft/art: 11 species present.

An overview of the Millbrook First Nation local fisheries activity within the identified LAA was provided in the TLRUS (MFC 2019). Additional information relating to the local Mi'kmaq fisheries was also reported in the MEKS and through direct engagement with the Mi'kmaq of Nova Scotia which supports the conclusions presented in the TLRUS (MFC 2019).

As requested by Round 2, Information Request (IR2) CEAA 2-54, fishing is traditional practice (historical and current) in the LAA. Fishing is generally for sustenance/subsistence, as well as for recreational purposes. Trout is the key fish species described in the TLRUS (MFC 2019) with additional species including brook and rainbow trout, sea trout, American eel, Atlantic salmon, herring, mackerel, gaspereau, various groundfish species, smelt, striped bass and sucker. Shellfish harvesting within the LAA include clams, lobster, mussels, snowcrab, and scallop (MFC 2019). Fishing is practiced across the LAA in most major rivers and lakes, as documented in the TLRUS and MEKS. Within the Beaver Dam Mine Site, there is documentation of trout fishing within Cameron Flowage/Killag River and possibly Mud Lake and Crusher Lake (MFC 2019). Within the 4km footprint of new construction for the Haul Road, there are no documented rivers or lakes that support the Mi'kmaq fisheries. However, adjacent to this new construction corridor and along the road footprint proposed for upgrades to construct the Haul Road, fishing locations are common, and Millbrook First Nation use of these lakes (and rivers) is well documented from the Beaver Dam Mine Site to the Mooseland Road (MFC 2019). AMNS acknowledges documented fish harvesting by Millbrook First Nation within the area directly surrounding the Project and the broader LAA.

There are a number of activities associated with the harvest and use of plants, animals and fish within the PA and in the LAA that relate to historical traditions and customs of the Mi'kmaq that are still practiced today. As described, the TLRUS (MFC 2019), the MEKS and residents of the Beaver Lake IR identify trapping and hunting activities, plant and berry gathering, and fishing in, near and surrounding the PA for purposes of sustenance, spiritual and cultural practice. The TLRUS (MFC 2019) described the frequency of use within the LAA which can be summarized as regular: weekly to annually across all seasons. This means the area was, and still is, an important resource area for the Millbrook First Nation community members and by extension, all Mi'kmaq of Nova Scotia, and any Project activities may have potential impacts on the ability of the Mi'kmaq of Nova Scotia to access certain areas to practice their rights where species with important cultural relevance may be found. Wild meat was traditionally a staple of the Millbrook First Nation diet, and a few of the harvesters interviewed for the TLRUS (MFC 2019) indicated they rely mainly on this food source and they share their food with other community members, rather than purchase their meat at a local supermarket.

Some Mi'kmaq community members have camps on Crown land where they go to enjoy peaceful recreational and traditional activities with family and community members. There are five camps documented within 1 km of the Haul Road and multiple other camp locations throughout the LAA (MFC 2019). The Millbrook community is concerned that noise and activity from the Beaver Dam Mine Site and the Haul Road will negatively impact their ability to enjoy the remoteness and quiet of the area, as well as impact wildlife patterns and their hunting practices.

The evidence presented above shows Mi'kmaw occupancy and land/resource use in the PA, LAA and wider region of Eskikewa'kik – are changing, and more limited but uninterrupted use from pre-contact times to today.

In summary, both those aspects, the economic and cultural motivations for traditional land and resource uses, feed into a third impetus: the need to express, affirm and exercise their Aboriginal rights to live their cultural heritage within Mi'kma'ki, and their Treaty rights to continue harvesting the resources of their traditional territory.

6.14.4.3 Touquoy Mine Site Baseline Conditions

The processing of Beaver Dam ore at the Touquoy Mine Site will not result in any additional impact to the Mi'kmaq of Nova Scotia, other than those effects already addressed and evaluated in the Touquoy EARD (CRA 2007a). Therefore, the effects assessment portion of this section will address only the Project in the context of the Beaver Dam Mine Site and Haul Road. The cumulative effect of the Touquoy Gold Project and the Project is considered in Section 8.

6.14.5 Consideration of Engagement Results

Key issues raised during Mi'kmaq engagement include concerns related to pathways of adverse effects from Project activities during construction and operation, including direct physical disturbance and habitat loss, sensory disturbance from elevated noise and light from the Beaver Dam Mine Site and haul trucks along the Haul Road, loss of access to the PA, and potential impact to the quality and quantity of flora and fauna used in traditional hunting, fishing, gathering and trapping activities. AMNS acknowledges there will be a loss of access to the land required to support the mine development for up to eight years (one year construction; five years operations; and two years for active closure). AMNS will continue to engage in discussions with the Millbrook First Nation, and the Mi'kmaq more broadly, regarding appropriate avoidance, access, and mitigation options as required.

Specific questions were noted on potential effects of accidents and malfunctions on current use of traditional lands and associated contingency planning for an unplanned release and the potential effects of climate change on the Project. These items are discussed further in Section 6.18 and Section 7. AMNS has developed an emergency response protocol with the Mi'kmaq to ensure their interests are protected in the unlikely case of an accident or malfunction, and to ensure appropriate communication if an emergency were to occur. Specific questions have also been raised relating to potential sensory disturbance from noise and light and their potential effect on traditional practices on the land surrounding the Beaver Dam Mine Site and Haul Road. Specific questions have also been asked about potential dust deposition into the adjacent forest and risk to human health. These project interactions are described and analyzed herein.

Concerns were expressed regarding the original Haul Road routing as it was planned to pass Beaver Lake IR 17 along Hwy 224. These were primarily concerns related to noise, air quality and health and safety. AMNS has addressed these concerns by revising the Project design to include construction of 4 km of new Haul Road to avoid travel along Hwy 224 past the Beaver Lake IR 17. This change from the Project Description (October 2015) is documented in Section 2.

The results of Mi'kmaq engagement have been considered and incorporated in the environmental effects assessment and are reflected in AMNS's commitments to involve the Mi'kmaq in the development and implementation of mitigation and monitoring measures and proposed compliance and effects monitoring programs. The specific engagement record describing the engagement efforts and how comments raised have been incorporated into the EIS is provided in Section 4 and Appendix A.5.

6.14.6 Effects Assessment Methodology

6.14.6.1 Boundaries

6.14.6.1.1 Spatial Boundaries

The spatial boundaries for the assessment of effects to Mi'kmaq of Nova Scotia are defined below.

- Project Area (PA): The PA is the most basic and immediate area of the Project and consists of the area of physical disturbance associated with the Construction and Operation of the Project, including the Beaver Dam Mine Site, the Haul Road and the Touquoy Mine Site, as described in Section 2. The PA encompasses three primary components from Marinette to Moose River Gold Mines, Halifax County, NS. The Beaver Dam Mine Site will be located at the end of the Beaver Dam Mines Road and the Haul Road will span from the Beaver Dam Mine Site to the Touquoy Mine [processing and exhausted pit (to be used to dispose Beaver Dam tailings)].
- Local Assessment Area (LAA): The LAA encompasses a 5 km radius from the PA. The LAA includes the maximum extent of physical disturbance from project and interactions with expected Mi'kmaq current use of lands and resources, and physical and cultural heritage (Figure 6.14-1). The LAA is the maximum area within which Project-related effects can be predicted or measured with a reasonable degree of accuracy and confidence.
- Regional Assessment Area (RAA): The RAA for the assessment of Indigenous Peoples is defined as the territorial boundaries of the *Eskikewa'kik* (meaning 'skin dressers territory'; Figure 6.14-1). The extent to which cumulative effects on the Mi'kmaq of Nova Scotia may occur depends on physical and biological conditions and the type and location of other past, present, or reasonably foreseeable future projects or activities that have been or will be carried out, as defined within the RAA.

Effects from the Project on Mi'kmaq of Nova Scotia may potentially occur within and immediately adjacent to the Project Area, therefore, the LAA has been selected as the appropriate boundary for the evaluation of this VC.

6.14.6.1.2 Temporal Boundaries

The temporal boundary for the assessment of effects to the Mi'kmaq of Nova Scotia extends through the Project, including construction (one year), Operation (five years) and Active Closure (two years) phases.

6.14.6.1.3 Technical Boundaries

The assessment of potential Project-related effects is limited by the availability of information, which has been obtained primarily through a balance of ongoing engagement, the TLRUS (MFC 2019) and MEKS (CMM 2016) conducted for this and related projects, and Mi'kmaq groups' reviews and submissions to IAAC regarding the EIS Guidelines and EIS. AMNS stived to achieve a good balance between first-hand knowledge shared through engagement and the various Indigenous use studies completed to date, and secondary sources, although the limited amount of published information regarding historical and current use does present a technical limitation as to the comprehensiveness and verification of the information provided.

6.14.6.1.4 Administrative Boundaries

Provincially, the Nova Scotia Environmental Assessment Regulations include a requirement to identify concerns of the Mi'kmaq of Nova Scotia about potential adverse effects and steps taken or proposed to be taken by AMNS to address concerns, as well as the steps taken to identify these concerns.

Federally, subparagraph 5(1)(c) of *CEAA 2012* requires the assessment of effects of changes to the environment on Aboriginal peoples, including: health and socio-economic conditions; physical and cultural heritage, including any structure, site or thing that is of historical, archaeological, paleontological or architectural significance; and current use of lands and resources for traditional purposes.

The governments of Nova Scotia and Canada, and the Mi'kmaq follow a TOR that lays out a process for Crown consultation with the Mi'kmaq. Procedural aspects of the Crown's duty to consult are delegated to AMNS.

6.14.6.2 Thresholds for Determination of Significance

To support analysis of Project effects, and to respond to Round 2 Information Requests (IR2s) CEAA 2-02, 2-39 and 2-53, a significant adverse residual effect on the Mi'kmaq of Nova Scotia is defined as a Project-related environmental effect that results in one or more of the following outcomes:

- Long-term (greater than 20 years) or permanent loss of the availability of, or access to, land and resources currently relied on for traditional use practices; or if long-term or permanent loss is expected, no allowance for agreed-upon compensation with the affected Mi'kmaq community(s). A twenty-year temporal scale was chosen to represent a generational loss of access to an area.
- Human health risk assessments are inherently conservative, and hence, development of a threshold of significance for human health is complicated, since risk estimates tend to be biased high, based on the degree of conservatism included in any given risk assessment. The threshold for a significant residual effect has been defined as a potential adverse effect to health, identified through the conclusions presented in the HHRA.
- An unmitigated loss of a physical or cultural structure, site or thing that is of historical, archaeological, paleontological or architectural significance to the Mi'kmaq.
- Short-term (less than 20 years) loss of availability of land and resources caused by displacement due to Project activities are not considered to be significant.

The significance of potential effects on potential or established Aboriginal or treaty rights is a matter of consideration by the Crown and Mi'kmaq representatives (Assembly of Nova Scotia Chiefs and the Governments of Canada and Nova Scotia).

For the Mi'kmaq of Nova Scotia, the following was applied to assess the magnitude of a predicted change (one or more of these aspects):

- Negligible
  - no loss of a structure, site or thing that is of historical, archaeological, paleontological or architectural significance to the Mi'kmaq of Nova Scotia as a result of Project development;
  - no observable change in the availability and baseline condition of lands and resources for traditional purposes; and
  - no change in baseline socio-economic condition of the affected Mi'kmaq communities from Project activities.
- Low
  - loss of a structure, site or thing that is of historical, archaeological, paleontological or architectural significance to the Mi'kmaq of Nova Scotia as a result of Project development, but only after a comprehensive evaluation by Mi'kmaq archaeological teams determines the loss is considered appropriate and mitigation measures are employed;

  - an observable change in the availability and baseline condition of the lands and resources for traditional purposes for a short temporal window (greater than 20 years) and with commitment to appropriate and negotiated accommodation and compensation with the affected Mi'kmaq community(s);
  - elevated risk of non-carcinogenic or carcinogenic health risk that do not exceed Risk Quotients and where Incremental Lifetime Cancer Risks (ILCR) related to the Project were not predicted to exceed the benchmark cancer risk level of 1 in 100,000; and
  - a positive potential change in baseline socio-economic condition of the affected Mi'kmaq communities from Project activities.
- Moderate
  - loss of a structure, site or thing that is of historical, archaeological, paleontological or architectural significance to the Mi'kmaq of Nova Scotia as a result of Project development, with mitigation measures;
  - an observable change in the availability and baseline condition of the lands and resources for traditional purposes for a short temporal window (less than 20 years) with no consideration of appropriate and negotiated accommodation and compensation with the affected Mi'kmaq community(s); and
  - elevated risk of non-carcinogenic or carcinogenic health risk that do not exceed Risk Quotients and where Incremental Lifetime Cancer Risks (ILCR) related to the Project were not predicted to exceed the benchmark cancer risk level of 1 in 100,000.
- High
  - loss of a structure, site or thing that is of historical, archaeological, paleontological or architectural significance to the Mi'kmaq of Nova Scotia as a result of Project development, without mitigation measures;
  - an observable change in the availability and baseline condition of the lands and resources for traditional purposes for a long term temporal window (>20 years);
  - elevated risk of non-carcinogenic or carcinogenic health risk that exceed Risk Quotients and/or where Incremental Lifetime Cancer Risks (ILCR) related to the Project were predicted to exceed the benchmark cancer risk level of 1 in 100,000; and
  - a negative potential change in baseline socio-economic condition of the affected Mi'kmaq communities from Project activities.

6.14.7 Project Activities/Interactions with Mi'kmaq of Nova Scotia

The assessment of potential effects on Indigenous Peoples includes consideration of changes in health and socio-economic conditions; physical and cultural heritage, including any structure, site or thing that is historical, archaeological, paleontological or architectural significance; and current use of lands and resources for traditional purposes.

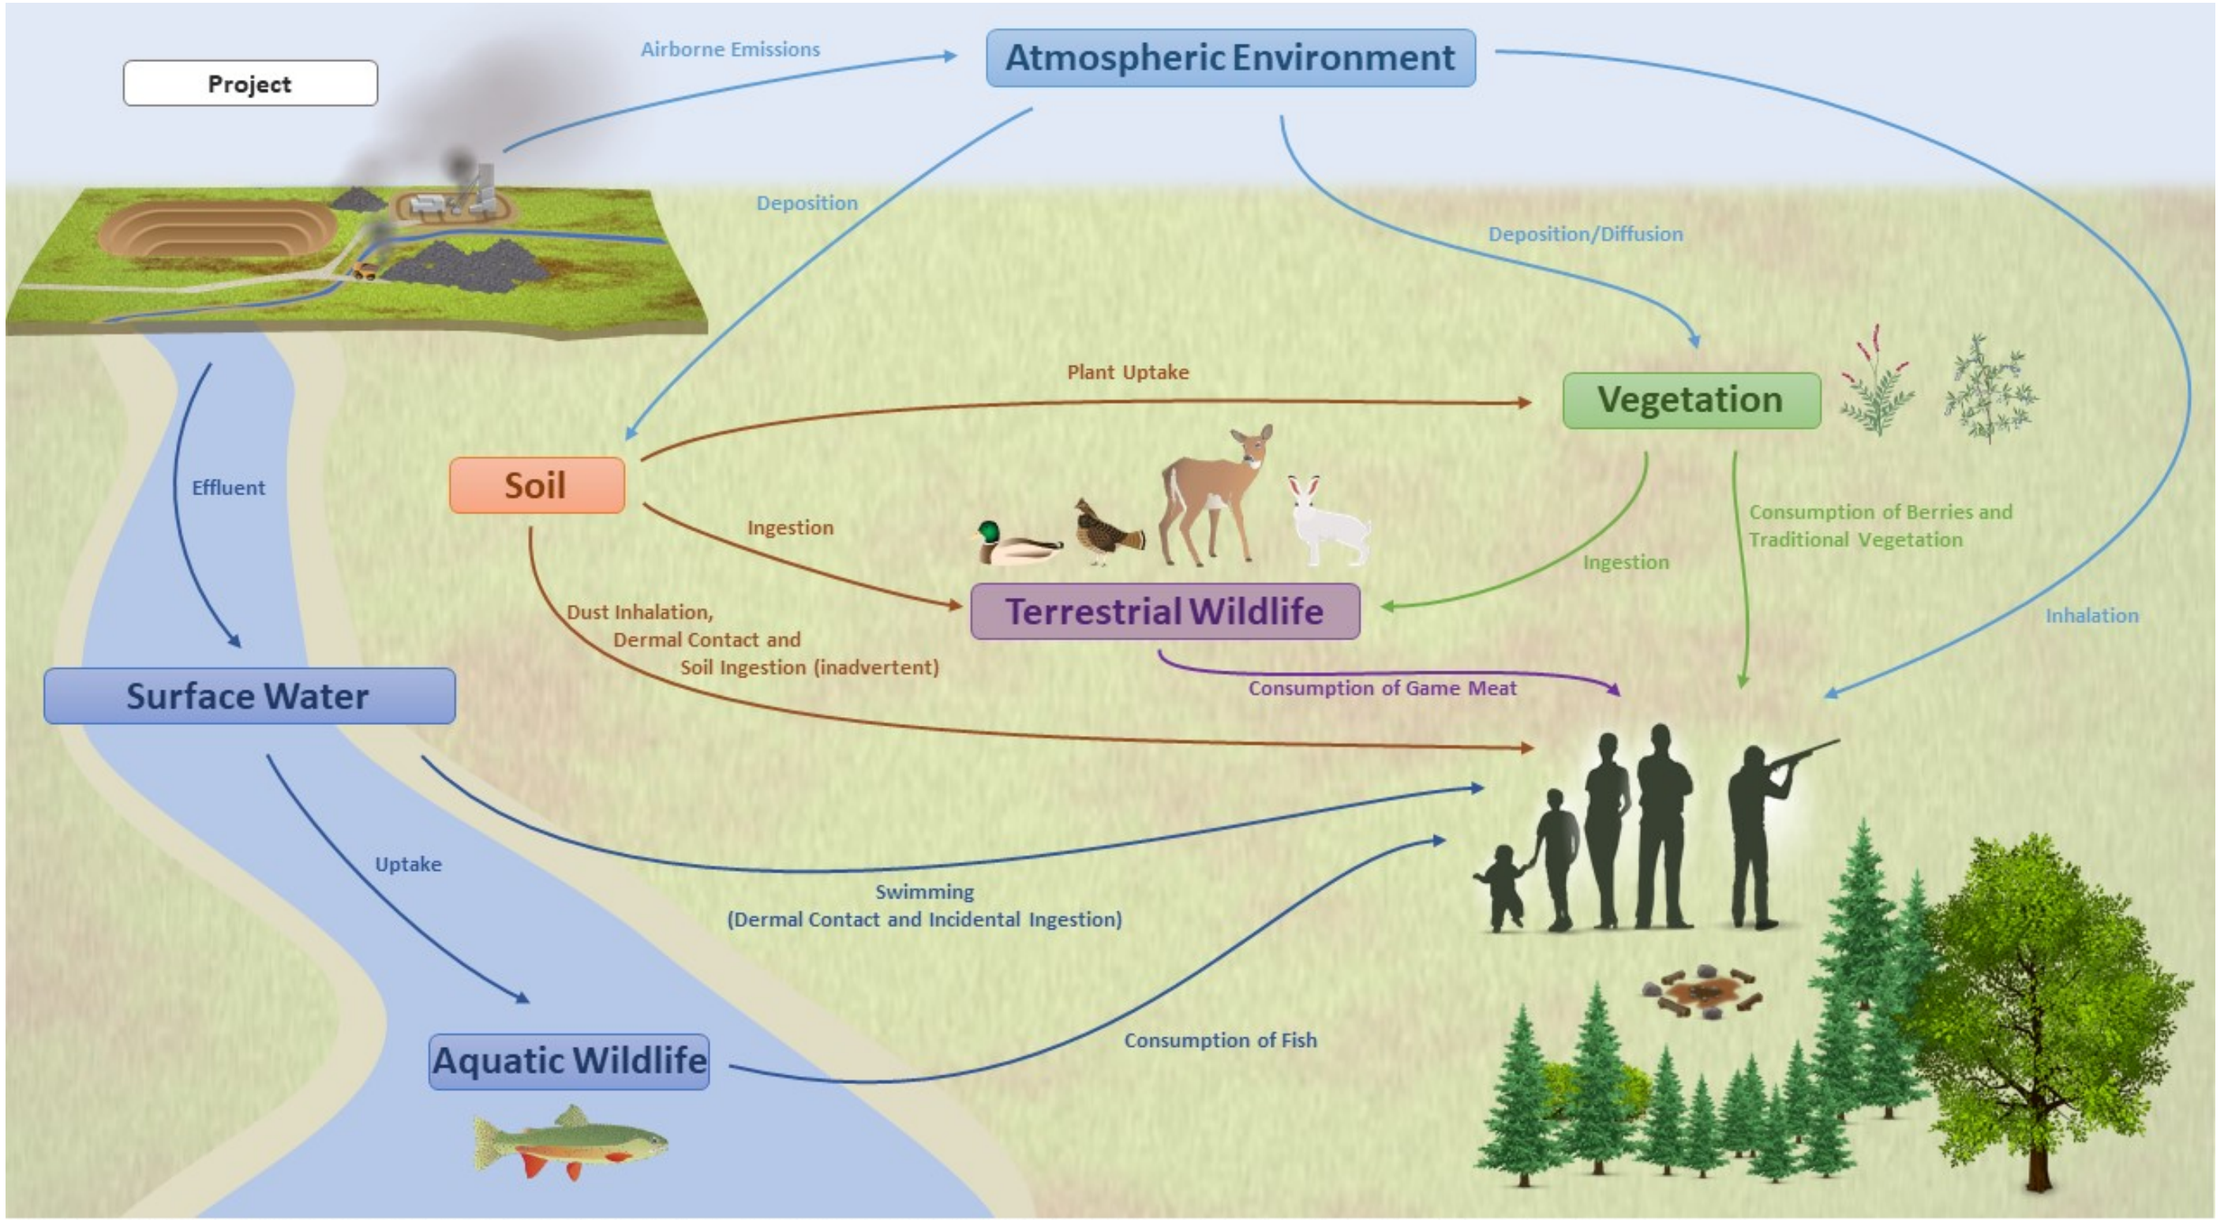
Potential interactions between Project activities and the Mi'kmaq of Nova Scotia are outlined in Table 6.14-3 and Table 6.14-4 below.

Table 6.14-3: Potential Project Activities/Interactions with Mi'kmaq of Nova Scotia at Beaver Dam Mine Site

Project Phase	Duration	Relevant Project Activity
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of construction (e.g., pre-stripping) • Till, Organic and waste rock from site preparation including transport and storage • Watercourse and wetland alteration in preparation of construction, including open pit dewatering • Surface infrastructure installation and construction • Collection ditches and settling pond construction • Local traffic bypass road construction • Mine Site road construction and lighting • Culvert and bridge upgrades and construction • General noise and lighting from construction activities • Wildlife vehicle interactions/collisions
Operations and Maintenance	5 years	• Drilling and rock blasting to access and extract ore • Management of waste rock • Management of till and organic stockpiles • Open pit dewatering • Site maintenance • Treatment of site surface water runoff and surface mine pumped water • General management of domestic wastes derived from operation and maintenance activities • Petroleum products management • Dust management • Culvert and bridge maintenance • General noise and lighting from operational activities • Wildlife vehicle interactions/collisions
Active Closure	2 years	• Site reclamation activities • Water treatment and management • Noise and lighting from active closure activities • Wildlife vehicle interactions/collisions
Post-closure	10+ years (monitoring)	• Water treatment and management

Table 6.14-4: Potential Project Activities/Interactions with Mi'kmaq of Nova Scotia along the Haul Road

Project Phase	Duration	Relevant Project Activity
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of construction • Watercourse and wetland alteration in preparation of construction • Auxiliary infrastructure installation and construction • Local traffic bypass road construction • Culvert and bridge upgrades and construction • General noise and light from construction activities • Wildlife vehicle interactions/collisions
Operations and Maintenance	5 years	• Transport of ore form Beaver Dam Mine Site to Touquoy Mine Site • Haul Road maintenance and repairs, including snow removal and deposition of sand for traction control • Petroleum products management • Dust management • Noise and light from Haul Road activity • Wildlife vehicle interactions/collisions
Active Closure	2 years	• N/A[(a)]
Post-closure	10+ years (monitoring)	• N/A



Note: [(a)] Decommissioning and Reclamation of the Haul Road is not expected. The Haul Road will be returned to owner for forestry Industry. N/A = not applicable.

The temporal scale of effects to the Millbrook First Nation and the Mi'kmaq of Nova Scotia more broadly will begin with initiation of site preparation activities, as the land and resources within the proposed site property boundaries at the Beaver Dam Mine Site and Haul Road will no longer be available for use and will continue throughout all Project phases until completion of the active closure phase. During the post-closure phase, the pit at the Beaver Dam Mine Site will be re-filling with water, and water treatment as required and monitoring is predicted to continue, but no other site activities would affect the site area usage for the Mi'kmaq, as active reclamation activities will be completed.

Many of the potential Project effects to the Mi'kmaq of Nova Scotia health and socio-economic conditions, and current use of lands and resources for traditional purposes, are via effects to VCs assessed as part of this EIS (including potential adverse effects to noise, air, light, geology/soil/sediment, surface water, groundwater, wetlands, fish and fish habitat, habitat and flora, birds, fauna, and SAR/SOCI). A summary of each of these relevant VC predicted residual effects (post mitigation) are described below in Table 6.14-5, and then are evaluated for potential interaction with the Mi'kmaq of Nova Scotia.

Where appropriate, individual VCs were included in a human health risk assessment (HHRA) completed by Intrinsik (2021), included in Appendix C.2, to evaluate potential risk to human health from the Project. This report assesses the potential for emissions from the Beaver Dam Mine Site and the Haul Road, released via Project activities, to change the chemistry of air, water and soils in the area, and whether the predicted changes have the potential to result in metals accumulation in, or on, vegetation, or other selected country foods that may be consumed by humans. In addition, this report also provides an assessment of other exposure pathways, such as recreational swimming (Cameron Flowage/Killag River), and inhalation and incidental ingestion of metals on dusts in air and soil. The focus of this assessment is on the Beaver Dam Mine Site and Haul Road, in areas outside of the proposed property boundary which could be accessed by the general public, including the Millbrook First Nation community members and the Mi'kmaq of Nova Scotia more broadly, during various activities. The Moose River was not evaluated due to demonstrated low water levels and limited opportunity for swimming in this receiving environment. Figure 6.14-3 documents the human health conceptual site visual model and Figure 6.14-4 documents exposure pathways considered in the HHRA. The complete HHRA is included in Appendix C.2 and is described in Section 6.14.7.2.

Note: COPC = Contaminants of Potential Concern.

Table 6.14-5: Project Interactions and Summaries for each Valued Components and Potential Effect to Mi'kmaq of Nova Scotia

Valued Component	Summary of Residual Effect	Potential Interaction with, and Effect to the Mi'kmaq of Nova Scotia (health and socio-economic conditions, current use, physical and cultural heritage)	Consideration in HHRA
Noise	Beaver Dam Mine Site will be in compliance with the nighttime Pit and Quarry Guidelines (55 dBa).The Haul Road will operate from 7am-11pm and will be in compliance with the evening Pit and Quarry Guidelines (60 dBa). Predicted blasting noise will meet the Nova Scotia Pit and Quarry Guidelines (NSEL 1999) criteria of 128 dBA at approximately 100+ m from the blast location.	Noise levels are predicted to meet the Pit and Quarry Guidelines (NSEL 1999) at the proposed property boundary at the Beaver Dam Mine Site and Haul Road and thus, there is limited noise exposure to the Mi'kmaq of Nova Scotia outside of the Project property boundaries. Elevated noise above background concentrations near the Beaver Dam Mine Site and Haul Road may affect wildlife patterns and as a result, affect traditional hunting practices by the Mi'kmaq of Nova Scotia within 400m (S, W, E) to 1,000m (N) of the Beaver Dam Mine Site and approximately 500m on either side of the Haul Road, based on the most conservative guideline (nighttime value of 45 dBA) identified for potential broad wildlife effects (Environmental Code of Practice for Metals Mines EC 2012c). Elevated noise is not expected to affect plant gathering or fishing activities or other recreational/commercial uses of the area directly surrounding the Project. Summary effects of noise on fauna are described below.	No
Air	Maximum predicted concentrations of parameters (i.e., TSP, PM_{10}, and $PM_{2.5}$) meet the assessment criteria for ambient air quality standards (NSAQA 2017 and CAAQS 2020) at the proposed Beaver Dam Mine Site and the Haul Road property boundaries. At the Haul Road property boundaries, these assessment criteria are met with applied mitigation of 80% chemical dust suppressants.	Elevated particulate levels above background concentrations outside of the Beaver Dam Mine Site and Haul Road property boundaries could be present on vegetation and berries and as a result, affect traditional gathering and food consumption practices and human health by the Mi'kmaq of Nova Scotia.	Yes
Light	Direct line of sight is possible up to 5 km from the Beaver Dam Mine Site property boundary where topography favors light propagation. Light intrusion into the forested habitat along the Haul Road up to 279m from the Haul Road property boundary.	Increased light levels above background levels near the Beaver Dam Mine Site could affect wildlife patterns and as a result, affect traditional hunting practices by the Mi'kmaq of Nova Scotia. While effects of light on wildlife are documented, it is still an emerging area of research. This is discussed in Fauna section below. Increased light levels are not expected to affect plant gathering or fishing activities or other recreational/commercial uses of the area directly surrounding the Project. There is no pathway for effect to human health from light.	No
Geology, Soils and Sediment	There is a potential for acid rock drainage based on 70 static tests and 5 humidity cell tests of mine rock materials Based on a number of conservative assumptions, the results indicate that there is very low potential for acidic conditions to occur during operations. During closure phase, there is potential for acidic conditions to occur (i.e., 50% of PAG is predicted to be acidic within 10 years); however, through mitigations (e.g., engineered cover and water management) these conditions can be mitigated. Monitoring will be undertaken during operations and closure to validate the geochemical source terms and impact predictions. If necessary additional mitigations will be applied.	Acidic conditions in predicted surface water quality from the Project could affect fishing practices in Cameron Flowage (Killag River) (receiving environment for mine discharge). This potential pathway for exposure is considered in the Surface Water VC. Mine rock will be tested during construction and operations as described in Metal Leaching/Acid Rock Drainage Plan (Appendix E.5). Material considered to have the potential for acid rock drainage will be stored in a designated area (i.e., PAG stockpile) located adjacent to the pit. Although water quality models indicate that there is a very low potential for acid conditions to occur during operations diversion ditches will be constructed around the PAG Stockpile so that water can be directed to the North Settling Pond for treatment, as necessary, prior to discharge. At closure, an engineered cover will be placed over the PAG to reduce infiltration of water into the pile. The area will be covered with soil and revegetated. Water from the PAG stockpile will be directed towards the pit. Monitoring will be undertaken throughout construction and operations to confirm impact predictions (i.e. geochemical characterization and water quality) and to adaptively manage PAG mitigations prior to closure. Monitoring will continue during active and post closure.	No* * Human exposure to soils outside the proposed property boundaries, which could be potentially influenced by atmospheric deposition from mining activities is described in the air VC and is included in the HHRA (dust deposition onto soils)
	Historical tailings present at Beaver Dam Mine Site will be fully delineated, tested and managed during construction. Disposal of historic tailings will be off-site at the Touquoy tailings management facility.	The applied monitoring and mitigation will limit potential impacts to Mi'kmaq human health, harvesting/gathering practices and/or recreation and other cultural pursuits. Release of sediment and contaminants associated with historical tailings could also affect downstream water quality in surface water systems (Cameron Flowage (Killag River), Mud Lake, Crusher Lake, Tent Lake watershed). An assessment was undertaken in 2019 and 2020 (Appendix E.9) to identify historical tailings within the Beaver Dam Mine Site. AMNS is committed to managing historic tailings encountered during construction and operations. Historic tailings will be stored in a designated area until it can either be shipped off-site to the Touquoy Tailings Management Facility (TMS) or in the exhausted pit. .Water originating from historic tailings will be directed to the North Settling Pond for treatment prior to release to the environment. Water treatment is designed to meet water quality objectives. and compliance as described in Surface Water VC. Human exposure to historic tailings will be limited because they are either going to be removed and managed/disposed of, to enable mining to occur, or left in their current stable condition (Appendix E.9). Furthermore, there will be no access for general public in the active mining area.	

Table 6.14-5: Project Interactions and Summaries for each Valued Components and Potential Effect to Mi'kmaq of Nova Scotia (continued)

Valued Component	Summary of Residual Effect	Potential Interaction with, and Effect to the Mi'kmaq of Nova Scotia (health and socio-economic conditions, current use, physical and cultural heritage)	Consideration in HHRA
	There is the potential for release of sediment from the road surface to be released to water bodies, especially at stream crossings.	Lessons learned from Touquoy sediment release incidents will be incorporated into the engineered designs of roads near water bodies and during road maintenance and snow clearing activities. These lessons include careful control of road height and drainage gradients near water bodies, as well as specialized sediment control measures near stream crossings that incorporate filter cloth into the road base design and application of specialized surface stabilizers on the road surface near water bodies. In addition, specialized ditching, check dams and sumps will be utilized as required. A monitoring plan for sediment in water bodies near the road will be implemented during and after construction to ensure control measures are and continue to be effective.	
Groundwater	Maximum radius of influence (groundwater drawdown) is predicted at a maximum of 1000 m (to the south) from the pit during operations, and less that this during closure, when the pit is re-filling with water. The nearest potable well is 5 km south of the Beaver Dam Mine Site (drilled well Beaver Lake IR 17). Groundwater seepage has been predicted through modelling efforts and these seepage rates have been included in operational and closure surface water modelling efforts to understand potential effect of groundwater seepage on surrounding surface water features.	At the end of mine operations, there is no significant impact to the reasonable use of groundwater at the Beaver Dam Mine Site property boundary. No impacts to groundwater quality and quantity are predicted approaching the regional assessment area, or at key receptors including Beaver Lake IR 17 or the nearest domestic well located along Hwy 224. Groundwater seepage was considered as part of the surface water quality modelling efforts. Due to the distance of Mi'kmaq communities and residences, and proposed surface water treatment, if required, during Closure Phase of the Project, predicted groundwater changes and groundwater seepage are not expected to affect the traditional practices or residences of the Mi'kmaq of Nova Scotia.	No
Surface Water	During construction, water will be directed to the North Settling Pond and treated (i.e., modular effluent treatment plant), as necessary, for elevated metals, originating from historic tailings, as well as sediments. Water will be monitored and tested prior to discharge to confirm it meets discharge criteria. The modular effluent treatment plant will remain as contingency during operations. During operations, mine contact water will be directed to the North Settling Pond where it will be tested and, if necessary, treated before release. Water from the topsoil and organic stockpiles will be directed to the East and South Settling Ponds where it will be treated for TSS before release. There is contingency to direct water from the East Settling Pond to the North Settling Pond if additional water treatment is necessary. Water quality modelling predicts elevated nitrite originating from the WRSA will require treatment in aeration ponds before release. Water quality monitoring will be undertaken a compliance points to confirm impact predictions and inform adaptive management as necessary. Water at the 100 m mixing zone in the Cameron Flowage/Killag River will be monitored to ensure meets water quality objectives. At closure, an engineered cover will be installed to encapsulate the PAG stockpile and reduce infiltration. Water from the site include the PAG stockpile will be directed to the pit to facilitate refilling. Water quality modeling predicts elevated levels of zinc and cobalt for the upper case only (i.e., most conservative case) for two months. Water will be treated at closure, as necessary, to ensure it meets discharge criteria. Geochemical characterization of waste rock and water quality monitoring will be undertaken throughout construction and operations to confirm impact predictions and inform adaptive management.	Due to the distance of Mi'kmaq communities and residences, and proposed surface water treatment, as/if required, during operations and during Closure Phase of the Project, surface water quality and quantity predictions are not expected to affect the traditional practices or residences of the Mi'kmaq of Nova Scotia outside of the Beaver Dam Mine Site property boundary during operations and closure phases of the Project. No known locations where Mi'kmaq residents draw directly from lakes or rivers for potable purposes (permanent or seasonal/temporary) have been identified, through direct engagement with Mi'kmaq communities or through the TLRUS and MEKS, in close proximity to the Beaver Dam Mine Site. In the absence of such locations being identified to AMNS, no evaluation of surface potable water sources was considered in the HHRA. However, evaluation of the predicted concentrations at the North Settling Pond and East Pond discharge (Cameron Flowage) have been compared to Canadian Drinking Water Guidelines within the HHRA. These locations are considered the worst-case scenario and these predictions demonstrate there is no concern associated with occasional consumption of surface water surrounding the Beaver Dam Mine Site. The potential for adverse health effects from recreational water use (i.e. swimming) in Cameron Flowage/Killag River have been considered in the HHRA. Swimming in the Moose River has been excluded from HHRA consideration due to low water levels in this river.	Yes
Wetlands	Of the 236 wetlands identified within the FMS Study Area, 128 (54%) will be avoided by Project design. A total of 108 wetlands are proposed for alteration, 74 of which will require only partial alteration. Indirect wetland impacts are expected from changes to local catchment areas and groundwater drawdown (open pit dewatering). Wetland compensation will be required to off-set the loss of wetland habitat from the Project. A preliminary Wetland Compensation Plan is attached as Appendix H.3.	Loss of wetland habitat is limited to the area directly surrounding the pit and associated infrastructure development for the proposed mine. Management of historical tailings will improve wetland quality in the local area and improve water quality, and overall watershed health. Wetland restoration opportunities will be identified in consultation with the Mi'kmaq of Nova Scotia with the goal to identify projects that would benefit the Mi'kmaq and local watersheds where wetland restoration would benefit traditional Mi'kmaq practices.	No
Fish and Fish Habitat	Spawning habitat for species known or expected is limited in the Beaver Dam Mine Site and Haul Road. Development of the Beaver Dam pit and associated mine infrastructure will require the alteration of Wetland 59 (open water marsh habitat with fish and fish habitat) and several smaller tributaries. Indirect impacts to fish and fish habitat have also been described. A draft Fish Habitat Offset Plan (Appendix J.3) has been developed to compensate for loss of fish habitat required for Project development. Site infrastructure has been micro-sited for fish habitat avoidance wherever practicable. A Fisheries Authorization will be required for the Project, and a Preliminary Fish Habitat Offset Plan for fish habitat offsetting is included in the EIS	The development of the pit will manage the containment/disposal of historical tailings. Areas where Mi'kmaq fishing activities are known or expected to take place surrounding the Beaver Dam Mine Site and Haul Road will not be affected by Project development. Access will be maintained to fishing locations throughout the LAA through a constructed bypass access road for Mi'kmaq and local people who want continued access to fish in the LAA. Evaluation of the potential exposure pathway of uptake of metals from surface water into fish and subsequent consumption by humans was considered in the HHRA.	Yes

Table 6.14-5: Project Interactions and Summaries for each Valued Components and Potential Effect to Mi'kmaq of Nova Scotia (continued)

Valued Component	Summary of Residual Effect	Potential Interaction with, and Effect to the Mi'kmaq of Nova Scotia (health and socio-economic conditions, current use, physical and cultural heritage)	Consideration in HHRA
Flora and Habitat	Ecosites are predominantly poor to medium nutrient regimes with acidic soils and dominated by mixedwood and conifer forest stands. Historical mining and impacts from timber harvesting have historically affected the habitat and flora communities with the Beaver Dam Mine Site and Haul Road. A total of 295 species of vascular plants were observed. Of these, six a SOCI. No SAR vascular plant species were observed. Twenty-three species of lichens were observed within the FMS Study Area. One of these, eight are SOCI and three are SAR.	A total of 14 occurrences of lichen and/or vascular plant SAR and SOCI will are expected to be directly impacted by the Project. The loss of these individual plants and lichens is not expected to have a significant impact on the Mi'kmaq of Nova Scotia and their traditional practices. New habitat loss to support Project development is minimized by active historical timber harvesting activities in this area and historical mining activities. Reclamation will involve revegetation of the disturbed areas with an approved mix of native seeds and potentially shrubs/seedlings. This Reclamation Plan will be developed in consultation with Mi'kmaq of Nova Scotia.	No
Fauna	A common assemblage of fauna was observed within the Beaver Dam Mine Site and Haul Road. The Beaver Dam Mine Site and Haul Road were evaluated for bat hibernacula potential through both desktop and field evaluations. No evidence of bat usage or suitable hibernacula habitat were observed. Three set of mainland moose (ACCDC S1; NSESA E) tracks were observed incidentally and during targeted moose surveys within, or in proximity to, the Beaver Dam Mine Site. Snapping turtle (SAR) uses portions of the Beaver Dam Mine Site, with documented turtle sightings adjacent to Wetland 59 and along roadsides near the Touquoy Mine Site, including the Haul Road. The Project will result in a loss of habitat for Fauna, increased habitat fragmentation, and potential sensory disturbance (noise and light) to wildlife in close proximity to the Beaver Dam Mine Site and Haul Road property boundaries.	Project activities are likely to result in localized avoidance of the Beaver Dam Mine Site and Haul Road and directly surrounding areas by some species. This potential avoidance would be due to changes in ambient noise levels and light levels in close proximity to the property boundaries, direct habitat loss, potential indirect habitat loss, and increased fragmentation. This potential change in wildlife patterns may affect the traditional practices of the Mi'kmaq of Nova Scotia in close proximity to the Beaver Dam Mine Site and Haul Road. This disturbance is limited spatially, and temporary in nature, with construction, operation and active reclamation of the Project resulting in up to eight years of potential local disruption to wildlife patterns. Evaluation of the potential exposure pathway of uptake of metals from soil or vegetation, uptake of metals in game species, and subsequent consumption by humans was considered in the HHRA.	Yes
Avifauna	Abundance and diversity of avian species observed was moderate to high based on observer experience in the geographic area. A common species assemblage of forest birds was observed, along with many priority species. Nine SAR and 23 SOCI avifauna species were observed in the Beaver Dam Mine Site and Haul Road. The Project will result in a loss of habitat for Fauna, increased habitat fragmentation, and potential sensory disturbance (noise and light) to avifauna in close proximity to the Beaver Dam Mine Site and Haul Road property boundaries.	Project activities are likely to result in localized avoidance of the Beaver Dam Mine Site and Haul Road and directly surrounding areas by some bird species. This potential avoidance would be due to changes in ambient noise levels, light levels, direct and indirect habitat loss and increased fragmentation. This potential change in bird usage patterns may affect the traditional practices of the Mi'kmaq of Nova Scotia in close proximity to the Beaver Dam Mine Site and Haul Road. This disturbance is temporary in nature, with construction, operation and active reclamation of the Mine resulting in up to eight years of potential local disruption to bird usage patterns.	No
Species at Risk	Mainland moose (ACCDC S1; NSESA E) tracks were observed surveys within, or in proximity to, the Beaver Dam Mine Site. Snapping turtle (SAR) was observed within the Beaver Dam Mine Site, the Touquoy Mine Site, and the Haul Road. Six SOCI vascular plant species were observed. Three SAR and eight SOCI lichen species were observed. Eight SAR and 17 SOCI avifauna species were observe. Three SOCI fish species were observed. Direct habitat loss is expected as a result of the Project. SOCI vascular plant loss includes one occurrence of southern twayblade. SOCI and SAR lichen loss includes blue felt lichen, salted shell lichen, eastern candlewax lichen, and slender monk's hood lichen.	Mobile species (birds, fish, moose) are expected to occupy adjacent suitable habitat for the eight years that the Project is being developed, operated and completion of active reclamation. The Beaver Dam Mine Site and Haul Road is located in a rural area, with limited development pressures in close proximity to the Beaver Dam Mine Site and Haul Road. This potential change in wildlife patterns, including SAR, may affect the traditional practices of the Mi'kmaq of Nova Scotia in close proximity to the Beaver Dam Mine Site and Haul Road.	No
Physical and Cultural Heritage	Thirteen sites/areas with elevated archaeological potential were identified with the Beaver Dam Mine Site. Most sites are associated with historical mining activities and Euro-Canadian archaeological resources. Three sites (Areas 1, 2 and 3) were identified as having elevated potential for historic Mi'kmaw archeological resources based on their proximity to a water source and terrain suitable for settlement/encampment. Three sites will be impacted by the Project.: Site 6 is located in an area identified as "Forge Hill". The features are identified as having moderate to high potential for historic Euro-Canadian archaeological resources related to historical mining activities. Areas 2 and 3 are located along the western shore of Cameron Flowage. Area 2 will be impacted by a topsoil stockpile north of the pit, and Area 3 will be impacted by the pit and an adjacent access road. Additional shovel tests were completed within Site 6, Area 2 and Area 3 in fall 2020. No Pre-contact Mi'kmaq archaeological resources were encountered.	Identified archaeological sites that will be affected by the Project are not Mi'kmaq resources. Identified areas of Mi'kmaq elevated potential within the Beaver Dam Mine Site for archaeological resources will be avoided. Identified and known Mi'kmaq archaeological features are outside of the proposed development footprint of the Project and thus will not be affected by Project development. No Pre-contact Mi'kmaq archaeological resources were encountered during the fall 2020 shovel tests of Areas 2 and 3 and Site 6.CRM Group recommends these areas be cleared of requirements for further investigation. In the event that archaeological deposits or human remains are encountered during construction/operation activities associated with the Beaver Dam Mine Project, all work in the associated area(s) should be halted and immediate contact made with the Nova Scotia Special Places Program, and with the KMKNO Archaeological Division.	No

Stemming from the technical conclusions presented in Table 6.14-5, a discussion of potential Project interactions with Millbrook First Nation traditional use of the land, and Project Interactions with Health and Socioeconomic Conditions is provided in the following sections, followed by proposed mitigation measures to minimize impact to the Millbrook First Nation and the Mi'kmaq of Nova Scotia more broadly. Throughout these subsections, feedback received from Millbrook and other Mi'kmaq communities relating to Project interactions, mitigation and accommodation conclusions are presented, where feedback has been provided.

AMNS is committed to on-going engagement with Millbrook First Nation, and the other Mi'kmaq of Nova Scotia communities throughout the environmental assessment, and the entire life cycle of the Project. Ongoing feedback and input from the community will allow for adaptive management of, in proposed mitigation measures, and monitoring plans. AMNS is committed to pursuing a process of meaningful engagement to ensure that:

- Engagement activities are inclusive, flexible and respect Indigenous decision-making and processes that are in place;
- Indigenous knowledge is included and considered in the EIS and further Project development; and
- Avoidance, mitigation, and other measures are developed with impacted Indigenous communities.

6.14.7.1 Project Interactions with Mi'kmaq Traditional Use/Rights

This section provides a discussion of Project interactions with Mi'kmaq traditional use and rights as described in Section 6.14.2 and 6.14.4, and provides Round 2 Information Requests (IR2s) responses to CEAA 2-49 and CEAA 2-54 (AMNS 2021a).

There will be a reduction in area available for hunting, trapping, gathering, fishing, spiritual ceremonies and other Millbrook and broader Mi'kmaq traditional activities within the Beaver Dam Mine Site and Haul Road. The infrastructure footprint (mine site and haul road) will result in direct habitat loss and the Project will restrict access within a proposed property boundary/compliance boundary for a period of eight years. This infrastructure footprint and property boundary are shown on Figure 6.14-5.

Plant species of significance to Millbrook First Nation, and the Mi'kmaq more broadly, were identified within the Beaver Dam Mine Site and Haul Road portions of the PA, and the surrounding LAA (Figure 6.14-1). Habitat adjacent to and surrounding the Project has the potential to support plant species of significance based on information presented in MEKS and TLRUS as well as engagement undertaken to date with the First Nations. These adjacent plant communities, not impacted by historic tailings, are expected to remain accessible to Millbrook community members. Access to these areas will remain with the construction of, proposed bypass road, which will be adjacent and parallel to the Haul Road and around the Beaver Dam Mine Site. AMNS does acknowledge that there will be loss of habitat resulting from the construction and operations of the mine and therefore altering the habitat and area available to the Millbrook First Nation and the broader Mi'kmaq community for their use. However, the loss of habitat that supports traditional plants does not pose a significant threat to Mi'kmaq use of the species, given their abundance and availability within close proximity, and the rural nature of the landscape surrounding the Beaver Dam Mine Site and Haul Road.

Additionally, due to the proximity of the Beaver Dam Mine Site and Haul Road to traditional harvesting areas as demonstrated in Section 6.14.3 and 6.14.4 through the TLRUS (MFC 2019) and MEKS, there will potentially be an area outside of the Beaver Dam Mine Site and Haul Road where Millbrook community members and other Mi'kmaq hunters may observe a changed pattern of wildlife movement. This area has been identified as a potential wildlife environmental effects zone. Within close proximity to the proposed property boundaries of the Beaver Dam Mine Site and Haul Road, there is the potential for sensory disturbance to wildlife and birds from noise and light above background conditions resulting in potential changes to wildlife patterns and by extension, hunting practices for the Mi'kmaq of Nova Scotia. There are limited Project effects expected to hunting, gathering and trapping activities beyond the potential Wildlife Environmental Effects Zone. This potential wildlife environmental effects zone is shown on Figure 6.14-5.

The Mi'kmaq may experience hunting limitations near the Beaver Dam Mine Site and Haul Road for the use of firearms. Participants in the TLRUS described how they might be displaced along the Haul Road and in proximity to the Beaver Dam Mine Site where they "may feel uncomfortable using their firearms for safety reasons" (MFC 2019, p. 54). This limited firearms zone is shown on Figure 6.14-5 and demonstrates the maximum potential "loss of harvesting area for those individuals who do not feel comfortable shooting towards an active mine or haul road" (MFC 2019).

These direct and indirect impact areas are described in Table 6.14-6.

Table 6.14-6: Beaver Dam Mine Project Direct and Indirect Impact Areas for Mi'kmaq Traditional Use

Direct or Indirect Impact Areas	Area (Hectares (ha))*
Direct Infrastructure Footprint – associated habitat loss	243 (34 ha of which is Crown land)
Direct Access Loss – compliance boundary	727 (123 ha of which is Crown land)
Indirect Wildlife Environmental Effects Zone	3261 (1108 ha of which is Crown land)
Indirect Limited Firearms Zone	4358 (1411 ha of which is Crown land)

*Area calculations were completed using available property boundaries from Government of Nova Scotia Geomatics Centre (not survey plans).

Details relating to Millbrook First Nation and Mi'kmaq of Nova Scotia traditional and current fish harvesting locations are described within the TLRUS and MEKS. In summary, fishing practice has been documented across the LAA and adjacent to the proposed Beaver Dam Mine Site and Haul Road. No fishing lakes or rivers are documented within the proposed 4km of new construction for the Haul Road, however, fishing has been documented within the Beaver Dam Mine Site (trout fishing) within the Killag River and possibly also within Mud and Crusher Lakes. These fishing locations have, in part, informed proposed mitigation measures, as described in Section 6.14.8 and detailed in CEAA 2-48 and proposed suitable alternative areas for traditional practices, as described in CEAA 2-49. Access to the lakes and rivers surrounding the Beaver Dam Mine Site and Haul Road will be maintained (Section 6.14.8 (mitigation)), however, direct access to Crusher and Mud Lakes will be limited during the temporal scale of the Project (i.e., eight years).

Fishing practices for Millbrook First Nation community members and other Mi'kmaq of Nova Scotia within lakes and rivers surrounding the Project will be maintained during Project construction and operations. All site water will be collected, managed and discharged to the receiving environment (Cameron Flowage/Killag River) in accordance with all regulatory requirements and in a manner which ensures protection of aquatic life. Monitoring programs will be designed and implemented to confirm these conclusions for the temporal life of the Project. Details relating to Project effects on fish can be found in Section 6.9.

Engagement with Millbrook First Nation on January 31, 2019 provided information that there is a potential for a housing development (69 lots) on the existing lands of the Beaver Lake IR 17. A review of the modelling results and a qualitative impact analysis on this potential development was completed. As the geography of the potential development is contained within the

existing Beaver Lake IR, the modelling efforts and impact assessment conclusions are valid and consistent for the entire lands of the Beaver Lake IR. A review of the key VCs for the residents and lands at Beaver Lake IR such as light, air quality, noise, surface water, groundwater, socio-economic and cultural resources was completed. All the predicted levels of impact for those VCs remain valid for the potential development. AMNS commits to maintaining an ongoing relationship with Millbrook First Nation and will continue engage on this potential development and the Beaver Dam Mine Project throughout all stages of permitting, construction, operation and closure.

Identified archaeological sites that will be affected by the Project are not Mi'kmaq resources. Identified areas of Mi'kmaq elevated potential within the Beaver Dam Mine Site and Haul Road for archaeological resources will be avoided. Identified or potential Mi'kmaq archaeological features (potential burial site west of Beaver Dam Mines Road) are outside of the proposed Beaver Dam Mine Site property boundaries and thus will not be affected by Project development. Discussions and review of the Project by the KMKNO archaeological division have occurred (Section 4 and Appendix A.5 for details on engagement and dialogue efforts with the KMKNO teams). To date, no additional archaeological sites have been identified within the Beaver Dam Mine Site.

Nortek Resource Solutions Inc. (Nortek) has completed a viewshed analysis of the Project to support a visual representative of where the Project will be visible from surrounding vantage points (Appendix M.2). This was completed to respond, in part, to CEAA Round 2 information request (IR2) CEAA 2-01.

The Zone of Visual Influence (ZVI) provides a spatial overview of where the proposed Project stockpiles will be visible across a 20 km radius. The Beaver Dam Mine Site is predominantly forested and therefore the existing forest stand data was included in the analysis. The analysis consisted of preparing a Digital Surface Model (DSM) which included the proposed stockpiles. Once the model was prepared, a visibility analysis was completed to determine all areas on the DSM in which the stockpiles are visible. This analysis focused on stockpile locations as they are the highest infrastructure proposed at the Beaver Dam Mine Site.

The ZVI was generated for the region within a 20 km radius of the Beaver Dam Mine Site. The Nova Scotia Provincial Digital Terrain Model (DTM) at 20 m resolution was used as a base layer for the analysis. The proposed stockpiles were rasterized and added to the base DTM so that they were included in the model. A visibility analysis was run using the upper rims of the stockpiles as targets and receptor heights of 1.7 m. The resulting raster was clipped with forest stand polygons that have an average height of 2 m or less which excluded areas were the forest is higher than eye height. The final results show where the proposed stockpiles will be visible assuming summer, leaf on forest conditions.

The Visual Zone of Influence (ZVI) (Appendix M.2) identifies where stockpiles (highest elevation features on the Beaver Dam Mine Site) are visible from the surrounding landscape. The NAG pile, which will be present during operations and closure, is 185m asl. The LGO and till stockpiles are 180m asl, which will both only be present only during operations. These are the highest infrastructure features associated with the Project. On the ZVI, these areas where stockpile(s) are predicted to be visible are shown in green. This ZVI was prepared to provide a general overview of where the Project will be visible from, and also to demonstrate a visual representation of what the visual influence will look like from specific locations. As shown in Appendix M.2 the Project stockpile(s) will be visible from the east and west of the Beaver Dam Mine Site including from West Lake, from the north of the Beaver Dam Mine Site in Como Lake, directly south of the Beaver Dam Mine Site, and also to the west of Beaver Lake IR along the north and south side of Highway 224. Commercial and recreational activities (boating, fishing, swimming) along Cameron Flowage will observe an adjusted viewplane with visible stockpile(s). The ZVI also demonstrates as a user moves farther away from the Beaver Dam Mine Site, the mine infrastructure will be visible from higher elevation points on the landscape, including several high points northwest of the Beaver Dam Mine Site and south of the mine including near Lake Alma. The user will not observe the infrastructure from the majority of lakes surrounding the Beaver Dam Mine Site, with the exception of those described above.

To support Project development, there will be a local bypass road constructed to allow for continued access around the Beaver Dam Mine Site and the lands to the north of the Beaver Dam Mine Site. Based on a review of the ZVI, the Project stockpiles will be visible from the bypass road directly south of the mine site and around the organic stockpile.

Through a review of the ZVI results, several photos were then taken from various vantage points to attempt to demonstrate specific locations where visual influence of the Project would be greatest. Visual Simulations 1 to 4 in Appendix M.2 show these four vantage points and what will be visual during operations and closure phases of the Project.

Visual Simulation 1 illustrates the view from the north side of the Beaver Dam Mine Site just north of Cameron Flowage, looking southwest towards the Project. The NAG stockpile will be visible during operations and closure phases, as shown on Figure 6.14-5. Visual Simulation 2 illustrates a similar view from the north side of the Beaver Dam Mine Site but looking farther southwest/west. The full extent of the NAG stockpile will be visible during operations and closure phases from this location, as shown on Visual Simulation 2. Visual Simulation 3 illustrates the view from west of the Beaver Lake IR on Highway 224 where the ZVI also predicted a visual change from the Project. The PAG, NAG and LGO stockpiles will be visible from this vantage point during the operation phase, as shown on Visual Simulation 3. During reclamation, only the PAG and NAG piles will remain. Finally, Visual Simulation 4 illustrates the view from a forestry road near Cope Brook, south of the NAG pile. From this location, the NAG stockpile will be visible during both the operations and closure phases. These four vantage points were selected to be representative of expected maximum change in viewscape and the locations where anticipated human activities is likely to occur (e.g., near access trails, lakes and other access points).

Once the construction, operation, and active closure phases are complete (i.e., eight years), access will be re-established within the Beaver Dam Mine Site for Millbrook First Nation and the broader Mi'kmaq of Nova Scotia community members. At this time, the site infrastructure will be dismantled and removed, the waste rock piles will be covered and revegetated, and drainage will be re-established. Drainage immediately adjacent to the pit will be directed to towards the exhausted pit to facilitate pit filling, which is expected to take approximately 13 years. With the exception of the pit area, where filling will be on-going and water monitoring will be occurring, traditional practices within the Beaver Dam Mine Site can resume. The landscape will be altered, with more limited forested cover for an extended period of time. This will likely affect the specific nature of traditional practices that will resume within the Beaver Dam Mine Site until the forest re-establishes. The majority of identified historical tailings and waste rock will have been managed and/or removed from the site thereby potentially improving the quality of the habitat. This is considered a positive impact of this Project on future traditional practices with the Beaver Dam Mine Site.

AMNS commits to ongoing engagement to assess any additional sites that have not been previously identified. The predicted impacts of the Project to the Mi'kmaq traditional use of the land are summarized below. These impacts are predicted to be low magnitude, as defined in Section 6.14.6.2 and in consideration of mitigation and accommodation. A low magnitude change is defined (in part) by an observable change in the availability and baseline condition of the lands and resources for traditional purposes for a short temporal window (<20 years) and with commitment to appropriate and negotiated accommodation and compensation with the affected Mi'kmaq community(s). AMNS is committed to appropriate and negotiated accommodation and compensation, as described in Section 6.14.8.

- It is the conclusion of AMNS that the permanent loss of habitat/plant species does not pose a significant threat to Mi'kmaq use of the species as a whole, given their abundance and availability within close proximity, and the rural location of the Beaver Dam Mine Site and Haul Road.
- The Beaver Dam Mine Site and Haul Road will be restricted for access. The Beaver Dam Mine Site area includes 123 ha of Crown land, with limited open water/lakes/recreational swimming or known fishing areas. Crusher Lake and Mud Lake are present within the Beaver Dam Mine Site, located on private land, and these two lakes, which may be used for fishing purposes (trout), will have limited access for the temporal scale of the Project (i.e., eight years).

- Access to the landscape surrounding the Beaver Dam Mine Site and Haul Road will be maintained. A local multi-use bypass road will be constructed parallel to the Haul Road and around the Beaver Dam Mine Site to allow for continued access to the lands to the north of the mine. This mitigation measure is described in detail in Section 6.14.8.
- Change in noise and light levels will meet compliance with guidelines at the Beaver Dam Mine Site and Haul Road property boundary. Elevated noise and light levels above background conditions are expected, but only in close proximity to the Beaver Dam Mine Site and Haul Road.
- Within close proximity to the proposed property boundaries of the Beaver Dam Mine Site and Haul Road, there is the potential for sensory disturbance to wildlife and birds from noise and light above background conditions resulting in potential changes to wildlife patterns and by extension, hunting practices. This area is documented as the Indirect Wildlife Environmental Effects Zone and includes approximately 1,108 ha of Crown land.
- Within close proximity to the proposed property boundaries of the Beaver Dam Mine Site and Haul Road, there is the potential for Mi'kmaq hunters to experience hunting restrictions. This area is documented as the Indirect Limited Firearms Zone and includes approximately 1,411 ha of Crown land.
- Access limitations within the Project property boundaries are for a temporal scale of eight years (construction, operations and the active closure).
- The assessment concludes that traditional practices within the Beaver Dam Mine Site can resume during the post-closure phase. The landscape will be altered, with more limited forested cover for an extended period of time until forest re-establishes. This will likely affect the specific nature of traditional practices that will resume within the Beaver Dam Mine Site.
- There will be a change in surrounding viewscape of the Project. Project stockpiles will be visible from several local vantage points around the Beaver Dam Mine Site including Como Lake and Cameron Flowage.
- No known physical and cultural sites of Mi'kmaq importance will be affected by Project development. A chance find protocols for archaeological resources will be implemented as part of the Project Environmental Protection Plan (EPP). Personnel will receive the appropriate level of EPP training to properly implement the chance find protocol.

These conclusions relating to Project impacts and the magnitude of these impacts have been shared with Millbrook First Nation through face to face meetings and discussions that included the preparation and delivery of a Summary of Effects document and a Plain Language Summary (Appendix A.1) on September 1, 2020. AMNS reviewed these conclusions in the draft Summary of Effects document in a face to face meeting with the Millbrook community engagement officer in late fall 2020. The Plain Language Summary was also shared with the KMKNO on November 2, 2020 and Sipekne'katik First Nation on May 7, 2021.

Subsequently, AMNS prepared IR2 responses for CEAA 2-48 and CEAA 2-49 for Millbrook First Nation which was shared with the community engagement officer on February 16, 2021 to support planned internal meetings with Millbrook community members. This IR response includes figures that show the proposed bypass roads/mitigation measures to allow continued access to the lands surrounding the Beaver Dam Mine Site and Haul Road, as well as the Project property boundaries (direct loss of access) and indirect potential zones of interactions (Wildlife Environmental Effects Zone and the Limited Firearms Zone). AMNS reviewed these figures with the Millbrook First Nation community engagement officer in a virtual meeting on February 3, 2021, in advance of sharing them on February 16, 2021, to request initial feedback from the Millbrook community engagement officer.

On April 1, 2021, this Mi'kmaq of Nova Scotia draft section of the EIS was shared with the Millbrook First Nation for review and feedback. The purpose of this review was twofold:

- A request to validate and provide feedback of impact conclusions and proposed mitigation; and

- To provide feedback on the level of specificity regarding the referencing of data in the TLRUS and to ensure the presentation is acceptable in consideration that the TLRUS is considered restricted and confidential.

The purpose of planned community meetings, as described by the Millbrook community engagement officer, is to receive feedback from specific families who have expressed an interest in the Project, relating to Project summary of impacts and proposed mitigation measures. This feedback is intended to supplement general feedback received from Millbrook First Nation through regular and on-going engagement efforts to date, as described in Section 4 and Appendix A.5.

At the time of submission of this updated EIS, no specific feedback has been received from the Millbrook First Nation. AMNS understands that community meetings have taken place and that a report summarizing these meetings is drafted. Regular and consistent communications to receive this feedback has been ongoing with Millbrook First Nation through April and May 2021. Although the feedback has not been received, AMNS will continue to reach out and find opportunities to address feedback in the Projects development plans.

It is anticipated that engagement will continue throughout and beyond the current environmental assessment process. This will require ongoing dialogue regarding potential impacts on Mi'kmaq communities, and AMNS is committed to continuing those discussions. AMNS looks forward to receiving feedback and commits to discussing with Millbrook First Nation how best to address their feed back into Project design, mitigation and monitoring measures and potentially additional monitoring and mitigation measures. Subject to any confidentiality concerns expressed by the Millbrook First Nation, AMNS will provide this information to the appropriate regulators.

6.14.7.2 Project Interactions and Mi'kmaq Health and Socio-economic Condition

Potential health impacts on Mi'kmaq communities are linked to the interconnected nature of the ability to access traditional territory to continue cultural practices, such as hunting, gathering and fishing – not only for their consumptive human health value, but also for mental and human health associated with cultural survival and continuity. While issues impacting Indigenous health are complex, the Mi'kmaq of Nova Scotia would view a loss of access to territory and the ability to exercise Aboriginal and Treaty rights in that area to extend to potential impacts to human health outcomes, based on the review of conclusions relating to gathering of berries and vegetation for human consumption, and hunting for sustenance purposes in the TLRUS (MFC 2019).

The Health Canada document "Useful Information for Environment Assessments" (HC 2015) was reviewed to determine the appropriate baseline information that should be included relevant to human health of First Nations. Table 6.14-7 presents the relevant information related to effects on human health of the Mi'kmaq of Nova Scotia based on the review of the Health Canada document.

As with the analysis of Project impacts to traditional use, some specificity relating to Mi'kmaq land use and baseline health and socio-economic condition is not fully understood, and as a result, some analyses relating to health and socio-economic conditions have been completed utilizing a series of assumptions. Assumptions relating to the Human Health Risk Assessment (HHRA), described in Section 6.14.7.2.1, are provided in the technical report in Appendix C.2. The assumptions in the HHRA have been reviewed against the information provided in the TLRUS (MFC 2019). The specificity of consumption rates required to utilize as inputs into the HHRA were not presented in the TLRUS (MFC 2019). As a result, the HHRA has been completed with assumed consumption rates Chan et al. (2017) and as described in Section 6.14.7.2.1.

AMNS has attempted to collect information through multiple methods, as described in Section 4 and Appendix A.5. Information has been received through direct engagement, the MEKS and most informatively, through the TLRUS, which supports and complements the analysis of Project impacts relating to health and socio-economic conditions. The TLRUS (MFC 2019) describes, with some specificity, the harvesting patterns of the Millbrook First Nation and specificity of country food consumption. AMNS understands that harvesting/hunting practices are regular (weekly and span across all four seasons). The TLRUS (MFC 2019) also documents that many Millbrook members, particularly local members of the Beaver Lake and Sheet Harbour IRS, are sustenance

harvesters, with hunting, fishing, and trapping practices as important contributions to their household income (MFC 2019). Harvesting includes big game, fish and shellfish and medicinal and ceremonial plant and tree species.

The TLRUS (MFC 2019) states that local residents of the Beaver Dam, Sheet Harbour and Millbrook IR's frequently use the area (i.e., range of use from weekly to yearly, and depending on availability of species) for hunting (i.e., deer, bear, rabbit, grouse, and porcupine) and rely on the wild harvest as an important food and dietary source. Equally, community members harvest berries when in season, and a number of plants that are also used for sustenance, as well as traditional medicines. The seasonal and recreational use of animals and plants important to the Millbrook community members supports the continuity of traditional practices and is important to the maintenance of their culture and the practice of their rights. Millbrook harvesting activities and practices are culturally important as they ensure the sharing and maintenance of cultural values and their practice. Millbrook First Nation community members use plants and animals harvested in the area for traditional sustenance purposes, health-related medicinal purposes, and spiritual and cultural purposes.

Table 6.14-7: Baseline Information Relevant to Human Health of the Mi'kmaq of Nova Scotia

Elements to Consider	Anticipated Effect
Location of First Nations in relation to the Project	The nearest First Nation (Mi'kmaq) reserves are the Beaver Lake IR 17, located approximately 5 km from the Project, and the Sheet Harbour IR, located approximately 25 km from the Project. The EIS has concluded that there are likely occasional use and modern day camps used by the Mi'kmaq in closer proximity to the proposed Project, based on conclusions relating to traditional practices in close proximity to the Project (MFC 2019). The locations of these camps are unknown, and as a result, have not been evaluated as specific receptors in any VCs.
Size of the Population Potentially Affected	An estimated total of 21 people are living at Beaver Lake and 15 people are living at Sheet Harbour IR. However, extended familial and broader community relationships exist at other Millbrook communities and also with other Mi'kmaq communities including, but not limited to, Pictou Landing First Nation, Sipekne'katik First Nation and Paqtnkek First Nation, and would indicate a larger potentially-affected population.
Presence of Drinking Water Intakes	The nearest domestic well is approximately 5 km south from the Project at the Beaver Lake IR 17. No other seasonal/temporary or permanent water usage has been documented in closer proximity to the Project through research completed for this EIS. As a result, no surface water withdrawal locations have been evaluated, although as mentioned in Table 6.14-4, an analysis of surface water concentrations at discharge locations within Cameron Flowage (presumed reasonable worst case surface water location from Project) has been completed against the Canadian Drinking Water Quality Guidelines.
Timing/Duration of Project	The Project will take place in stages – first construction, followed by operations, and reclamation. It is anticipated that the period from construction through active reclamation is eight years. The mine will limit access to specific areas for hunting, fishing and harvesting purposes for that period. After this period, during post-closure, monitoring and water treatment (if/as required) in the pit will be on-going, but access to the areas surrounding the pit will be re-established for the Mi'kmaq.
Recreational Use of Surface Water	The Project, as planned with constructed bypass roads, allows for continued access to areas of documented use, with the exception of Mud Lake and Crusher Lake. Swimming may occur within Cameron Flowage during high flows (Spring and Fall). The HHRA evaluated risk to recreational swimming and also accidental ingestion of surface water during swimming.
Country Food Harvesting	Based on the information compiled through the TLRUS and MEKS, historical information and secondary sources, and findings during site visits, it is concluded that there is a documented Mi'kmaq use of the Project site and surrounding areas for subsistence harvesting of food and medical plants, fish and furbearing animals. Historical and current information indicates that the Mi'kmaq would have and continue to conduct these activities in the Beaver Dam Mine Site and Haul Road and surrounding areas.
Location of Traditional Resource Use	

Fishing is traditional practice (historical and current) in the LAA. Fishing is generally for sustenance/subsistence, as well as for recreational purposes. Trout is the key fish species described in the TLRUS (MFC 2019) with additional species including brook and rainbow trout, sea trout, American eel, Atlantic salmon, herring, mackerel, gaspereau, various groundfish species, smelt, striped bass and sucker. Shellfish harvesting within the LAA include clams, lobster, mussels, snowcrab, and scallop (MFC 2019).

Fishing is practiced across the LAA in most major rivers and lakes, as documented in the TLRUS and MEKS. Within the Beaver Dam Mine Site, there is documentation of trout fishing within Cameron Flowage/Killag River and possibly Mud Lake and Crusher Lake (MFC 2019). Within the 4km footprint of new construction for the Haul Road, there are no documented rivers or lakes that support the Mi'kmaq fisheries. However, adjacent to this new construction corridor and along the road footprint proposed for upgrades to construct the Haul Road, fishing locations are common, and Millbrook First Nation use of these lakes (and rivers) is well documented from the Beaver Dam Mine Site to the Mooseland Road (MFC 2019).

Some Mi'kmaq community members have camps on Crown land where they go to enjoy peaceful recreational and traditional activities with family and community members. There are five camps located within 1 km of the Haul Road and multiple other camp locations throughout the LAA. These camp locations in close proximity to the Haul Road (within 1 km) may experience indirect Project impacts due to wildlife pattern adjustment or adjustments in hunting patterns where hunters may feel uncomfortable using their firearms for safety reasons.

The TLRUS (MFC 2019) asked participants specific questions relating to the annual percentage of harvesting completed within the LAA and what the impact might be from displacement from the area (socio-economic impacts). AMNS understands that the TLRUS (MFC 2019) concludes that Millbrook First Nation community members may need to assume the cost to purchase additional meat at a local grocery store, and/or they may choose to hunt elsewhere. Detailed analysis of the potential effects of this change in pattern is not fully understood. No information was provided documented Mi'kmaq commercial forestry or logging operations but there is documented trapping of furbearers for cash sale of the furs.

The following sections describe the human health risk assessment and potential impact to the socio-economic, mental, and social well-being of the Millbrook First Nation community and more broadly, the Mi'kmaq of Nova Scotia.

6.14.7.2.1 Human Health Risk Assessment Summary of Methods and Results

The HHRA was completed by Intrinsik Corp. to support the EIS and also to respond to Round 2 Information Requests (IR2s) CEAA 2-38, CEAA 2-52 and CEAA 2-53. The HHRA evaluated the following VCs to support the analysis of Project impact to the Mi'kmaq of Nova Scotia: Air, Surface Water, Fish and Fish Habitat, and Fauna. Table 6.14-4 outlines the technical conclusions for each VC and the justification for inclusion in the HHRA. Activities in the area could include traditional hunting and plant gathering, fishing, swimming, hiking, use of ATVs, and camping. The HHRA identified possible exposure pathways such as:

- inhalation of air containing dusts;
- incidental soil and dust ingestion;
- ingestion of berries and/or traditional vegetation, game meats and fish; and
- incidental consumption and dermal contact to surface waters through recreational activities (swimming).

These exposure pathways were included in the assessment for the Project. The HHRA followed a standard screening level risk assessment approach using methods outlined by Health Canada (2012; 2016a; 2016b; 2018 as cited in Appendix C.2). The steps of a HHRA involve conducting a Problem Formulation, which involves identifying the ways by which people could be exposed to chemicals released from mining activities (which are known as exposure pathways), the identification of Chemicals of Potential Concern (known as COPCs), and identifying the characteristics of people who could be exposed (known as receptors), based on the types of activities that could occur in the area of the mine. This stage was followed by an Exposure Assessment (to estimate the potential rate of exposure to COPCs) and Toxicity Assessment (which estimates exposure rates which are considered to be without risk of adverse health effects, or of negligible risk) and a Risk Characterization step. Activities in the area could include traditional hunting and plant gathering, fishing, hiking, use of ATVs, and camping. The HHRA identified possible exposure pathways

such as inhalation of air containing dusts; incidental soil and dust ingestion; ingestion of berries and/or traditional vegetation, game meats and fish; incidental consumption and dermal contact to surface waters through recreational activities (swimming), which were all included in the assessment.

Since most of the dust generated from the Beaver Dam Mine Project is expected to be related to the transportation along haul roads, the chemical composition of the dust considered in the HHRA is specifically associated with source of metals in road construction, which is proposed to be waste rock related to mining activities at the Beaver Dam Mine Site. The waste rock will be used to construct interior mine roads. Screening of these sources resulted in several metals/metalloids meriting further assessment in the HHRA (aluminum; antimony; arsenic; barium; beryllium; boron; cadmium; chromium; cobalt; copper; lead; manganese; mercury; molybdenum; nickel; strontium; vanadium and zinc).

With regard to other potential substances released by mining activities, the following can be stated:

- Criteria air contaminants (TSP; PM_{10}; $PM_{2.5}$, NO_x; SO_2) are assessed in the air quality assessment (Appendix C.1), relative to provincial and federal air quality standards and objectives. These substances were also re-evaluated in a supplemental modelling effort by GHD (2021a), due to infrastructure changes. These are not evaluated further in this report, and results of comparisons to air quality guidelines are provided Appendix C.1.
- Metals in dusts ($PM_{2.5}$ and PM_{10}) merit further evaluation. The specific COPCs identified above (based on the relevant geochemistry of the dust sources) are assessed further in response to Provincial IR NSE 2-129. No metals on particulate matter exceeded their respective short term (24 hour) air quality guidelines or long term (chronic) inhalation toxicity reference values. A copy of this IR response is located as Appendix B of the HHRA (Appendix C.2).
- VOCs were concluded to be insignificant at this site, and hence are not evaluated further (predictions are provided in Appendix C.1).

For metals from water release of effluent into Killag River at Cameron Flowage, predicted future concentrations in the receiving environment (Appendix D of Appendix P.4 [Mine Water Management Plan] and Appendix C.2) were screened against Canadian Drinking Water Quality Guidelines (CDWQG) to identify potential COPCs related to recreational water usage.

Dust deposition from mine site activities was predicted by GHD (Appendix C.1), based on proposed operations and activities at the mine site, using standard methods. Predicted deposition rates were provided for the maximum point of impingement (MPOI) associated with mine site activities, as well as the receptor location with the highest dust deposition rate [e.g., Deepwood Estates (R7)]. These predictions were used to estimate potential future soil, vegetation and game meat concentrations in the Study area, using standard risk assessment equations provided by Health Canada and US EPA (e.g., US EPA OSW, 2005; US EPA, 1993a). Effluent release into the nearby receiving environment (i.e., Cameron Flowage on the Killag River) during construction, operation and post-closure are predicted by GHD (Appendix P.4). These data are used to evaluate potential exposures related to recreational swimming, and fish consumption.

Potential exposures to releases of the COPCs from the proposed Beaver Dam Mine Project for people who could spend time in areas near the Beaver Dam Mine Site or Haul Road were estimated using standardized equations by Health Canada (2012) and US EPA (2003; 2004a). Consumption rates for various foods which could be harvested from the area near the proposed mine, such as leafy vegetation, berries, fish and game meats (e.g., deer; grouse; hare and duck), were identified from the First Nations Food, Nutrition and Environment Study (FNFNES) for the Atlantic region (Chan et al, 2017), and are consistent with traditional knowledge report (Millbrook First Nation and Moccasin Flower Consulting, 2019) and ongoing engagement with Millbrook First Nations. Soil ingestion and dust inhalation exposure rates were identified from Health Canada (2012). Exposure rates from swimming and incidental water ingestion were identified from both Health Canada (2012) and US EPA (2003; 2004a). Chronic

Toxicity Reference Values (TRVs), which are exposure levels of COPCs for a life-time below which adverse effects are not anticipated, or which are associated with negligible risk levels, were identified from Health Canada (2010), World Health Organization (2010), US EPA (1996; 1993a) and other notable regulatory agencies. Potential risks were characterized by comparing the predicted exposure levels from all exposure pathways to the TRV, to predict a Risk Quotient (RQ) for non-carcinogens. An RQ less than 0.2 for the Project scenario, or less than 1.0 for the Baseline + Project scenario, are considered to indicate that risks associated with the Project are negligible. For carcinogenic chemicals, an Incremental Lifetime Cancer Risk (ILCR) for all life stages is calculated. A benchmark cancer risk level of 1 in 100,000 (i.e., 1×10^{-5}) is used to assess risk, and cancer risks are deemed negligible when the estimated ILCR is less than the benchmark value of 1 in 100,000 (i.e., ILCR ≤ 1.0).

The non-carcinogenic risks from soil and dust exposures, the consumption of country foods harvested from the vicinity of the Mine Site, and recreational water use (i.e., swimming), as well as soil ingestion, are considered to be negligible based on the assessment. The predicted ILCRs for arsenic are below the benchmark ILCR of 1 in 100,000 in all scenarios and assessment cases. Therefore, the potential for adverse health effects from arsenic exposure are considered negligible. The risk assessment results indicate that risks to people consuming country foods from the area, or spending time in the area, will not increase appreciably following mine development.

Based on the assessment conducted, the following can be concluded:

- Metals are naturally occurring in the environment and are present within existing soils and vegetation in the region. Mine activities will result in increased deposition of dust in the vicinity of the Mine Site outside the PDA, particularly related to Haul Road activities;
- Dustfall predictions indicate that the areas outside the PDA that will potentially receive higher dustfall rates are generally located near the Haul Road. Based on the estimated future soil concentrations of all metals considered, some accumulation within vegetation is anticipated to occur, but that accumulation would likely be localized to areas most affected by dust loadings which are generally limited in size and closer to the Beaver Dam Mine Site and Haul Road boundaries;
- It is considered unlikely that ore dust deposition and effluent releases from the Beaver Dam Mine Project at the rates considered in this assessment would result in levels of metals in country foods, soils and dust, and surface water (*via* recreational water use) that would be harmful to human health. Predicted risks associated with consumption of country foods are considered to be negligible

6.14.7.2.2 Socio-Economic, Mental, and Social Well-Being

The Project is planned for an eight-year timeframe within the proposed Beaver Dam Mine Site and Haul Road property boundaries. As described above, the HHRA has determined that there is a low risk of direct human health effects from this Project within and surrounding the Beaver Dam Mine Site and Haul Road. However, AMNS understands that this Project may result in an impact to the socio-economic, mental and social well-being of the Mi'kmaq of Nova Scotia.

The Project may impact the economic condition of the Mi'kmaq communities. This impact could be felt in either a positive or negative way. Some of these potential changes, related to the economic condition of Mi'kmaq individuals, families and at the community level, include changes in income, population, housing conditions, employment, cost of living and food security.

With loss of access to the Beaver Dam Mine Site, AMNS acknowledges that patterns of traditional use (hunting; trapping; medicinal, food or cultural-use plants; and recreational use of water) may change for the Millbrook First Nation and other Mi'kmaq community members. This may result in a shift to other areas to practice traditional use, or a reduction or stoppage of the use of traditional resources in the local area, and potentially the need to purchase of goods to replace these traditional resources. These shifts could

increase the cost of living for Millbrook First Nation and other Mi'kmaq families who rely on traditional resources. There are also possible positive effects on the economic condition for both the Millbrook community members and the broader Mi'kmaq community with provision of potential new job opportunities and improved socio-economic conditions through increased income. However, it is also possible that the Project may cause worker shortages in other businesses if people are recruited away from their current jobs in the community, and it is also possible that loss of access to the land and resources may have a direct effect on an individual's income.

AMNS anticipates that the Project will have limited effect on Mi'kmaq use of navigable waters. Inside the property boundary of the proposed Beaver Dam Mine Site, there are only two small lakes (Mud Lake and Crusher Lake) and no major riverways. The watercourse draining from Crusher Lake to Mud Lake to Cameron Flowage/Killag River is not navigable by canoe, and as a result, the effect on navigable waters from Project development is predicted to be low.

As previously discussed in this section, there is an impact on traditional practices for Millbrook First Nation and more broadly, the Mi'kmaq of Nova Scotia, due to a loss of access, which potentially includes Mi'kmaq forestry and logging operations and traditional practices in the context of moderate livelihood. Forestry activities have been documented historically. Insight into Millbrook and the Mi'kmaq of Nova Scotia forestry and logging activities has been documented. The TLRUS (MFC 2019) and MEKS describe the harvesting of wood and wood products as a general aspect of Mi'kmaq traditional practice to support carvings and specialty wood items. As a result, lack of access to this area of Crown land (123 ha) could impact the Mi'kmaq of Nova Scotia ability to harvest wood and wood products and may affect Mi'kmaq forestry and logging activities that may be present within this area. Limited information has been provided relating to specific use of the Beaver Dam Mine Site and Haul Road for commercial trapping and hunting, but the TLRUS (MFC 2019) and MEKS both report trapping and hunting efforts within and surrounding the Beaver Dam Mine Site and Haul Road and TLRUS participants describe that they sell furs for cash.

It is acknowledged that the Millbrook First Nation and other Mi'kmaq communities use the Beaver Dam Mine Site and surrounding area for traditional and recreational purposes and possibly for non-commercial/trade economy purposes. These activities will be limited during Project construction, operation and active closure to areas surrounding the Beaver Dam Mine Site, which will have an effect on the Millbrook First Nation and broader Mi'kmaq community members who carry out these activities. The TLRUS (MFC 2019) indicates that Millbrook individuals currently use the Beaver Dam Mine Site specifically to gather food for sustenance for themselves and/or their family members and thus, for these people, the loss of access into the Beaver Dam Mine Site and Haul Road for the eight-year period may affect their food security and require an adjustment to either hunt and gather in other areas adjacent to their traditional area (refer to mitigation measures in Section 6.14.8), or purchase food instead.

The Project will provide employment opportunities for individuals from the Mi'kmaq communities, including the youth. There may be an increase in public and community services in the area once the Project is developed, resulting from increased population and economic activity in the local area around the Beaver Dam Mine Site. This may also raise the cost of living in close proximity to the mine. The mine will provide added employment and economic opportunities to the area, and the Mi'kmaq are anticipated to benefit from this increased economic activity.

The development of the mine will change the baseline conditions in the local area. There will be an increase in background noise, dust, and light in close proximity to the mine. This may affect the spiritual and cultural experience and sense of well-being for the Millbrook First Nation community members and the Mi'kmaq of Nova Scotia more broadly on the landscape adjacent to the Beaver Dam Mine Site and Haul Road.

Once the construction phase, operation phase, and active closure are complete (eight years), access will be re-established within the Beaver Dam Mine Site for all Mi'kmaq of Nova Scotia. With the exception of the pit area, where filling will be on-going and

water monitoring will be occurring, commercial and traditional practices within the Beaver Dam Mine Site can resume. The landscape will be altered, with more limited forested cover for an extended period of time until forest cover re-establishes. This will likely affect the specific nature of traditional practices that can resume within the Beaver Dam Mine Site.

Collectively these potential changes as a result of the proposed mine development are expected to have an impact on the economic, mental and social well-being of Millbrook First Nation and the Mi'kmaq of Nova Scotia. Mitigation measures have been developed through engagement with Millbrook to reduce the impacts of the Project for their community and their individual community members. Although there may be specific individual examples of negative economic impact as a result of changed traditional practices (for example), generally, the overall conclusion is that this Project will have a net positive impact on the Mi'kmaq of Nova Scotia through an increase in job opportunities and economic prosperity in the local region around the Project. Moreover, mitigation measures proposed to allow continued access to lands surrounding the Beaver Dam Mine Site and Haul Road, and the availability of Crown land adjacent to the Project. The development of the Project is also expected to have an impact on the mental and social well-being of the Mi'kmaq of Nova Scotia. Similar to economic condition changes, the Project may have a negative localized impact on Millbrook First Nation and other Mi'kmaq individuals partaking in traditional practices within close proximity to the mine. AMNS acknowledges this localized effect and has committed to mitigation measures to maintain access to lands surrounding the Project and has reviewed available Crown land surrounding the property that can continue to be used by Millbrook First Nation and the Mi'kmaq of Nova Scotia. The temporal scale of the Project is short (i.e., eight years), and impacts are localized in nature, so impacts are not considered significant once mitigation measures are applied, as described in Section 6.14.8 (residual effects).

From a socio-economic perspective, interest has been expressed by the Mi'kmaq of Nova Scotia to work toward benefit agreement(s). These discussions and negotiations are ongoing and are privileged and confidential discussions between AMNS and the Mi'kmaq of Nova Scotia. While not required by the Crown or legislation, such agreements are considered a best practice. AMNS had a Memorandum of Understanding (MOU) with the ANSMC through the KMKNO from 2014-2016. A renewed MOU was proposed in 2018 and is pending approval by ANSMC in January 2021. Once the MOU is approved, it is expected that AMNS will develop an Impacts Benefits Agreement (IBA) with the ANSMC through the KMKNO Benefits Office. In addition, AMNS will seek to develop a Benefits and Compensation Agreement with Millbrook First Nation related to the Project. These discussions are separate to those referred to above, however, and AMNS will work to coordinate the two agreements to avoid duplication and overlap.

A Plain Language Summary (PLS) and a Summary of Effects is provided in Appendix A.1. Both documents have been shared with Millbrook First Nation on September 1, 2020. The PLS was also shared with KMKNO on November 2, 2020 and Sipekne'katik First Nation on May 7, 2021. This dialogue, as described above and in Section 4, is expected to be strengthened and on-going throughout the life of the environmental assessment process, and the Project in general.

6.14.8 Mitigation

Mitigation measures and monitoring associated with related VCs are key to avoiding effects on the Mi'kmaq of Nova Scotia, as detailed in each VC section. The Project has been planned to minimize footprint disturbance and impacts to Millbrook First Nation and the Mi'kmaq of Nova Scotia wherever possible and practicable. There are limited expected indirect effects on the Mi'kmaq of Nova Scotia based on the assessment of effects for related VCs (Table 6.14-5). This evaluation is based on the implementation of the proposed mitigation measures and associated monitoring as a result of direct and indirect effects as outlined in the VC sections. These mitigation measures are not repeated in detail in this section but generally including dust mitigation and monitoring, treatment of discharge water if/as needed prior to discharge into Cameron Flowage/Killag River during both the operations and closure phases of the Project, surface and groundwater monitoring programs, implementation of erosion and sediment control measures

throughout the life of the Project, management and disposal of historical tailings when they are required to be disturbed, fisheries offsetting, wetland compensation, and wetland, lichen and moose monitoring programs.

There are also direct proposed mitigation measures to reduce impact on traditional practices, Mi'kmaq archaeological features (if identified) and the socio-economic, mental and social well-being of the Mi'kmaq of Nova Scotia. These mitigations are described in detail below and in Table 6.14-8 and in response to Round 2 Information Requests (IR2s) CEAA 2-48 and 2-49.

Table 6.14-8: Description of Potential Suitable Alternative Areas for Mi'kmaq Traditional Use

Suitable Alternative Area (named by major lake and shown on Figure 6.14-7)	Description of Known Characteristics(a)	Limitations
1: Otter Lake	Crown land Ease of access – no implication to access to this area from Project from Hwy 224, and accessible with mitigations (CEAA 2-48) from Haul Road/ATV Route 320 Close to camp locations Resource quality (outside of indirect areas of potential impact) Quietness/seclusion Based on review of TLRUS, long-term familial connection to the area and suitability for inter-generational knowledge transfer	
2: Kent Lake	Crown land Ease of access (through mitigation measures described in CEAA 2-48) Close to camp locations Resource quality (outside of indirect areas of potential impact) Based on review of TLRUS, long-term familial connection to the area and suitability for inter-generational knowledge transfer	There will be elevated noise and dust levels above background during the temporal scale of the Project. Expected sky glow from the Mine Site.
3: West Lake	Crown land Ease of access – no implication to access to this area from Project Resource quality (outside of indirect areas of potential impact)	There will be elevated noise and dust levels above background during the temporal scale of the Project. Expected sky glow from the Mine Site.
4: Como Lake	Crown land Ease of access (through mitigation measures described in CEAA 2-48) Close to camp locations Resource quality (outside of indirect areas of potential impact) Based on review of TLRUS, long-term familial connection to the area and suitability for inter-generational knowledge transfer	There will be elevated noise and dust levels above background during the temporal scale of the Project. Expected sky glow from the Mine Site.
5: Lake Mulgrave	Crown land Ease of access (through mitigation measures described in CEAA 2-48) Close to camp locations Quietness/seclusion Resource quality (outside of indirect areas of potential impact) Based on review of TLRUS, long-term familial connection to the area and suitability for inter-generational knowledge transfer	

Note: (a) Crown land, similar size to area of lost access from Project development, ease of access, close to a camp, quietness/seclusion, long-term familial connection to the area, resource quality, and suitability for inter-generational knowledge transfer.

The Beaver Dam Mine Site and Haul Road will limit access to Millbrook First Nation and other Mi'kmaq of Nova Scotia for a period of eight years. The proposed property extents of the Beaver Dam Mine Site and Haul Road encompasses a 727-ha area, of which

123 ha is Crown land (Figure 6.14-5). Figure 6.14-5 shows the proposed property boundary of the Beaver Dam Mine Site, and the proposed 30m property boundary on either side of the centre line of the proposed Haul Road. There will be restricted access to this area for eight years to allow for construction, operation and active reclamation of the Project. Outside of this area of restricted access, mitigation measures are proposed to allow continued access to the Millbrook First Nation community members and other Mi'kmaq of Nova Scotia communities to lands surrounding the Beaver Dam Mine Project to continue traditional practices on the landscape.

As a key proposed mitigation measure, a multi-use bypass road is planned to support Project development (Figure 6.14-6A). This multi-use bypass road is designed to allow pick-up truck/vehicle traffic and ATV traffic to transverse the length of the upgraded Haul Road without having to interact directly with the haul trucks (Figure 6.14-6A). This bypass road will allow continued access for the Mi'kmaq of Nova Scotia and specifically, Millbrook First Nation community members, to lands and lakes used for traditional purposes to the south and north of the Beaver Dam Haul Road between Highway 224 and the Mooseland Road, to the east and west of the Beaver Dam Haul Road between Highway 224 and the Beaver Dam Mine Site, as well as access to the lands north of the Beaver Dam Mine Site. The TLRUS (MFC 2019) describes traditional practices near the Beaver Dam Haul Road including areas around Lake Alma, Ferry Lake, Southwest Lake, Lower and Middle Beaver Lake, Otter Lake, Rocky Lake, Como Lake, and Lake Mulgrave including fishing, trapping, collection of specialty wood and medicinal plants, berry gathering, and hunting. This proposed mitigation measure (i.e., the construction of a parallel bypass road), will allow continued access to these areas for traditional practices during the eight years when the Project is active.

This bypass road to support continued traditional practices in the lands surrounding the Project are described in more detail below and shown in detail on Figures 6.14-6B to 6.14-6F.

Access from Hwy 224 west along the original portion of the Northern Timber haul road will still be available for the Millbrook First Nation and the Mi'kmaq of Nova Scotia. Where the existing Northern Timber haul road joins with the proposed Beaver Dam Haul Road (Figure 6.14-6B), there will be a stop sign/crossing location. Haul truck drivers will be trained on locations of crossings/stop signs and will proceed with caution at these crossing locations.

Two crossing locations (with stop signs) are planned where ATV trail Route 320 and ATV trail Route 367 currently join the existing Northern Timber haul road, which is proposed to be upgraded for the Project (Figure 6.14-6C). The haul trucks will have the right-of-way at these locations. However, as described, truck drivers will slow down to allow crossings when vehicles are visually observed, will be trained on locations of crossings/stop signs and will proceed with caution at these locations. These two crossing locations will allow community members to exit from the proposed bypass road, cross the Beaver Dam Haul Road, and continue north on ATV trail Route 320 or south on Route 367. These two ATV Routes accesses lands and lakes to the north and south of the Beaver Dam Haul Road where documented traditional practices occur.

The Beaver Dam Mines Road from Hwy 224 to the Beaver Dam Mines Site will be upgraded as part of the proposed Haul Road. Where Route 323 joins with the proposed Haul Road (Figure 6.14-6D) there will be another stop sign/crossing location. Specifically, this will allow access for Millbrook First Nation and other Mi'kmaq of Nova Scotia communities to the ATV trail Route 323 to the east and west of the Beaver Dam Mines Road. Smaller trails are also present to the west of the Beaver Dam Mines Road and access across the Beaver Dam Haul Road will be possible for ATVs and trucks to reach these trails and areas west of the Beaver Dam Mines Road to continue their traditional practices. The TLRUS (MFC 2019) describes traditional practices in close proximity to the Beaver Dam Haul Road from Hwy 224 to the Beaver Dam Mine Site including areas around Kent and Tent Lake, River Lake/West River Sheet Harbour, and areas to the east of the Beaver Dam Mines Road as far east as Lake Mulgrave, including fishing, trapping, collection of specialty wood and medicinal plants, berry gathering, and hunting.

McCallum Environmental Ltd.

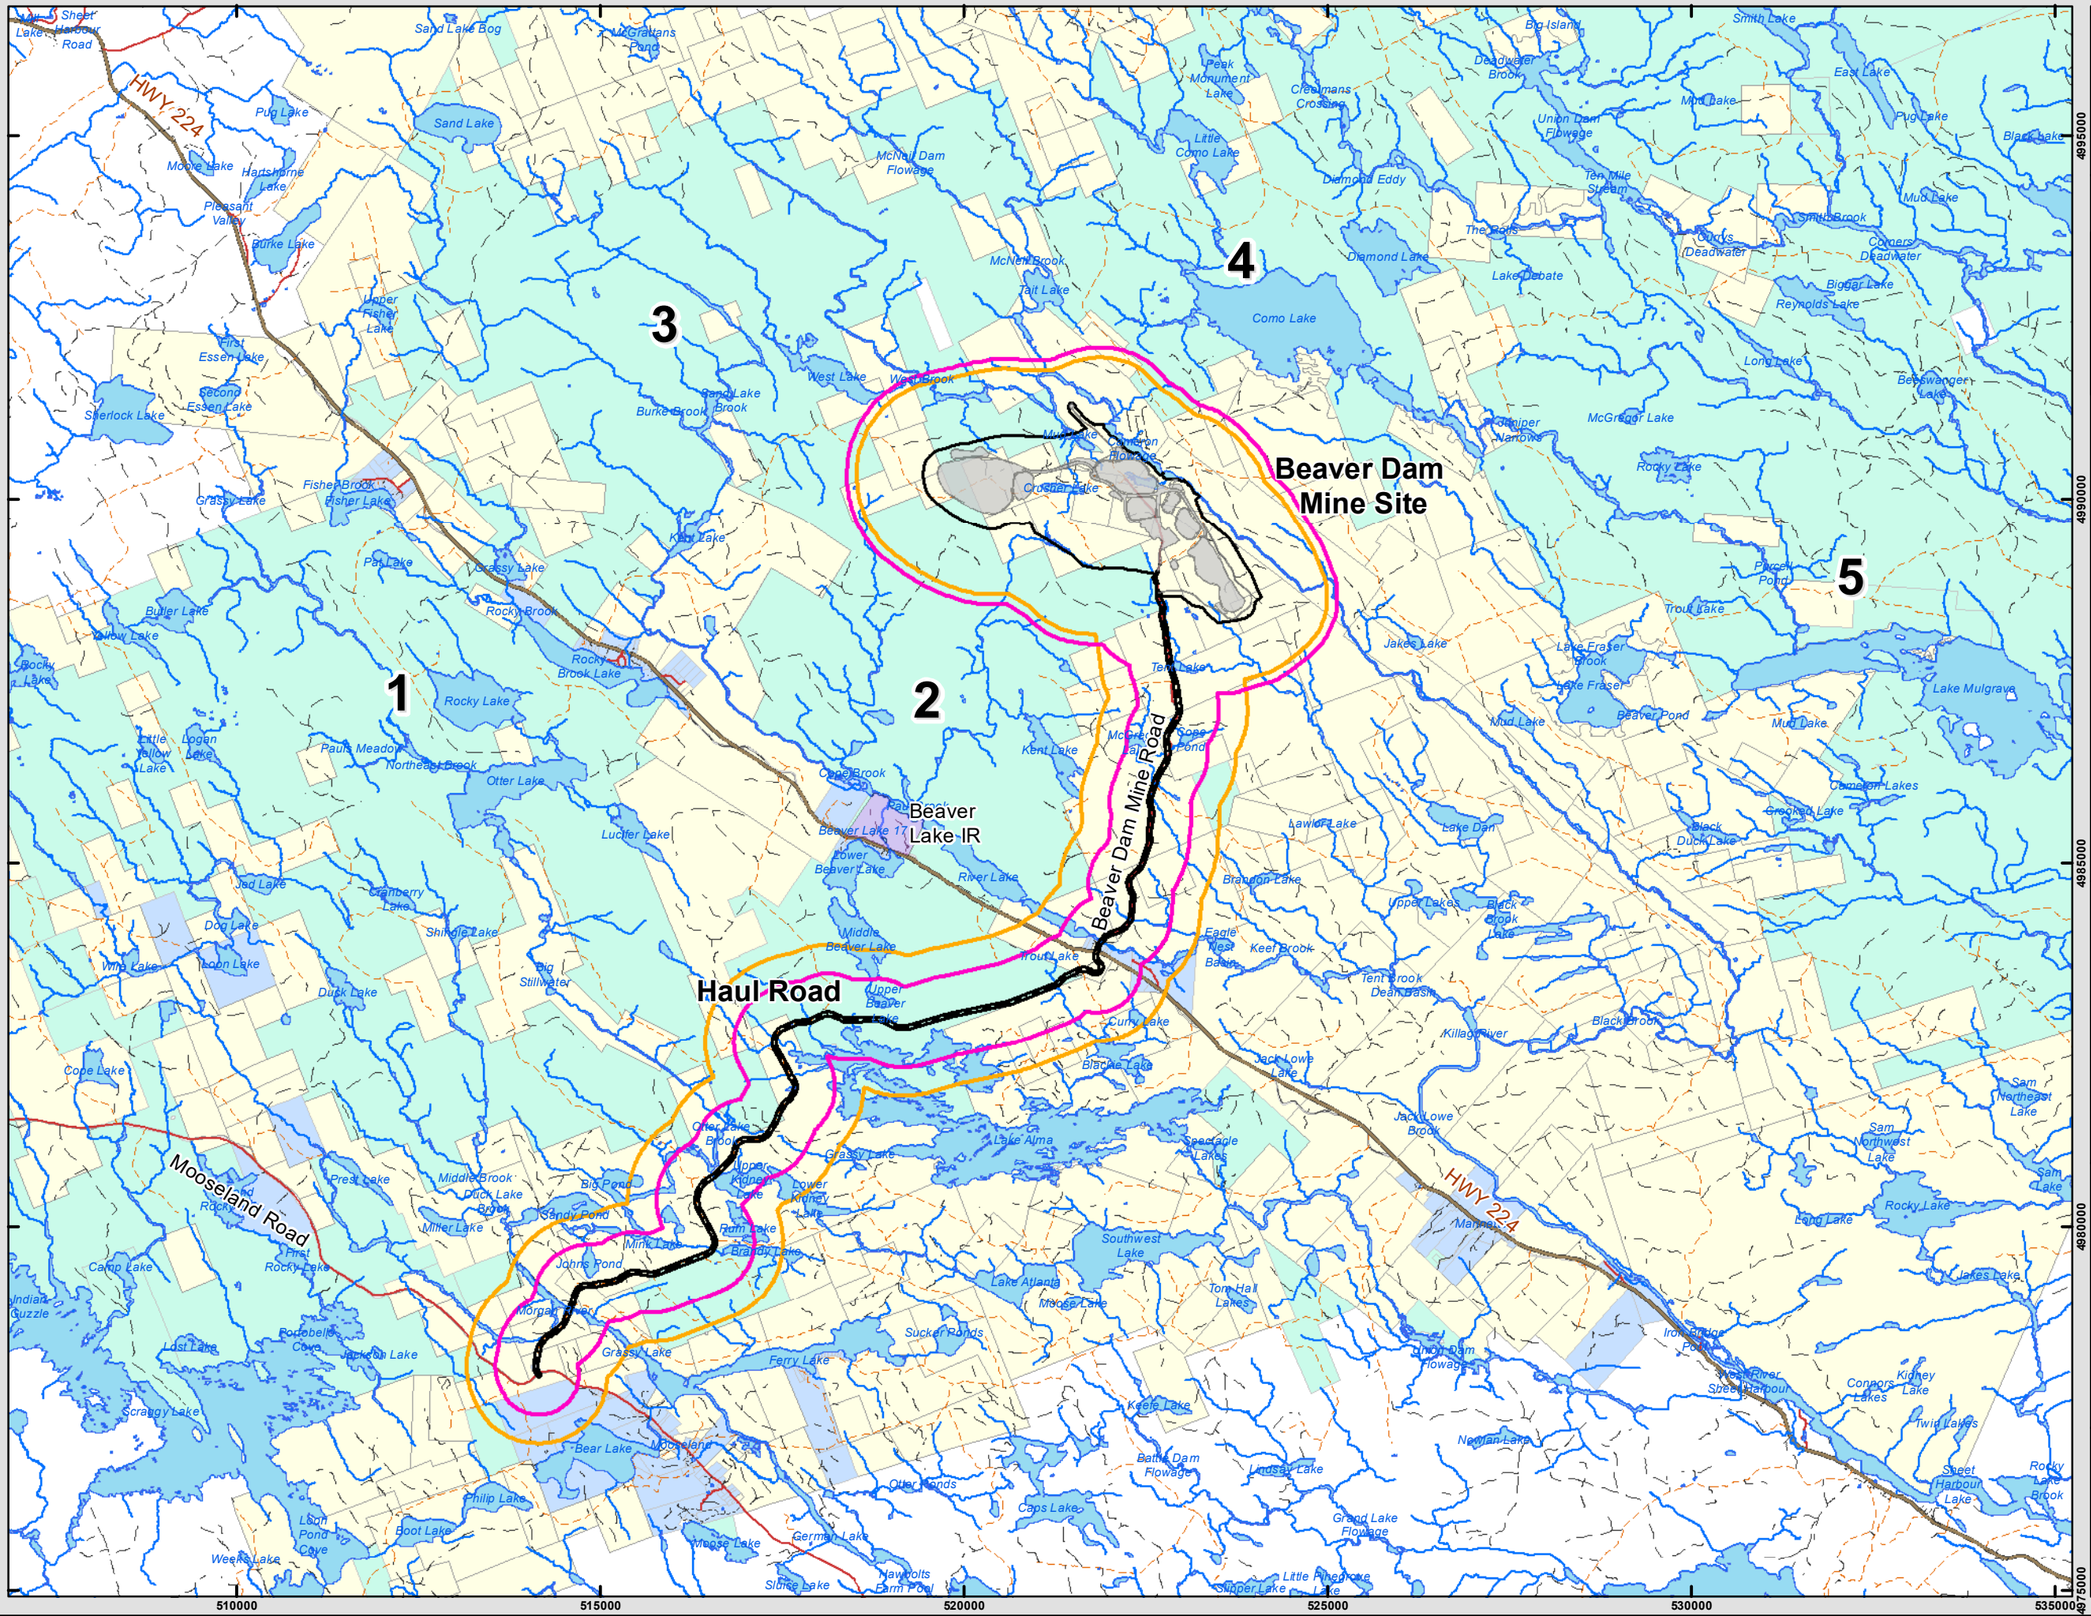
Document Name: BD_EIS_Figure6-14-5Primary Mitigation Proposed Bypass1e

The proposed bypass road will continue around, and to the east of, the Beaver Dam Mine Site to allow access for Millbrook First Nation and other Mi'kmaq of Nova Scotia community members to the north of the mine to join with ATV Route 394, including areas around Como Lake and areas east and west of this lake (Figure 6.14-6E). This bypass road will allow access to lands and lakes north of the Beaver Dam Mine Site to continue traditional practices. The TLRUS (MFC 2019) describes traditional practices north of the Beaver Dam Mine Site around Como Lake and Lake Mulgrave, including fishing, extensive trapping, and hunting.



ATV Route 320 allows access from Hwy 224 to the lands to the west of the Beaver Dam Mine Site (Figure 6.14-6). In order to allow Project development, Route 320 will end at the western end of the Beaver Dam Mine Site, where the WRSA is proposed. There is a proposed ATV trail connection to the south of the WRSA to allow access from the western side of the Beaver Dam Mine Site east to the Beaver Dam Mine Road bypass road (Figure 6.14-6F). AMNS plans to provide permitting and financial support to the local ATV club(s) for this ATV trail. This mitigation measure will allow continued transport from Route 320 west of the Beaver Dam Mine Site to the lands south, east and north of the Beaver Dam Mine Site, to allow Millbrook First Nation and other Mi'kmaq of Nova Scotia community members to continue to access lands around the mine to practice their traditional practices.

Through direct engagement with Millbrook community members and conclusions provided within the TLRUS and MEKS, AMNS has been able to confirm areas of Mi'kmaq traditional use surrounding the Beaver Dam Mine Site and Haul Road. Mitigation measures described in CEAA 2-48 will allow on-going access to the lands surrounding the Project where traditional use has been documented, during the eight years where direct access to the mine will be limited. However, after consideration of these mitigation measures, the Project is expected to limit traditional practices within the direct areas, and potentially affect traditional practices within the indirect areas described in Table 6.14-8. As a result, alternative areas have been described, where traditional practices may continue during the life of the Project.

Tracts of crown land are present in close proximity to the Project (Figure 6.14-7). These tracts of land are adjacent to the Project Area and, in most cases, overlap with areas with documented traditional use (MFC 2019). These areas of land are publicly owned, not limited by provincial or federal parks and protected areas, are all accessible and available with consideration of the mitigation measures described in CEAA 2-48. These areas are presented as potential suitable alternative areas for traditional practices to continue, during the eight-year temporal scale of the Project.

The TLRUS (MFC 2019) confirms a definition of traditional use areas, and what uses these areas provide for community members of the Millbrook First Nation. This documentation of traditional land use areas extends beyond a physical description of quality of the land to support hunting, fishing, trapping and other traditional practices. Traditional areas are also described as "remote", places where community members can experience "solitude and peace while conducting their TLRU activities", and where there is a generational connection to the specific locations where traditional practices take place (MFC 2019, p. 26). Community members describe their temporal connection to specific locations where they complete their traditional practices, with over 40 years returning to the same locations to fish and hunt (MFC 2019). Also, Millbrook community members describe their generational connection to camp locations throughout the TLRUS (MFC 2019), with their own memories of visiting a camp location as a youth in the 1950 to 1970's, and then introducing these same camp locations to their grandchildren. These camp locations are "special because of the long history of use" and they bring back memories of their own childhood and uncles/father's use of the same locations (MFC 2019, p. 36). Millbrook First Nation community members document their hunting and fishing practices in the same locations within the LAA over the last 50 years (MFC 2019).

As part of the TLRUS (MFC 2019), community members were asked about potentially having to go elsewhere to practice their traditional activities. One community member described that generational connectivity to the land. They said, "I would definitely be missing out on places… where my father fished, and my grandparents fished" (MFC 2019, p.40).

The TLRUS (MFC 2019) offers a description of the conditions that support Millbrook First Nation traditional practices at a specific location: **"Ease of access, close to a camp, quietness/seclusion, long-term familial connection to the area, resource quality, and suitability for inter-generational knowledge transfer"** (MFC 2019, p 46).

By extension, a "suitable alternative area" to practice, as documented in CEAA 2-49, will have similar characteristics to current traditional practice areas that are used by the Millbrook First Nation and other Mi'kmaq of Nova Scotia community members within and surrounding the proposed Project and that are described above (bolded) and in the TLRUS (MFC 2019). Suitable alternative areas shown on Figure 6.14-7. These areas are described below in Table 6.14-8 in the context of provision of similar characteristics to those described by the TLRUS (MFC 2019). These areas are recommended as potential suitable alternative areas based on AMNS review of the TLRUS (MFC 2019), a review of available crown land surrounding the Project, and on-going engagement with Millbrook First Nation and the Mi'kmaq of Nova Scotia, given the limited access to 123 ha of Crown land within the Beaver Dam Mine Site and Haul Road property boundaries, and given the potential for indirect impact to traditional practices with the Indirect Wildlife Environmental Effects Zone (1,108 ha of Crown Land) and the Limited Firearms Zone (1,411 ha of Crown land), as described in Table 6.14-6. These proposed suitable alternative areas have been shared with Millbrook First Nation. The Millbrook First Nation community engagement officer is coordinating community meetings with specific families who are interested in providing feedback on Project impacts, mitigation measures proposed, and potentially suitable alternative areas for continuation of traditional practices, to, in part, mitigation for loss access associated with the Project for the eight year mine life.

The purpose of these community meetings, as described by the Millbrook community engagement officer, is to receive feedback from specific families who have expressed an interest in the Project, relating to Project summary of impacts and proposed mitigation measures. This feedback is intended to supplement general feedback received from Millbrook First Nation through regular and on-going engagement efforts to date.

At the time of submission of this updated EIS, no specific feedback has been received from the Millbrook First Nation. AMNS understands that community meetings have taken place and that a report summarizing these meetings is drafted. Regular and consistent communications to receive this feedback has been ongoing with Millbrook First Nation through April and May 2021. Although the feedback has not been received, AMNS will continue to reach out and find opportunities to address feedback in the Projects development plans.

It is anticipated that engagement will continue throughout and beyond the current environmental assessment process. This will require ongoing dialogue regarding potential impacts on Mi'kmaq communities, and AMNS is committed to continuing those discussions. AMNS looks forward to receiving feedback and commits to discussing with Millbrook First Nation how best to address their feed back into Project design, mitigation and monitoring measures and potentially additional monitoring and mitigation measures. Subject to any confidentiality concerns expressed by the Millbrook First Nation, AMNS will provide this information to the appropriate regulators.

These areas are shown on Figure 6.14-7. The description of suitable alternative areas was shared with Millbrook First Nation on February 3, 2021, and the proposed locations of these areas has also been shared with Millbrook First Nation on February 16, 2021. AMNS looks forward to receiving Millbrook First Nation feedback.

In the event that archaeological deposits or human remains are encountered during construction activities associated with the Beaver Dam Mine Project, all work in the associated area(s) will be halted and immediate contact made with the Nova Scotia Special Places Program and with the KMKNO Archaeological Division.

Feedback from Millbrook First Nation and the Mi'kmaq of Nova Scotia has been requested relating to these specific proposed mitigation measures. These requests have been made during face to face meetings, through direct engagement efforts (emails

and phone calls), and through the sharing of the draft Mi'kmaq of Nova Scotia Effects Assessment (Section 6.14) and draft Round 2, Information Responses (IR2s) to CEAA 2-48 and CESS 2-49 (summary of Project impacts, mitigation measures and suitable alternative areas) specifically with Millbrook First Nation on February 16, 2021.

The mitigation measures as described in detail above, and in Table 6.14-9 have been developed through ongoing discussions with Millbrook First Nation and the Mi'kmaq of Nova Scotia. Environmental monitoring and follow-up monitoring, as described in Section 6.14.10 will be include the opportunity for Mi'kmaq participation, including in planning and executing wetland compensation, wildlife monitoring, and fisheries productivity offsetting projects.

Table 6.14-9: Mitigation for Potential Effects on the Mi'kmaq of Nova Scotia

Project Phase	Mitigation Measures
EIS Review	Support Mi'kmaq third party review of AMNS's EIS, including mitigation and monitoring programs.
EIS Review	Continuing to provide the opportunity for Mi'kmaq to delineate the specificity of Mi'kmaq traditional use, and meet with the Mi'kmaq to receive feedback on EIS conclusions and impacts.
Pre-construction	Provide Mi'kmaq land users the opportunity to walk the Beaver Dam Mine Site and Haul Road with Proponent representatives to identify and document sensitive sites prior to construction
Pre-construction	Provide a tour of the Beaver Dam Mine Site and Haul Road and information on Project operations to interested Mi'kmaq peoples.
Pre-construction	Develop a Mi'kmaq Communication Plan with the Mi'kmaq of Nova Scotia that outlines an ongoing two-way communication process throughout the lifecycle of the Project.
Pre-construction	As part of the existing communications process, AMNS will build upon and strengthen a Complaints Management and Action Program for Mi'kmaq input in advance of Project commencement, as an opportunity for having grievances heard and addressed, and development of an communication protocol.
Pre-construction	Possible establishment of an environmental protection committee to review proposed and develop additional environmental mitigation protocols, oversee monitoring procedures and review/evaluate results. This committee should have representation from Proponent environmental experts, as well as Mi'kmaw representatives from Millbrook First Nation, Unama'ki Institute of Natural Resources, the Mi'kmaq Conservation Group, and NSE.
Construction	Design and construct bypass roads allow for travel routes to by-pass the Beaver Dam Mine Site and Haul Road and allow access to areas surrounding the Project.
Construction	In the event that Mi'kmaw archaeological features are encountered during construction or operation of the Project, all work in the area will be halted and immediate notification made to the Special Places Coordinator, Nova Scotia Museum, the KMKNO and the communities of Sipekne'katik and Millbrook As part of the EMS, AMNS will ensure mitigation measures are undertaken to prevent irreversible damage to Mi'kmaq archaeological resources and known burial site(s), including ensuring all Project activities are within the defined Project property boundaries only.
On-going	AMNS will provide various opportunities for Mi'kmaq participation in the Project, including opportunities to participate in environmental monitoring and implementation of Mi'kmaq projects such as fish habitat offsetting, wetland compensation, and others. AMNS will continue to engage with the Mi'kmaq on various Project benefits.
On-going	Engage in open dialogue with affected communities relating to issues of limited Mi'kmaq access to the Beaver Dam Mine Site and Haul Road for the eight year project window and continue to review and discuss mitigation options including suitable alternative crown land access in close proximity to the Beaver Dam Mine Site and Haul Road.
On-going	Continue to engage with the Mi'kmaq of Nova Scotia to determine how they would like to participate and integrate traditional knowledge into the Reclamation and Closure Plan for the Project. AMNS will also provide the opportunity for the Mi'kmaq to provide input on species end land uses, revegetation, reclamation techniques, and for Mi'kmaq members to join the reclamation team to execute this Project phase.
On-going	Commitment to developing and conducting a Mi'kmaq Cultural Awareness Program for staff and contractors. Scope to be determined based on further discussions.

Millbrook First Nation and the Mi'kmaq of Nova Scotia will be provided with the opportunity to engage on the verification of the nature and extent of the effects on current use of lands and resources for traditional purposes, to determine the effectiveness of mitigation measures, and to ensure ongoing and adaptive management of any unanticipated outcomes. A Draft pilot Emergency Response Mi'kmaq Communications Plan has been developed and is being implemented with Indigenous groups to ensure the Mi'kmaq of Nova Scotia are kept informed and are able to provide feedback on key issues related to the Project; and, to implement an emergency response protocol, in the unlikely event of an incident.

6.14.9 Residual Effects and Significance

The predicted residual environmental effects of the Project on the Mi'kmaq of Nova Scotia are assessed to be adverse, but not significant following implementation of applicable mitigation measures (Table 6.14-10). Potential residual effects to the Mi'kmaq of Nova Scotia's physical health from Project-related changes to the environment (e.g., changes to country foods, water, and soils) are anticipated to be not significant. Potential pathways of effects on human health associated with consumption of or contact with country foods, water and soils will be minimized by implementing mitigation measures such as dust control, water management infrastructure and processes and water treatment (if required). Mitigation measures to reduce atmospheric emissions will be implemented to minimize potential related effects on human health, and the residual risk to human health from inhalation of Project-related dust and airborne contaminants is considered low.

Mitigation measures and conclusions relating to impacts to traditional practices and socio-economic, mental and social well-being will continue to be evaluated directly with Millbrook First Nation and the Mi'kmaq of Nova Scotia throughout the environmental assessment process, and throughout the lifecycle of the Project. AMNS has reviewed with Millbrook First Nation and the Mi'kmaq of Nova Scotia the proposed mitigation measure of a multi-use bypass road to access to lands surrounding the Haul Road and north of the Beaver Dam Mine Site, as well as the availability and proposed suitability of nearby Crown land as partial mitigation for loss of access during the eight years that the mine will be limiting access to the Beaver Dam Mine Site and Haul Road.

Table 6.14-10: Residual Effects of the Project on Mi'kmaq of Nova Scotia

Project - VC Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction – Beaver Dam Mine Site and Haul Road Direct effect on archaeological resources and burial site	Ensure no Project activities occur outside of PA, education and procedures in place as part of the EPP to halt work and notify the Mi'kmaq if archaeological deposits are encountered.	N No interactions with known archaeological Mi'kmaq resources and burial sites are expected. Identified resources will be avoided	PA VC confined to the mine site	N/A This project interaction is not expected to be affected by timing	ST VC interaction will occur during construction phase	O VC interaction will occur once	IR VC remains at the end of the activity	None	Not Significant
Construction – Beaver Dam Mine Site and Haul Road Direct habitat loss, including wetlands, and loss of plants of significance to the Mi'kmaq	Minimize footprint as per Project design, implementation of mitigation and monitoring as per other VCs to minimize indirect effects, engagement and involvement of the Mi'kmaq throughout Project (including monitoring and compensation)	L Mitigation strategies and best management practices reduce the magnitude of impact	PA VC confined to the mine site	A timing is applicable and clearing and grubbing will be completed outside of the growing season wherever practicable	ST VC interaction will occur during construction phase	O VC interaction will occur once	PR VC remains at the end of the activity	Loss of plant specimens, habitat loss. Reclamation will restore some native plant species but not expected to return to baseline	Not Significant
Construction and Operations – Beaver Dam Mine Site and Haul Road Direct and indirect impacts to fish and fish habitat	Minimize footprint as per Project Design, erosion and sediment control to minimize impact, and water quality treatment, if required. Fisheries Act Authorization and Fish Habitat Offset Plan	L Mitigation strategies and best management practices reduce the magnitude of impact	PA/LAA Direct effect within PA, indirect effect within LAA	A Seasonality (spawning) windows applicable	MT VC interaction will occur during construction, operations and active reclamation	O/S Effects will be once from direct impacts, effects will be sporadic from indirect impacts	IR VC interactions are permanent	Habitat loss, change in water quality/quantity. Positive change in water quality due to historical tailings management	Not Significant
Construction and Operations – Beaver Dam Mine Site and Haul Road Indirect impacts to fauna- loss of habitat; noise and fragmentation	Minimize footprint as per Project Design, utilize existing roads wherever practicable, provision of bypass roads to maintain access.	L Mitigation and best management strategies reduce magnitude of impact	PA/LAA Direct effect within PA, indirect effect within LAA	A Seasonality (breeding windows) applicable	MT VC interaction will occur during construction, operations and active reclamation	R effects will be regular from indirect impacts	PR Traffic will reduce on roads once operations cease	Habitat loss, potential changes in species movement patterns	Not Significant
Construction and Operations – Beaver Dam Mine Site and Haul Road Predicted noise and air potential interaction with traditional practices surrounding the Project	Utilize berms and other mitigation where required to reduce noise levels to minimize indirect impact to Mi'kmaq; share noise study results and involve Mi'kmaq in data collection. Use of chemical dust suppressants on Haul Road to ensure 80% dust control.	L noise and dust levels predicted to be elevated above background but in compliance at the property boundaries,	LAA Noise will potentially affect wildlife patterns in close proximity to the Mine (LAA)	N/A This project interaction is not expected to be affected by timing	MT VC interaction will occur during construction, operations and active reclamation (2-3 yrs) phases of the Project	R VC interaction will occur at regular intervals throughout the Project	R VC interaction will recover to baseline after Project activities are completed	Sensory Disturbance	Not Significant

Table 6.14-10: Residual Effects of the Project on Mi'kmaq of Nova Scotia (continued)

Project - VC Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction and Operations – Beaver Dam Mine Site and Haul Road Predicted Light levels and potential interaction with traditional practices surrounding the Project	Maintenance of forested canopy wherever practicable within the Project property boundaries. Limit unnecessary lighting at Beaver Dam Mine Site; utilization of potential green energy options	L Light levels are predicted to meet guidelines at residences. Elevated light levels above background will be present up to 2 km from the Mine	LAA light from the Beaver Dam Mine Site is predicted to extend into the LAA	A Timing is applicable as visual effect is adjusted based on foliage on trees	MT VC interaction will occur during construction, operations and active reclamation (2-3 yrs) phases of the Project	R VC interaction will occur at regular intervals throughout the Project	R VC interaction will recover to baseline after Project activities are completed	Sensory Disturbance	Not Significant
Construction, Operations and Closure, Beaver Dam Mine Site and Haul Road Potential impact to human health from the Project	Implement mitigation and monitoring measures identified for each VC for the life of the Project as required	L Adverse health effects from dust exposure, the consumption of country foods harvested from the vicinity of the Mine Site, and recreational water use are not anticipated.	LAA This project interactions resulting in potential health effects extend into the LAA	N/A This project interaction is not expected to be affected by timing	MT VC interaction will occur during construction, operations and active reclamation (2-3 yrs) phases of the Project	R VC interaction will occur at regular intervals throughout the Project	R VC interaction will recover to baseline after Project activities are completed	Human Health	Not Significant
Construction, Operations and Closure, Beaver Dam Mine Site and Haul Road Potential impact to the economic, social and mental well being of the Mi'kmaq of Nova Scotia from the Project	Continue discussions with the Mi'kmaq to determine appropriate mitigation and compensation requirements, where appropriate. Proposed multi-use bypass road. Potentially suitable alternative tracts of Crown land are available surrounding the Beaver Dam Mine Site and Haul Road. Mi'kmaq participation in monitoring programs and development of Reclamation and Closure Plan for the Project.	L	LAA	A	MT VC interaction will occur during construction, operations and active reclamation (2-3 yrs) phases of the Project	C	PR	Change in economic, social and mental well being of the Mi'kmaq of Nova Scotia	Not Significant
Construction, Operations and Closure – Beaver Dam Mine Site and Haul Road Restriction and loss of access for traditional practice during construction, operations and active reclamation of the Mine	Continue discussions with the Mi'kmaq to determine appropriate mitigation and compensation requirements, where appropriate. Proposed multi-use bypass road. Potentially suitable alternative tracts of crown land are available surrounding the Beaver Dam Mine Site and Haul Road	L Mitigation strategies and best management practices reduce the magnitude of impact	LAA Access restriction is confined to PA; hunting effects may be felt within LAA due to sensory disturbance and/or firearm restrictions	N/A This project interaction is not expected to be affected by timing	MT VC interaction will occur during construction, operations and active reclamation (2-3 yrs) phases of the Project	R VC interaction will occur regularly	R VC returns to baseline conditions at the end of the activity	Loss of Access	Not Significant

Table 6.14-10: Residual Effects of the Project on Mi'kmaq of Nova Scotia (continued)

Project - VC Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction, Operations and Closure – Beaver Dam Mine Site and Haul Road Development of Project	Continue confidential discussions with the Mi'kmaq of Nova Scotia (parallel to the federal environmental assessment) to identify employment, community and economic benefits.	L Considerable and tangible opportunities for Mi'kmaq communities	RAA Opportunities can be considered across the RAA	N/A This project interaction is not expected to be affected by timing	MT to LT Opportunities will extend past operational period into reclamation and post closure.	C There are continuous opportunities throughout all project phases.	R VC returns to baseline conditions at the end of the activity	Benefits to the Mi'kmaq of Nova Scotia	Not Significant

Notes: See Section 5.11, Table 5.11-1 for definitions of the below characteristics.

Magnitude		Geographic Extent			Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area		N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment	Area	A	Applicable	MT	Medium-Term	S	Sporadic	IR	Irreversible
M	Moderate	RAA	Regional Assessment	Area			LT	Long-Term	R	Regular	PR	Partially Reversible
H	High						P	Permanent	C	Continuous		

A significant adverse environmental effect for the Mi'kmaq of Nova Scotia has not been predicted for the Project for the following reasons, with consideration of the ecological and social context of the LAA surrounding the Project:

During Construction:

- Direct impacts to terrestrial habitat, flora and fish habitat will be minimized through on-going Project design and micro-sighting of infrastructure footprints, where practicable.
- Construction work and methods will be considerate of fish spawning timing windows and the breeding bird season.
- Construction noise and light will be limited and temporary in nature with an approximate 12 month duration.
- Changes to access for the Mi'kmaq of Nova Scotia to the Beaver Dam Mine Site and Haul Road will be evaluated through on-going dialogue between individual Mi'kmaq communities and AMNS as part of broader impact benefits and compensation discussions. A multi-use bypass access route has been planned to allow access to areas surrounding the Haul Road and north of the Beaver Dam Mine Site. There are available possible alternative suitable areas with the potential to support for the continuation of traditional practices (equivalent sized tracts of crown land).

During Operations:

- Noise and air concentrations will be elevated above regulatory criteria only within the proposed property boundaries, and elevated above background near the Beaver Dam Mine Site and Haul Road during this period. The likelihood of mobile receptors being regularly in close proximity to noise generation sites is low. A potential Indirect Wildlife Environmental Effects Zone and an Indirect Limited Firearms Zone has been described, and mitigation measures for the effect to Mi'kmaq hunters with a potential change in hunting patterns within these zones have been proposed through the construction of a multi-use bypass road and potential suitable alternative areas with the potential for the continuation of traditional practices.
- It is considered unlikely that ore dust deposition from the Beaver Dam Mine Site and Haul Road at the rates considered in this assessment would result in levels of metals in country foods, soils and dust that would be harmful to human health, based on the risk assessment conducted. Adverse health effects from soil and dust exposure, the consumption of country foods harvested from the vicinity of the Beaver Dam Mine Site and Haul Road, and recreational water use (i.e., swimming) are not anticipated.
- Changes to access for the Mi'kmaq of Nova Scotia will be evaluated through on-going dialogue between individual Mi'kmaq communities and AMNS as part of broader impact benefits and compensation discussions. There are available possible alternative suitable areas for the continuation of traditional practices (equivalent sized tracts of Crown land).

During Active Closure:

- Noise will be elevated above baseline during active closure (i.e., 2 years) involving mobile equipment and then lower to baseline levels during the post-closure period. During post-closure, pit refilling, water treatment, if required, and associated monitoring will be on-going. However, Mi'kmaq access to the site is anticipated to be restored during post closure.
- Changes to access for the Mi'kmaq of Nova Scotia will be evaluated through on-going engagement between individual Mi'kmaq communities and AMNS as part of broader impact benefits and compensation discussions. There are available possible alternative suitable areas with the potential to support of the continuation of traditional practices (equivalent sized tracts of crown land).

6.14.10 Proposed Compliance and Effects Monitoring Program

AMNS commits to providing the opportunity for Mi'kmaq participation in community-based monitoring programs and development of the Reclamation and Closure Plan. As the Project moves forward, discussions will continue with the Mi'kmaq of Nova Scotia regarding participation opportunity in the development, implementation and evaluation of proposed compliance and effects monitoring programs. These could include monitoring programs such as:

- Wetland Monitoring;
- Wildlife Monitoring, including Moose; and
- Other monitoring programs such for air, surface water, groundwater, and noise.

In addition, AMNS will hold periodic meetings with the Mi'kmaq of Nova Scotia, including Millbrook and Sipekne'katik First Nations, to review overall environmental compliance and effects monitoring programs associated with other VCs, and provide data and results of monitoring programs. On-going dialogue will continue with the Mi'kmaq of Nova Scotia regarding participation in, and implementation of, monitoring programs for the Project.

The effects monitoring program will verify the effectiveness of mitigation measures associated with minimizing any potential effects to human health from consumption of or contact with country foods, water and soils, and results will be shared with local Indigenous groups.

6.15 Physical and Cultural Heritage

6.15.1 Introduction

6.15.1.1 Summary of Physical and Cultural Heritage Before the Updates

Baseline archaeological screening and reconnaissance confirmed presence of eight Sites and five Areas with elevated potential for encountering archaeological resources, including historic Euro-Canadian and Mi'kmaq resources. Many Euro-Canadian resource were identified as twentieth century artifacts from historic mining and industrial activities in the area. The Haul Road, as specified at the time of 2015 site reconnaissance and including the proposed new section of road, was cleared of any requirement for further archaeological investigation.

The previous infrastructure footprint of the Beaver Dam Mine Site impacted archaeological Site 6, as a result of mine road construction. Site 6 exhibits elevated potential for encountering historic Euro-Canadian archaeological resources from the early 1900s. The features at this site were noted to be twentieth century historical mining features only. Mitigations for the potentially impacted sites/areas were recommended by the CRM Group and accepted by Nova Scotia Communities, Culture and Heritage. As a result of mitigations and detailed design planning, the predicted residual environmental effects of Project development and production on physical and cultural heritage are assessed to be adverse (low), but not significant.

6.15.1.2 Summary of Updates to Physical and Cultural Heritage

As a result of PA modifications and continued infrastructure micro-siting since the 2019 EIS submission, additional archaeological screening and reconnaissance were conducted in 2019 in the western and southeastern Beaver Dam Mine Site expansions. Two areas, Areas 4 and 5, were identified that had elevated potential for encountering Mi'kmaw archaeological resources. Neither will be impacted by Project development. Previously identified Areas 2 and 3 will be impacted by a topsoil stockpile and open pit. These areas are noted to exhibit elevated potential for encountering Pre-contact and/or early historic Mi'kmaq archaeological resources.

The current infrastructure footprint of the Beaver Dam Mine Site will impact archaeological Site 6, Area 2 and Area 3. Additional shovel testing was completed within these locations in fall 2020 to assess the presence of historic and Mi'kmaq archaeological resources prior to development. Eleven positive shovel test was encountered, one within Area 2 and 10 within Site 6, all with material recovered dating from the late 19th to early 20th centuries associated with historic structures, geotechnical testing, and the continued development of road infrastructure. Additionally, field reconnaissance of a newly proposed topsoil storage pile (TSSP) location, immediately southeast of Site 6, within 100 m of the north side of Crusher Lake, was also conducted in fall 2020.

Site 6, Area 2, Area 3 and the remainder of the Beaver Dam Mine Site and Haul Road is recommended to be cleared for any further archaeological investigation. As a result, Project effects remain not significant.

Table 6.15-1: Updated Subsections from the 2019 Revised Environmental Impact Statement – Physical and Cultural Heritage

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
-	-	6.15.1 Introduction	• new
6.15.1 Rationale for Valued Component Selection	No	6.15.2 Rationale for Valued Component Selection	-
6.15.2 Baseline Program Methodology	Yes	6.15.3 Baseline Program Methodology	• Addition of 2019 field surveys. • Additional survey areas as a result of PA modification for infrastructure micro-sitting.
6.15.3 Baseline Conditions	Yes	6.15.4 Baseline Conditions	• Present results from 2019 archaeological assessment. Addition of Table 6.15-2 summarizing archaeological sites/areas. • Additional survey areas as a result of PA modification for infrastructure micro-sitting.
6.15.4 Consideration of Consultation and Engagement Results	No	6.15.5 Consideration of Engagement Results	-
6.15.5 Effects Assessment Methodology – **Boundaries**	Yes	6.15.6 Effects Assessment Methodology – **Boundaries**	• Adjusted PA description. • PA modification for infrastructure micro-sitting.
6.15.5 Effects Assessment Methodology – **Thresholds for Determination of Significance**	Yes	6.15.6 Effects Assessment Methodology – **Thresholds for Determination of Significance**	• Updated significance threshold and magnitude assessment. • Reflect changes in VC baseline conditions and improve significance assessment criteria. • Response to IR2 CEAA 2-02.
6.15.6 Project Activities and Physical and Cultural Heritage Interactions and Effects	Yes	6.15.7 Project Activities/Interactions with Physical and Cultural Heritage	• Updated based on archaeological assessment results and changes to baseline conditions. Changes to project timelines. • Reflect changes in VC baseline conditions and updates to project infrastructure and operations.
6.15.7 Preferred Alternative Haul Road	Yes	Section removed	• The Preferred Alternative Haul Road is no longer being considered and has been removed from the Project Description.
6.15.8 Mitigation and Monitoring	Yes	6.15.8 Mitigation	• Updated based on archaeological assessment results and changes to baseline conditions. • Reflect changes in VC baseline conditions and updates to project infrastructure and operations.
6.15.9 Residual Effects and Significance	Yes	6.15.9 Residual Effects and Significance	• Updated based on field survey results and changes to significance threshold determination. • Change to magnitude determination • Reflect changes to significance threshold and magnitude assessment.
6.15.10 Proposed Compliance and Effects Monitoring Program	No	6.15.10 Proposed Compliance and Effects Monitoring Program	• Updates to reporting and Mi'kmaq engagement commitments. • Bolster Mi'kmaq engagement.

Notes: PA = Project Area; LAA = Local Assessment Area; RAA = Regional Assessment Area- = no update; IR2 = Round 2, Information Requests; CEAA = Canadian Environmental Assessment Agency; EIS = environmental impact statement.

6.15.2 Rationale for Valued Component Selection

Physical and cultural heritage are provincially regulated through the *Special Places Act*, which supports the preservation, regulation, and study of archaeological, historical, and paleontological sites and artifacts remains deemed to be important parts of Nova Scotia's natural or cultural heritage. The areas historical importance for post-Contact land use and recreational value are important considerations for the mine development.

6.15.3 Baseline Program Methodology

In 2008, Cultural Resource Management Group (CRM Group), undertook an archaeological screening and reconnaissance program at the Beaver Dam Mine Site on behalf of Acadian Mining. At that time, a surface mine was in early-stage planning as well as associated mine features including a crusher, a settling pond, stockpiles of overburden and product, and service roads.

In 2014, CRM Group was retained on behalf of AMNS to conduct archaeological screening and reconnaissance at the Beaver Dam Mine Site using the current site development plan. Building upon the research and reconnaissance undertaken on the property in 2008, CRM Group revisited several of the sites previously noted, as well as identified other features related to previous site activities (sawmill and possible cookhouse sites). The 2014 archaeological screening and reconnaissance consisted of a visual inspection of the ground surface and did not involve sub-surface testing. As part of the 2014 archaeological assessment, an archaeological screening was completed prior to site reconnaissance. CRM Group reviewed documents available through the Nova Scotia Archives, the Department of Natural Resources and Crown Land Information Management Centre. The screening included a review of land grant records, legal survey, historical maps, local and regional histories, topographic maps, and aerial photos.

In 2015, CRM Group was retained on behalf of AMNS to conduct additional archaeological reconnaissance. Changes to the layout of the proposed facility led to additional archaeological reconnaissance being undertaken in the summer of 2015. Previously investigated mine features that were proposed, such as the WRSP and the crusher site had been reconfigured. Two till piles, two ore piles, two settling ponds, and the ROM/crusher/service pad site were added to the Project. The reconnaissance was focused within the pit, the waste rock stockpile, the till piles, the ore piles, the settling ponds, and the ROM/crusher/service pad site.

CRM Group was also retained in 2015 to complete archaeological reconnaissance of the proposed Haul Road where upgrades to the existing road will be conducted. The focus of the reconnaissance was on Beaver Dam Mines Road and Moose River Cross Road (so-called), which are portions of the proposed Haul Road that require upgrades to allow for truck travel. The water crossings exhibited the highest potential in the background research and were the focus of the reconnaissance. In 2016, CRM Group completed archaeological reconnaissance of a proposed 4.0 km new section of the Haul Road, located west of Hwy 224 (Section 2, Figure 2.3-2).

In 2018, the PA was modified to allow for the micro-siting of infrastructure. CRM Group was retained to conduct an additional archaeological screening and reconnaissance of the western waste rock stockpile (western extent of the Beaver Dam Mine Site), which was to be located on the west side of Crusher Lake.

In 2019, the PA was again modified, as described in Section 2. As a result, CRM Group was retained to undertake additional archaeological screening and reconnaissance of the Beaver Dam Mine Site within the western NAG waste rock stockpile expansion and the southeastern organic materials stockpile expansion.

The 2015, 2016, 2018, and 2019 archaeological reconnaissance for the Beaver Dam Mine Site and Haul Road consisted of a visual inspection of the ground surface and did not involve sub-surface testing. Although the initial ground search did not involve

sub-surface testing, the investigators were watchful for topographic or vegetative anomalies that might indicate the presence of buried archaeological resources. Subsequent shovel tests were completed in fall 2020 in noted archeological areas where development is proposed: Site 6, Area 2 and Area 3. A total of 310 shovel tests were excavated. Additionally, field reconnaissance of a newly proposed topsoil storage pile (TSSP) location, immediately southeast of Site 6, within 100 m of the north side of Crusher Lake, was also conducted in fall 2020.

The Touquoy Mine Site was previously subjected to archaeological reconnaissance in November 2006. No additional disturbances are anticipated at the Touquoy Mine Site as a result of the Beaver Dam Mine Project and therefore no additional work was completed.

The archaeological reports are included in Appendix N.1 to N.7.

6.15.4 Baseline Conditions

Updates to physical and cultural heritage baseline conditions reflected within this section are as a result of additional surveys required by changes to the PA in order to incorporate the micro-siting of Project infrastructure.

6.15.4.1 Beaver Dam Mine Site

Site reconnaissance in 2008, completed as part of the archaeological assessment, noted 6 features, of which Sites 1 to 5 were within close proximity to Crusher Lake. Site 6 was located northwest of the lake. Two areas along the Cameron Flowage were identified as being high potential for pre-European contact resources (Areas 2 and 3 as presented in Appendix N.6). In addition to these features and high potential areas, numerous industrial features were identified along the northern shore of Crusher Lake. CRM Group recommended that the features and the high potential areas be subject to shovel testing and the industrial features subject to detailed documentation if any of them fell within areas of future development.

An archaeological screening was undertaken at the Beaver Dam Mine Site in 2014 that identified that the land within the study area was historically part of the greater Mi'kmaq territory known as *Eskikewa'kik,* meaning 'skin dressers territory'. The Maritime Archaeological Resource Inventory does not identify any registered archaeological sites within the study area. However, the lack of archaeological data may represent a lack of archaeological investigation and not an absence of archaeological sites. The Beaver Dam Mine Site property was historically developed for industrial use since the late-1800s. Aerial photographs from 1982 and 1992 indicate that the mine underwent a significant amount of development during this time period. This development likely destroyed any features that may have been present in the area.

Archaeological screening conducted in 2014 identified that, based on the environmental setting and Indigenous Peoples land use, as well as the Property's long history of industrial use, the Beaver Dam Mine Site exhibits high potential for encountering Pre-contact and historic Indigenous Peoples archaeological resources and high potential for encountering historic Euro-Canadian archaeological resources.

Based on the field reconnaissance completed as part of the 2014 archaeological assessment, historic features that had been identified in the Beaver Dam Mine Site footprint were determined to have been destroyed, likely by mining activities previously undertaken on the site during the 1980s.

CRM Group recommended that any development around the features identified during the 2008 or 2014 reconnaissance would require shovel testing and intensified historical research. In addition, any development around Crusher Lake should be subjected

to intensified reconnaissance (i.e., shovel testing). The pit and waste rock stockpile study areas, as they were oriented at the time of reconnaissance in 2014, were cleared of any requirement for further archaeological investigation.

The additional archaeological screening and reconnaissance within the Beaver Dam Mine Site in 2015 determined that one historic feature (Feature 5, Cookhouse) was identified within the then proposed Till Pile 2 study area and Feature 4 (Mill) were in proximity to the mine activities. Subsequent adjustments of the mine layout put these features within an access road to the western waste rock stockpile. No archaeological features or areas of archaeological potential were identified within any of the other study areas, either during the background or field reconnaissance. It was recommended that either a program of shovel testing be conducted around the possible cookhouse (Feature 5) prior to disturbance or a buffer of 20 m be put in place around the feature to protect it from any mining activities. No further archaeological work is required for the rest of the Till Pile 2 study area. CRM Group recommended that any development around the features identified in 2008 and/or 2014 would require shovel testing and intensified historical research in advance of disturbance. Other areas, as they were oriented at the time of reconnaissance in 2015, were cleared of any requirement for further archaeological investigation.

Further archaeological screening and reconnaissance in 2018 of the western waste rock stockpile concluded that there were two sites/areas that had elevated potential for encountering archaeological resources: Site 6, a historic cabin as described in the 2008 archaeological assessment, located on the eastern side of a logging road that runs through the western portion of the study area, exhibited elevated potential for encountering archaeological resources related to the historic Beaver Dam Gold District, and Area 1, located approximately 25 m north of Crusher Lake, ascribed elevated potential for encountering Mi'kmaw archaeological resources. Site 6 was revisited and investigated further in 2018. This site has the potential to be impacted by construction of the access road leading to the western waste rock stockpile. CRM Group recommended that an intensified reconnaissance be conducted if any development is set to occur within 100 m of Crusher Lake. It was also recommended that shovel testing be conducted in advance of any disturbance in the proximity of Site 6 or Area 1, or if development is set to occur around any historic feature identified in the 2008 and 2014 reconnaissance. The remainder of the western waste rock stockpile study area, as it was oriented at the time of reconnaissance in 2018, is recommended to be cleared for any further archaeological investigation.

Additional archaeological screening and reconnaissance in 2019 of the western and southeastern Beaver Dam Mine Site expansions identified two areas, Areas 4 and 5, that had elevated potential for encountering Mi'kmaw archaeological resources. Both areas are within the southeastern expansion study area and exhibit elevated potential for Pre-contact and/or early historic Mi'kmaw archeological resources. Areas 4 and 5 are located on level, elevated plateaus on the western side of the Killag River, measuring approximately 20 x 10 m and 20 x 20 m, respectively. No sites/areas of elevated archaeological resource potential were identified within the western expansion study area. If any development is to occur within Areas 4 or 5, CRM Group recommends that shovel testing be conducted in advance of any disturbance. These areas are currently outside the PA and will therefore be avoided. As such, it is recommended that the western and southeastern expansion areas be cleared of any requirements for further archaeological investigation.

Additional archaeological investigations and shovel testing was completed within Site 6, Area 2 and Area 3 in fall 2020. Eleven positive shovel test was encountered, one within Area 2 and 10 within Site 6, all with material recovered dating from the late 19th to early 20th centuries associated with historic structures, geotechnical testing, and the continued development of road infrastructure. No positive shovel tests were encountered in Area 3. No Pre-contact Mi'kmaq archaeological resources were encountered during shovel tests. In conjunction with the 2020 shovel testing program, the newly proposed TSSP impact area, southeast of Site 6, was subject to field reconnaissance. Given the rocky, wet, and sloped nature of the terrain encountered during field reconnaissance, as well as disturbance resulting from forestry and mining activities, the proposed TSSP impact area is ascribed low potential for encountering Pre-contact and early historic Mi'kmaw archaeological resources and historic Euro-Canadian archaeological resources.

A summary of all archaeological sites/areas identified within Beaver Dam Mine Site, during all assessment years, is presented in Table 6.15-2.

Table 6.15-2: Details of Archeological Resources Identified during Field Reconnaissance at the Beaver Dam Mine Site

Site ID	Site Description
Site 1	A collapsed wooden structure revealed the remains of a log cabin, 40 m north of Crusher Lake. Based on the observed artifacts, it is possible that Site 1 represents the remains of a twentieth century structure.
Site 2	Potential remains of a partially in-filled cellar, 20 m southeast of Site 1. No visible structural remains.
Site 3	Depression features of potentially in-filled cellar, 30 m east of Site 2.
Site 4	A small, partially collapsed wooden structure, 70 m southeast of Site 3. Visual examination suggests the feature may represent the remains of a twentieth century outhouse.
Site 5	Potential remains of a moss-covered foundation, 10 m north of Crusher Lake. The feature may be related to mineral exploration and/or extraction activities.
Site 6	Two depressions east of a logging road that runs west of Crusher Lake. The features are identified as having moderate to high potential for historic Euro-Canadian archaeological resources. The area is identified as "Forge Hill". Additional shovel tests completed Fall 2020. Ten positive shovel tests encountered late 19th to early 20th century materials.
Site 7	Remains of a mill, 14 m east of an unnamed stream and north of the mine road north of Crusher Lake. The mill Is identified on a historic map (1928) and is estimated to have been built in 1904.
Site 8	A possible cookhouse is indicated on a historic map (1928), on the north side of the mine road north of Crusher Lake. No structural remains were encountered, but a sight depression and iron pot were observed.
Area 1	A level, elevated plateau north of Crusher Lake identified as having elevated potential for historic Mi'kmaw archeological resources.
Areas 2 & 3	Level, elevated plateaus on the western side of the Cameron Flowage identified as having elevated potential for historic Mi'kmaw archeological resources. Additional shovel tests completed Fall 2020. One positive shovel test in Area 2 encountered late 19th to early 20th century materials.
Areas 4 & 5	Level, elevated plateaus on the western side of the Killag River identified as having elevated potential for historic Mi'kmaw archeological resources.

6.15.4.2 Haul Road

An archaeological screening and reconnaissance conducted for the Haul Road in 2015 and 2016 identified that water crossings along the Haul Road, in particular the West River Sheet Harbour, would have been important transportation corridors for the Mi'kmaq and their ancestors prior to the arrival of European settlers. Faribault (1898) depicts several features in the vicinity of the Haul Road. This includes a camp within three kilometres of the alignment of the Haul Road and several dams located in the vicinity of Moose River Cross Road. Although no other features were depicted, dams would suggest further activity not noted on the Faribault map. Several houses and a Mi'kmaq community (Beaver Lake IR 17) are located adjacent to what is now Hwy 224. The section of the Haul Road along Mooseland Road passes two camps, several structures noted as "Icelanders huts", and a dam at the south end of Cope Lake. The review of Faribault indicates there was heavy activity in the area and that many of the modern road alignments follow closely to the historic alignments. The Maritime Archaeological Resource Inventory does not identify any registered archaeological sites within the study area. However, the lack of archaeological data may represent a lack of archaeological investigation and not an absence of archaeological sites.

During the 2015 and 2016 field reconnaissance, water crossings exhibited the highest potential in the background research and were the focus of the field investigations. The field reconnaissance did not identify any areas along the Haul Road that were ascribed high archaeological potential.

Based on the recommendations of the 2015 and 2016 archaeological reconnaissance, the alignment of the Haul Road, as specified at the time of 2015 site reconnaissance and including the proposed new section of road (Section 2, Figure 2.3-2), was cleared of any requirement for further archaeological investigation.

The current Haul Road alignment has been captured under the existing archaeological screening and reconnaissance programs.

6.15.4.3 Touquoy Mine Site

The entire Touquoy Mine Site was previously subjected to archaeological reconnaissance in November 2006. An archaeological screening was conducted by CRM Group to evaluate the archaeological potential within the proposed Touquoy development limits. The results of the study indicated that there is a low archaeological potential ascribed to the area. No additional disturbances are anticipated at the Touquoy site as a result of the Beaver Dam Mine Project.

6.15.5 Consideration of Engagement Results

Issues raised during public and Mi'kmaq engagement relating to physical and cultural heritage include potential disturbance of pre- and post-European contact archaeological resources.

The results of the public and Mi'kmaq engagement have been considered in the environmental effects assessment, including the AMNS's commitments on mitigation and monitoring measures and proposed compliance and effects monitoring programs, as well as the AMNS's broader commitment to ongoing public and Mi'kmaq engagement. Specific to evaluating the effect on physical and cultural heritage, these are found within the following environmental effects assessment.

6.15.6 Effects Assessment Methodology

6.15.6.1 Boundaries

6.15.6.1.1 Spatial Boundaries

The spatial boundaries used for the assessment of Project effects to physical and cultural heritage is the PA, as defined below.

The PA encompasses three primary components from Marinette to Moose River Gold Mines, Halifax County, NS. The Beaver Dam Mine Site will be located at the end of the Beaver Dam Mines Road and the Haul Road will span from the Beaver Dam Mine Site to Moose River Gold Mines, where the Touquoy Mine Site [processing and exhausted pit (to be used to dispose Beaver Dam tailings)] is located. The PA was modified in 2019 as a result of the expansion of the Beaver Dam Mine Site and ongoing modifications to the Haul Road design, as described in Section 2. These changes have been captured under the existing and additional archaeological screening and reconnaissance programs.

There is no LAA or RAA for physical and cultural heritage, as the loss or destruction of heritage or archaeological resources could occur only within the disturbed footprint of the Project (Section 5.5, Figure 5.5-1).

6.15.6.1.2 Temporal Boundaries

The temporal boundaries used for the assessment of effects to physical and cultural heritage are limited to the construction phase of the Project. Construction is estimated to take approximately one year.

6.15.6.1.3 Technical Boundaries

No technical boundaries were identified for the effects assessment of physical and cultural heritage.

6.15.6.1.4 Administrative Boundaries

Physical and cultural heritage are provincially regulated through the *Special Places Act*. In order to conduct any archaeological work, a Heritage Research Permit must be issued by the Minister of the Department of Communities, Culture, and Heritage.

6.15.6.2 Thresholds for Determination of Significance

A significant adverse effect is an uncontrolled (without appropriate study, analysis and mitigation measures in conjunction with the Province and Mi'kmaq archaeologists as required) disturbance to, or destruction of, any unassessed historical or cultural resource of importance in context of the *Special Places Act*. The assessment of historical or cultural features is considered complete when the feature has undergone intensified historical research involving archeological shovel testing, where required, surveyed plans, photography and videography.

For physical and cultural heritage, the following logic was applied to assess the magnitude of a predicted change in baseline documented conditions at the Beaver Dam Mine Site and Haul Road:

- Negligible – no direct or indirect impacts are expected to identified archaeological features
- Low – impacts are expected to historical mining feature(s) only, with consideration of all mitigation and in consultation with appropriate regulatory and Mi'kmaq agencies. No direct or indirect impacts to Mi'kmaq archaeological features are expected.
- Moderate – direct impacts to Mi'kmaq and/or other archaeological features are expected, with consideration of all mitigation and in consultation with appropriate regulatory and Mi'kmaq agencies.
- High – direct impacts to Mi'kmaq and other archaeological features are expected, without consideration of all mitigation and without consultation with appropriate regulatory and Mi'kmaq agencies.

6.15.7 Project Activities/Interactions with Physical and Cultural Heritage

Potential interactions between Project activities and physical and cultural heritage resources are outlined in Table 6.15-3 and 6.15-4 below.

Table 6.15-3: Potential Project Activities/Interactions with Physical and Cultural Heritage at Beaver Dam Mine Site

Project Phase	Duration	Project Interaction
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Drilling and rock blasting in preparation of construction • Topsoil, till and waste rock transport and storage from site preparation • Watercourse and wetland alteration • Mine Site road construction and maintenance • Site infrastructure installation and construction • Settling pond construction
Operation	5 years	• Adjustment of site infrastructure • Continued potential interaction with areas of elevated archaeological resource potential
Active Closure	2 years	• N/A
Post-closure	10+ years (monitoring)	• N/A

Note: N/A = not applicable.

Table 6.15-4: Potential Project Activities/Interactions with Physical and Cultural Heritage along Haul Road

Project Phase	Duration	Project Interaction
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of construction • Till and waste rock from site preparation transport and storage • Watercourse and wetland alteration in preparation of construction • Haul road construction and upgrades
Operation	5 years	• Adjustment of site infrastructure • Continued potential interaction with areas of elevated archaeological resource potential
Active Closure	2 years	• N/A[(a)]
Post-closure	10+ years (monitoring)	• N/A[(a)]

Note: [(a)] Decommissioning and Reclamation of the Haul Road is not expected. The Haul Road will be returned to owner for forestry Industry. N/A = not applicable.

There is low potential for the Project to interact with identified heritage resources that have been associated with historic mining at or near the Project site. The Project will endeavor to avoid the areas identified above.

The current infrastructure footprint of the Beaver Dam Mine Site will impact archaeological Site 6, Area 2 and Area 3, originally identified in 2008 and presented in subsequent archeological reports (Appendix N.1 to N.7). The identified archaeological features around Crusher Lake (Site 1-5, Site 7, Site 8 and Area 1, as presented in Appendix N.6 are not anticipated to be impacted by the current infrastructure footprint. A ditch is planned within 100 m of the western side of Crusher Lake. While no archeological features were found in this area, intensified reconnaissance (shovel testing) will be undertaken if the ditch cannot be micro-sited further away from Crusher Lake. As planned, Site 6 will be impacted by the access road to the western NAG waste rock stockpile, Area 2 will be impacted by a topsoil stockpile north of the pit, and Area 3 will be impacted by the pit and an adjacent access road. The CRM Group assessments indicate that Site 6 exhibits elevated potential for encountering historic Euro-Canadian archaeological resources from the early 1900s. Areas 2 and 3 are noted to exhibit elevated potential for encountering Pre-contact and/or early historic Mi'kmaq archaeological resources, however, the original shoreline has been altered by the created of Cameron Flowage and no resources were discovered during the assessments to date. Additional shovel tests were completed in these areas in Fall 2020 to assess for presence of Mi'kmaq archaeological resources prior to development. Of the 11 positive shovel tests were

encountered, one within Area 2 and 10 within Site 6, all material recovered dates from the late 19th to early 20th centuries, associated with historic structures, geotechnical testing, and the continued development of road infrastructure. No Pre-contact Mi'kmaq archaeological resources were encountered during shovel tests.

Mitigations for the potentially impacted sites/areas are presented in Section 6.15.8 and were recommended by the CRM Group and accepted by Nova Scotia Communities, Culture and Heritage.

There have been no identified archaeological sites/areas along the current Haul Road alignment.

If areas of known heritage resources are to be impacted, further work will be undertaken to document these resources. If heritage resources are identified during construction of the mine, then all work will stop in the immediate vicinity until said resources can be further studied. The potential for heritage resources to be impacted exists primarily during the construction phase of the Project.

There is no potential for the disturbance of cultural or physical heritage resources during the operational and reclamation phases of the Project based on studies to date.

There are no known federal decisions that could affect physical and cultural heritage in the PA, or that could affect structures, sites, or items of historical, archaeological, paleontological, or architectural significance of non-Indigenous peoples.

6.15.7.1 Touquoy Mine Site

The Touquoy Mine Site is currently operational. There are no effects to physical and cultural heritage anticipated to be caused by the processing of ore and the management of tailings (exhausted pit) from the Beaver Dam Mine Site. Effects to physical and cultural heritage at the Touquoy Mine Site were only anticipated to potentially occur during the initial construction phase, which is complete. No additional cultural resources were encountered during the Touquoy Mine Site development and all activities related to continued ore processing and tailings management will occur within the existing disturbed footprint.

6.15.8 Mitigation

Mitigation for physical and cultural heritage at the Beaver Dam Mine Site and the Haul Road are described below. Mitigation measures and monitoring programs at the Touquoy Mine Site are anticipated to be completed during the construction and site preparation phase and will not be applicable for the Beaver Dam Mine Project.

Based on the current Beaver Dam Mine Site infrastructure footprint and Haul Road alignment, archaeological Site 6, Area 2 and Area 3 are the only identified sites/areas anticipated to be impacted by the Project. All materials encountered date from the late 19th to early 20th centuries. No Pre-contact Mi'kmaq archaeological resources were encountered during shovel tests.

The 2014, 2015, 2016, 2018, 2019 and 2021 archaeological reports recommend that the Project, as it is currently orientated, be cleared of any requirement for further archaeological investigation. Based on these archaeological assessments, the mitigation measures presented in Table 6.15-5 were recommended by CRM Group and accepted by Nova Scotia Communities, Culture and Heritage. The archaeological investigations included a background study with Mi'kmaw engagement.

A comprehensive mitigation table for all VCs is provided in Section 9.

Table 6.15-5: Mitigation for Physical and Cultural Heritage

Project Phase	Mitigation Measures
Construction	A program of archaeological shovel testing was conducted in fall 2020, in advance of any disturbance to Site 6, Areas 2 and 3. CRM Group cleared these areas of any requirement for further archaeological investigation
	If any development is to occur within 100 metres of Crusher Lake, intensified reconnaissance (i.e., shovel testing) should be conducted to identify any additional features.
	If any development is to occur specifically around the historic features identified during the 2014, 2015, 2016, 2018 and 2019 reconnaissance, intensified historical research and archaeological shovel testing should be conducted in advance of disturbance.
	Any further changes in the layout of the mine and associated facilities be evaluated as to potential impacts to archaeological resources.
	In the event that archaeological resources or human remains are encountered during ground disturbance activities, it is required that all activity stop, and the Coordinator of Special Places, Nova Scotia Communities, Culture, & Heritage Department be contacted.
Operation	In the event that archaeological resources or human remains are encountered during ground disturbance activities, it is required that all activity stop, and the Coordinator of Special Places, Nova Scotia Communities, Culture, & Heritage Department be contacted.
Active Closure	N/A
Post-Closure	N/A

6.15.9 Residual Effects and Significance

The predicted residual environmental effects of Project development and production on physical or cultural heritage resources are assessed to be adverse, but not significant. The overall residual effect of the Project on physical or cultural heritage resources is assessed as not significant after mitigation measures have been implemented and are summarized in Table 6.15-6.

A significant adverse environmental effect for physical and cultural heritage has not been predicted for the Project for the following reasons, with consideration of the ecological and social context of the PA of the Project:

- During Construction.

Although the loss of Site 6 is anticipated, appropriate mitigation and evaluation will be completed prior to construction at this location. The features at this site were noted to be twentieth century historical mining features only. Additional shovel tests were completed in these areas in fall 2020 and CRM Group recommends the area be cleared of any requirement for further archaeological investigation.

Although disturbance to Areas 2 and 3 is anticipated, appropriate mitigation and evaluation will be completed prior to construction at these locations. Additional shovel tests were completed in these areas in Fall 2020 and No Pre-contact Mi'kmaq archaeological resources were encountered. CRM Group recommends the area be cleared of any requirement for further archaeological investigation.

No impacts to any other archaeological sites/areas are predicted based on the proposed development of the Project.

The Project will work to micro-site water management infrastructure beyond 100 m from Crusher Lake as is practicable, but if not possible, intensified reconnaissance (shovel testing) will be undertaken in this area.

- Operations: No impacts are predicted based on the studies completed to date.
- During Closure: No impacts are predicted based on the studies completed to date.

Table 6.15-6: Residual Effects for Physical and Cultural Heritage

Project - VC Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction – Beaver Dam Mine Site and Haul Road (Identification and/or damage to physical and cultural heritage resources – Site 6 and Areas 2 and 3)	Evaluate changes to layout for potential impacts to archaeological resources. Complete intensified historical research, additional shovel pit testing, where required, and detailed documentation at archeological features prior to disturbance cause by Project activities, in conjunction with Mi'kmaq agencies as required. Contact Coordinator of Special Places, Nova Scotia Communities, Culture, & Heritage Department if human remains or archaeological deposits are identified.	L Site 6 will be lost due to Project activities. This site contains the remains of a twentieth century structure. Impacts to Areas 2 and 3 will be minimized where practicable. These areas underwent additional shovel tests in fall 2020 and were cleared of further investigation.	PA Effects confined to the PA.	N/A VC is not expected to be affected by timing.	P Effects are permanent.	O Effects will occur once within the life of the Project.	IR VC will not return to baseline conditions.	Loss of resource	Not significant

Notes: See Section 5.11, Table 5.11-1 for definitions of the below characteristics.

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	IR	Irreversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	PR	Partially Reversible
H	High					P	Permanent	C	Continuous		

6.15.10 Proposed Compliance and Effects Monitoring Program

As noted above, there is no determined need for compliance or effects monitoring programs related to physical and cultural heritage. In the event that archaeological resources or human remains are encountered during ground disturbance activities, it is required that all activity stop, and the Coordinator of Special Places, Nova Scotia Communities, Culture, & Heritage Department be contacted. Chance find protocols for archaeological resources will be implemented as part of the Project Environmental Protection Plan (EPP). Personnel will receive the appropriate level of EPP training to properly implement the chance find protocol.

Proposed follow up and monitoring programs have been reviewed with the Mi'kmaq of Nova Scotia during engagement efforts including meetings, sharing of technical documents (Draft EIS, poster boards, Summary of Mi'kmaq Effects and Proposed Mitigation Measures, Plain Language Summary). On-going engagement with the Mi'kmaq will continue through the EA process and associated permitting relating to follow up programs and monitoring.

6.16 Socio-economic Conditions

6.16.1 Introduction

6.16.1.1 Summary of Socio-economic Conditions Before the Updates

The proposed Beaver Dam Mine Project (the Project) 2017 Environmental Impact Statement (EIS) (AGC 2017) submission section on Socio-economic conditions found positive benefits, specifically related to potential tax revenue and jobs created, based on a study completed in 2015. Baseline assessment information was compiled pre-2017, with updates in a Revised 2019 EIS (AMNS 2019a).

6.16.1.2 Summary of Updates to Socio-economic Conditions

The updates to the socio-economic conditions in this section are based on an updated financial analysis for the Project. In addition, a major engagement effort in 2020 resulted in new information that was assessed for impact. Included in this update is an assessment of policy documents and plans, which establishes goals and objectives for both the Local Assessment Area (LAA) and Regional Assessment Area (RAA) by local, provincial, national, international, and Indigenous authorities (Figure 6.16-1). Based on the policy and plan review, and the themes identified from the 2020 engagement activities, topic areas for analysis were identified. Finally, the impact of the global pandemic on baseline conditions is also accounted for within this updated section. A summary or road map of updates specific to the sub-section in Socio-economic Conditions for the Updated 2021 EIS is provided in Table 6.16-1.

6.16.2 Rational for Valued Component Selection

Socio-economic factors can be defined as relating to or concerned with the interaction of social and economic conditions. The Project EIS Guidelines (CEAA 2016) specifically reference that the analysis should "recognize interrelationships, system functions and vulnerabilities."[1]

The Project is assessed a varying geographical scale. The Project is situated near Marinette, Nova Scotia (Figure 16.6-1) is the regional context for this assessment (RAA). Socio-economic assessments also consider impacts at the provincial scale. Each scale of geographical resolution is examined for the appropriate interactions and valued components relevant to Socio-Economics.

Themes and topic areas for the socio-economic analysis are based on best practices of the mining industry, regional and provincial strategy documents, qualitative data gathered through public and rights holder engagement, and guidance provided in the Project EIS Guidelines (CEAA 2016). Atlantic Mining NS Inc. (AMNS) policy documents, corporate commitments and values relating to socio-economic aspirations and goals also influence the themes and topic areas assessed. The analysis is informed by "Social impact assessment in the mining sector: Review and Comparison of indictor frameworks" This report identifies a list of social impacts specific to the mining sector based on a best management practices review.

[1] Source: Section 6.1.10 of the Beaver Dam Mine Project Guidelines (CEAA 2016).

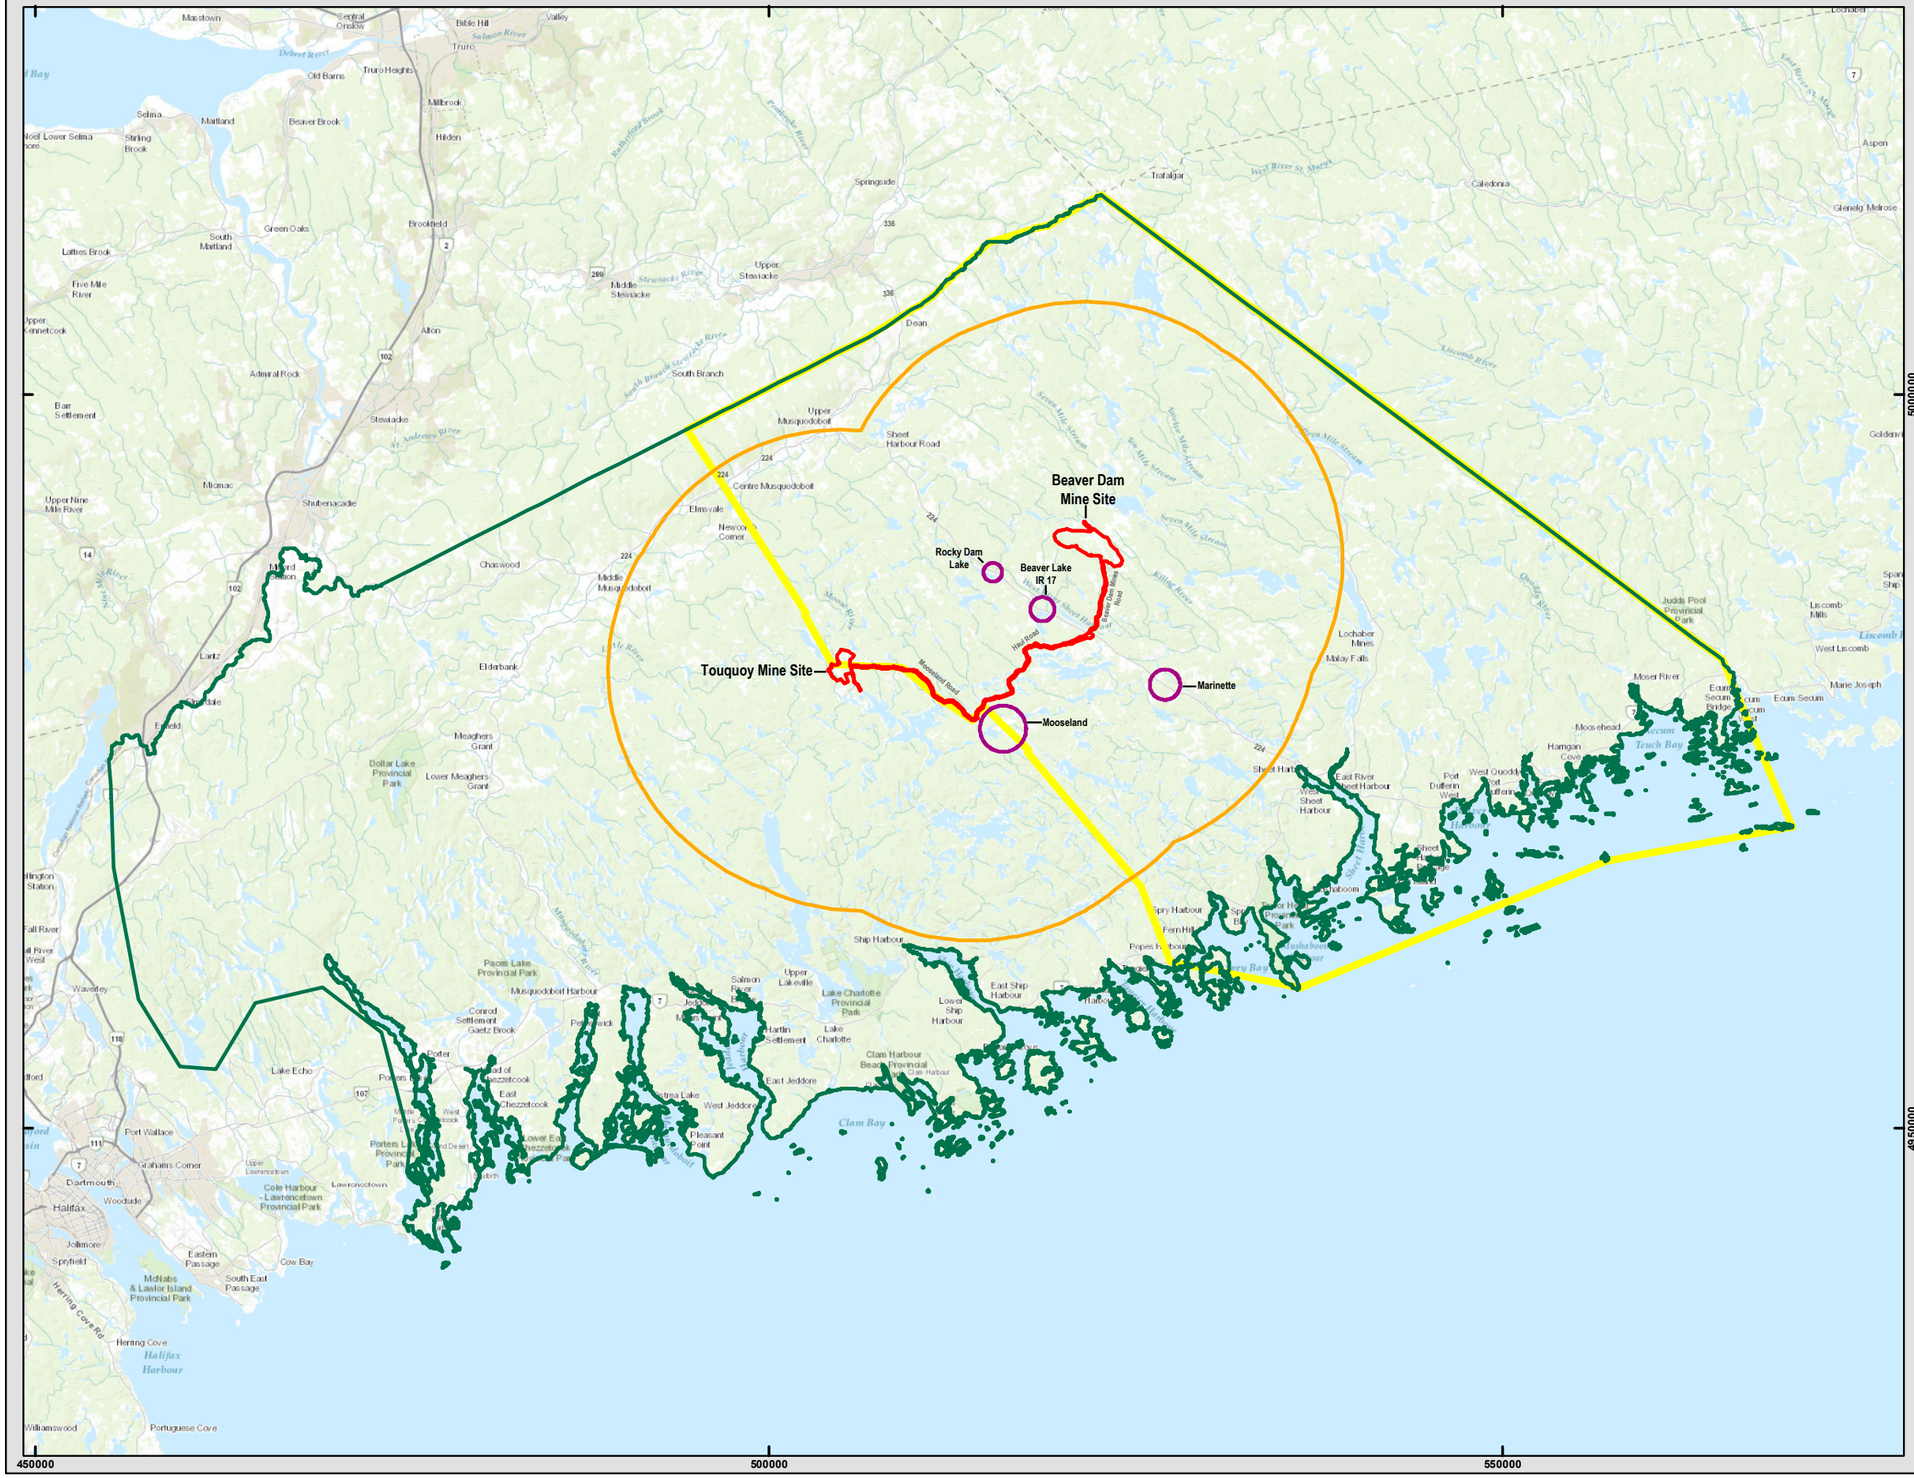

Table 6.16-1: Updated Subsections from the 2019 Revised Environmental Impact Statement – Socio-economic Conditions

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
-	-	6.16.1 Introduction	• New
6.16.1 Rationale for Valued Component Selection	No	6.16.2 Rationale for Valued Component Selection	• N/A
6.16.2 Baseline Program Methodology	Yes	6.16.3 Baseline Program Methodology	• Incorporated provincial and federal plan alignments
6.16.3 Baseline Conditions	Yes	6.16.4 Baseline Conditions	• Updated data and incorporated COVID impacts
6.16.4 Viewshed Analysis	No	6.16.5 Viewshed Analysis	• Updated viewshed analysis
6.16.5 Consideration of Consultation and Engagement Results	Yes	6.16.6 Consideration of Engagement Results	• Updated based on 2020 engagement results
6.16.6 Effects Assessment Methodology	Yes	6.16.7 Effects Assessment Methodology	• N/A
6.16.7 Project Activities and Socio-economic Interactions and Effects	Yes	6.16.8 Project Activities/Interactions with Socio-economic Conditions	• Updated to reflect changes in baseline, project elements and engagement results
6.16.8 Preferred Alternative Haul Road	Yes	Section removed	• Preferred Alternative Haul Road sections and references are removed from the EIS.
6.16.9 Mitigation and Monitoring	No	6.16.9 Mitigation	• Updated to reflect new mitigation and monitoring
6.16.10 Residual Effects and Significance	Yes	6.16.10 Residual Effects and Significance	• Updated based on new data
6.16.11 Proposed Compliance and Effects Monitoring Program	No	6.16.11 Proposed Compliance and Effects Monitoring Program	• N/A

Note: EIS = Environmental Impact Statement; N/A = not applicable; - = no update.

The aspirations, goals and directions of key organizations that influence the socio-economic conditions are used to assess the Socio-Economic Valued Components (VC). Policy documents, plans and strategic documents used in this assessment are summarized in Table 6.16-2. This table focuses on project alignment with strategic document. The Sustainable Development Goals of the United Nations are included in this table to provide best practices for the mining industry.

Effects to Indigenous Peoples from the Project are assessed in Section 6.14 Mi'kmaq of Nova Scotia. The Strategic Pillars of the Kwilmu'kw Maw-klusuaqn Negotiation Office (KMKNO) are included in the strategic documents summarized in Table 6.16-2 to understand interrelationships.

Table 6.16-2: Beaver Dam Mine Project Alignment Strategic Document Review

Strategic Document Review for Socio-Economic Valued Component	Alignment	Company Document/Initiative
Halifax Partnership		
Grow rural economic development by focusing on broadband/cellular infrastructure, tourism, resource extraction, agriculture, business retention and expansion activities.	Direct Alignment	Vision, Guiding Principles and Commitments
Develop and implement a multi-year plan to attract expatriates back to Halifax.	Direct Alignment	KPMG report regarding jobs
Work with the business community to identify and promote experiential learning opportunities for post-secondary students.	Direct Alignment	Apprenticeship Program
Identify and share existing programs, services and outcomes related to the workforce attachment of Mi'kmaq/Indigenous People, African Nova Scotians and other groups at risk of exclusion.	Direct Alignment	Commitment regarding empowered people diverse teams.
Increase people's access to the outdoors by leveraging the municipality's natural assets.	Direct Alignment	Construction of Haul Road bypass
Develop a climate strategy and implement programs and activities to support energy efficiency and the use of renewable energy in HRM.	Direct Alignment	Variety of Green Initiatives; 2020 Annual Report Page 7
One Nova Scotia		
Nova Scotia will be averaging a net gain of 1,000 working age persons per year.	Direct alignment	KPMG report regarding jobs
With the cooperation of the federal government, Nova Scotia will be receiving annually its proportionate share of all new international immigrants to Canada.	Direct Alignment	KPMG report regarding jobs
10% of foreign students stay in Nova Scotia (up from 5%).	Limited Alignment	KPMG report regarding jobs
The Nova Scotia economy will be home to 50% more high-growth start-up firms.	Direct Alignment	Suppliers' policy and KPMG Cochrane Hill Assessment
Nova Scotia will have increased the total annual value of exports (international and inter-provincial) by 50%.	Limited Alignment	KPMG report regarding benefits to Canada
The number of Nova Scotia firms participating in export trade will have increased by 50 per cent.	Limited Alignment	
Nova Scotia will have a labour force participation rate at least as high as the Canadian rate, bringing more Nova Scotians into permanent attachment to the labour market.	Direct Alignment	KPMG report regarding jobs
The employment rate for First Nations and African Nova Scotians (ANS) will be equal to the provincial average.	Direct Alignment	KPMG report regarding jobs; Diversity and Inclusion Policy; Equal Employment Opportunity Policy
Nova Scotia's youth unemployment rate will be at, or better than, the national rate in that year.	Direct Alignment	KPMG report regarding jobs
The proportion of Nova Scotia's working age population with a post-secondary certificate, diploma or degree, including apprenticeship completion, will have increased from the current 65% to 75%.	Direct Alignment	Apprenticeship Program
Through both individual initiative and expanded collaboration, and with support from government, Nova Scotia's universities and the NSCC will have doubled research funding.	Direct Alignment	Apprenticeship Program; St. Mary's University research project regarding historical tailings

The VC is socio-economic conditions, and is divided into themes, which are further broken into topics for more detailed analysis During the detailed review of the policy documents and plans impacting the LAA and RAA and comments and feedback from the public; themes emerged. These themes were further grouped into topics for analysis and to assess interrelationships. The themes included:

- Workforce Development;
- Demographics;
- Healthy Communities;
- Land Use;
- Parks and Open Space, Tourism;
- Roads and Traffic; and
- Impact on Government Revenues.

From a socio-economic perspective, the Project will generate employment and economic activity during all Project phases and has the potential to attract new residents to the RAA. During construction and operation there will be significant labour force needs to support the Project's activities. Additionally, with the number of jobs projected at the Beaver Dam Mine Site, increased traffic to and from the mine site from both the staff and visitors, and from trucks that will transport materials to the Touquoy Mine Site will result. Indirect employment will be generated by the Project by external contractors and suppliers.

Tax revenues and royalties will be generated by the Project that will benefit all levels of government: federal, provincial and municipal. Increased economic activity by suppliers and external contractors will contribute to government revenue as well as the local economy.

The increased economic activity has the potential to impact adjacent communities by attracting new residents, creating demand for housing, more traffic, creating opportunities for social conflict, increase the usage of public infrastructure such as health facilities, recreation facilities and other social services. The interrelationship between a positive impact, such as population growth, and other socio-economic topics, such as family doctor availability are identified, where possible.

6.16.3 Baseline Program Methodology

The KPMG report titled "Economic Impact Assessment of the Beaver Dam Mining Project" from November 2020 is based on public information released in the National Instrument (NI) 43-101 (AMNS 2019b). Since this report was issued, financial models for the Project are and will continue to be updated, and the benefits could vary upward or downward depending on the final allocation of Construction, Operation and Sustaining Capital spend. AMNS estimates that an additional 12 to 20 million dollars will be spent on the Project. Therefore, the economic impacts outlined in the "Economic Impact Assessment of the Beaver Dam Mining Project" are conservative (Appendix O.1).

Using financial data provided by AMNS, KPMG studied the static economic impacts that "measure the cascading effects that are produced by an injection of cash in a given territory."[2] The KPMG report uses Statistics Canada Input-Output (I-O) model

[2] Source: Economic Impact Assessment of the Fifteen Mile Stream Mining Project

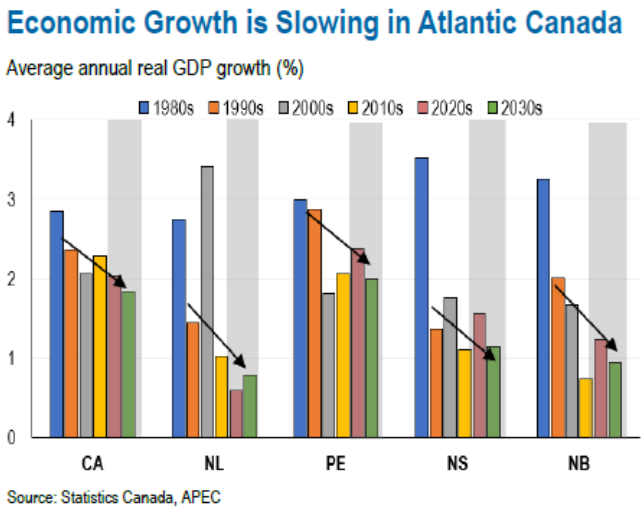
(Appendix O.1). Other reports commissioned by AMNS from which data was taken include "Economic Impact Assessment of the Moose River Consolidated Project" (Appendix O.2) and "Regional Economic Impact Report." Although the Regional Impact Report focuses on another proposed project, there is data and conclusions that apply to other AMNS projects.

Additional data sources for the socio-economic analysis came from a variety of online sources, published reports, primary data collection and observations that were then synthesized and summarized. Using professional judgement and experience, determinations were made regarding the characterization of residual effects (Section 6.16.12). Qualitative data was gathered from the local community engagement activities, which informs the socio-economic potential impacts of the Project. This qualitative data was gathered through meetings, emails and phone calls to the community relations contact line, open houses, Community Liaison Committee (CLC) meetings and other opportunities for stakeholders to provide data on potential community impacts, identify issues of importance and aspirations for the Project.

6.16.4 Baseline Conditions

The baseline conditions before the mine construction and operation are established to fully understand the potential impacts on the VCs. From this, projections and assessment are made comparing the pre-mine conditions to post mine construction and operation.

COVID-19 has created great uncertainly and the impacts of it may be felt for years. This makes it difficult to forecast future economic conditions. The extent to which the long-term impacts of COVID on the economy and society as whole will be felt is a point of debate and is difficult to quantify while Nova Scotia, Canada and the World continue to be in the midst of this unprecedented public health crisis. In this section, baseline conditions pre-COVID and post-COVID are discussed. During this time of uncertainly, this analysis assumes continued impacts from COVID-19 during 2021 with recovery occurring in 2022 and beyond.



6.16.4.1 The Nova Scotia Economy – Pre COVID

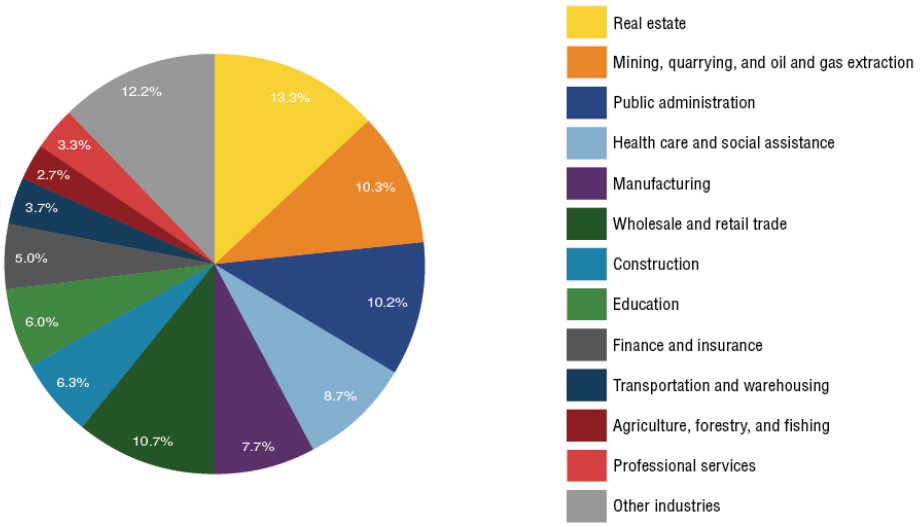
Nova Scotia had the slowest growth in Canada between 1990 and 2009 (Figure 6.16-2). Since then, however, Nova Scotia has seen significant increases in its Gross Domestic Product (GDP), particularly over the last four years. Given the poor economic performance compared to other provinces in 1990s and early 2000s, the Province of Nova Scotia established a commission, "to provide advice to government, business and community leaders on new directions to realize economic growth across economic sectors in all regions of the province." The Now or Never Report (OneNovaScotia 2014) stated a series of troubling conclusions. It also set ambitious goals for the province. The Report's core message was "*Nova Scotia is today in the early stages of what may be a prolonged period of accelerating population loss and economic decline*." The Now or Never Report (OneNovaScotia 2014) identified a series of indicators to track progress against the goals of the report.[3]

The Province of Nova Scotia established 19 goals for addressing and reversing the economic decline identified by the Now or Never Report (OneNovaScotia 2014). These goals are focused on achieving inclusive economic growth, quality education, healthy population and systems, and safe and connected communities. Before the pandemic, there had been progress made on several of these goals, but many still required progress. Data continues to emerge on how the pandemic has impacted the provinces progress on the One Nova Scotia Goals.

[3] Bulletin 1, December 2020 Atlantic Provinces Economic Council.

Figure 6.16-2: Economic Growth Rates in Canada (1980s to 2030s)

In addition to the goals and objectives established by the Now or Never Report, the Province of Nova Scotia became a signatory to the Atlantic Growth Strategy (the Strategy). The Strategy, launched in 2016 by the Government of Canada and Atlantic provincial governments, is designed to strengthen local economies and fuel innovative companies in the region (Figure 6.16-3). The key areas of focus for the Strategy are:



- attract and retain a skilled workforce and immigrants;
- foster greater business innovation, drive leading-edge technology and general new breakthrough ideas;
- reach Climate Change targets and advance Clean Growth in Atlantic Canada;
- create long term growth and high-quality jobs through Trade, Investment and Tourism; and
- support growth, engage and connect people through infrastructure.

The economic outlook of Nova Scotia has improved in the last few years. Pre-COVID, Nova Scotia had a growing economy, with gains in population and the lowest employment rate in 45 years.

6.16.4.2 Baseline Conditions – Post COVID

In March 2020, the province of Nova Scotia in response to a worldwide pandemic, issued a series of public health orders that closed many parts of the economy and limited the movement of people and goods. Nova Scotia was not unique, and the restrictions of this province were mirrored around the country and the world. Not only was the local economy disrupted but so was the broader global economy. It was, and continues to be, a time of uncertainty and devastation for many. Nova Scotia, in terms of number of COVID cases and deaths, has fared better than many other places in Canada and around the world. Nonetheless, the impacts on our communities and economy are severe. In April 2021, Nova Scotia again responded to an increase COVID cases, which resulted in some sectors of the economy be restricted or closed. The impact of this is not included in this analysis.

Figure 6.16-3: Main Industries in Atlantic Canada, 2016 (Percentage of Total Gross Domestic Product)

All levels of government stepped in to provide support to deal with the economic disruption when the public health orders were issued in March 2020. For the province of Nova Scotia, this has resulted in a projected deficit of $778.8 million, which is a deterioration of $883.9 million from the budgeted surplus in the 2020 to 2021 estimates[4]. Government revenues were also impacted. Ordinary Revenue and other recoveries to government is forecasted to decrease by $186.6 million from the budget estimates in the December 2020 Forecast Update[5]. Furthermore, there is a projected decrease of $598.5 million in Provincial Tax revenue. There is also an expected increase in expenses of $708.7 million from original budget estimates for the 2020/2021 fiscal year. Nova Scotia Net Debt is forecast to increase by $1.1 billion in 2020/2021, relative to the budget estimate.

Halifax Regional Municipality (HRM) has experienced significant job losses. During the worst period, HRM saw a 10 percent (%) loss in total employment. Young people and female employees were impacted in greater numbers.[6] In HRM, there was a loss of 23,200 workers in July 2020. The federal government created and delivered financial programs, such as the Canada Emergency Response Benefit (CERB), to support impacted employees but these programs are not anticipated to become a permanent figure of the social safety net. Between March 15 and October 3, 2020, over $84.64 billion was paid through CERB and Employment Insurance benefits. In Nova Scotia, there were over 214,550 applicants to the CERB program.[7]

In September of 2020, the Federal government launched a "transition" program designed to assist people to move from the crisis of early COVID to recovery. The Canada Recovery Benefit and other similar programs are now in place. The impacts of the reduction of the significant dollars injected in the Canadian and Nova Scotian economy by CERB are unknown.

[4] Forecast Update – December 17, 2020 Treasury Board of Nova Scotia.

[5] Forecast Update – December 17, 2020 Treasury Board of Nova Scotia.

[6] Source: https://halifaxpartnership.com/research-strategy/economic-response-and-recovery-plan/economy-covid-19-recovery/

[7] Source: https://www.canada.ca/en/services/benefits/ei/claims-report.html.

The Nova Scotian recovery began September 2020 with a gain of employees in HRM of 4,600 in January 2021.[8] Halifax is experiencing a rapid pace of recovery, but it is unknown if the rural areas of HRM are experiencing the same recovery. The Atlantic Chamber of Commerce has stated that job losses have been great in rural areas.[9] However, there continues to be public health restrictions which have placed significant barriers to key industries such as tourism and the hospitality sector which will hamper recovery in 2021, and potentially beyond. Of the complex interactions arising from COVID is that even with job losses due to the public health restrictions, the Atlantic Provinces Economic Council predicts that "Labour challenges will remain despite the temporary slack due to COVID."[10]

Other impacts of COVID include:

- Short term reductions to in-migration and immigration. Immigration is down 50% across the Atlantic region.[11]
- High unemployment for youth and those with lower education and in low-wage groups.
- Negative impacts on key industries including tourism, primary industry, manufacturing, construction, retail, and restaurants.[12]
- Rapid innovation in new technologies, particularly supporting remote work environments and reductions in length of time to provide internet to underserved areas of the province.[13]
- Reductions on municipal tax revenues and services.[14]
- A move to remote working in the short and possibly medium term. The long-term impacts of this in Nova Scotia are yet to be fully analyzed. However, this could have benefits on the rural economy.[15]
- Concerns about wage gap growing and racialized, low-income and lower educational people not benefiting from the COVID recovery.
- Emergence of a stronger green economy during this time of economic and social restructuring.
- Increased migration to Nova Scotia and impacts on housing market as Nova Scotia is perceived as being "safe" during the pandemic.[16]

6.16.4.3 Local Context and Population

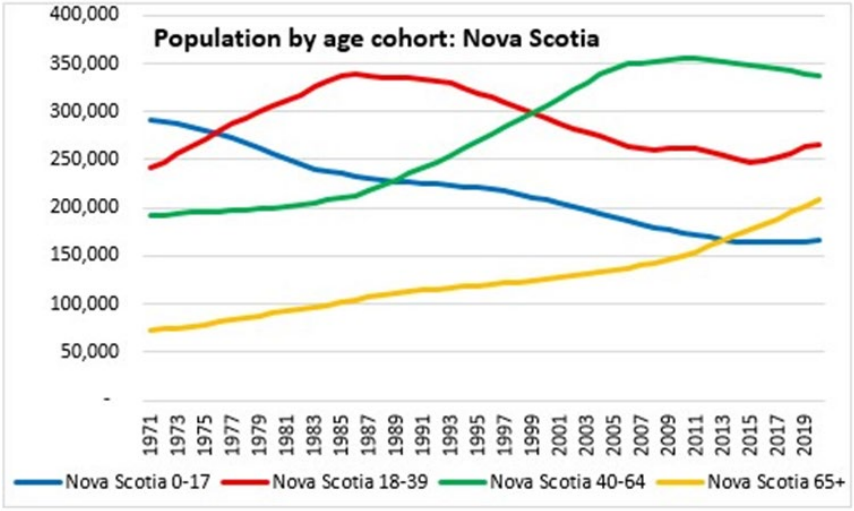
Nova Scotia has a population growth problem, which was clearly identified in the Now or Never Report. Although urban areas have seen increases in populations, rural areas continue to lag behind. Population estimates of September 2020 estimate that Nova Scotia's population is 979,351, and the almost 1% growth in population was the third largest population growth since 1971.[17]

Regardless of the encouraging signs particularly within Halifax but more broadly for the entire province, the Nova Scotia population experiences more deaths than births (Figure 6.16-4). Nova Scotia continues to lag behind all other provinces in Canada. According to the Atlantic Provinces Economic Council (APEC),[18] "without net in-migration, Atlantic Canada's population would be shrinking." Immigrants, interprovincial migrants and non-permanent residents are the reason population growth is occurring.

The Project Area (PA) is in a largely unpopulated area within rural HRM. The closest population centre to the Beaver Dam Mine is Sheet Harbour; however, there are small communities that are nearer to the Haul Road. For the purposes of this study, the rural eastern portion of HRM will serve as a boundary when discussing demographic impacts (Section 6.16.9.1 where spatial boundaries are discussed).

Figure 6.16-4: Atlantic Provinces Population Charts

Nova Scotia, in 2020, had the third highest median age in Canada at 45. This median age has remained relatively stable since 2016, but was rapidly rising from 43 between 2011 to 2015. Although Nova Scotia's population median age is no longer increasing, Nova Scotia still is "older" than most other provinces in Canada and the over 65 cohort continues to rise, with a total number surpassing the under 17 age group (Figure 6.16-5). [19]



The Eastern Rural area is a sub-area within the Census Metropolitan Area (CMA) and is composed of several census track areas. The Great Halifax Partnership collated and analyzed this data in "Halifax Community Profile: Eastern Rural."

[17] Source: https://novascotia.ca/finance/statistics/news.asp?id=16179

[18] Source: Bulletin 1, December 2020 Atlantic Provinces Economic Council.

[19] Source: https://novascotia.ca/finance/statistics/news.asp?id=16179 Median Age: July 1, 2020.

Figure 6.16-5: Population Age Cohorts in Nova Scotia

The population of Eastern Rural HRM is 19,189 people as of the 2016 Census, which is a reduction of 1.7% in population since the 2011 Census (Table 6.16-3). This is consistent with recent historical trends.[20]

Table 6.16-3: Population Trends Eastern Halifax Regional Municipality

Category	Nova Scotia	Halifax CMA	Eastern Rural
Population, 2016	923,598	403,390	19,189
Population, 2011	921,727	390,328	19,528
Growth, 2011 to 2016	0.2%	3.3%	-1.7%
Annualized Growth, 2011 to 2016	0.0%	0.7%	-0.3%

Note: CMA = Census Metropolitan Area.

Compared to a population increase of 3.3% for HRM and 0.2% for Nova Scotia as a whole, the Eastern Shore is experiencing population decline. In general, the Eastern Shore a has lower percentages of its population in the youth and working age categories and high percentage in the senior categories.[21]

The labour force in the Eastern Rural declined between 2011 to 2016 and labour force participation fell from 62.1 to 60.7%. This is substantially below the 67% labour force participation rate for Halifax CMA. The trades and transport occupation, along with sales and services group are the two largest occupation groups.[22]

Generally speaking, rural areas, such as the Eastern Shore, are projected to continue to lose populations, continue to see reductions in working age populations, have fewer young people and school age children and experience labour force challenges.

[20] The Sheet Harbour, Nova Scotia Business Case prepared by the Greater Halifax Partnership http://www.halifaxpartnership.com/site/media/Parent/Appendix%20A-%20Sheet%20Harbour%20Business%20Case.pdf

[21] Halifax Community Profile: Eastern Rural, prepared by the Greater Halifax Partnership: April 2018

[22] Page 6, Halifax Community Profile: Eastern Rural April 2018

The APEC states, "Employers looking to expand in the region should pay close attention to their ability to secure workers when choosing locations for their operations."[23]

Census Tract 2050154.04 (CT) includes Sheet Harbour and several surrounding communities including the Beaver Dam area, north and east to the Halifax County boundary. The total population base of this CT was 3,221 in the 2016 Census, a decline of 6.5 % from 2011. In comparison, the population of Nova Scotia increased by 0.2% and HRM increased by 3.3%. The population density in the CT is 1.8 people per square kilometer (73.4 in HRM and 17.4 in Nova Scotia) (Statistics Canada 2016).

The age distribution in the Sheet Harbour CT indicates an older population with a median age of 54.9, (Nova Scotia – 45.5, HRM – 41.0). In 2016, 16.6% of the population were under the age of 20, and 29.6% of the population was 65 years or older. The male (49.3%) and female (50.7 %) populations are nearly equal. The area is predominantly English (first language) speaking (98.3%) (Statistics Canada 2016).

The cultural origins of the area are mainly Canadian/European; 6% identify as First Nations and about 1% are of other origin (Statistics Canada 2016). The population identifies with a Christian religion (89%) with nearly 10% having no religious affiliation (Statistics Canada 2011). The population of this CT remained relatively constant from the 2016 Census with 8% noting having moved within the previous year as compared to 16.8% having moved in the area 5 years previously (Statistics Canada 2016).

Of the population between 25 and 64 years of age, at least 24% have attained a high school diploma only and 48.6% have received a post-secondary education (apprenticeship or trade certificate – 34%, college diploma/university certificate – 50%, university degree (bachelor's or higher) – 19%) (Statistics Canada 2016).

The average full time employment income in 2015 of people 15 years or older $48,177. The average family income is $65,958 (after tax average - $57,205).

Unemployment rates in Eastern Nova Scotia in 2016 averaged 15.2% (range of 14.7 to 16.5%). The unemployment rate for Eastern Nova Scotia for three-month average, issued in February 2021 is 13.2 %.[24]

6.16.4.4 Community Infrastructure

The Project is located 31 kilometres (km) from Sheet Harbour via the public road system. Sheet Harbour is a community of about 800 people but the Sheet Harbour Chamber of Commerce states that the catchment for the area is approximately 5,000 people. The Port of Sheet Harbour, upgraded in 1988, is the second largest port facility in the HRM and includes an Industrial Park as well as a 500-foot Common User Dock. The 129-acre Industrial Park is marketed as a location for manufacturing, processing and transportation facilities and has additional development potential.[25]

Sheet Harbour is a local commercial centre that provides the following amenities for the surrounding areas:

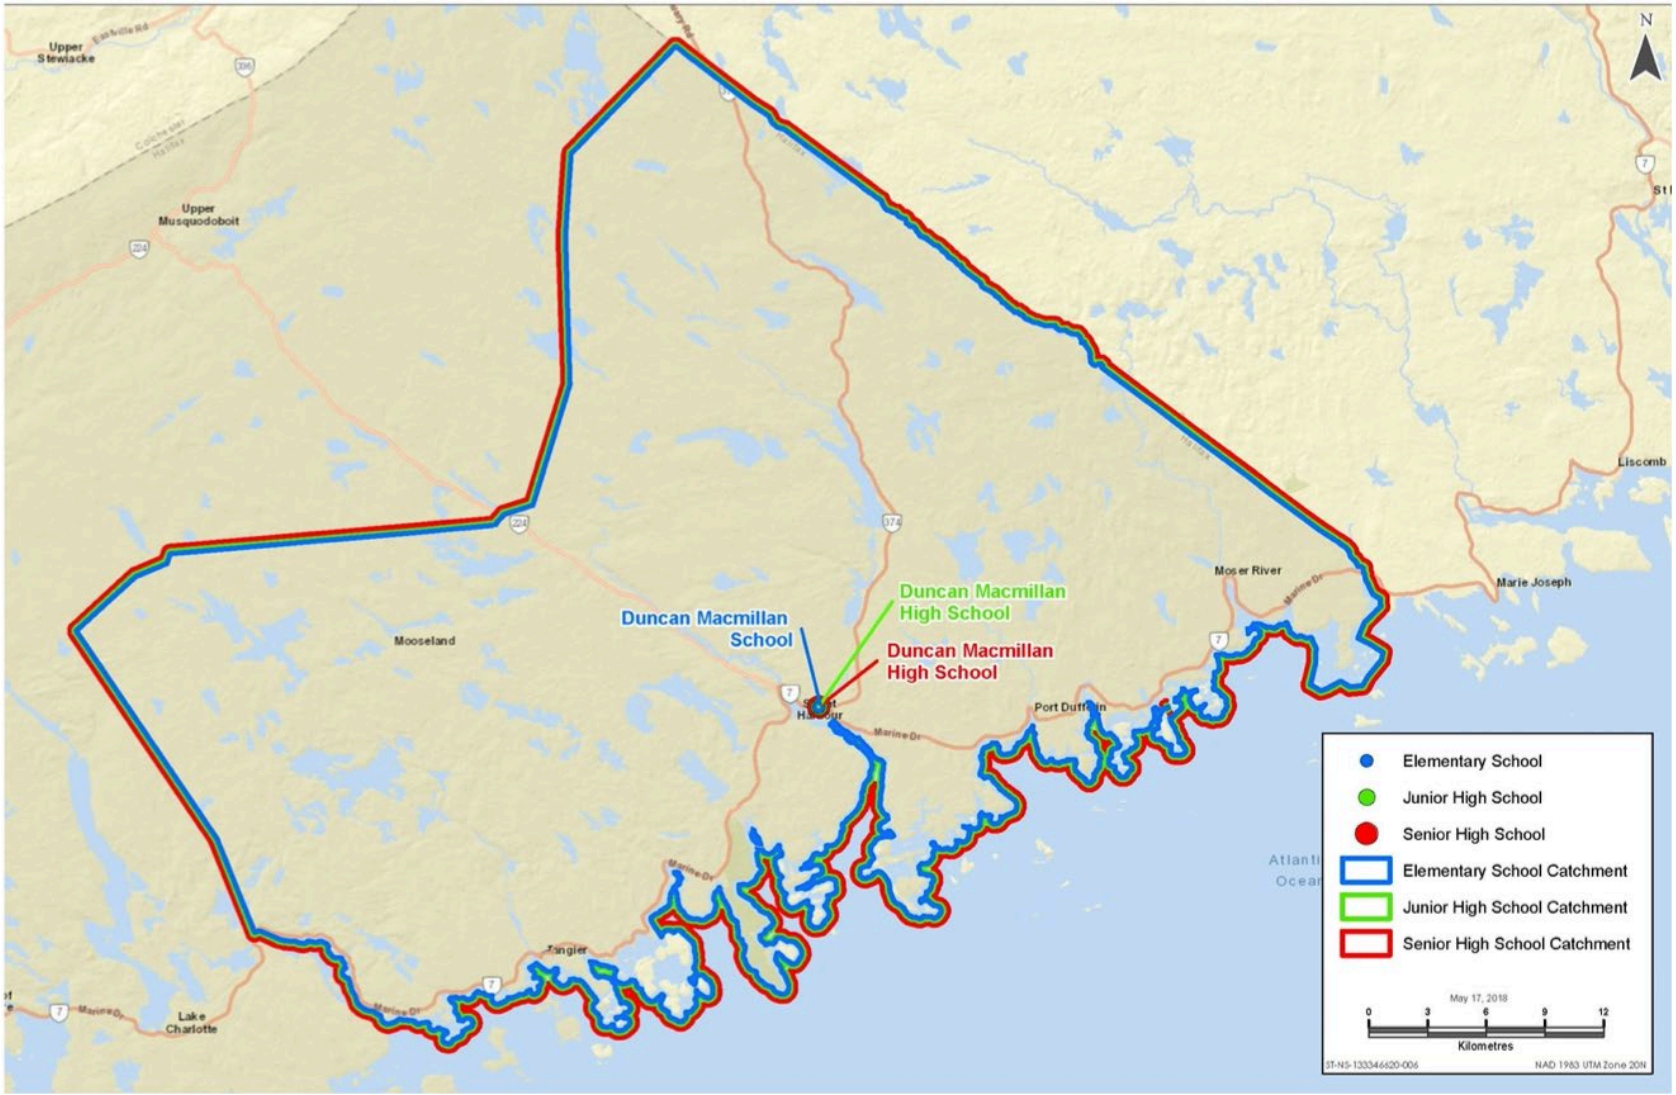
- Eastern Shore Memorial Hospital;
- Sheet Harbour Branch of the Halifax Public Library System;

[23] Source: APEC Looking Ahead – Bulletin 3: February 2021

[24] Table 14-10-0354-01 Regional unemployment rates used by the Employment Insurance program, three-month moving average, seasonally adjusted.

[25] Source: http://sheetharbourchamber.com/sheet-harbour/

- Marine Drive School Pre-Primary to Grade 12 school;
- Royal Canadian Legion Branch 58;
- Halifax Recreation Facilities;
- Harbourview Lodge Continuing Care Centre;
- LEA Place Women's Resource Centre;
- Living Water Baptist Church;
- Mooseland and Area Community Hall;
- MUSGO Rider Cooperative Ltd – Rural Transportation Association;
- Otter Pond Demonstration Forest;
- Sheet Harbour & Area Chamber of Commerce;
- Sheet Harbour & Area Ground Search and Rescue;
- Sheet Harbour Snowmobile and All-Terrain Vehicle (ATV) Club;
- Sheet Harbour Marina;
- Sheet Harbour Radio;
- Sheet Harbour Wildlife Association; and
- Gerald Hardy Memorial Society - Food Bank.



The local school for Sheet Harbour is Marine Drive Academy, which replaced the Duncan MacMillan School in September 2020.[26] This new modern school has an enrollment of 267 students from pre-primary to Grade 12 but can accommodate a population of 530 students. General population growth caused by the Project has the potential to increase the school age population, which has been in decline in the Eastern Shore area, resulting in closing of schools in the general area. The catchment for this school is presented in Figure 6.16-6.[27]

Historic school enrollment and projected enrollment are shown in Table 6.16-4.

[26] Long Range Outlook, Halifax Regional Centre for Education, November 2019, Pg 203.

[27] Source: http://sheetharbourchamber.com/nova-scotia-business-development/

Figure 6.16-6: Sheet Harbour School Catchment Areas

Table 6.16-4: Historic Enrollment and Enrollment Projections, Marine Drive School

Historic Enrollment (past 10 years):										
Year	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017
Enrollment	400	366	370	356	330	320	290	269	256	241

Current Enrollment (as of Sept. 30):

Year	2018
Enrollment	261

Enrollment Projection (next 10 years):

Year	2019	2020	2021	2022	2023	2024	2025	2026	2027	2018
Enrollment	261	266	260	271	265	253	243	238	235	234

Source: Long Range Outlook, Halifax Regional Centre for Education, November 2019, Pg 204

The projected decline in enrollment reinforces and further substantiates the demographic data regarding the age of the population in the area and the overall population decline.

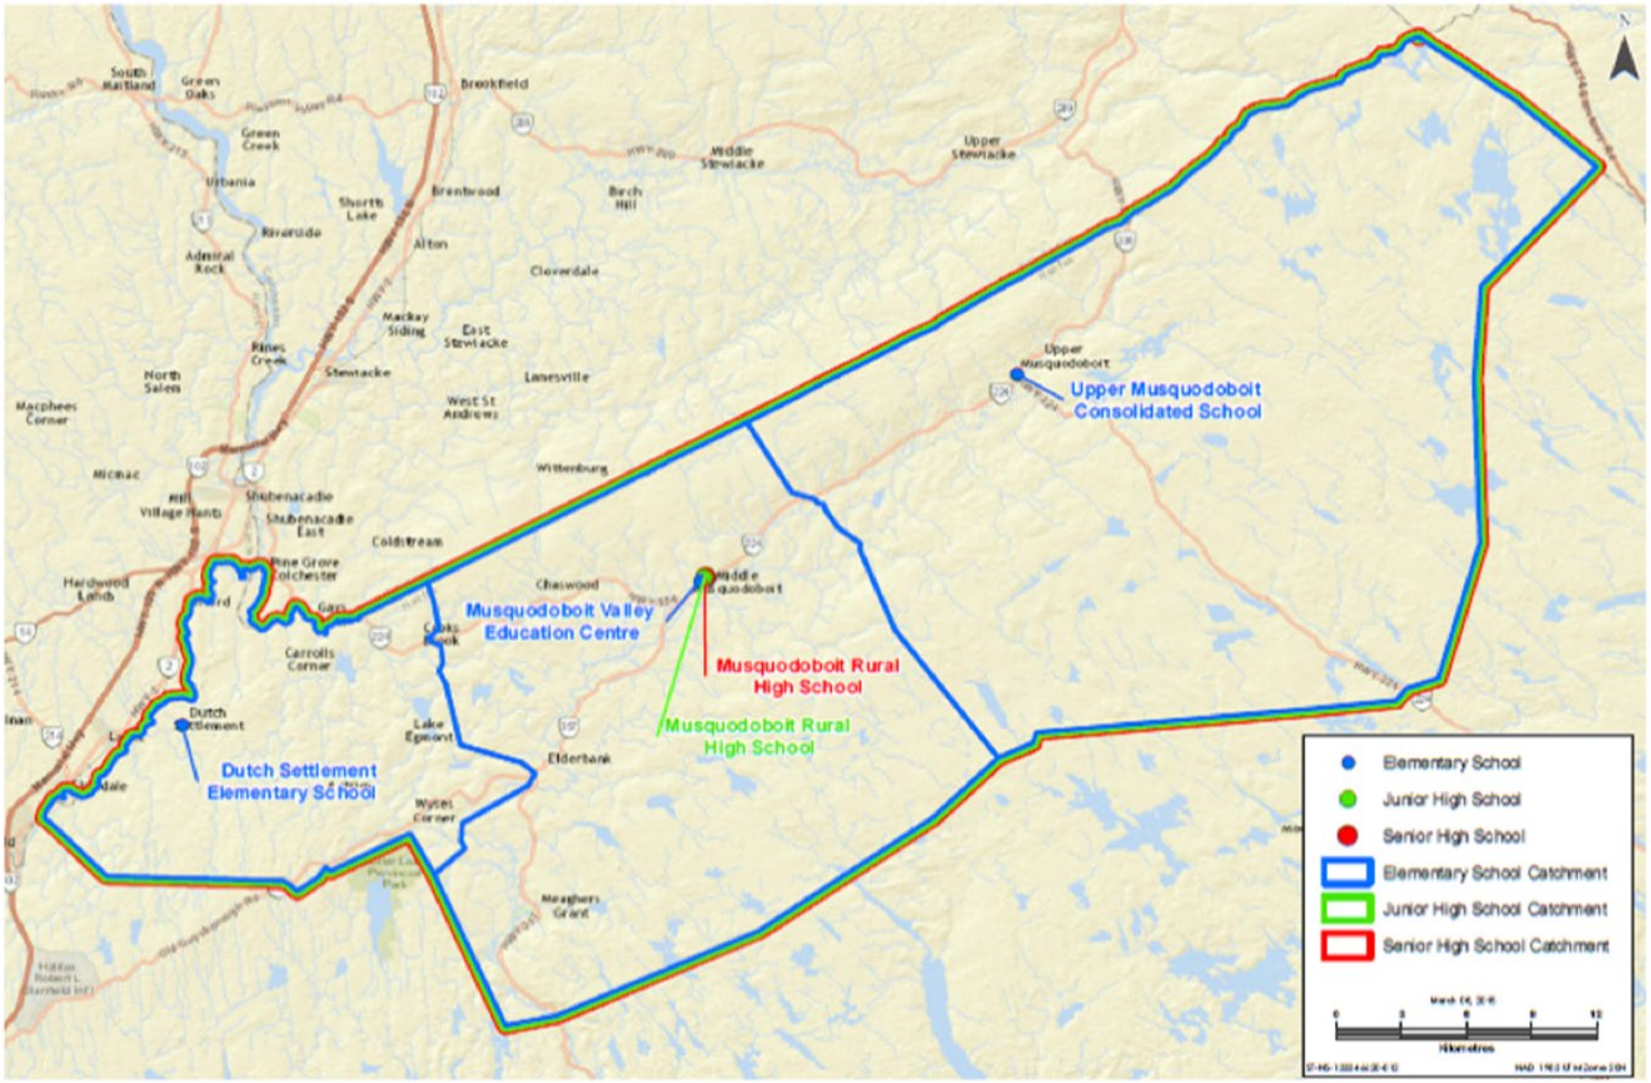
The Musquodoboit Rural High Family of Schools serves the Middle and Upper Musquodoboit areas and includes three elementary Schools and Musquodoboit Rural High (MRH). MRH, with a school capacity of 497 student, predicts a minor increase in enrollment of 20 students to 290 students by 2028 and has a school utilization rate of 54%.[28] Dutch Settlement Elementary, which has a school utilization rate of 79%. It is more fully utilized than Musquodoboit Valley Education Centre and Upper Musquodoboit Consolidated Elementary both of which have significant ability to absorb new students with utilization rates of 42 and 55% respectively.

The catchment areas for this family of schools are presented in Figure 6.16-7.

The closest hospital for the Beaver Dam Mine Site is the Eastern Shore Memorial Hospital (ESMH), which has a 24-hour emergency department, a variety of clinics and services, and hospital beds. The emergency department at the ESMH experiences frequent closures due to staff shortages. As of March 1, 2019, the Nova Scotia Health Authority estimates that 5.0% of the population in the Central Zone (HRM, Eastern Shore and West Hants areas) is without a family doctor.[29]

6.16.4.5 Recreational Facilities

According to HRM, the recreational facilities of the eastern shore portion of HRM are, "purposely separate from each other in order to retain their unique identities but all are experiencing difficulty sustaining their respective facilities." Funding for recreational facilities is difficult to justify as there are more facility space per capita then recreational standards outline." HRM assessment of recreation indicates that the declining and aging population contribute to the lack of investment in new recreational space.[30]



A new recreational facility is being considered for Sheet Harbour and funding sources are being secured for its ultimate development. HRM has allocated capital funding to support the development of an Eastern Shore Lifestyle Centre, as the existing facility, the Sheet Harbour Lions Community Centre is non-operational.

Figure 6.16-7: Musquodoboit Rural High Family of Schools

Source: Long Range Outlook, Halifax Regional Centre for Education, November 2019, Pg 390.

6.16.4.6 Local Economy

As of December 2017, Statistics Canada reported 613 businesses located in the Eastern Rural area of HRM. Most have fewer than five employees and 88% have less than 20 employees. There are nine businesses with over 100 employees, with three in transportation and warehousing, two in mining, quarry and oil and gas extraction, one in manufacturing, one in wholesale trade, retail trade and accommodation and food services. The Touquoy Mine is one of the nine businesses with over 100 employees. Sheet Harbour also is the home to of a variety of commercial amenities such as overnight accommodations, NSLC, drugstore, grocery store, gas stations, hardware store, banks and credit unions.

Coastal areas along the Eastern Shore are being promoted as an eco-tourism destination due to its topography, coastal access and views and its natural beauty. The Wild Islands Tourism Advancement Partnership mission is, "to position and advance Musquodoboit Harbour to Sherbrooke as a dynamic new in-demand destination offering the best designed touring, outdoor and nature infrastructure and experiences in Nova Scotia."[31] The Eastern Shore is an Area of Interest as a Marine Protected Area by Fisheries and Oceans Canada. This focus of having tourism as an economic development driver is reinforced in the Eastern HRM Strategic Plan prepared in 2014.[32]

The Eastern Shore has lower total household incomes then both the Nova Scotia average and the broader HRM region. Approximately one-sixth of all income received is from government transfers, versus one-tenth for Halifax. This is again likely due to the number of seniors who received payments such as Old Age Security or the Guaranteed Income Supplement.[33]

6.16.4.6.1 Housing

Housing more generally within the Eastern Rural HRM area is characterized by residency in single detached houses, with an average household size of 2.3 people per dwelling (ppd).[34]

Housing Starts within CT 2050154.04, which is the area that encompasses the proposed mine and the Sheet Harbour areas have been slow with six in 2020, five in 2019, five in 2018 and six in 2017.[35] In the Census division for Halifax East, the total number of housing starts was 146. In October 2020, there were 43 rental units listed as available in Halifax County East. The total number of households in Halifax County East in core housing need, meaning it does not meet one of more standards for housing adequacy, suitability or affordability and if it would have to spend 30% of more of its pre-tax income to pay the median rent is 9.8% as of October 2020.

6.16.4.6.2 Temporary Housing

There are several temporary housing accommodation options including: bed and breakfasts (2), motels (3), and campgrounds (2) in the Sheet Harbour area that cater to both tourist and business traffic. Most are seasonal operations (May to October) but some offer service outside of the tourist season.

[35] Data taken from CHMC Housing Portal.

6.16.4.6.3 Water, Wastewater, and Solid Waste Management

Water supply in the region is by drilled or dug well. Wastewater is managed through individual septic fields. Solid waste management is handled by the municipality in the form of weekly garbage and recyclable collection. Waste transfer stations are located at Middle Musquodoboit and Sheet Harbour and solid waste is disposed of at the Otter Lake Waste Processing and Disposal Facility.

No central water services are available in Sheet Harbour, although HRM has received requests for both central water and sewer. Municipal Council is monitoring the extent of the environmental or public health concerns and may investigate the feasibility of services in the future.[36]

The nearest known domestic well is approximately 5 km southwest from and down-gradient of the Beaver Dam Mine Site, at a residence along Highway 224. Potable water for the mine will be sourced from Crusher Lake as discussed in the Project Description (Section 2). Recreational water quality is assessed in the Human Health Risk Assessment (Appendix C.2). This assessment indicates that while there is uncertainty, the incremental increase in risk related to recreational water uses (e.g., swimming) exposure is likely negligible. For fish consumption, baseline exposure was considered in the assessment, and some incremental increase over baseline could occur in the future scenarios. In addition, homes, seasonal cottages/camps, and campgrounds may be impacted by project development and operation, such as Camp Kidston, located approximately 20 km west of the Beaver Dam Mine Site (and 3.4 km north of Touquoy), which uses groundwater as a source for public drinking water, and offers recreational boating, swimming, and fishing on Long Lake.

Wells are also located near the Haul Road. A seasonal dwelling with an onsite well is within 100 m of the Mooseland Road. Also, the community of Mooseland is located to the south of the entrance to the Haul Road where there are both season and permanent dwellings with onsite water systems. The Human Health Risk Assessment (Appendix C.2) concludes there is no impact to groundwater wells resulting from the Project.

6.16.4.7 Roads and Traffic

This part of HRM is protected by the Royal Canadian Mounted Police (RCMP), based in Sheet Harbour, and is considered to have a very low crime rate (Greater Halifax Partnership).

The crime rate, including violent crime, property crime and other crime (expressed per 10,000 people), in Halifax County (outside the urban core) is generally half of the corresponding urban Halifax crime rate. The five-year average of total crime incidents is 485 /10,000 in the county. The provincial rate in 2015 was 1,172/10,000 (Statistics Canada 2016). Violent crime has risen but total crime has decreased.

The Halifax Regional Fire and Emergency Service has fire stations located at Sheet Harbour, Upper Musquodoboit and Middle Musquodoboit that are near to the Site. They also have several other stations on the Eastern Shore that can be called out depending on the complexity and severity of an incident.

[36] Source: Municipality Planning Strategy for East Shore (East), policy E-13.

6.16.4.8 Parks and Open Space

The Project lies in a broad area of diverse landscapes with varying degrees of present day and historical human activities that have modified what we see currently. The land surrounding the Project has typically been used as forest resource management/harvesting and mineral exploration associated with the Beaver Dam deposit. This activity has allowed for increased public access with interconnected resource and logging roads that extend between Mooseland Road east to Highway 224 and to Highway 374.

The Study Area has lands with different levels of provincial protection located in proximity to the PA. These areas include:

- **Game Sanctuaries** – Game Sanctuaries were established early in the 20th century to protect wildlife and a "nucleus of breeding stock". Today, wildlife management tools reduce the risk of extinction, but the game sanctuary designation remains as a tool for government to regulate lands, "where unusual concentrations of wildlife are vulnerable to site specific threats."[37] Game Sanctuaries are enabled under the *Nova Scotia Wildlife Act*.
- **Wilderness Areas** – These are provincially significant protected areas which are designated under the *Nova Scotia Wilderness Areas Protection Act*. Forestry and road development are not permitted. Other activities such as mining, vehicle use, building structures or trails, and managing or removing plants are prohibited except in certain circumstances as outlined in the legislation.[38] Hunting is permitted.
- **Nature Reserves** – Nature reserves are areas selected to preserve and protect, in perpetuity, representative and special nature ecosystems, plant and animal species, features and natural processes.[39] Scientific research and education are the primary uses of nature reserves and recreation is generally restricted. Nature Reserves are protected under the *Nova Scotia Special Places Protection Act.*

The approximate distances of these areas from the PA (i.e., Beaver Dam Mine Site, Haul Road, and Touquoy Mine Site) are summarized in Table 6.15-5. These areas are presented on Figure 6.16-8.

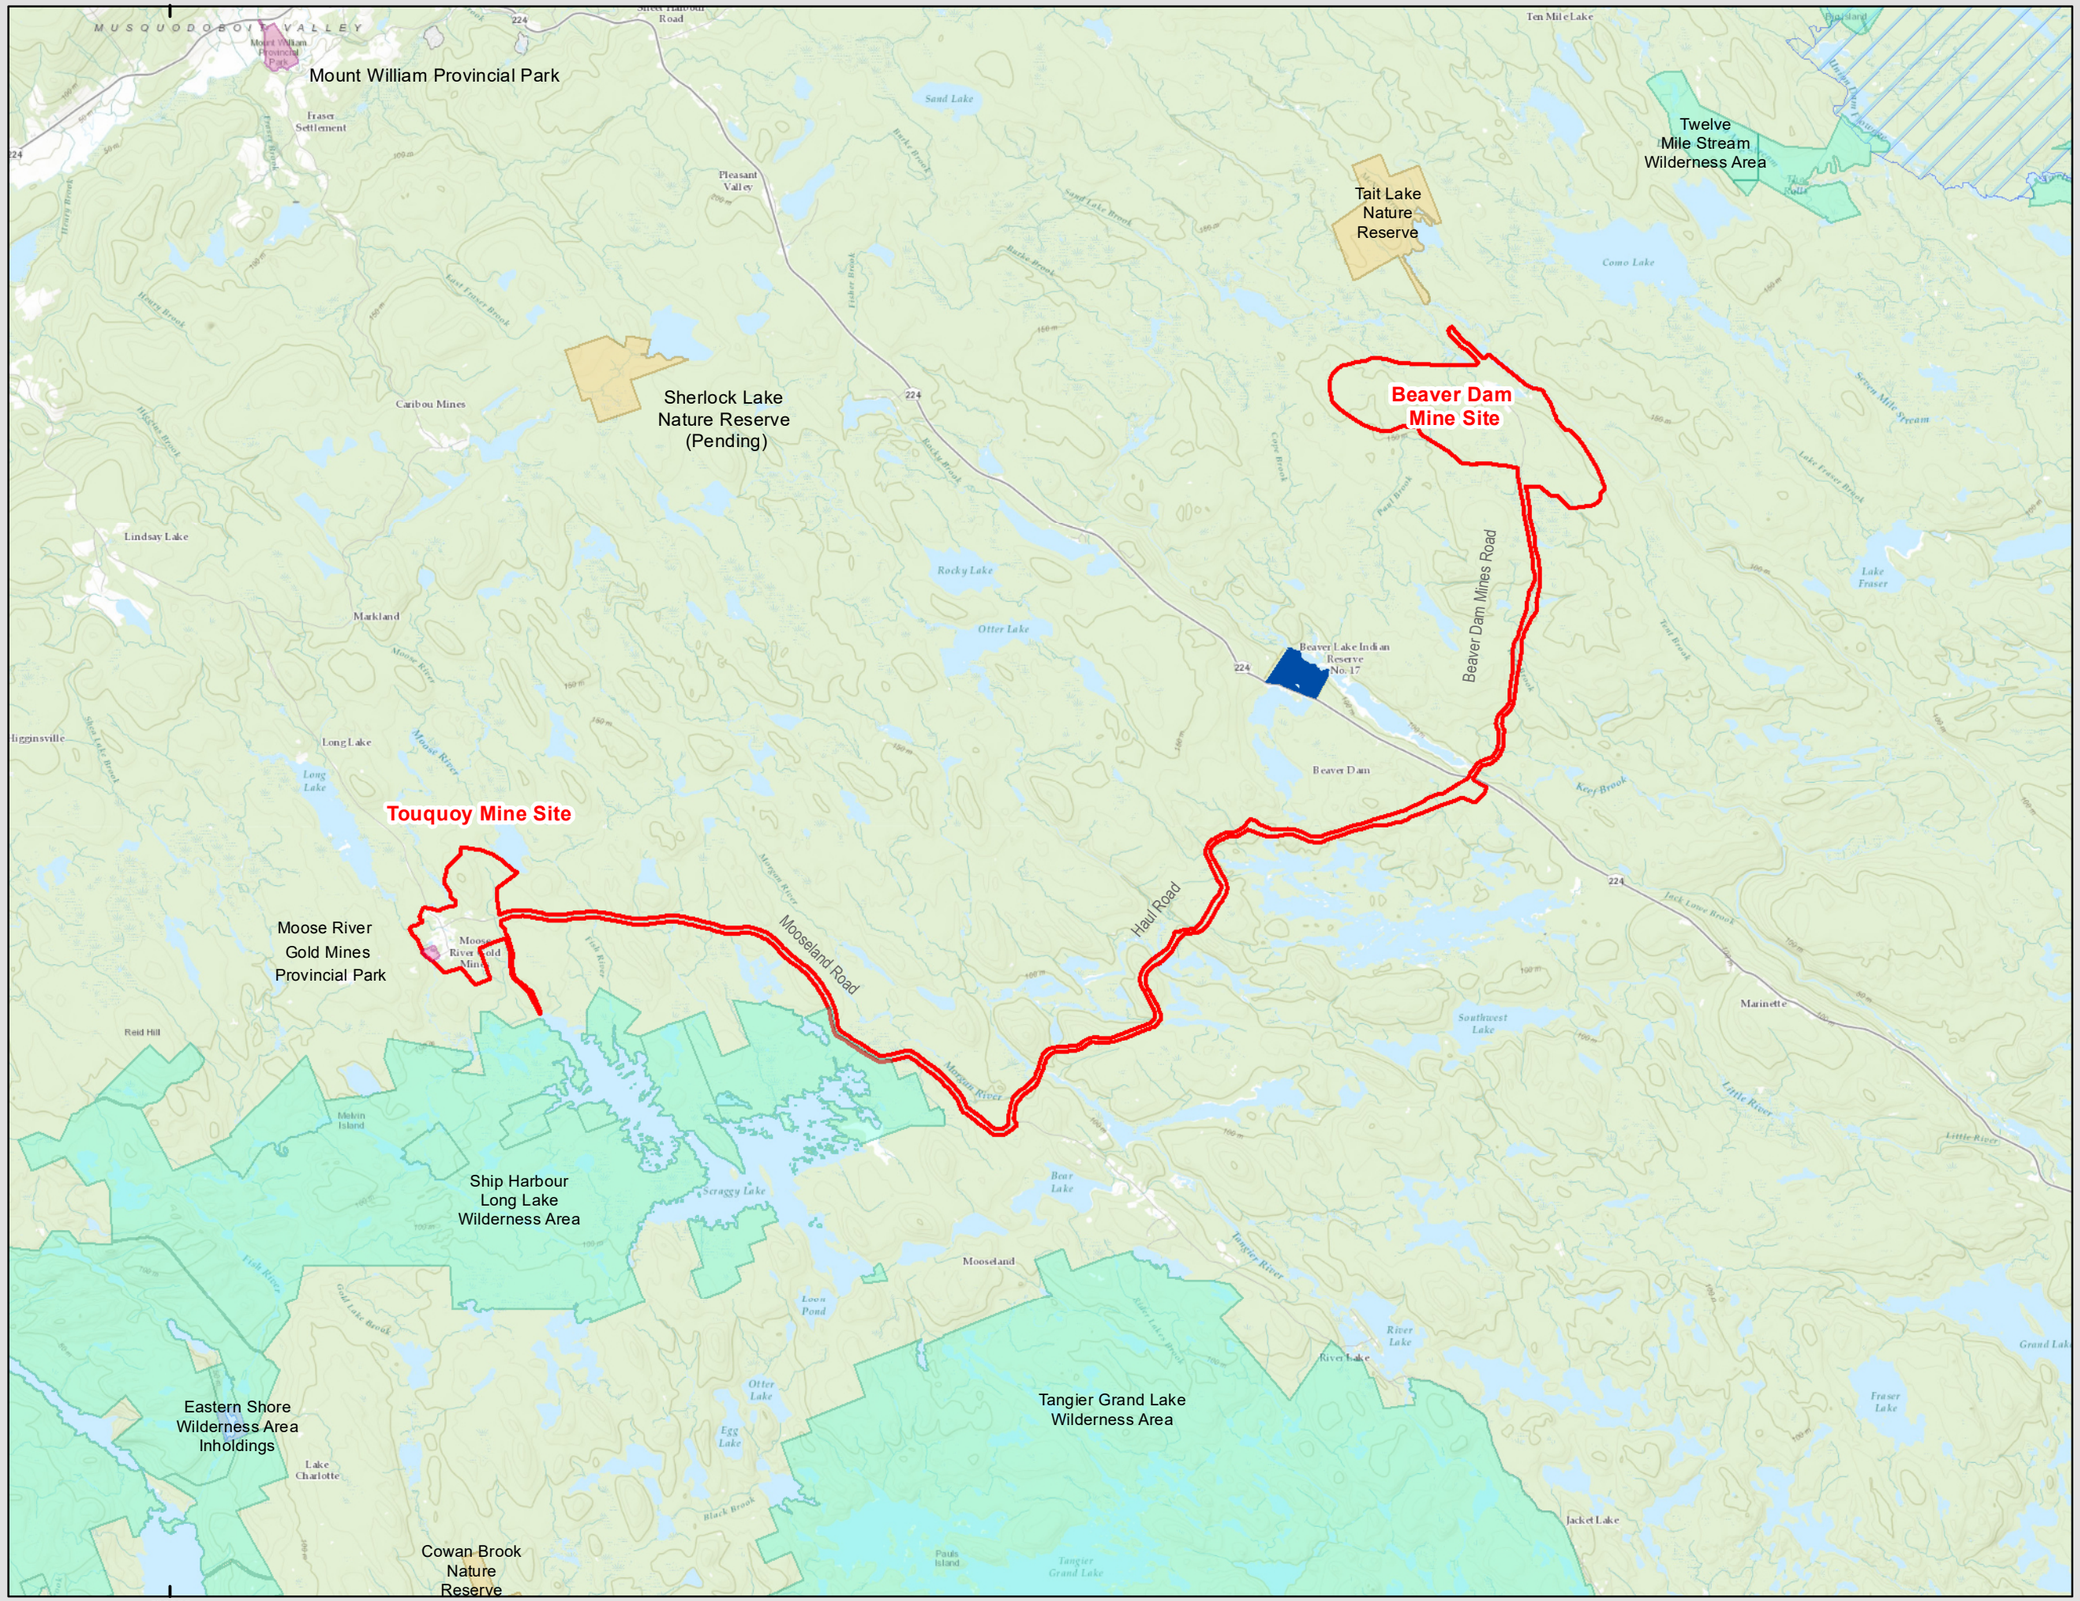

Table 6.16-5: Protected Areas with Provincial Designation

Provincially Designated Areas	Approximate Distance (from the Beaver Dam Mine Project)	Direction	Type of Designation
Tait Lake Nature Reserve	1 km from Beaver Dam Mine Site	North	Nature Reserve
Cowan Brook Nature Reserve	9.5 km from Touquoy Mine Site	South	Nature Reserve
Twelve Mile Stream Wilderness Area	4.5 km from Beaver Dam Mine Site	Northeast	Wilderness Area
Liscomb Game Sanctuary	7.3 km from Beaver Dam Mine Site	East	Game Sanctuary
Tangier Grand Lake Wilderness Area	2.2 km from intersection of Moose River Cross Road and Mooseland Road	South	Nature Reserve
Ship Harbour Long Lake Wilderness Area	Adjacent to Mooseland Road	West	Nature Reserve

Document Name: BD_EIS_Figure6-16-XProtectedAreas

The presence of unauthorized cabins and hunting blinds on private land is a good indicator that the area is used for hunting and fishing activity. The area is open to several seasons of hunting, the most popular include deer, bear, snowshoe hare, ruffed grouse, and ring-necked pheasant. Recreational fishing occurs in areas near the Beaver Dam Mine Site. Camp Kidston, which operates only in the summer months, is located 3.5 km northeast (upstream) of the Touquoy Mine Site, and offers swimming, water activities, and canoeing as part of its program. In addition, the camp uses groundwater as a source for public drinking water.

There is no documented, observed or anecdotal evidence that supports recreational swimming in the area of the Beaver Dam Mine Site. However, through engagements there are reports of swimming in the rivers and lakes adjacent to the Haul Road. There are many structures that are built on lands that are not owned by private individuals that appear to be used by multiple parties throughout the region. Scraggy Lake has a number of private land holdings on its shore that have some type of cottage and outbuildings. A total of 12 cottages/camps were noted during a survey in July 2007 and a survey of aerial photographs from 2016 did not reveal any additional camps. Scraggy Lake camp owners have seen very limited boating canoe use and mainly in the spring if any as low water levels in the summer present extra challenges for navigability (rocks). Swimming is not a typical activity in Scraggy Lake.

6.16.4.9 Tourism

Tourism is not significant within the communities directly adjacent to the proposed Beaver Dam Mine Site. Upon review of tourism promotional materials and website, the following tourism and cultural assets are noted in near the Touquoy Mine Site portion of the PA.[40] These tourism assets are described below and presented on Figure 6.16-9:

- Icelandic Memorial Society of Nova Scotia – This society interprets the history of Iceland Immigration to Nova Scotia. The Markland Settlement, situated between the village of Caribou Gold Mines and Moose River Gold mines, was home to 32 Icelandic families between 1875 to 1882. Today, there is a memorial cairn at the entrance, a log cabin replica and interpretive signage.[41]
- Moose River Gold Mine Museum and Moose River Gold Mine Provincial Park – located at 6990 Moose River Road provides interpretation on the 1936 mine collapse and generally on gold mining. It consists of a main building, picnic/day use area and outhouse facilities.
- Touquoy View Deck – In 2019, AMNS constructed a viewing decking for the public to view the pit area of the Touquoy mine. The view deck is serviced by a large parking area and included interpretative signage.

Mooseland and Marinette, Nova Scotia the two communities directly adjacent to the mine and haul road do not have any tourism sites promoted by Nova Scotia Tourism in the 2020 Doers and Dreamers Guide.[42] Sheet Harbour and Middle Musquodoboit have restaurants, breweries, over night accommodations and other tourism related activities. Sheet Harbour has a Visitor Information Centre to serve the travelling public.

The Wild Islands Tourism Advancement Partnership is guiding the 100 Wild Island Campaign to, "position the area from Musquodoboit Harbour to Sherbrooke as a one-of-a-kind sustainable tourism destination that is recognized internationally."[43] This initiative focuses on the coastal areas of the eastern shore and not the inland area where the PA is located but is within the RAA.

Document Name: BD_EIS_Figure6-16-XProtectedAreas

COVID has taken a heavy toll on tourism globally. The Tourism Forecast for 2020 suggested that tourism revenues in Nova Scotia will decline by $1.7 billion, and that total revenues will not surpass $900 million.[44] It is difficult to predict when the tourism industry will approach pre-COVID levels. In 2018, Nova Scotia tourism revenues reached $2.61 billion but had a stated goal of trying to reach $4 billion but this will be unattainable with COVID.[45] The Eastern Shore has a minor share of tourism visitation at 5%. Most of the visitors to the eastern shore visited Sheet Harbour (21%), Musquodoboit Harbour (29%) and Sherbrook (16%).[46] The Eastern Shore has low levels of business travel, with only 3%.

6.16.4.9.1 Indigenous Communities

There are two First Nations (Mi'kmaq) reserves in the area of the Project. Beaver Lake Indian Reserve 17 and Sheet Harbour Indian Reserve 36, which are approximately 5 km southwest and 20 km south of the Project, respectively. Both of these communities are part of Millbrook First Nation and are discussed in more detail in Section 6.14.4. First Nations communities rely primarily on the fishing industry as a source of income, as is the case with the Millbrook First Nation, but Millbrook in particular has significant economic interests and successful businesses in and around the primary community of Millbrook Additional information on Indigenous Communities can be found in Section 6.14.

6.16.4.10 Health and Well-being

The Project site extending from Beaver Dam to Moose River is covered under the Nova Scotia Health Authority, which provides services through community-based facilities located at Middle Musquodoboit (Musquodoboit Valley Memorial Hospital [MVMH]) and Sheet Harbour (Eastern Shore Memorial Hospital [ESMH]). Both facilities offer a community emergency department (MVMH 8 am to 8 pm; ESMH 24 hour) and a variety of other inpatient and outpatient services.

Table 6.16-6: Hospitals Offering Services to the Project Area

Hospital	Services	Beds
Musquodoboit Valley Memorial	Acute Home Nursing Care, Clinical nutrition, Diabetic Clinic and Meals-on-Wheels, Diagnostic services including laboratory, EKG and radiology, Emergency services, Family Practice, Mental Health, Occupational therapy, Outpatient services, Palliative services, Public health, Physiotherapy, Social work	6
Eastern Shore Memorial	Palliative and Respite Care, Acute Care, Outpatient/Emergency, Ambulatory Care, Diagnostic Imaging, Laboratory Services, Physiotherapy, Occupational Therapy, Clinical Nutrition, Social Services, Adult Day Clinic, Diabetic Clinic, Meals-on-Wheels, Addiction Prevention and Treatment Services, Public Health Home Care Nova Scotia, Nova Scotia Hospital Outreach, IWK Health Centre - Metal Health and Family Services	Not Specified

[46] Community Report – 2019 Visitor Exit Survey https://tourismns.ca/sites/default/files/2021-01/2019%20VES%20Community%20Report.pdf.

An elder care facility, Harbourview Lodge Continuing Care Centre, is attached to ESMH. Braeside Nursing Home is located in Middle Musquodoboit. Social services are offered in both centres. Several denominations of churches are found between Sheet Harbour and Middle Musquodoboit.

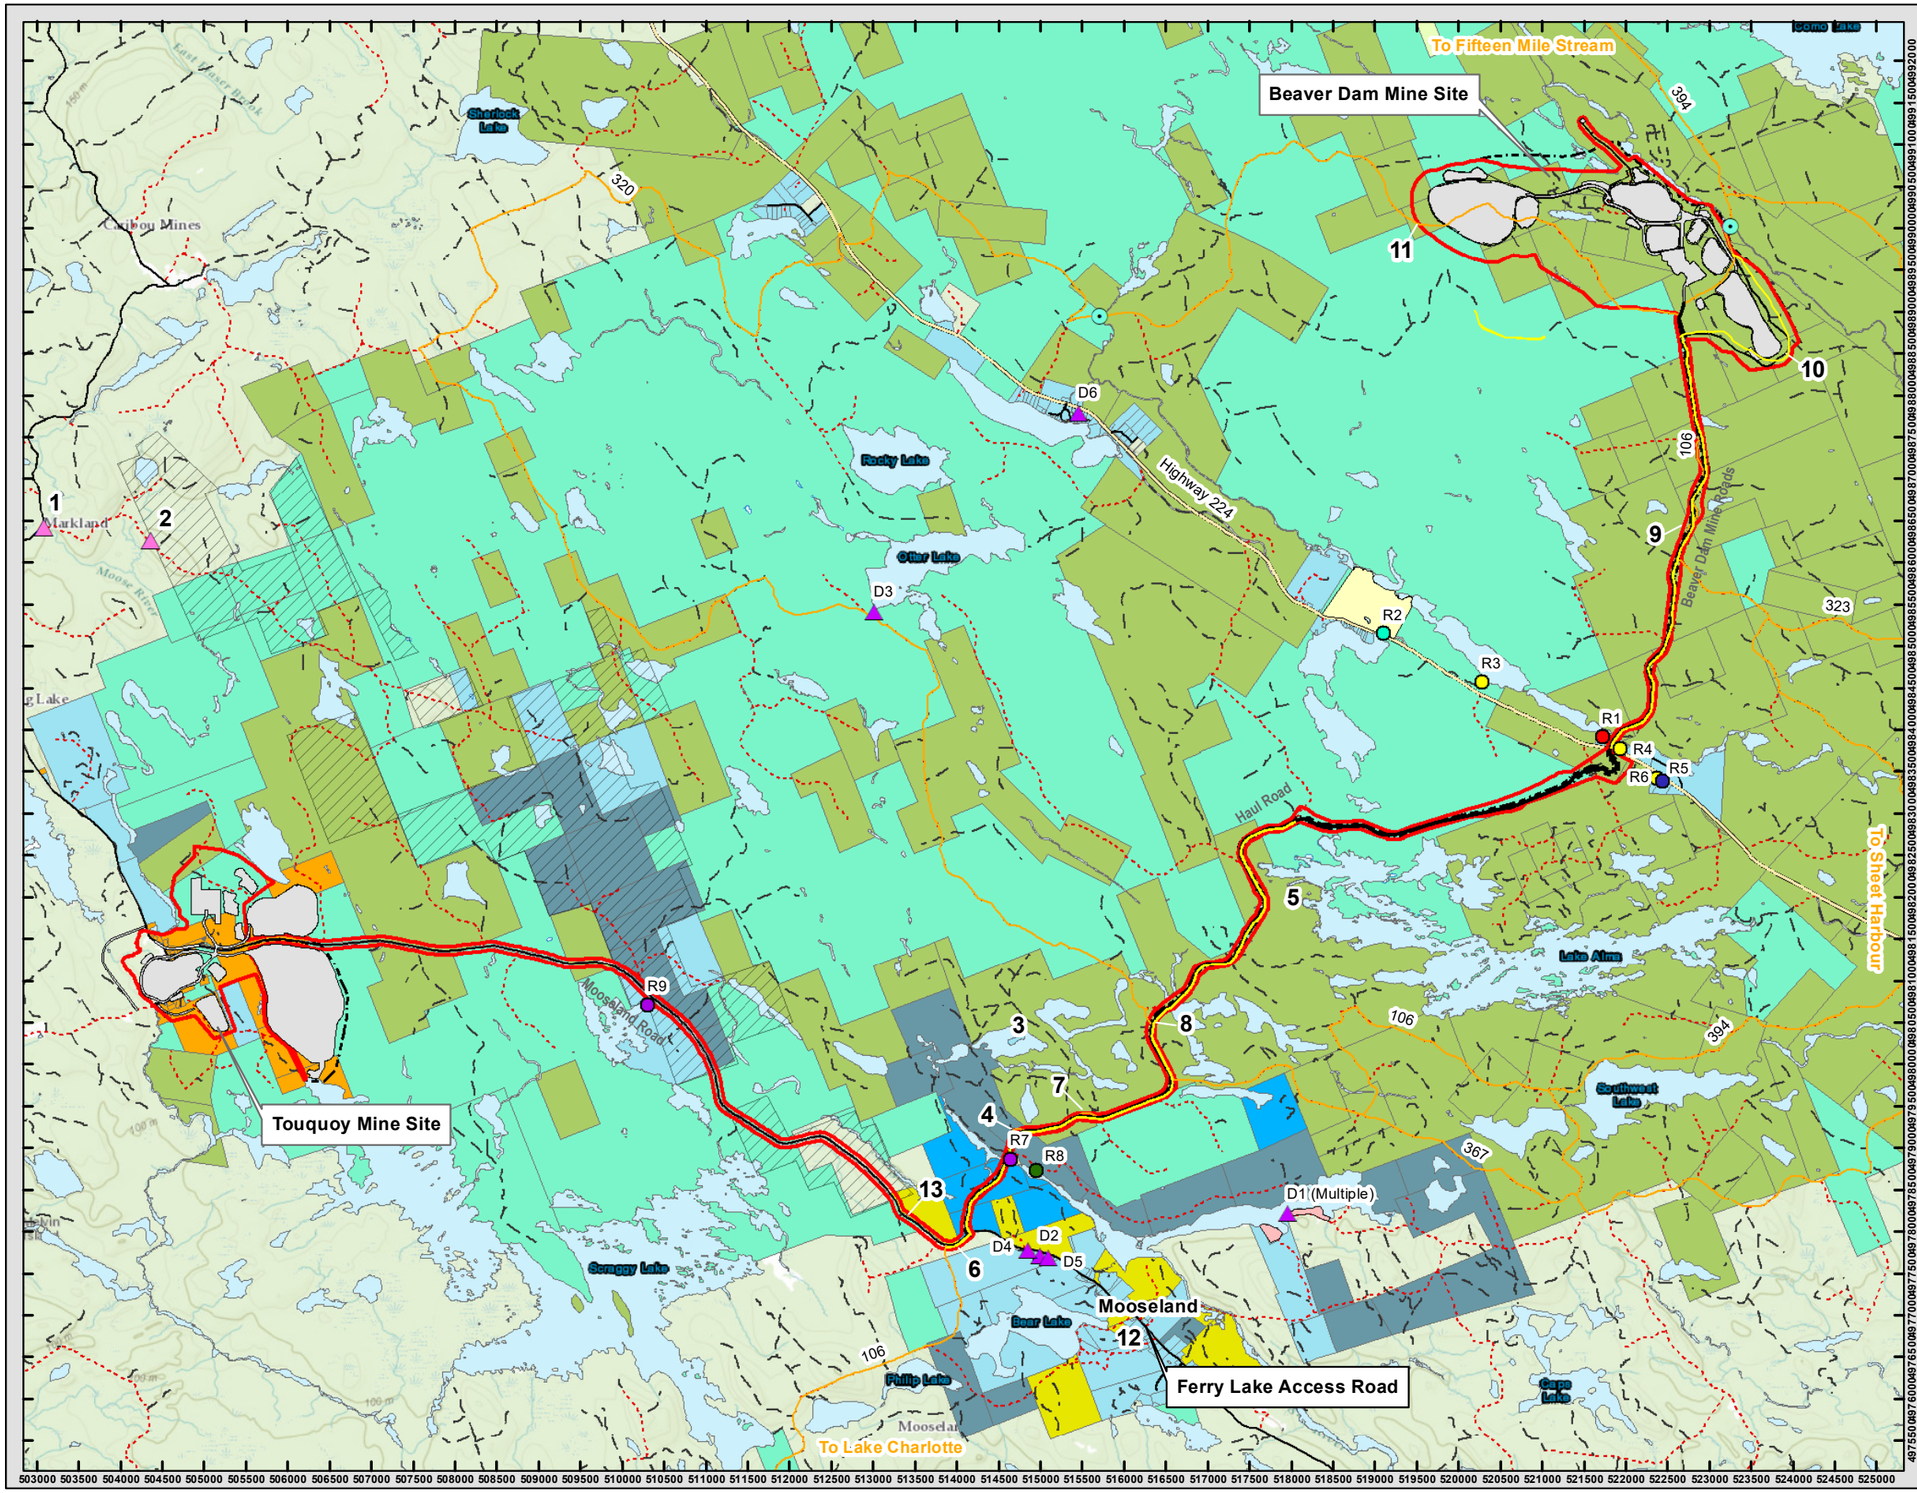
6.16.4.11 Emergency Services

The Eastern Shore area of HRM is serviced by the RCMP, which is based in Sheet Harbour. It provides services such as criminal records checks, non- emergency complaints, outside detachment emergency phone, general information, reporting a crime, fingerprints and police certificates. It is open Monday to Friday, 8 am to 4 pm. No recent crime statistics are available for the Sheet Harbour area. There are also RCMP detachments in Musquodoboit Harbour and Middle Musquodoboit.

Fire Station 28 in Sheet Harbour is a composite fire service (i.e., containing both professional and volunteer fire fighters). Fire Station 39, located in Upper Musquodoboit is a volunteer fire department that provides service to the rural parts of HRM as does the composite Fire Station 38 in Middle Musquodoboit.

6.16.4.12 Land and Resource Use

6.16.4.12.1 Existing Land Use



The Beaver Dam Mine Site is in the Halifax Regional Municipality approximately 20 km north-northeast of Sheet Harbour and 7 km east of Highway 224 in Marinette, NS. The surrounding area is undeveloped land that has had resource use (forestry, mining) for a century or more. The Project site is accessed by the Beaver Dam Mines Road (BDMR) which is a privately owned road up to the Mine Site. BDMR is used frequently by the public and appears to be considered a public right of way by the public. Beyond the mine site, private roads developed by forestry companies access the interior areas of the region. The network of roads is extensive and provides access to the public for recreational activity, namely for hunting, fishing, and ATV use. There is one permanent resident on Beaver Dam Mines Road, located close to the intersection of Beaver Dam Mines Road and Highway 224 (Figure 6.16-10). The next nearest resident to the Mine Site, is more than 5 km to the west. The Haul Road entrance from the Mooseland Road is approximately 800 m from a cluster of permanent and seasonal residences (Figure 6.16-10).

The proposed Haul Road is located through an area of managed forest by several forest companies and is part a logging road network. The Haul Road will also include approximately 4 km of new road construction. The existing Haul Road, known locally as the old dump road, connects Highway 224 west to Mooseland Road. There are no residences along this private road; however, there is camp near the Tangier River which is primarily used as a hunting camp during the fall hunting season (Figure 6.16-10).

The Mine Site is located on land predominantly owned by Northern Timber Nova Scotia Limited and the Province of Nova Scotia. Northern Timber also owns the Beaver Dam Mines Road and land adjacent to it. One parcel of Crown land is adjacent to the Beaver Dam Mines Road (Figure 6.16-10).

The Haul Road is a private logging road owned by the various landowners that include Northern Timber and the Province, and for the last 1.5 km owned by Musquodoboit Lumber Co. and Prest Bros. Ltd. AMNS has acquired access rights to the Musquodoboit Lumber Co. and Prest Bros. Ltd. lands and is in negotiations with Northern Timber for usage of its lands.

Municipal planning regulations are administered by Halifax Regional Municipality. The Beaver Dam Mine Site and Touquoy Mine Site are located in the Musquodoboit Valley and Dutch Settlement Plan Area. The Land Use By-law and Municipal Planning Strategy for this area were last amended in November 2018. The area is zoned mixed use and extractive facilities, of which mining related infrastructure is one, are permitted within this zoning designation. The by-law for mixed-use land use prescribes minimum separation distances from features such as lot lines, dwellings, watercourses, domestic wells, and residential zones. The resource mining is not specified in the by-law as it is governed in the provincial and federal regulatory process.

McCallum Environmental Ltd.

The majority of the haul route is located in the Eastern Shore (East) Plan Area, while a minor portion is located in the Musquodoboit Valley and Dutch Settlement Plan Area.[47] The area is zoned mixed use under the Musquodoboit Valley and Dutch Settlement Land Use By-law, and rural resource under the Eastern Shore (East) Land Use By-law.

6.16.4.12.2 Indigenous Peoples Land and Resource Use

The Confederacy of Mainland Mi'kmaq (CMM) was retained in 2009 by GHD Limited on behalf of the AMNS to complete a Mi'kmaq Ecological Knowledge Study (MEKS) for the proposed Beaver Dam Mine Project at the Beaver Dam Mine Site. In 2015, CMM was retained to update the MEKS, due to changes in the Haul Road to include approximately 4 km of new construction. CMM was then retained again in 2016 to finalize the MEKS to include the revised PA and any additional information.

In addition to the MEKS cited above, in 2018, a Traditional Land and Resource Use Study (TLRUS; MFC 2019) was undertaken by Millbrook First Nation to document historical and current use of the Project Area and surrounding areas by the Millbrook First Nation. This document was shared with AMNS under a confidentiality agreement. AMNS has integrated information obtained from the TLRUS, with permission from Millbrook First Nation, in appropriate sections of the EIS.

There are a number of activities associated with the harvest and use of plants, animals and fish within the PA and in the LAA that relate to historical traditions and customs of the Mi'kmaq that are still practiced today. As described, the TLRUS (MFC 2019), the MEKS and residents of the Beaver Lake IR identify trapping and hunting activities, plant and berry gathering, and fishing in, near and surrounding the PA for purposes of sustenance, spiritual and cultural practice. The TLRUS (MFC 2019) described the frequency of use within the LAA which can be summarized as regular: weekly to annually across all seasons. This means the area was, and still is, an important resource area for the Millbrook First Nation community members and by extension, all Mi'kmaq of Nova Scotia, and any Project activities may have potential impacts on the ability of the Mi'kmaq of Nova Scotia to access certain areas to practice their rights where species with important cultural relevance may be found. Wild meat was traditionally a staple of the Millbrook First Nation diet, and a few of the harvesters interviewed for the TLRUS (MFC 2019) indicated they rely mainly on this food source and they share their food with other community members, rather than purchase their meat at a local supermarket.

Some Mi'kmaq community members have camps on Crown land where they go to enjoy peaceful recreational and traditional activities with family and community members. There are five camps documented within 1 km of the Haul Road and multiple other camp locations throughout the LAA (MFC 2019).

Additional details on potential impacts to traditional harvesting is provided in Section 6.14 (Mi'kmaq of Nova Scotia) and the Human Health Risk Assessment (Appendix C.2).

6.16.4.13 Natural Resource Use

Natural resources include forestry, mining, and water. As previously stated, the region of the Project has had considerable activity related to forest harvesting activities and locally from mineral exploration and mining activities extending more than 100 years. There is no water use for any purpose currently. Historically, a flume was known to have been used from Crusher Lake to power mills for forestry and mining activity. There is a historic tailings management area under the proposed mine pit that is discussed in Geology, Soils and Sediment Quality (Section 6.5).

[47] Confirmed through review of Explore HRM mapping system.

6.16.5 Themes and Topic Areas

As a result of the data gathered as part of the baseline assessment, stakeholder and rights holder engagement and a review of local, provincial, and international objectives, several key lines of inquiry are identified. Themes are pervasive ideas that arose from the data gathering, which are broken into more detailed topic areas that will be analyzed to assess impacts against the baseline conditions. The topic areas reflect issues that have been identified as important to the nearby local communities, the region or the province as a whole.

The following section provides an analysis of the potential impacts on themes and its component topics.

6.16.5.1 Workforce Development

6.16.5.1.1 Introduction

Many of the objectives and goals for the province and Atlantic region link to the development of a sustainable workforce to support economic growth, business development and business retention. In fact, the Now or Never Report identifies the need to shift our demographics so that the tax base can sustain services (OneNovaScotia 2014). Nova Scotia must grow, attract immigrants, improve labour force participation, and pursue equitable economic growth. The idea of equitable economic growth is a key concept for the provincial government, as it is widely recognized that certain groups are not equally benefiting or fully participating in the economy, while others benefit more

The following topic areas are identified as important topics of the Workforce Development theme.

6.16.5.1.2 New Employment – Direct and Indirect

In November 2020, KPMG completed an Economic Impact Assessment of the Project (Appendix O.1) which evaluated the benefits coming from the construction and operation of the Project to Nova Scotia and Canada. The KPMG Assessment does not include potential benefits from exploration or closure, and reclamation activities.

The KPMG Assessment considers direct employment as well as indirect. Direct effects are direct expenditures and include the salaries paid to AMNS or prime contractors' staff, and other revenues generated (Appendix O.1). Indirect effects are the incomes from the demand for goods and services generated by the project in other sectors. This would include suppliers selling their goods and services, such as professional and engineering services, specialized technical services, and other similar services. Indirect impacts include salaries paid to employees of the various suppliers and revenues generated by these suppliers.

In Nova Scotia alone, Beaver Dam Mine Project is expected to create 137 jobs (Full-time equivalents [FTE]) during the one year of the construction phase and 311 (FTE) jobs during the five years of operations. Of particular note are the number of indirect jobs, a total of 161 FTE's, projected to be created. Refer to Section 6.16.5.1.8 for a description of suppliers and additional analysis on this potential impact (Tables 6.16-7 and 6.16-8).

Table 6.16-7: Economic Impacts on Nova Scotia Stemming from the Construction – Beaver Dam Mine Project

Nova Scotia Province	Direct Effects(a)	Indirect Effects	Total
In millions of dollars			
Total value added, of which:	**15.1**	**3.2**	**18.3**
Salaries and wages before income taxes	11.6	2.1	13.7
Other revenues before income taxes	3.5	1.1	4.6

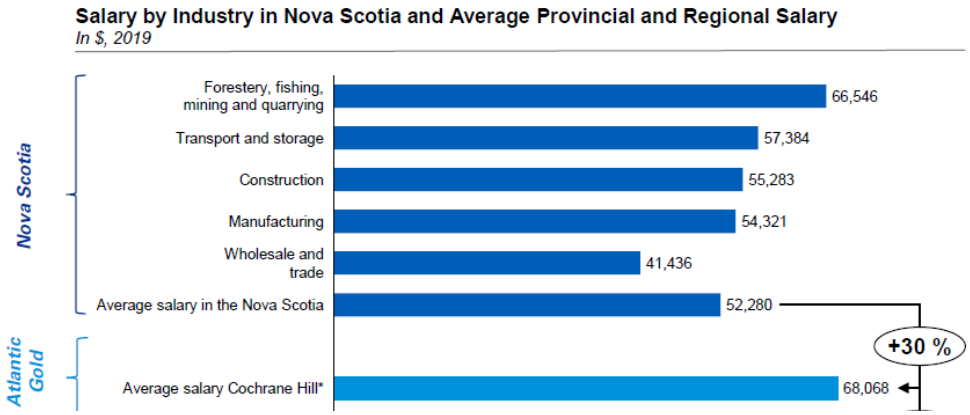
Notes: For one year, in millions of dollars and in person-years.
Due to rounding, the sum of items may not add up to the total. FTE = Full-time equivalent.

Table 6.16-8: Economic Impacts on Nova Scotia Stemming from Operations – Beaver Dam Mine Project

Nova Scotia Province	Direct Effects	Indirect Effects	Total
In millions of dollars			
Total value added, of which:	**8.8**	**22.4**	**31.2**
Salaries and wages before income taxes	8.8	15.5	24.3
Other revenues before income taxes	0.0	6.9	6.9
In person-year (FTE)			
Jobs in person-years	**150**	**161**	**311**

Source: Simulations of Statistics Canada based on data from AMNS, KPMG Assessment (Appendix O.1).



Notes: Typical year, in millions of dollars and in person-years.
Due to rounding, the sum of items may not add up to the total. FTE = full-time equivalent.

In an analysis of the Regional Impact of the proposed Cochrane Hill Gold Project commissioned by AMNS in 2020,[48] KPMG noted that the average salaries to workers at the mine is 30% above the provincial average (Figure 6.16-11). The Beaver Dam mine is not any different in terms of the salary comparison than the proposed Cochrane Hill Gold Mine Project and provides a valuable indicator regarding the quality of the employment.

For Canada as a whole, the mine is projected to create 157 jobs (FTE equivalents) during construction and 421 (FTE equivalents) during operations over the five years of operations (Tables 6.16-9 and 6.16-10).

[48] Source: KPMG Regional Economic Impact, 2020.

Source: Simulations of Statistics Canada based on data from AMNS, KPMG Analysis (Appendix O.1).

Note: Typical year, in millions of dollars and in person-years.
Due to rounding, the sum of items may not add up to the total. FTE = Full-time equivalent.

6.16.5.1.3 Training Opportunities

AMNS supports apprenticeships through a partnership with the Nova Scotia Community Colleges. In 2021, apprenticeships exist in Heavy Equipment Technician, Millwright, Instrumentation, and Electrician trades.

AMNS is currently developing an apprenticeship programme that would lead to Red Seal Certification for women in trades. In 2018, AMNS began training four millwright apprentices and two heavy equipment apprentices. AMNS plans to include future opportunities for Industrial Electricians and Instrumentation Technician apprenticeships.

AMNS fully supports each apprentice through employment to ensure they receive the required hours on the job and while they attend the educational portion of the apprenticeship at a recognized institution. As AMNS continues to grow in the province of Nova Scotia, it plans to grow the apprenticeship program to meet the need for Red Seal qualified tradespeople.

6.16.5.1.4 Opportunities for Advancement in Career

AMNS offers a variety of career advancing opportunities and has a mission to provide the local community with good employment leading to internal career progression. Through structured professional development and education assistance, AMNS enhances the skills of the internal workforce and extended family community by applying a "Grow our own Success"[49] approach. Specific career advancing training includes:

- a structured Work Performance System that incorporates training and development plans for all employees;
- internal development programs including a Mentoring Program, Leadership Development Programs, Leadership Essentials Series;
- Women's Internal Network;
- the ability to pursue career development through funding for formal accredited courses of study and safety courses including funding First Aid Certification for employees;
- payment of Professional Memberships;
- comprehensive onboarding and safety training for all employees and contractors;
- train-the-trainer customized for unique industrial environment;
- under development is PC usage and keyboarding support for non-tech users with potential to expand to extended family and local community; and
- site wide development opportunity in work-focused courses including time management, communication skills, managing effective meetings, and more.

AMNS commits to encourage a safe and tolerant workplace and has adopted an Equal Employment Opportunity Policy from the parent company St Barbara Limited.[50]

[49] Source: Grow your Own Success is an internal strategy document.

6.16.5.1.5 Labour Force Participation

Nova Scotia has established a goal of having a labour force participation rate as high as the Canadian rate (Table 6.16-11). Labour force participation is defined as "the number of people of working age who are active in the labour market – either employed or unemployed – as a ratio of the total working-age population."[51] The Province has tracked the progress toward this goal and has determined that it is "Not Progressing/Not On Track."[52] The gap between the Canadian participation rate and the Nova Scotian rate is larger than the baseline of 0.8 established by the Now or New Report (OneNovaScotia 2014).

Table 6.16-11: Labour Participation Rates between Nova Scotia and Canada

Age Group	Gap
15-19	2
20-24	4
25-29	0.9
30-34	0.5
35-39	-1.2
40-45	-0.6
45-49	-0.9
50-54	-1.3
55-59	-2.9
60-64	-6.9

Source: Gap Between the NS and CA Participation Rates by 5 Year Age Groups (2018) Data Table – One NS Dashboard.

The difference in labour participation rates between Canada and Nova Scotia by age group is shown in Table 6.16-11. The largest gap in participation rates occurs in the older age demographics. The younger demographic is above the national average, meaning that a higher number of younger people are participating in the labour force. Although no stated data as to why Nova Scotia's labour participation rate is below the national average, reasons could include:

- outmigration of younger people looking for job opportunities;
- Nova Scotia being marketed as a retirement destination;
- health and accessibility restrictions at workplaces making it harder for older workers to find suitable employment; and
- discouraged workers who cannot find employment may be more common in older workers.

The Project will provide many direct and indirect jobs, which could potentially attract older workers back to the workforce or assist in keeping the prime working age demographic in Nova Scotia.

[51] Source: https://www.onens.ca/goals/goal-7-labour-force-participation-rate March 3,2021.

[52] Source: https://www.onens.ca/goals/goal-7-labour-force-participation-rate March 3, 2021

Promoting equitable economic growth includes supporting a strong labour force while considering Diversity and Inclusion. AMNS has a Diversity and Inclusion policy to, "facilitate a diverse and representative workforce and management structure."[53]

6.16.5.1.6 Impact on Educational Attainment

AMNS will need a relatively large labour force with skills or education to complete specialized tasks. The Mineral Resourcing Engineering program at Dalhousie graduates individuals who suited for employment in the mining sector. Other university programs, such as accounting, environmental sciences, communication, and geology, will help supply AMNS's employment needs. The Nova Scotia Community College also graduates a variety of students in programs of interest to AMNS.[54] These range from Office Administration to a variety of apprenticeship and ticketed professions, Law and Security, GIS Technician, plus many others. Given Nova Scotia's stated goal of keeping new graduates in the province, graduates from post secondary programs to jobs with above average salaries is a support to this goal.

AMNS also provides coop opportunities to university students, which can be a requirement of attaining a degree in their chosen fields.

6.16.5.1.7 Youth Employment Rate

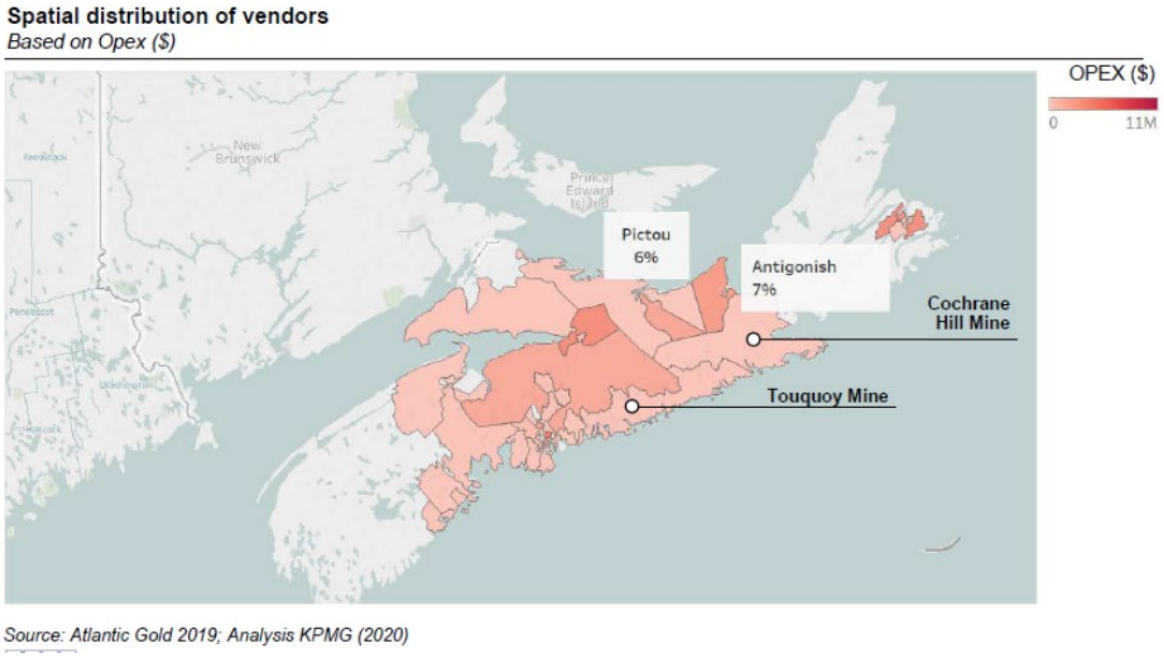
Youth Employment (for ages 15 to 24) is a goal of the province, but also through engagement with communities the need to provide employment opportunities for the next generation was identified as desirable to sustaining our economy and our local communities. The gap between the rates of employment of young people and the rest of the population have been closing in recent years. The impacts of COVID 19 on youth employment rates has been significant and it is too early to tell what the long-term recovery will be.

AMNS has no data to indicate the breakdown of its future workforce and if the impacts to this group will be measurable or significant. However, by providing employment opportunities it may help the younger generation decide to stay in Nova Scotia instead of moving away for potential employment opportunities.

6.16.5.1.8 Suppliers

AMNS undertook a study in 2020 to understand the regional impacts of the proposed Cochrane Hill Gold Project, and used the supplier data from the Touquoy Mine to project supplier spending for that proposed project. No regional impact report exists for Beaver Dam, but the Cochrane Hill Study provides locational data of current suppliers to Touquoy. This data can be used to assist in making projects regarding potential suppliers for Beaver Dam. The supplier data "heat map" is shown below, with the darker colour showing the areas of more spending and the lighter areas with less spending. During construction for Touquoy the spending was distributed as illustrated in Figure 6.16-12.

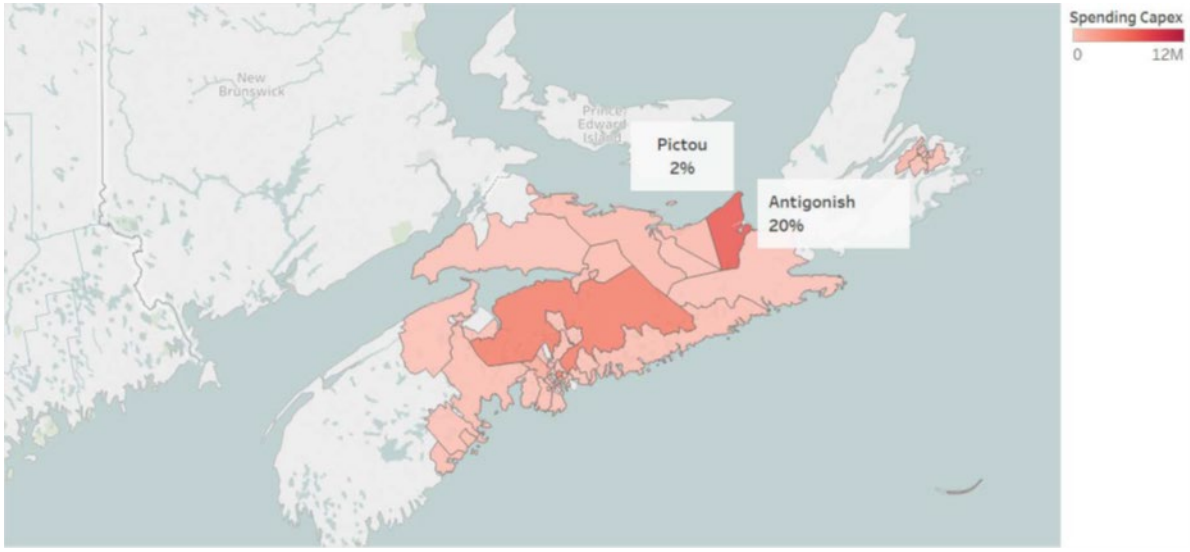
It is anticipated that the supplier spending will be distributed in a similar way as for the Touquoy mine site, with benefits both within the LAA and RAA.



The AMNS Supplier Code of Conduct commits to using suppliers who match the corporate values. This requires that suppliers comply with the Supplier Code of Conduct. The elements of this Code include the following:

[53] Source: Diversity and Inclusion Policy https://stbarbara.com.au/wp-content/uploads/2021/02/Board-Policy-Diversity-and-Inclusion-Policy.pdf.

[54] Source: Programs of the NSCC for 2021-2022 https://www.nscc.ca/admissions/program_openings/default.aspx#School-tab



- Anti-bribery and corruption;
- Diversity and inclusion;
- Health and Safety;
- Modern Slavery; and
- Sustainability.

Figure 6.16-12: Supplier Data Heat Maps

Source: Atlantic Gold 2019; Analysis KPMG (2020)

During operations, spending from Touquoy is spread more evenly through Nova Scotia.

6.16.5.2 Demographics

6.16.5.2.1 Introduction

To sustain the province, Nova Scotia must grow its population and change the demographic make up so that the population is younger.[55] During engagement with the public, we often heard about the need for jobs for "their children" or the desire for the next generation or stay or return "home" (Appendix A.4a). Although urban Halifax is growing, the Eastern Shore has not seen the same growth in population. The depopulation of the rural areas results in aging infrastructure not being replaced, local services consolidating in larger centres, business community reductions, and general lack of community vitality. When a population is decreasing, it is difficult to justify new infrastructure investments.[56]

During engagement, often-repeated themes were poor roads and the need to find younger people to take over positions within the community (Appendix A.4a). Some organizations stated that they are having difficulty finding volunteers and taking leadership responsibilities within the community. It was important to note that AMNS's team did observe organizations having younger people within its ranks.

The following topic areas are identified as important aspects of the demographics theme.

6.16.5.2.2 In-migration

In-migration from other provinces or countries is a goal of Nova Scotia and in recent years there has been significant progress made toward reaching the provincial goal.[57] AMNS provides employment that is higher than the provincial average, which creates opportunities to support in-migration.

6.16.5.2.3 Rural Repopulation

AMNS has an active workforce attraction strategy focused on recruiting and attracting local employees, but also recognizes that employees may also be required to relocate from other places in Canada or the world.[58]

The proposed Beaver Dam Mine Site is approximately 1.5 hours commuting time from the peninsula of Halifax; however, depending on the volume of traffic and weather conditions travel can extend to 2 or more hours. AMNS recognizes that the commuting distance and time to the Project is a barrier to workers who live in urban HRM. In 2019, the average commuting time for Canadians was 24 minutes. Halifax has 3% of its population who spend 60 minutes or more travelling to work.[59] The commuting time data is a good indicator of how long workers or potential workers are prepared to commute.

[55] Source: Now of Never Report (OneNovaScotia 2014).

[56] Source: https://fcm.ca/sites/default/files/documents/resources/report/rural-challenges-national-opportunities.pdf

[57] Source: https://www.onens.ca/goals/goal-2-international-immigration

[58] Source: One NS Goal and Atlantic Growth Strategy both include immigration goals to support growth.

[59] Results from the 2016 Census: Long Commutes to work by Car: Release Date: February 2019.

A long commute may be a discouragement to potential employees, and it has impacts on personal health, environmental health, infrastructure, and individuals' personal finances. Studies have suggested that men are more likely to have long commutes then woman, due to household responsibilities.[60] Long commuting distances may also reinforce barrier for women in the workforce.

The proposed Beaver Dam Mine Site and the existing Touquoy Mine Site will require on-site workers. Although a post-COVID world may entrench remote working as a viable option for some office work, the operational staff who run the mill, work at the pit and drive the trucks will need to be on site. The distance from the nearest population centre and the need to recruit new staff may encourage workers to relocate to adjacent rural communities, such as Mooseland, Marinette, Sheet Harbour and the surrounding communities.

6.16.5.3 Healthy Communities

6.16.5.3.1 Introduction

It is well understood that healthy communities need more than just employment opportunities. Healthy communities include, for example, cultural activities, food security, links to open space, recreational amenities, economic and racial equality, a sustainable population, personal and community wellness, adequate housing, and a healthy environment. A healthy community can be defined as, "a place where healthy built, social, economic and natural environments give citizens the opportunity to live to their full potential."[61]

AMNS supports healthy communities through its Donations Sponsorships Community Programs, which guide community investments to contribute to the communities in which it operates. The policy states, "St Barbara's aim is to make a positive, meaningful and sustainable difference to those communities in a fair, transparent and ethical manner and to build strong relations based on respect, trust and transparency."[62]

The following topic areas are identified as important aspects of the Healthy Communities theme.

6.16.5.3.2 Hospitals

The main hospitals that would service the Project are the Musquodoboit Valley Memorial and the Eastern Shore Memorial Hospital (ESMH). Musquodoboit Valley Memorial and the Eastern Shore Memorial Hospital are subject to frequent closures of its emergency department. It was reported that during December 2020 the emergency departments for three hospitals servicing the Eastern Shore communities were closed 40 times, with the ESMH closing 14 times, Musquodoboit Valley Memorial closing 13 times, and Twin Oaks Memoria closing 13 times.[63] Staffing shortages of doctors and nurses is a long-standing issue.[64] New reports indicate that these closures are a concern for local residents. The Nova Scotia Health Authority is working with local community members in Sheet Harbour to assist with recruitment, but this work has been delayed by COVID.

[60] Results from the 2016 Census: Long Commutes to work by Car: Release Date: February 2019 where example studies are referenced.

[61] Policy on Heathy Community Planning, prepared by the Canadian Institute of Planner: 2018.

[62] Donations, Sponsorships and Community Programs Policy, page 4 https://stbarbara.com.au/wp-content/uploads/2018/03/Donations-Sponsorships-Community-Programs-Policy-approved-10-December-2019.pdf.

[63] Source: https://globalnews.ca/news/7561843/eastern-shore-physician-discusses-impacts-of-rising-emergency-department-closures/.

[64] Source: https://globalnews.ca/news/7556686/emergency-closures-eastern-shore-ns/.

Although the province supports rural development and growth through encouraging rural resource uses and tourism, for example, increases in population would put increased pressures on rural health care providers. AMNS does include on site first responder capabilities by having trained staff. The impact of the proposed mine site and the potential population growth it may bring could have impacts on existing hospital services, but these are not expected to be significant. Further study may be helpful to understand the impact AMNS's operations on short- and long-term population growth.

6.16.5.3.3 Primary Care Provider Availability

Finding a family doctor for many in Nova Scotia is a challenge. The Nova Scotia Health Authority releases monthly statistics tracking the number of people looking for a primary care provider. As of March 1, 2021, 6.1% of the population of Nova Scotia, or 60,154 Nova Scotians were registered on the Need a Family Practice Registry. In the Eastern Shore Cluster, 559 people were registered, or 3.2% of the population.[65] This is an increase of 1.2% from March 2020.

Any population growth is likely to have a negative impact on primary care provider availability if no additional family doctors are recruited and established in the LAA.

6.16.5.3.4 Seniors Support

An elder care facility, Harbourview Lodge Continuing Care Centre, is attached to ESMH. Braeside Nursing Home is located in Middle Musquodoboit. Social services are offered in both centres.

AMNS has been active in supporting seniors' facilities, particularly during the COVID pandemic. Contributions include:

- $5,000 contribution to Braeside Seniors home in April 2020 for the purchase of technology to support calls with family members;
- $1,000 to Braeside for garden equipment;
- $3,000 to Harbourview Seniors Home in Sheet Harbour; and
- Approximately $1,000 to High Crest Seniors Home in Sherbrooke.

6.16.5.3.5 Schools

Most school aged children in the LAA and RAA attend the Pre-Primary to Grade 12 school in Sheet Harbour. This school is seeing declining attendance (Section 6.16.4.4). The mine operation has the potential, with increased employment and potential relocations to the area, to support this school population.

6.16.5.3.6 Recreational Facilities

Recreational facilities are integral part of community wellness. In Mooseland, there is a Community Hall, which serves as a hub for residents of Mooseland. The facility is the home base for the Mooseland and Area Community Association, which host a variety of small events, such as card parties and community suppers for local residents. The Hall is a former school, which then became a fire hall and is now a community hall. This Hall is important to the local residents of Mooseland. AMNS is currently in discussions to support the Association's activities through a long-term partnership arrangement.

[65] Source: https://www.nshealth.ca/files/finding-primary-care-provider-nova-scotia-march-2021.

The Eastern Shore Lifestyle Centre, to be ultimately located in Sheet Harbour, is a major community initiative where significant funders will need to come to the table to support the development of a regional recreation centre. Rural development projects such as these helps attract residents to the area and AMNS sees opportunities to support its development.

By supporting recreational facilities, AMNS wants to increase the attractiveness of the local communities to potential future employees of the mine site. Recreational facilities are important when trying to attract new residents to communities. AMNS is prepared to consider supports to recreational and community facilities as part of employee attraction to the area.

6.16.5.3.7 Housing

Housing options along the Eastern Shore are limited. Most residences are in private ownership and there is a lack of rental housing. Increased population growth could apply pressure on the existing housing market and impact housing prices. Increased demand may also result in new housing developments and forms. Increased housing demand can also result in increased greenfield development or redevelopment of existing brownfield sites or residential dwellings.

As of March 2021, house prices in HRM have increased substantially, which appears to be encouraging potential purchasers to look for more affordable housing options outside of urban Halifax. The long-term impact of this housing inflation is unclear but it may impact general affordability of homes in the RAA.

6.16.5.3.8 Location Taxation

HRM is the local taxation authority. In 2020/2021, the municipality projected property total tax revenues of $509,169,000 for residential, commercial and resource properties.[66] The KPMG Assessment provides projections, both direct and indirect, of the Project on municipal revenues. It is anticipated that during the one year of construction, the Municipality will receive a $500,000 increase in revenues. During the five years of operations, the local taxation authority is projected to receive $1.2 million per year in revenue from AMNS.

6.16.5.4 Land Use, Recreational and Indigenous

6.16.5.4.1 Introduction

The land use of the area is mainly forestry and recreational. The Community of Mooseland is located near the junction of the Haul Road with the Mooseland Road and no haulage will occur through the community itself. Through engagement, AMNS learned of a variety of activities, uses and locations of importance to local users (Appendix A.4a Public Engagement Activity Log). Any land use interactions resulting from the Project will apply the appropriate mitigation measures. The potential land use interactions, sensitive receptor locations (i.e., used in modelling for noise, air and light) and specific dwellings in proximity to the Beaver Dam Mine Site identified through engagement are described in Tables 6.16-12 to 6.16-14 and shown in Figure 6.19-10.

The following topics are identified as important aspects of the Land Use theme.

[66] Source: 2020-21 Budget Recast Budget; Halifax Regional Municipality

Table 6.16-12: Beaver Dam Mine Project Potential Land Use Interactions

Feature #	Use	Impacted Party	Description	Potential Interaction	Perceived Level of Interaction by User	Severity of Interaction	Likelihood of Interaction	Potential Mitigation	Level of Interactions after Mitigation
1	Cairn	Icelandic Society	Heritage memorial and location of interpretative signage	Low	Low	Low	Low	None required	Low
2	Cabin/Interpretive Area	Icelandic Society	Re-creation of an original cottage and the location of the original homesteads	Low	Low	Low	Low	None required	Low
3	Sandy Pond Island (Prest Property)	Marilyn Prest	No dwelling at this time.	Low	Low	Low	Low	None required	Low
4	Property access road	Marilyn Prest	Access road to Sandy Pond Island property	High	High	High	High	Provide access to Sandy Pond Island via Haul Road bypass and construction of a field driveway.	Low
5	Lake Alma access/boat launch/camps	Lake Alma properties	Multiple camps (10-20) along Lake Alma	Medium	Low	Low	Low	Allow access to Haul Road so people can access their camps.	Low
6	ATV Trail	Recreational ATV clubs, snowmobilers	Off-road pilot project area where ATV's will be permitted on the public ROW	Low	Low	Low	Low	Work with TIR to upgrade Mooseland Rd and provide sufficient shoulder for ATV traffic	Low
7	ATV Trail/Vehicle access	Recreational ATVs, snowmobilers, local hunters and fishers, possibly Indigenous, local community members; Lake Charlotte ATV Club, PUMA ATV Club, ATVANS, and Sheet Harbour ATV and Snowmobile Club	Trail #106 of the provincial ATV trails runs along the south portion of the haul route between Mooseland Road and Trail #367. Concerns regarding vehicle (truck) access along the Haul Road between Mooseland Rd and Hwy 224, specifically for boating/camp access	High	High	High	High	Build ATV trail alongside proposed haul route between Mooseland Rd and ATV Route 367. Build service road along side Haul Road.	Low
8	Haul Road Crossing	ATV clubs, snowmobilers, local residents, potentially Indigenous	Allow for east- west travel. This would connect Trail #367 to Trail# 320	High	High	High	High	Create a controlled crossing point on a Haul Road.	Medium
9	ATV Trail	Sheet Harbour ATV Club; ATVANS, other recreational users, potentially Indigenous	Trail# 106 runs along the BDMR.	High	High	High	Low	Build BDMR bypass road between Hwy 224 and mine site	Low
10	Mine Site Rd	ATV clubs, snowmobilers, NSSA, hunters and fishers, potentially Indigenous	Trail# 106 re-routed around the mine site.	High	High	High	High	Construction of a bypass road around the mine site for recreational traffic	Low
11	ATV Trail, property access	ATVANS, Rocky Lake Residents, Indigenous	Trail #320 dead-ends at mine. Access to camps (multiple) on Ten Mile Lake via ATV Trail #320, which will be severed due to Beaver Dam Mine Site.	High	High	High	High	Construction of an ATV trail that links trail# 320 to the BDMR bypass.	Low
12	Ferry Lake Access Road (also known as River Road)	Mooseland Residents; Ferry Lake property owners	Mooseland residence concerns about alternate ATV access point if trail closures.	Low	High	Low	Low	Construct Haul Road bypass so users do not use the Ferry Lake access road to access Lake Alma and other locations.	Low
13	Proposed alt Haul Road/Mooseland Road access point	Gillis, Glawson and adjacent properties	Noise concerns regarding proximity of planned Mooseland Road/Haul Road access point and to address recreational parking	Low	High	Low	Low	Consider installation of parking area to address parking concerns.	Low

Table 6.16-13: Dwellings in Proximity to Beaver Dam Mine

Structure ID	Structure Description	Distance from PA	Distance from Closest Mine Site	Dwelling Type	Seasonal/ Permanent	Potable Well (Y/N)	Well Type
D1	Ferry Lake (Multiple Properties)	3.5 km east of Haul Road	5 km South of Beaver Dam Mine Site	Multiple properties	Seasonal		
D2	4305 Mooseland Road (Gillis Property)	850 m east of Haul Road	9 km east of Touquoy Mine Site	House/cottage	Seasonal	Yes	Dug

R7	Tangier River (Deepwood Estates Property)	Yes	Yes	Yes	Directly Adjacent - South side of Haul Road	9 km southeast of Touquoy Mine Site	Cottage	Seasonal	Yes	Dug well
R8	Tangier River (John Dickson Leasehold property)	Yes	Yes	Yes	350 m Southwest of Haul Road	9 km southeast of Touquoy Mine Site	Trailer(s)	Seasonal	Inconclusive	-
R9	5579 Mooseland Road (Lloy Property)	Yes	Yes	Yes	Directly Adjacent - East side of Mooseland Road	5 km East of Touquoy Mine Site	Cottage	Seasonal	Yes	Dug well

Notes: Approximate locations show in Figure 6.16-10.

For more details regarding Receptor Locations and completed Modelling refer to Sections 6.1 (Noise), 6.2 (Air), and 6.3 (Light) and Appendices B.2 (Updated Noise Impact Assessment Technical Report), C.1 (Air Emissions Assessment Technical Report), and D.1 (Light Impact Assessment).

6.16.5.4.2 Snowmobiling and ATV Use

The ATV Association of Nova Scotia is the umbrella association for the recreational ATV clubs, which are located throughout the province.

Three main clubs are active within the LAA. These are:

- PUMA ATV Club located in Dean;
- Sheet Harbour Snowmobile and ATV Club located in Sheet Harbour; and
- Lake Charlotte ATV Association in Lake Charlotte.

The LAA is heavily used by ATV and snowmobiles, which includes both ATV Clubs and other recreational users. It is difficult to estimate with accuracy the number of non-club members who use the trails within the LAA. Consultation with the local clubs shows that the trails are part of the formal ATV network that connects different communities to each other. The trails used by the ATV clubs are well organized and numbered, and organized events occur on this trail regularly. The trails are part of a larger pan-provincial ATV and snowmobile network.

The ATV associations have "ATV highways" which are numbered. Perhaps the most well used of these highways is Trail# 367, (known locally as the H Road) which is travelled by the Lake Charlotte members when travelling from Lake Charlotte to Sheet Harbour (Figure 6.19-10). The riders travel over Trail# 106, cross Mooseland Road to the Haul Road and then turn south on to Trail# 367. It is estimated that 2,000 riders a year travel this route (Figure 6.16-10).[67]

Another well-traveled route is from Sheet Harbour along Trail# 367, crossing the Haul Road to connect to Trail# 320 (Figure 6.16-10). This route takes riders to Otter Lake, a popular Lake for fishing and recreation purposes. There is also a camp located on Otter Lake which is privately owned but is known locally as a resting place or emergency stopping location for recreational users (Figure 6.19-10 and Appendix A.4a). According to engagement, Trail# 367 has been a stopping spot for over 50 years and connects to many canoeing and fishing waterways, including Blacky's Meadow, Otter Lake Flowage and Shingle Lake (Appendix A.4a).

Trail# 320 continues North and then turn west to cross Highway 224 (Figure 6.16-10). ATV clubs and non-club members who live in the Rocky Brook Lake area use Trail #320 to access recreational lands to the west of Killag. Engagement with Rocky Brook Lake residents indicated that the connection of Trail #320 to Trail #394 is important for residents and for the broader ATV community (Appendix A.4a). Rocky Brook Lake resident use Trail #320 for dog walking, ATV riding, hiking and general access to nature (Appendix A.4a). None of the Rocky Brook Lake residents, as of the date of an engagement with them in December 2020, are members of an ATV club.

Though engagement, it has been identified that the intersection of the Mooseland Road and Trail# 106 is a concern as this location is used as a parking location for boats and recreational vehicles heading toward the Tangier Grand Lake Wilderness Area (Figure 6.16-10). Both the Mooseland and Area Community Association and individual property owners in the area have provided pictures and videos showing that trucks, cars and trailers parked on the Mooseland Road, unload their gear and ATV or snowmobile for the day (Appendix A.4a). According to community members, this creates a potentially unsafe traffic and pedestrian situation once the Haul Road is operational. AMNS will investigate options during detailed road design to address this concern and find a solution to increase safety. Options may include creating parking area or altering the access to the Haul Road. Mitigations will be

[67] Personal Communication with S. Foley, Lake Charlotte ATV Club.

reviewed by the Mooseland community members through the development of a working group before implementation (Appendix A.6 draft Public Engagement Plan).

6.16.5.4.3 Active Transportation and Recreation

Local residents and recreational users have indicated that the proposed Haul Road is used for local walking and hiking, with no formal trails or active transportation pathways in the area. A search of NS Trails online Trail Finder[68] showed no designated trails within the project area, nor is there any tourism literature found promoting the Project Area as a hiking or outdoor adventure location. Hikes are occasionally held at the Otter Pond Demonstration Forest, which is outside of the PA but is within the LAA.[69]

Within the project area there is evidence of recreational usage. The Glawson, Prest, and Gillis family, along with several individuals who made submissions to the Impact Assessment Agency of Canada (IAAC) website, describe multigenerational usage within the LAAA and RAA for skating, tobogganing, canoeing, swimming, fishing, hunting and group outings.[70] In particular, Krista Gillis and Mitchell Glawson have spoken about the importance of having access to nature and the places they visited as children, and where they now take the next generation (Appendix A.4a). Residents of Rocky Brook Lake spoke of the importance of walking and interacting with nature, as did Frank and Brenda Lloy and Deborah Marlborough, both of whom own houses near the proposed Haul Road. Access to the recreational areas is by truck, jeep, foot, ATV and snowmobile. Community members have expressed the expectation that access to land and nature be maintained (Section 3 and Appendix A.4a).

AMNS is committing to a series of bypass routes to allow continued access to the recreational areas and to allow continued recreational usage. The bypass roads are shown in Figure 6.16-10.

6.16.5.4.4 Access to Camps

Several camps are located around the PA, but not within it. Through the construction of series of bypass roads and Haul Road crossings, access to all camps will be maintained. Specific locations are described in Table 6.16-15 and Figure 6.16-10.

Table 6.16-15: Locations of Camps around the Project Area

Owner Name	Location	Map Reference[(a)]	Access Routes
Musquodoboit Lumber Company – Leaseholder: John Dickson	Near the bridge where the Haul Road crosses the Tangier River	R8	Haul Road
Darren Lasaga Camp	Otter Lake	D3	Via Highway 224 to Trail #320
Harry Casey et al. Camp	10 Mile Lake	Not shown	Via Trail #320 to Trail #394
Jeff Bevis Camp	Lake Alma	Not shown	Summer: Truck access via Highway #224 to Trail #394 Winter: ATV/snowmobile access via Haul Road to Trails# 367 and #106

Deepwood Estates Camp and Property - Property in AMNS ownership as of December 2020	Tangier River	R7	Access Via Haul Road
Marilyn Prest – Land only	Island	3	Haul to trail which starts west of Tangier River

Notes: [(a)] Figure 6.16-10.
ATV = All-terrain vehicle.

Access to all camps will be maintained through the construction of a bypass road which will consist of a single 4 m lane and with a 1 m shoulder on each side, for a total of a 6 m right-of-way. This bypass road will start at Mooseland Road and connect to the existing forestry road that intersects with the stretch of proposed new portion of the Haul Road to the west. The Haul Road Bypass specific location will be determined as part of the detailed design.

6.16.5.4.5 Haul Route Safety

The Haul Route will be used to transport ore between the processing facility at Touquoy and the Beaver Dam Mine Site. Most of the Haul Route will be privately maintained by AMNS, but a short portion of the Haul Route will use the Mooseland Road, a public road. The Mooseland Road between the Touquoy mine site and the entrance to the Haul Road is primarily a gravel road with some paving.

Local Mooseland residents have expressed concern about public safety along the Haul Route, particularly along the Haul Road (the portion of the Haul Route between Mooseland Road and Highway 224) and at the entrance of to the Haul Road from Mooseland Road (Figure 6.16-10, Section 2, Figure 2.3-3 and Appendix A.4a). The concern relates to shared usage of the Haul Road with light traffic, ATV and snowmobile traffic. This community concern is proposed to be mitigated by the construction of a series of bypass roads that will separate recreational and light vehicle traffic from the AMNS haul truck traffic itself. Dedicated at-grade crossings will be constructed to cross the Haul Road. All crossings will provide adequate stop sighting distances for recreational users. The Haul Road Bypass will have a minimum of three formal crossings for ATVs and light vehicles, with specific designs and location will occur during detailed design. It is anticipated that crossings will be located at the junction of the Haul Road, and Trail #320, to provide access to the Marilyn Prest lands, and at the Haul Road and existing forestry road to the west. The Beaver Dam Mines Road (BDMR) will also have a bypass road built to the same specification as detailed above. The BDMR bypass will include at least one crossing to access a newly created trail that will connect Trail #320 to Trail #106. This trail will be built and operated by the local ATV clubs through a separate permitting process. All crossings will be signed.

AMNS will develop an Access and Safety Management Plan that will guide Haul Road Usage. Other mitigations to address safety concerns are established in Table 3.7-3 of the Section 3 (Public Engagement), particularly related to Indicators of Success for engagement activities.

The Access and Safety Plan will be developed through the establishment of an Ad Hoc Advisory group that will include residents, representatives of the ATV/snowmobile associations, representative from the Rocky Brook Lake area and other stakeholders. (Appendix A.6). AMNS intends to establish Ad Hoc Advisory Group in 2021.

6.16.5.4.6 Noise

A noise assessment was undertaken and is presented in Section 6.1. The assessment evaluated 19 receptors situated at varying distances to the Project (i.e., mine site and haul road). The assessment indicated that the closest receptors are within noise Nova Scotia Pit and Quarry Guidelines (NSEL 1999), which include 65 dBA during daytime and 60 during the evening. Although mining operations will be 24 hours, transport of ore by Haul trucks will be limited to daytime and evening hours (i.e., 7 am to 11 pm). A

noise complaint operational procedure will be developed and established before construction to ensure that residents complaints are addressed. In response to IR2 CEAA 2-32 a draft noise complaint process that includes contact information, formal investigation, and follow-up mitigations to address residents' concerns to the extent possible and is included as Appendix A in the draft Public Engagement Plan (Appendix A.6). In addition, AMNS will continue to engage with local communities with respect to their concerns throughout the life of the Project.

6.16.5.4.7 Hunting and Fishing

The land around the PA has a concentration of lakes and forests, which make it a popular for hunting and fishing.

The PA is in Deer Hunting zone 106, which covers almost all of the Eastern Shore from the edge of urban HRM to the far end of Guysborough county. In 2019, the last year reported by the Province, reporting showed that the Eastern Shore had less than 5% of all reported bucks and anterless deer taken in Nova Scotia.[71] This is consistent with previous years. Halifax County does have higher levels of upland game, which includes snowshoe hare, ruffed grouse and pheasant, harvested then other areas of the province.[72] There is no data specific to the project areas regarding hunting for upland game. During engagement, many reported that this area was a popular hunting location, particularly in the fall of the year (Section 3 and Appendix A.4a).

Through engagement efforts, AMNS has learned that there are many lakes that are regularly visited by the local season and permanent residents. It has also been reported to AMNS that some recreational fishers leave boats moored in Lake Alma for the summer.

AMNS heard concerns that the Haul Road may restrict hunting. The 2020 Hunter manual indicates that no person shall discharge a firearm or hunt within 30 m of a travelled portion of any highway or within 182 m of a woods operation.[73] This would remove the area adjacent from the Haul Road from hunting during the operation of the Haul Road.

Impacts on access to fishing locations within the LAA and RAA will be maintained by the bypass roads. Harry Casey, a resident of the area who is an active fisherman, has identified all lakes he and others in his circle use for fishing. Access to all lakes and fishing areas will be maintained upon construction of the bypass routes (Section 3 and Appendix A.4a).

6.16.5.5 Parks and Open Space, Tourism

6.16.5.5.1 Introduction

Nova Scotia has a variety of formal parks and open spaces which provide space for recreational pursuits, protect sensitive or important habitats, and create opportunities for people to be in nature. Parks and Open Space also serve the tourism goals of the province and local communities.

The following topic areas are identified as important aspects of the Parks and Open Space, Tourism theme.

[71] Source: https://novascotia.ca/natr/hunt/deer-stats.asp

[72] Source: https://novascotia.ca/natr/hunt/uplandgame-stats.asp#calculated15

[73] Source: https://novascotia.ca/natr/hunt/pdf/Hunting_Summary.pdfm Pg 90.

6.16.5.5.2 Protected Areas and Wilderness Areas

There are no protected and wilderness areas within the PA. There are Protected areas within the LAA (Table 6.16-5).

The closest Protected area to the Project Area is the Ship Harbour Long Halke Wilderness Area (Figure 6.16-9), which is directly adjacent to the Mooseland Road. Noise and air assessment indicates that impacts are within regulated guidelines (Section 6.1 and Section 6.2, respectively).

6.16.5.5.3 Local Community Sites

Through engagement with the local community, AMNS has identified several community sites which have been identified as important to the local community (Table 6.16-16).

Through conversations with local stakeholders, AMNS learned of a "date rock". According to local knowledge, the date was carved into the rock when the road (referred to herein as the Haul Road) was built. Some of the older community members re-paint the date so that it visible and keep the site clear of brush (Section 3 and Appendix A.4a).

Picture 1: Date Rock

AMNS was contacted by a resident of Ferry Lake to express concerns (Section 3 and Appendix A.4a). Ferry Lake is the location of a several cottages, which do not appear to be used year-round. Ferry Lake is outside the LAA. Through engagement, AMNS learned that there were concerns that the road that Ferry Lake property owners use to access their properties (River Road) may experience increased traffic. With the construction of a bypass road, existing recreational use traffic will continue to travel along the Haul Road bypass road.

6.16.5.5.4 Tourism Opportunities

Tourism is not a significant activity in or near the PA or with in the communities immediately adjacent to it. The Project is not anticipated to have any impacts on Tourism activities. The RAA does have many tourism assets and the 100 Wild Islands continues to be a focus. However, the PA is inland and is not located on a public road and will not be visible to the traveling public.

6.16.5.5.5 Regional Visitation

AMNS has heard through public engagement that, although the PA and local communities may not have significant draw for tourism, that it does attract people from the broader region, which is undefined, to use the trails, fish and hunt. No data exists on the regional visitation for recreational purposes. However, with the construction of the planned bypass routes, access to the crown land is still available for those who hunt, access points will be constructed to the lakes of the area and other recreational activities can continue to occur. The bypass routes will provide improved access to the areas in question.

Table 6.16-16: Community Sites

Community Site	Location	Discussion
Date Rock	Along the Haul Road between Mooseland Road and Highway 224	Request by community members to maintain the rock. Rock will be maintained or, if required, moved to a site acceptable to the community.
Otter Lake	Otter Lake is a popular recreational area located to the north of the Haul Road, along Trail #320	This area is a destination for family and outdoor recreational pursuits. The cabin, located on the shore of Otter Lake, is a known stopping location. Access to Otter Lake will not be restricted and the Haul Road bypass will include a crossing to access Trail #320. Otter Lake can also be directly accessed from Hwy 224.
Lake Alma	Lake Alma is located to the south of the Haul Road	Lake Alma is a fishing and boating, and there are a l camps located near it on or on its shores. During engagement, at least one person indicated that he left his boat moored during the summer in Lake Alma. Lake Alma can be accessed from Highway 224 and via Trails # 394 and 106. Access to Lake Alma from Mooseland will be maintained via the Haul Road bypass.
10 Mile Lake	Located west of the Mine Site and Cameron Flowage	There are camps located on 10 Mile Lake and this area is also identified for recreational uses. This area is accessed via Trail # 394. Trail # 106 and #320 both connect to Trail #394. Trail# 320 will be dead-ended at the Project Area boundary. A new connector trail between Trail #320 and the BDMR Bypass will be created, as will a Mine Site Bypass that will allow ATV and light vehicles to access Trail#394 and the 10 Mile Lake area.
Otter Lake Demonstration Forest (OLDF)	To the southeast of the community of Mooseland	The OLDF is, "…a place for all Nova Scotians to learn about forest ecology and the sustainable management of our nature.
Mooseland and Area Community Hall	4032 Mooseland Road	This is a community centre that is used for local residents. AMNS is in talks with the Mooseland and Area Community Association (MACA) to develop a partnership. MACA is identified in the draft Public Engagement Plan (Appendix A.6) as a key stakeholder and includes several commitments regarding ongoing information sharing and relationship development.
Ferry Lake	Located approximately 4 km southwest from the Haul Road	Seasonal dwellings are located on the southern shore of Ferry Lake. No impact to residents are predicted based on the impact assessment. A technical memorandum assessing possible linkages is provided in Appendix F.9. The technical memorandum concludes that there are no impacts from dust, noise or surface and groundwater quality to Ferry Lake residents.,

Notes: AMNS = Atlantic Mining NS Inc.; ATV = All-terrain vehicle; BDMR = Beaver Dam Mines Road.

6.16.5.6 Roads and Traffic

6.16.5.6.1 Introduction

The Beaver Dam Mine Project, during operations, will transport ore from the Beaver Dam Mine Site to the Touquoy processing facility for processing. The number of haul trucks is based on a number of factors including size and availability in Nova Scotia. Two scenarios were assessed one with 95 trucks and 164 trucks (one way). Additional traffic on the Haul Road will including maintenance vehicles to provide a combination of services include trucks designated to apply dust mitigations.

The haul route for the ore will be primarily over private roads but will include travel on the Mooseland Road between the entrance of the Haul Road, known locally as the "Old Dump Road" and the Touquoy mine site. The Mooseland Roads falls under the jurisdiction of the Department of Transportation and Infrastructure Renewal.

The following topics are identified as important aspects of the Roads and Traffic theme.

6.16.5.6.2 Road Infrastructure

The Mooseland Road is designated a Class D road according to the Department of Transportation and Active Transit (NSTAT), which are Intermediate Weight Roads (45,500 kg).[74] The Mooseland Road is a gravel road for most of the distance where the mine trucks will travel, but AMNS is working with NSTAT to assess what upgrades may be required. The Mooseland community has asked that the currently unpaved portion of Mooseland Road between Touquoy and the Haul Road entrance be upgraded, and AMNS supports this request to NSTAT.

Public sources of data for traffic are available and were used to the greatest extent possible. Observations made by the Project team through the course of EIS work from 2015 to present indicate that there is great variability in numbers and frequency on the public (e.g., Highway #224) and the local roads (e.g., Beaver Dam Mines Road). Records of traffic over a nine-year period (2004-2014 the current data set available) show annual average daily traffic on Highway 224 between Beaver Dam Mines Road., and Pleasant Valley Road to range between 150 to 340 vehicles per day. Beaver Dam Mines Road is used as a resource road and no traffic counts are publicly available and no baseline studies were completed for this aspect; however, it is estimated at approximately 10 vehicles per day. Based on observations, the traffic and vehicle types on the Beaver Dam Mines Road is dependent on activities taking place/time of year. Increased local traffic was more evident during hunting season in the fall/winter and lower during spring thaw when road conditions were poor.

The remaining portion of the ore haul road along the Mooseland Road to the Touquoy Mine Site is on a public road limited public information on traffic. The Touquoy Mine Site is operational and thus traffic now consists of local residents, service vehicles and mine workers forming the new baseline. Data is not available from Nova Scotia Department of Transportation and Infrastructure Renewal (NSTIR) on this route and based on observation it is assumed the number of vehicles is within the same range as traffic (types, count and frequency) as on Highway 224. The data for Highway 224 has therefore been used in the assessment of this portion of the Haul Route.

Table 6.16-17: Highway 224 Section 025 Beaver Dam Mines Road (Marinette) to Pleasant Valley Road Traffic Count

Start Date	Location Description for Count	Group	Type	% TRK	Average Daily Traffic	Average Annual Daily Traffic	Direction
June 27, 2007	1 km West of Fisher Lake Road (Westbound)	A	VC	:8	168	150	W
June 27, 2007	1 km West of Fisher Lake Road (Eastbound)	A	VC	:3	169	150	E
November 12, 2009	1 km West of Fisher Lake Road	A	TC		336	340	
October 17, 2011	1 km West of Fisher Lake Road	A	TC		295	290	
November 22, 2012	1 km West of Fisher Lake Road	A	TC		254	370	
September 3, 2013	1 km West of Fisher Lake Road	A	VC	:1	386	340	

[74] Source: https://novascotia.ca/tran/trucking/roaddesignation.asp

6.16.5.6.3 Private Road Infrastructure

The Haul Road connects Highway 224 and Mooseland Road. Currently, local traffic from seasonal properties, forestry and recreational activities use the proposed Haul Road. In the past (not observed during baseline studies) it is reported that the Haul Road will have intermittent high use periods (up to 100 truck trips per day) associated with forestry worker trucks from logging activities. The Haul Road includes three bridge upgrades including one bridge that crosses the Tangier Rivere, which will require upgrades for the mine operations, which AMNS will undertake. The existing bridge will form part of the Haul Road bypass route and a new bridge will be installed to accommodate mine truck traffic. The other two bridges requiring upgrades are located along the Beaver Dam Mine Road.

The BDMR is a gravel private road but is maintained closer to a public road standard as it is used for forestry trucks. Northern Timber (NT) and its contractors were the main users of the road and during peak operations, NT estimates approximately 3,000 use this road per year. The BDMR has two bridges, both of which will require upgrades for mine operations. The existing bridges will form part of the bypass route and a new bridge will be installed to accommodate mine truck traffic.

When mining ceases, the bypass routes, Haul Road upgrades and BDMR upgrades will remain providing improved transportation infrastructure to the PA.

6.16.5.6.4 Public Road Crossing

The haul road for the Project is primarily on private roads, except for the portion on the Mooseland Road. There is a planned crossing of Highway 224, which will be designed to NSTAT standards, including stop sighting distance requirements.

6.16.5.6.5 Pedestrian Safety

Little pedestrian activity has been seen along the Haul Route during field visits. There are no sidewalks and the area is sparsely populated. Through engagement, AMNS has learned that there are hikers, hunters and dog walkers who use the Haul Road. With the construction of the bypass road, continued usage will be permitted and enabled (Section 3 and Appendix A.4a). With the construction of the Bypass Routes, hikers and walkers will be separated from the mine truck traffic. The Bypass route will improve safety for pedestrians.

6.16.5.6.6 Project Duration Changes

The maximum anticipated daily volume on the Highway 224 and Beaver Dam Mines Road associated with the Beaver Dam Mine Project would therefore be 175 (passenger and service vehicles). However, based on use of the Haul Road, intermittent service vehicle schedules and car-pooling, the number on Highway 224 could be reduced by 50% to around 85 to 90 per day over a 24-hour period or roughly 4 per hour on Highway 224. For staff and service vehicles this increase may come from the north or south depending on the current or planned residences of workers and the direction from which deliveries are made. During construction, Highway 224 will likely be used to transport equipment from Touquoy Mine Site to/from Sheet Harbour to Beaver Dam, but the frequency and volume is not determined. Highway 7 to the Mooseland Road is available as an east-west then north route option to the Touquoy Mine Site as well thereby reducing the number on Highway 224.

Traffic on Highway 224 will therefore remain within the traffic count ranges as provided by the former NSTIR. Highway 224 will be crossed at Beaver Dam Mines Road, south of Beaver Lake IR 17, by the project related trucks transporting ore to the processing facility but will not travel north or south on Highway 224 and therefore not add to the overall traffic count on that highway corridor. Project and service vehicles will also use the Haul Road and Highway 224.

The Haul Road portion from the Mooseland Road to Touquoy Mine Site will have an increase in traffic by haul trucks transporting ore to the Touquoy Mine Site and addition of Project related staff vehicles and possibly service vehicles (e.g., 3/4-ton trucks).

Traffic volumes on those existing roads are unknown and variable both seasonally and annually. Project activities will increase the traffic levels by an average 95 trucks per day for approximately 16 hours a day during the operation phase of the Project. As noted above the baseline for this portion of the ore Haul Road has been assumed to be in the range for Highway 224 and therefore the Project related traffic increase should be within the existing range based on published data (150 to 340 per day).

6.16.5.6.7 Foreseeable Projects – Traffic Impacts

- Proposed Cochrane Hill Gold Project – No project related changes to traffic volumes or frequency on Highway 224 are anticipated due to the location of Cochrane Hill being of some distance from Beaver Dam. That Project would be accessed by staff and service vehicles via Highway 7, 347, and 348.
- Proposed Fifteen Mile Stream Gold Project – No project related changes to traffic volumes or frequency on Highway 224 are anticipated as that project would be accessed by staff and service vehicles via Highway 7 and 374.

6.16.5.7 Impact on Government Revenues

6.16.5.7.1 Introduction

The KPMG study provides information on the impact on federal and provincial revenues of the potential Project. In addition to this project specific study, AMNS commissioned a further study, Economic Impact Assessment of the Moose River Consolidated (MRC) Project, which assesses the cumulative economic impact of the MRC (Appendix O.2).[75] The MRC includes Touquoy, Beaver Dam Mine, Fifteen Mile Stream Gold and Cochrane Hill Gold, which are separate but interrelated projects.

The KPMG Economic Impact Assessment (Appendix O.1) assesses both direct and indirect impacts of the Project. Direct effects are the revenues that flow directly from the spending of the Project. The indirect effect is the income effects that come from the goods and services created by the Project in other sectors, such as from suppliers selling their good and services.

Gross Domestic Project (GDP) is another key metric when considering economic impacts (Appendix O.1). Given the Province's stated goal to decrease the net debt to GDP ratio, the amount of contribution to the GDP is also important to understand. The Province is interested decreasing this ratio because, "the size of the GDP is a common measure of the province's tax base from which to draw revenue, and thus a measure of its ability to pay down the debt."[76] All spending directly contributes to the GDP, and the royalties and taxes contribute to the government's ability to pay down the debt.

Table 6.16-18: Distribution of Spending: Beaver Dam Mine Project (Over the Entire Life of the Project)

Spending Category	Value Added ($M)	As a Percentage of the Total (%)
Construction (1 year)	27.7	5.3
Operation (5 years)	489.6	93.1
Sustaining capital	8.3	1.6
Total	**525.6**	**100**

Source: KPMG Economic Impact Assessment (Appendix O.1).

Notes: Due to rounding the sum of items may not add up to the total. $M = million dollars.

[75] Source: Economic Impact Assessment of the Moose River Consolidated Project – February 2021.

[76] Source: https://www.onens.ca/goals/goal-19-net-debt-gdp.

When considering the Moose River Consolidated (MRC) project, which includes existing Touquoy Mine, proposed Beaver Dam Project, proposed Fifteen Mile Stream Gold Project and the proposed Cochrane Hill Gold Project, the projected economic spin-offs are much more significant. Within the context of the social-economic analysis, the four project's cumulative impact provides an opportunity for the province to make headway on the One Nova Scotia Goal 19. With a projected impact of over $1 billion over 10 years and the creation of over 11,409 jobs, the MRC cumulative impact is significant.[77]

Table 6.16-19: Impact on Value Added and Employment for Nova Scotia Stemming from Overall Expenses related to the Moose River Project (Over the Entire Life of the Project)

Nova Scotia	Value Added ($M)	Jobs (In Person-years)
Exploration	49.9	397
Construction	375.5	2,803
Operation (over life of mine)	640.2	8,209
Total	**1,067.4**	**11,409**

Sources: Statistics Canada, AMNS, KPMG Economic Impact Assessment (Appendix O.1).

Note: Due to rounding, the sum of items may not add up to the total. $M = million dollars.

AMNS has based its total spending, and its contribution to the GDP, on the 2019 N1 43-101 report, which is a public facing document. Since this report was issued, AMNS increased its estimates for the project. Due to increased spending on items such as water management and new costs associated with the construction of a bypass road, the total project costs will increase by 12 to 20 million dollars. This represents approximately a 2 to 4% increase in overall spending from the 2019 study, which translates into a commensurate increase in economic impact of the Project. These increased as not reflected in the 2019 NI 43 101, and therefore not included in the results from the Input-Output Model used in the Economic Impact Assessment Report or the Economic Impact Assessment of the MRC (Appendix O.2).

The following are identified as important topics of the Impacts on Government theme.

6.16.5.7.2 Provincial Taxation and Benefits

For the Beaver Dam Mine Project, AMNS plans to spend $525.6 million in Nova Scotia over a 5-year period, which includes construction.

During the 1-year construction period, the province of Nova Scotia would see increases in revenue to the provincial government of $1.3 million. During the five years of operations, the province would see $4.8 million in additional revenues. The projected revenues are presented in Table 6.16-20, the revenues are expressed in millions.

Table 6.16-20: Projected Provincial Revenue from the Beaver Dam Mine Project

Jurisdiction	Timing	Royalties	Personal Income Tax	Taxes on Products	Taxes on Production	Total
Province of Nova Scotia	Construction (1 year)	N/A	0.8	0.4	0.1	1.3
Province of Nova Scotia	Operations (5 years)	0.6	1.4	2.7	0.1	4.8

Note: N/A = not applicable.

[77] Source: Economic Impact Assessment of the Moose River Consolidated Project, Pg 5.

If the Beaver Dam is considered within the MRC Project, then the cumulative impact of the total project is much greater. Although Beaver Dam is being evaluated as a standalone project, from a socio-economic analysis perspective it is linked to the other project as there is the use of shared infrastructure and that much of the baseline data provided is at a regional scale. In addition, socio-economic conditions are about interrelationships which makes it difficult to assess socio-economic factors project by project. Therefore, from a socio-economic perspective, the Project is contributor toward to the overall MRC Project.

Table 6.16-21: Projected Provincial Revenue from the Moose River Consolidated Project

Jurisdiction	Personal Income Tax	Taxes on Products	Taxes on Production
Province of Nova Scotia	10.4	20.9	32.2

6.16.5.7.3 Federal Taxation and Benefits

During the approximate one-year construction period, the federal government would see increases in revenue of $1.4 million. During the five years of operations, there would be $3.4 million in additional revenues. The projected revenues are broken out as follows (expressed in millions):

Table 6.16-22: Projected Federal Revenue from the Beaver Dam Mine Project

Jurisdiction	Timing	Personal Income Tax	Taxes on Products	Taxes on Production	Total
Government of Canada	Construction (1 year)	1.2	0.2	0	1.4
Government of Canada	Operations (5 years)	1.8	1.6	0	3.4

Similar to the previous section, when the project is considered within the context of the MRC, the project will generate $32.2 million during construction and $93.2 million during operations.

6.16.6 Viewshed Analysis

Nortek Resource Solutions Inc. (Nortek) has completed a viewshed analysis of the Project to support a visual representative of where the Project will be visible from surrounding vantage points (Appendix M.2). This was completed to respond to IR2 CEAA 2-01.

The Zone of Visual Influence (ZVI) provides a spatial overview of where the proposed Project stockpiles will be visible across a 20 km radius. The Beaver Dam Mine Site is predominantly forested and therefore the existing forest stand data was included in the analysis. The analysis consisted of preparing a Digital Surface Model (DSM) which included the proposed stockpiles. Once the model was prepared, a visibility analysis was completed to determine all areas on the DSM in which the stockpiles are visible. This analysis focused on stockpile locations as they are the highest infrastructure proposed at the Beaver Dam Mine Site.

The ZVI was generated for the region within a 20 km radius of the Beaver Dam Mine Site. The Nova Scotia Provincial Digital Terrain Model (DTM) at 20 m resolution was used as a base layer for the analysis. The proposed stockpiles were rasterized and added to the base DTM so that they were included in the model. A visibility analysis was run using the upper rims of the stockpiles as targets and receptor heights of 1.7 m. The resulting raster was clipped with forest stand polygons that have an average height of 2 m or less which excluded areas were the forest is higher than eye height. The final results show where the proposed stockpiles will be visible assuming summer, leaf on forest conditions.

The Visual Zone of Influence (ZVI) (Appendix M.2) identifies where stockpiles (highest elevation features on the Beaver Dam Mine Site) are visible from the surrounding landscape. The NAG pile, which will be present during operations and closure, is 185 masl. The LGO and till stockpiles are 180m asl, which will both only be present only during operations. These are the highest infrastructure features associated with the Project. On the ZVI, these areas where stockpile(s) are predicted to be visible are shown in green. This ZVI was prepared to provide a general overview of where the Project will be visible from, and also to demonstrate a visual representation of what the visual influence will look like from specific locations. As shown in Appendix M.2 the Project stockpile(s) will be visible from the east and west of the Beaver Dam Mine Site including from West Lake, from the north of the Beaver Dam Mine Site in Como Lake, directly south of the Beaver Dam Mine Site, and also to the west of Beaver Lake IR along the north and south side of Highway 224. Commercial and recreational activities (boating, fishing, swimming) along Cameron Flowage will observe an adjusted viewplane with visible stockpile(s). The ZVI also demonstrates as a user moves farther away from the Beaver Dam Mine Site, the mine infrastructure will be visible from higher elevation points on the landscape, including several high points northwest of the Beaver Dam Mine Site and south of the mine including near Lake Alma. The user will not observe the infrastructure from the majority of lakes surrounding the Beaver Dam Mine Site, with the exception of those described above.

To support Project development, there will be a local bypass road constructed to allow for continued access around the Beaver Dam Mine Site and the lands to the north of the Beaver Dam Mine Site. Based on a review of the ZVI, the Project stockpiles will be visible from the bypass road directly south of the mine site and around the organic stockpile.

Through a review of the ZVI results, several photos were then taken from various vantage points to attempt to demonstrate specific locations where visual influence of the Project would be greatest. Visual Simulations 1 to 4 in Appendix M.2 show these four vantage points and what will be visual during operations and closure phases of the Project.

Visual Simulation 1 illustrates the view from the north side of the Beaver Dam Mine Site just north of Cameron Flowage, looking southwest towards the Project. The NAG stockpile will be visible during operations and closure phases, as shown on this figure (Appendix M.2). Visual Simulation 2 illustrates a similar view from the north side of the Beaver Dam Mine Site but looking farther southwest/west. The full extent of the NAG stockpile will be visible during operations and closure phases from this location, as shown on Visual Simulation 2. Visual Simulation 3 illustrates the view from west of the Beaver Lake IR on Highway 224 where the ZVI also predicted a visual change from the Project. The PAG, NAG and LGO stockpiles will be visible from this vantage point during the operation phase, as shown on Visual Simulation 3. During reclamation, only the PAG and NAG piles will remain. Finally, Visual Simulation 4 illustrates the view from a forestry road near Cope Brook, south of the NAG pile. From this location, the NAG stockpile will be visible during both the operations and closure phases. These four vantage points were selected to be representative of expected maximum change in viewscape and the locations where anticipated human activities is likely to occur (e.g., near access trails, lakes and other access points).

6.16.7 Reclamation and Closure

AMNS is committed by legislation to reclamation planning that is focused on safety and creating physically, chemically and biologically stable elements that are self sustaining ecosystems in keeping with the surrounding natural areas. AMNS also has publicly stated the desire to continue to engage the public and the Mi'kmaq of Nova Scotia in reclamation planning through the CLC and information sessions/workshops prior to the active closure phase (Sections 2, 3, 4, 6.14). These sessions are typically the time to discuss site-specific reclamation objectives such as plant types, the degree to which recreational use features such as trails, boat launches, docks, and interpretive panels will be incorporated into the final reclamation plan.

The reclamation planning phase presents opportunities for involvement for several groups including public, community, Mi'kmaq, academic institutions, environmental groups and others. Additional engagement opportunities exist during actual reclamation activities for earthworks, shoreline development, revegetation programs, habitat development and restoration) reclamation involvement, employment, research and long-term monitoring programs.

6.16.8 Consideration of Engagement Results

Section 3 Public Engagement summarizes engagement that has occurred through the Environmental Assessment. This section breaks issues into:

- Issues Raised During Stakeholder Engagement 2015-2019 (Table 3.7-2); and
- Key Issues Raised During 2020 Public Engagement Meeting (Table 3.7-3).

During the 2020 engagement, the main concerns raised are be summarized under the following topics:

- Haul Road Access and Recreational Usage;
- Traffic;
- Noise; and
- Improved Communications.

Concerns about recreational usage and the impact of the Haul Road on recreational usage was the most common concern expressed. In particular, stakeholders wanted assurance that they would be able to access locations, camps and routes that were used for recreational purposes. AMNS learned about the importance of this recreational access to many in the community of Mooseland and to the residents of Rocky Brook Lake.

To address this concern, AMNS is proposing a series of bypass roads to provide access to recreational areas, camps, hunting and fishing areas and ATV routes. The Bypass routes will be built and maintained by AMNS during the life of the project, and the public will be engaged through various means to adapt to any concerns that arise. AMNS is also exploring a partnership with the Sheet Harbour ATV Club to support the construction of short trail to support recreational vehicle access near the mine site.

Concerns about increase in traffic on the Mooseland Road and on the Haul Road was also expressed by some stakeholders. The maintenance of the gravel portion of the Mooseland Road and the impact that the mining trucks will have on the road was a concern. AMNS is working with NSTAT to assess what upgrades will be required on the Mooseland Road and supports the community's request to have the section of the Mooseland Road between Touquoy to the entrance of the Haul Road paved. AMNS, in response to concern about traffic speeding in the community of Mooseland, is working with the Community and NSTAT to install Radar Speed Signs to gather data on speeding and to respond to community concerns about speeding.

AMNS heard from community members about parking of trucks and trailers on Mooseland Road near the entrance to the Haul Road. The concern is that the increase in truck traffic from the ore trucks will create a safety concern. AMNS is working with NSTAT and the local community to address this concern through detailed design of the entrance of the Haul Road.

Noise impacts are addressed in Section 6.1.

AMNS, in response to the comments from the public, developed a draft Public Engagement Plan (Appendix A.6), which includes a variety of commitments to improve communication and consultation with stakeholders. Elements of the plan include regular open

houses with the community, the use of ad hoc committees to address specific issues, identification of key stakeholders and an action plan to address issues and opportunities.

During the 2015-2019 engagements, the issues raised during public consultation engagement relating to socio-economic considerations include potential adverse effects associated with potential effects to natural environments (e.g., surface water, groundwater, air emissions, etc.) during planned Project activities and unplanned accidents and malfunctions, such as traffic accidents. Questions on access to land and changes to land use were noted by members of the public and landowners, as well as the Mi'kmaq of Nova Scotia in terms of access to traditional land and resources. Maintenance of existing access for recreation, such as ATV, fishing, etc., was also identified as an issue. Volume of trucks on existing public roads was expressed as a key concern in terms of safety and road condition. Members of the public and Mi'kmaq community members expressed interest in employment and economic development opportunities associated with the Project.

The results of the public consultation and Mi'kmaq engagement have been considered in the environmental effects assessment, including AMNS's commitments to include the Mi'kmaq in the development and implementation of mitigation and monitoring measures and proposed compliance and effects monitoring programs, as well as AMNS's broader commitment to ongoing public consultation and Mi'kmaq engagement. Specific to evaluating the effect on socio-economic considerations, these are found within the following environmental effects assessment.

6.16.9 Effects Assessment Methodology

6.16.9.1 Boundaries

6.16.9.1.1 Spatial Boundaries

Since the Project site is remote, the spatial boundary for socio-economic conditions assessment of potential impacts to the local economy extends beyond the footprint of the Project (Beaver Dam Mine Site), and are classified as the PA, LAA, and RAA. Since there is no opportunity for the purchase or exchange of goods and services within the Project footprint. The LAA spatial boundary, extends to parts of Eastern Halifax County. This boundary captures all economic exchange and movement connected to potential project-related employment and trades in goods and services based on population density and proximity to the Project (Figure 6.16-1). Given the Beaver Dam Mine Site's remote location, within the LAA, there is a "local community area" (LCA) where potential impacts are evaluated and assessed.

The Project Socio-economic RAA captures all potential socio-economic considerations (Figure 6.16-1) with the exception of the economic parameters referenced in the KPMG reports (Appendix O.1 and Appendix O.2), which are focussed on provincial and national scales.

The Project has the potential to cause direct and indirect effects to socio-economic conditions beyond the footprint of the Project, the defined LAA and RAA are the most appropriate spatial boundaries, respectively (Figure 6.16-1).

6.16.9.1.2 Temporal Boundaries

The Project four distinct phases - Construction (1 year), Operation 5 years) and Active Closure (2 years) and Post-Closure Monitoring (10+ Years). These phases define the temporal boundary for assessment of impacts on the socio-economic conditions of the Project. Post closure monitoring is estimated to be 10+ years with monitoring data informing the focus and extent of future monitoring activities as well as determine adaptive management measures that may be necessary. Overall, the goal is to achieve a physically, chemically, and biologically stable landforms that can support self-sustaining ecosystems.

6.16.9.1.3 Technical Boundaries

Economic effects potential is a qualitative assessment based on a comparison of the relative scale of predicted Project-related employment levels (person-hours; wages) with existing employment opportunities within the HRM, especially the area between Middle Musquodoboit and Sheet Harbour. Statistical data is used where available for these VCs.

6.16.9.1.4 Administrative Boundaries

The Nova Scotia Municipal Government Act (1998 c.18 s.1) empowers the HRM to enact and enforce a Municipal Planning Strategy (MPS; HRM MPS 2014) that describes Halifax's approach to planning within its jurisdiction. The MPS outlines criteria for Council and planning staff to consider when evaluating development proposals and issuing development permits. Together with the Land Use Bylaw and Subdivision Bylaw, the MPS controls future land use and development in the Municipality. Recreational activities, such as hunting and fishing are regulated by the Province of Nova Scotia under the Wildlife Act and for hunting migratory birds by federal authority under the Migratory Birds Convention Act, 1994 and Migratory Birds Regulations.

6.16.10 Project Activities/Interaction with Socio-economic Conditions

Potential interactions between Project activities and Socio-economic Conditions are outlined in Tables 6.16-23 to 6.16-25.

Positive socio-economic impacts are associated with the Project, including long-term employment gain and/or sustained activity within the area. All phases of the Project will provide employment opportunities for local residents and Indigenous Peoples, as well as provide tax revenue for the municipal, provincial, and federal levels of government. It is anticipated that additional labour force will be required during construction and a smaller, but still significant, labour force will be required during operation.

With increase job opportunities and supplier needs, the potential to have a positive impact on community vitality and development exists. There is potential for increased relocation to the area of the mine of working age people and their families. This may increase the general population and help support the local school. Rural depopulation is a concern and by having jobs in the area, people will be attracted to this area.

Table 6.16-23: Potential Project Activities/Interactions with Socio-economic Conditions at Beaver Dam Mine Site

Project Phase	Duration	Relevant Project Activity
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Drilling and rock blasting in preparation of construction • Topsoil, till and waste rock transport and storage from site preparation • Wetland and watercourse alteration • Mine Site road construction • Surface infrastructure installation and construction • Collection and settling pond construction
Operation and Maintenance	5 years	• Rock blasting to access and extract ore • Surface water management • Petroleum products management • Site maintenance and repairs
Active Closure	2 years	• Infrastructure demolition • Site reclamation
Post-Closure	10+ years (monitoring, adaptive management)	• Environmental Monitoring • Adaptive Management

Table 6.16-24: Potential Project Activities/Interactions with Socio-economic Conditions along the Haul Road

Project Phase	Duration	Relevant Project Activity
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of construction • Till and waste rock from site preparation transport and storage • Watercourse and wetland alteration • Haul road construction and upgrades
Operation and Maintenance	5 years	• Ore transport along Haul Road • Haul road maintenance and repairs
Active Closure	2 years	• N/A[(a)]
Post-closure	10+ years (monitoring, adaptive management)	• N/A

(a) Decommissioning and Reclamation of the Haul Road is not expected. The Haul Road will be returned to owner for forestry industry. N/A = not applicable.

Table 6.16-25: Potential Project Activities/Interactions with Socio-economic Conditions at Touquoy Mine Site

Project Phase	Duration	Relevant Project Activity
Construction	1 year	• Tailings pipeline, make-up water pipeline alteration, and relocation of reclaim infrastructure
Operation and Maintenance	5 years	• Surface water management • Petroleum products management • Site maintenance and repairs
Active Closure	2 years	• Infrastructure demolition • Site reclamation
Post-Closure	10+ years (monitoring, adaptive management)	• Environmental Monitoring • Adaptive Management

With increases in working age populations, comes a deeper pool of potential volunteers for community organizations. Through engagement AMNS heard that local community groups were having difficulty attracting volunteers. Increases in population also help support the business case for increased recreational programs and infrastructure.

Indirect employment will be generated by the Project through the use of external contractors and suppliers. Emphasis on the local economy may shift slightly from Middle Musquodoboit to Sheet Harbour depending on contract services for mine operation, however the overall regional economy will benefit equally from both sites operating simultaneously.

The construction of a new portion of road and upgrades to existing roads will provide local residents and recreational users improved access to the interior areas of the region (Section 2, Figure 2.3-2). The bypass road will improve access to the current recreationally used lands.

Traffic will increase on the Mooseland Road between Touquoy and the Haul Road entrance. With upgrades to the Mooseland Road, the Mooseland Road will be able to accommodate the increased traffic and the condition of the Mooseland Road will improve, similar to the public road improvements, the paving of the Moose River Road to the north, that occurred to access the Touquoy mine site.

The potential exists for the population within the RAA to increase. This would have positive benefits for local community organizations, support recreational infrastructure requests, support local school populations, and require additional housing which could result in

additional property tax revenue. With an increase in population, increased pressure on the health system may occur and the need to a great variety of housing types and tenures. Rental housing may be under stress to accommodate workers, contractors, and supplier staff.

The potential does exist for a mobile equipment accident along the Haul Road. Haul trucks will travel daily from the Beaver Dam Mine Site to the Touquoy Mine Site, which is discussed in the Accident and Malfunction (Section 6.18). The number of return truck trips per day will be an annual average of approximately 190 for 16 hours per day, 350 days per year for the duration of the mine Project (5 years). The maximum number of truck trips will occur in years 2 to 3 of operations with significant reduction in year 1 and years 4 to 5. During construction (approximately 1 year), the number of trips will be less. The Haul Road will be dual lane and designed to facilitate the safe passage of two-way truck traffic at 70 km per hour. Speed limit and right-of-way signage will be installed, and all haul truck operators will receive operator training to minimize the risk of haul truck collisions. All intersections will be designed to NSTIR Standards. A haul truck accident may result in fuel and/or other spills, fires, and/or injury or death to site workers and the general public. Discussions with NSTAT will identify additional mitigation measures that may be required, in particular at the Hwy 224 crossing.

The economic and community benefits of this project are significant. The Project supports many of the provincial growth goals and the Atlantic Growth Strategy. Most adverse impacts identified by stakeholders are address through mitigations.

6.16.10.1 Touquoy Mine Site

The Touquoy facility is currently operational. There are no effects to socio-economic conditions anticipated to be caused by the processing of ore and the management of tailings (exhausted pit) from the Project. The primary effect of the continued use of the Touquoy facility on socio-economic conditions is the provision of employment for an additional four years in the processing facility.

6.16.11 Mitigation

Recreational activities that currently occur within the spatial boundaries of the Project, such as hunting and fishing, will, for safety reasons, be restricted during construction and operation. Recreational users will be notified of restricted access by signage at the entrance to the Beaver Dam Mine Site. Site restrictions will be within the PA and within the fly rock management area during blasting activities only. Liaison with local recreational groups, such as ATV associations, will be undertaken. Access to other recreational areas near the Beaver Dam Mine Site will be maintained through the construction of a series of bypass roads. Engagement with user groups will continue throughout the life of the project and operational procedures will be adjusted with advice of the user groups.

A potential adverse effect on socio-economic conditions is related to a risk for mobile vehicle accidents along the Haul Road, in particular at the Highway 224 crossing. Speed limit and right-of-way signage will be installed, and all haul truck operators will receive operator training to minimize the risk of collisions. Intersection requirements and additional mitigation measures will be determined through discussions with NSTIR.

Table 6.16-26: Proposed Mitigation for Socio-economic Conditions

Project Activity	Mitigation Measures
Construction	• Restriction of recreational activities within the spatial boundaries of the Project. Notification will be provided by signage. • Communication Plan to communication access information to key stakeholders (Sections 3 and 4 [Public Engagement and Indigenous Peoples Engagement, respectively]). • Liaison with any local recreation groups, such as ATV associations through an Ad Hoc group. • Equipment maintenance. • Reduction of mobile equipment accident risk through discussions with NSTIR, appropriate signage, and operator training.
Operation	• Restriction of recreational activities within the spatial boundaries of the Project. Notification will be provided by signage. • Liaison with local recreation groups, such as ATV associations. • Equipment maintenance. • Limiting haul truck operational hours to approximately 16 hours per day. • Reduction of mobile equipment accident risk through discussions with NSTIR, appropriate signage, and operator training. • Ongoing engagement with community associations, CLC and residents to assess and adaptively manage the site. • Potential housing and employment studies to monitor impacts on population growth and housing market.
Active Closure	• Ongoing engagement with community associations, CLC and residents to assess and adaptively manage the site.

6.16.12 Residual Effects and Significance

There are no significant adverse environmental effects anticipated on socio-economic conditions, once mitigation measures are applied. Positive impacts are anticipated in the form of direct and indirect employment, and tax revenues for municipal, provincial, and federal governments. Additionally, improvements to local roads will be completed as part of the Project, which will provide improved access to the region's interior.

Significant adverse environmental effect for Socio-economic Conditions are not predicted for the Project. This determination includes consideration of the ecological and social context of the LAA surrounding the Project:

- **During Construction:** Changes occur but are similar to those that have occurred or will occur in other areas of the LAA and in line with the ecological and social context of the LAA surrounding the Project.
- **During Operations:** Changes occur but are similar to those that have occurred or will occur in other areas of the LAA and in line with the ecological and social context of the LAA surrounding the Project.
- **During Active Closure:** Changes occur but are similar to those that have occurred or will occur in other areas of the LAA and in line with the ecological and social context of the LAA surrounding the Project.

Table 6.16-27: Residual Effects and Significance Rating Criteria

Criteria	Description of Ratings
Direction	• **Positive**: the change results a measurable positive effect • **Negative**: the change results a measurable negative effect • **Neutral**: there is no measurable change
Magnitude	• **Negligible**: the impact is not measurable or minimally measurable • **Low**: The impact has interaction if less than 3 other topic areas and can be measured within the LAA • **Medium**: The impact as interactions with more than 7 topic areas or 2 or more topic areas and can be measured within the LAA, and RAA • **High**: The impact has interactions all other themes and many topic areas and can be measured at the RAA level and beyond
Duration	• **Short-term**: effect is restricted to Construction Phase and EOM Phase • **Long-term**: Effect occurs in Construction Phase and EOM Phase and/or persists in PC
Geographical Extent	• **Discrete**: effect is limited to the Project Area (PA) • **Local**: effect is limited to the Local Assessment Area • **Potential Regional**: effect persists to the Regional Assessment Area
Reversibility	• **Reversible**: effect can be reversed • **Partially reversible**: effect can be partially reversed • **Irreversible**: effect cannot be reversed, is of permanent duration
Frequency	• **Intermittent**: VC interaction or effect will occur at irregular intervals throughout any Project Phase • **Regular**: effect occurs on a regular basis but not continuous basis • **Continuous**: effect occurs constantly (e.g., every model timestep in a given Project Phase).

Residual effects of the Project on the socio-economic VC identified are characterized using standard criteria, including magnitude, geographical extent, duration, frequency, reversibility, and context of the effect (Table 6.7-28). The residual effects assessment concludes with a determination of Significance. The screening of project effects, mitigation measures, and the projections regarding impacts are assessed in aggregate to determine whether the residual impacts are “Not Significant” or “Significant” according to the following definitions:

- **Significant Residual Effect:** have high magnitude, be of potential regional geographic extent and of medium to long term duration, occur at any frequency and partially reversible to irreversible.
- **Insignificant Residual Effect**: are negligible to moderate magnitude, are restricted to the PA, are intermittent or short term in duration, occur at any frequency and are reversible to partially reversible.

Table 6.16-28: Residual Environmental Effects for Socio-economic Conditions

Theme Areas	Topics within Theme Area	Linkages to other Plans and Guiding Documents	Pathway	Mitigation	Direction	Magnitude	Duration	Geographical Extent	Reversibility	Frequency	Residual Effect
Workforce Development	Training Opportunities	One NS Goal, Atlantic Growth Strategy	Apprenticeship training program and internal training opportunities provide opportunities for certifications and training.	N/A	Positive	L	Short Term	RAA	N/A	C	Insignificant
	Opportunities for Advancement within career	One NS Goal	Internal hiring and opportunities for graduates provided by AMNS employment opportunities, support career advancement.	N/A	Positive	L	Short Term	RAA	N/A	C	Insignificant
	New employment - direct and indirect	One NS Goal, Atlantic Growth Strategy	Beaver Dam will provide new employment opportunities, both through direct and indirect sources.	N/A	Positive	H	Short Term	LAA	N/A	C	Significant
	Labour Force attachment	One NS Goal	New high quality employment opportunities provide opportunities for working age people to attached to the labour force.	N/A	Positive	L	Short Term	RAA	N/A	C	Insignificant
	Impact on Educational Attainment	One NS Goal, Atlantic Growth Strategy; SDG	Apprenticeship training program supports educational attainment and providing opportunity for graduates of both NSCC and university programs.	N/A	Positive	N	Short Term	RAA	N/A	C	Insignificant
	Youth Employment Rate	One NS Goal; Halifax Partnership	Employment opportunities for young people (under 30) through both direct and indirect sources.	N/A	Positive	N	Short Term	RAA	N/A	C	Insignificant
	Suppliers	Halifax Partnership, One NS Goal	There will be need for suppliers from the local areas to provide supports, which may impact the suppliers labour needs.	N/A	Positive	M	Short Term	RAA	N/A	C	Significant
	Labour Force Attachment - Indigenous	One NS Goal; Halifax Partnership; KMKNO Pillars	MOU and IBA provide support to Mi'kmaq lead employment programs.	N/A	Positive	N	Short Term	RAA	N/A	C	Insignificant
Demographics	In-Migration	Halifax Partnership, One NS Goal, Atlantic Growth Strategy	New employment opportunities may attract new residents to the province.	N/A	Positive	N	Short Term	LAA	N/A	C	Insignificant
	Rural Re-Population	Halifax Partnership, One NS Goal	New employment opportunities may attract new residents to the LOA supporting communities that are seeing population declines.	Monitoring of population growth related to mine operations	Positive	N	Short Term	LAA	N/A	C	Insignificant
Healthy Communities	Hospitals	SDG	With new populations and industry, local hospital usage may increase.	N/A	Negative	N	Short Term	LAA	R	C	Insignificant
	Family Doctor Availability	SDG	New resident may impact family doctor availability.	N/A	Negative	N	Short Term	LAA	R	C	Insignificant
	Seniors Supports	SDG	Through Community investment AMNS has made and plans to continue to make investments to seniors related initiatives.	N/A	Positive	N	Short Term	LAA	R	I	Insignificant
	Schools	SDG	If rural re-population occurs, there may be an increase in school populations.	N/A	Positive	N	Short Term	LAA	R	C	Insignificant
	Recreational Facilities		Potential increase of recreational facilities or support for new recreation facilities planned for the area.	N/A	Positive	N	Short Term	LAA	R	I	Insignificant
	Housing	SDG	Impact on housing availability requires further study and is market dependent	Monitoring of population increase on housing market		U	Short Term	LAA	R		
	Climate Change and Energy	SDG					Short Term				
	Local Taxation	Once Nova Scotia	Direct and indirect benefits to the local, provincial and federal governments.	N/A	Positive	L	Short Term	LAA	R	C	Insignificant

Table 6.16-26: Residual Environmental Effects for Socio-economic Conditions (continued)

Theme Areas	Topics within Theme Area	Linkages to other Plans and Guiding Documents	Pathway	Mitigation	Direction	Magnitude	Duration	Geographical Extent	Reversibility	Frequency	Residual Effect
Land Use, Recreational	Snowmobiling and ATV Use	Halifax Partnership	Support and upgrades to existing and proposes off-road trail systems and potential partnership opportunities.	Construction of bypass roads.	Positive	N	Long Term	LAA	R	C	Significant
	Active Transportation	HRM Policies	Increased traffic on public roads in limited locations may create concerns about walking and biking safety.	Construction of bypass roads	Negative	N	Long Term	LAA	R	C	Significant
	Access to Camps		With the construction of a haul road, access to camps will be maintained or possibly improved.	Construction of bypass roads	Positive	N	Long Term	LAA	R	C	Significant
	Haul Road Safety		The existing haul road will have increase operational safety parameters which will improve the safety on the road by separating heavy traffic from recreational users, small vehicles and non motorized usage.	Construction of bypass roads	Positive	N	Short Term	LAA	R	C	Significant
	Noise		See section on noise.	See Chapter ???					R		
	Hunting and Fishing	Halifax Partnership	The haul road and mine site may impact hunting by altering migration patterns and by reducing hunting opportunities near the mine site and haul road, as required by the relevant act. Access to fishing areas will be improved, potentially leading to increased recreational fishing.	Construction of bypass roads	Negative	L	Short Term	LAA	R	C	Significant
Parks and Open Space, Tourism	Protected Areas and Wilderness Areas	Halifax Partnership	No impact.	N/A	Neutral	N	Short term	LAA	N/A	N/A	Insignificant
	Local Community Sites	SDG	No impact.	Protection of Date Rock	Neutral	N	Short Term	LAA	R	C	Insignificant
	Tourism Opportunities	Halifax Partnership, One NS Goal	Potential for increased attraction to the area to view mining related activities.	N/A	Positive	N	Short Term	LAA	N/A	N/A	Insignificant
	Regional Visitation	Halifax Partnership, One NS Goal	No anticipated impact.	N/A	Neutral	N	Short Term	LAA	N/A	N/A	Insignificant
Roads and Traffic	Traffic Impact		Increased traffic on public roads in limited locations may create concerns about walking and biking safety.	Access and Safety Plan	Negative	M	Short Term	LAA	R	C	Insignificant
	Road Infrastructure		Potential for improvements to public roads to address increased usage by proponent. Increased usage may result in negative impacts or degradation of public road infrastructure.	Insert language about paying for paving.	Negative and Positive	M	Long Term	LAA	R	C	Insignificant
	Private Road Infrastructure		Private road will be improved to a high standard, which will be left in place after mine operations cease.	N/A	Positive	N	Long Term	LAA	R	C	Insignificant
	Public Road Crossings		Improvements to road crossings at the haul road and highway 224.	Install crossings to allow access to other lands	Positive	N	Permanent	LAA	R	C	Insignificant
	Pedestrian Safety		Increased traffic on public roads in limited locations may create concerns about walking and biking safety.	Access and Safety Plan	Negative	N	Short Term	LAA	R	C	Insignificant
Impact on Government Revenues	Provincial Taxation and Benefits	One Nova Scotia	Direct and indirect taxation benefits to the province.	N/A	Positive	L	Short Term	RAA	R	C	Insignificant
	Federal Taxation and Benefits	Atlantic Growth Strategy	Direct and indirect taxation benefits to the province.	N/A	Positive	L	Short Term	RAA	R	C	Insignificant

Notes: Section 5.11, Table 5.11-1 and Table 6.16-27 for definitions of the below characteristics.

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	LAA	Local Assessment Area	N/A	Not Applicable	ST	Short-Term – within life	O	Once	R	Reversible
L	Low	RAA	Regional Assessment Area	A	Applicable	LT	Long-Term Beyond life	I	Intermittent	IR	Irreversible
M	Moderate					P	Permanent	R	Regular		
H	High							C	Continuous		

6.16.13 Proposed Compliance and Effects Monitoring Program

Given the variability of COVID impacts and the complexity of modeling socio-economic impacts during this time of social and financial upheaval, AMNS's compliance and effects monitoring program includes the following:

- Ad-Hoc Committee for the development and monitoring of the Access and Safety Plan for the Haul Road.
- Housing Assessment study to assess impacts of AMNS staffing on local markets.
- Rural Impact Study to assess impacts of in-migration, job creation and economic activity on LAA

6.17 Assessment of Valued Components within Federal Jurisdiction

6.17.1 Introduction

6.17.1.1 Summary of Assessment of Valued Components within Federal Jurisdiction Before the Updates

This section summarizes the changes to the environment that may be caused by a Project on environmental components listed in paragraph 5(1)(a) of CEAA 2012. This includes fish and fish habitat as defined in the *Fisheries Act*, migratory birds as defined in the *Migratory Birds Convention Act, 1994,* and species designated by the *Species at Risk Act.*

6.17.1.2 Summary of Updates to Assessment of Valued Components within Federal Jurisdiction

The assessment of Valued Components (VCs) within Federal Jurisdiction on the Project has been updated to reflect updates of the Project Description (Section 2) and to address Round 2, Information Requests (IR2) issued by the Impact Assessment Agency of Canada (IAAC, formerly the Canadian Environmental Assessment Agency [CEAA 2019]) and Nova Scotia Environment (NSE 2019). This includes:

- adjustments to Project Description (Section 2);
- updates to reflect the modernized *Fisheries Act* and more detailed effects assessment, particularly related to evaluation of indirect effects to fish and fish habitat;
- updates to monitoring programs for Avifauna;
- development of a draft Wildlife Mitigation and Monitoring Plan (Appendix P.7) and associated Landbird Species at Risk (SAR) Mitigation and Monitoring Plan (Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]);
- development of a draft Lichen Mitigation and Monitoring Plan (Appendix P.6);
- ongoing and continued engagement with Mi'kmaq of Nova Scotia, key stakeholder grounds (i.e., community and recreational associations) and members of Public; and
- *Fisheries Act* Authorization will be required based on confirmed direct and indirect impacts to fish and fish habitat.

An outline of updates to the assessment of VCs within Federal Jurisdiction on the Beaver Dam Mine Project are summarized in Table 6.17-1.

Table 6.17-1: Updated Subsections from the 2019 Revised Environmental Impact Assessment - Assessment of Valued Components within Federal Jurisdiction

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
-	-	6.17.1 Introduction	• New
6.17.1 Environmental Effects within Federal Jurisdiction	Yes	6.17.2 Environmental Effects within Federal Jurisdiction	• Updates to for this subsection are outlined in the rows below
Numbered heading title was not used	Yes	6.17.2.1 Fish and Fish Habitat	• Updates to reflect the modernized *Fisheries Act* and more detailed effects assessment, particularly related to evaluation of direct and indirect effects to fish and fish habitat • Updates as a result of revisions to Project infrastructure (Section 2 Project Description), and IR2s
Numbered heading title was not used	Yes	6.17.2.2 Migratory Birds	• Updates to the Project Description (Section 2) • Updated monitoring program.
Numbered heading title was not used	Yes	6.17.2.3 Species at Risk	• Development of a Lichen Mitigation and Monitoring Plan • Project layout modification for infrastructure micro-sitting • Updates as a result of revisions to Project infrastructure (Section 2), and IR2s. • Development of a Wildlife Mitigation and Monitoring Plan and the associated Landbird SAR Mitigation and Monitoring Plan (Appendix A of Appendix P.7 Wildlife Mitigation and Monitoring Plan)
6.17.2 Environmental Effects on Federal or Transboundary Lands	No	6.17.3 Environmental Effects on Federal or Transboundary Lands	• N/A
6.17.3 Environmental Effects on Indigenous Peoples	Yes	6.17.4 Environmental Effects on Indigenous Peoples	• Ongoing and continued engagement
6.17.4 Power or Duty by Federal Authority	Yes	6.17.5 Power or Duty by Federal Authority	• *Fisheries Act* Authorization will be required based on confirmed direct and indirect impacts to fish and fish habitat
6.17.5 Environmental Effects Incidental of Decisions Made by a Federal Authority	No	6.17.6 Environmental Effects Incidental of Decisions Made by a Federal Authority	• N/A

Notes: - = no update; IR2s = Round 2, Information Requests; SAR = Species at Risk; EIS = Environmental Impact Statement; N/A = not applicable.

6.17.2 Environmental Effects within Federal Jurisdiction

This section summarizes those changes to the environment that may be caused by the Project on environmental components listed in paragraph 5(1)(a) of *CEAA 2012*. This includes fish and fish habitat as defined in the *Fisheries Act*, migratory birds as defined in the *Migratory Birds Convention Act, 1994,* and species designated by the *Species at Risk Act.* These VCs have been discussed in greater detail in Sections 6.9 (Fish and Fish Habitat), 6.12 (Avifauna), and 6.13 (Species of Conservation Interest and Species at Risk) and are summarized below. It is not anticipated that changes to the environment arising as a result of a federal decision will affect migratory birds or species at risk, once appropriate mitigation and compensation is considered. It has been determined that fish and fish habitat as defined in the *Fisheries Act* will require a federal authorization/decision. This is discussed in greater detail in the following sections.

6.17.2.1 Fish and Fish Habitat

Development of the Project will result in direct and indirect impacts to fish and fish habitat mostly within the construction phase of the Project during development of the open pit and its associated infrastructure. Impacts to fish and fish habitat are also expected during operations of the mine from on-going dewatering efforts within the open pit, surface water management of mine contact water, and resulting changes to flow patterns in adjacent stream systems.

Construction of the Haul Road is expected to result in direct impacts to fish and fish habitat mostly within the construction phase of the Project during clearing, grubbing and construction of new road components, culvert installation, and road widening where necessary. During construction, positive direct impacts to fish and fish habitat are also expected where current culverts that are hung or crushed can be either replaced or removed and fish passage and habitat re-established. All direct and indirect impacts to fish and fish habitat have been quantified and described in detail within this EIS with the understanding that a *Fisheries Act* Authorization will be required for the Project. These fish and fish habitat losses are included in the draft Fish Habitat Offset Plan (Appendix J.3).

Direct impacts to fish and fish habitat will result from dewatering lands that overly the open pit and associated infrastructure. Mitigation will be implemented to reduce the potential for direct fish mortality where fish are observed through fish rescue efforts prior to commencement of construction and completion of relevant construction activities. Construction activities will occur in confirmed fish habitat within approved timing windows for construction (June 1 to Sept 30) to reduce potential for mortality of eggs and juvenile fish, especially within Wetland 59. A preliminary fish rescue plan has been described in Section 6.9.8.2.2 and in IR2 response CEAA 2-11.

Maintaining water quality and quantity downstream in the Project (PA) and Local Assessment Area (LAA) is paramount for limiting broader fish and fish habitat impacts within each affected watershed associated with the PA. Water treatment is planned during construction to treat for metals associated with historic tailings to ensure that effluent discharge from the Beaver Dam Mine Site into Cameron Flowage/Killag River will comply with all regulatory guidelines to ensure the protection of aquatic health. Although water quality modelling does not predict exceedances of metals during operations this water treatment module will remain on site as a precautionary mitigation. In addition, a separate water treatment will be established on the Beaver Dam mine site to during operations to treat for elevated N species during operations. Indirect impacts to down-gradient watershed water quality and quantity within the PA and LAA that may affect fish and fish habitat are not expected from the Haul Road infrastructure (re-alignment and widening) once best management practices construction methods for culvert installation and mitigation strategies are implemented during road widening and re-alignment.

6.17.2.2 Migratory Birds

Project construction and operation will cause temporary and medium-term loss of habitat for birds and may cause disturbance or displacement of species. The baseline condition of the PA is a mix of disturbed habitats resulting from historical mining and forestry activities, and intact mixed wood forest habitats and wetlands. Habitat fragmentation may alter habitat suitability for those species which rely on interior forest conditions.

Lighting at the Beaver Dam Mine Site may cause disturbance or displacement of species, while attracting other species, or may cause general behavioral changes (DaSilva et al. 2015). For those species which may be attracted to lights (i.e., insectivores), lights may increase potential for direct mortality of these species or may increase habitat suitability by supplementing their source of prey.

Increased truck and vehicular traffic will increase noise levels, which may displace and/or disturb birds. Heavy machinery operation during open pit development, road construction, and construction of mine infrastructure will increase dust generation, which may affect surrounding vegetation and, consequently, birds (Farmer, 1993). Blasting and drilling of in-situ rock during open pit mining will increase dust emissions, which may affect surrounding vegetation and, consequently, birds (Farmer, 1993).

There is the potential for migratory bird mortality during clearing activities. Birds (particularly injured or fledglings) may get trapped in the open pit or collide with other Project infrastructure (crushers or trucks), which could lead to death or injury. Vehicle activity and heavy machinery operation may cause bird injury or mortality.

The overall effect of the Project on birds and bird habitat is assessed as not significant after mitigation measures have been implemented. Mitigation measures are detailed in Section 6.12.9.

6.17.2.3 Species at Risk

Three priority species have been identified or are expected to reside within watercourses in the PA (American eel, Atlantic salmon, and Brook trout). Although these species are not listed under provincial or federal endangered species legislation, Fisheries and Oceans Canada (DFO) has indicated that American eel and Atlantic salmon are currently being reviewed for protection under SARA. This is discussed further in the Fish and Fish Habitat Section 6.9.4.2.3. Standard mitigation and monitoring for fish and fish habitat (Section 6.9.8) will address direct and indirect effects to Atlantic salmon, Brook trout, and American eel.

Development of the Beaver Dam Mine Site and upgrading and construction of new sections of the Haul Road (Section 2, Figure 2.3-2) will result in direct impacts to vascular and non-vascular individuals and to flora communities at the full or partial forest stand level. Micro-siting of infrastructure has been completed to avoid priority flora and lichen species and has reduced the direct impact of the Project on flora and lichens. A Lichen Mitigation and Monitoring Plan has been developed (Appendix P.6).

The division and micro-siting of the waste rock storage areas (non-acid generating [NAG] waste rock and potential acid generating [PAG] waste rock) has relocated infrastructure out of the confirmed critical function zone for three historical locations of boreal felt lichen, south of the Beaver Dam Mine Site. The critical function zone is used to protect critical habitat for boreal felt lichen (NSLF, 2020).

Micro-siting and PA modifications of the Beaver Dam Mine Site has allowed for avoidance of all eight of the known locations of frosted glass-whiskers and reduced the number of individuals of blue felt lichen directly impacted from three to two, which are proposed for translocation (Appendix P.6). These two occurrences are located within the proposed NAG waste rock storage area and open pit area. Ten species of conservation interest (SOCI) lichen will be directly impacted by Beaver Dam Mine Site

infrastructure: six occurrences of salted shell lichen, two occurrences of slender monk's hood lichen and one eastern candlewax lichen. No priority vascular flora are anticipated to be directly impacted within the Beaver Dam Mine Site. The most recent Project design changes avoided two clusters of Wiegand's sedge by relocating the eastern waste rock storage area.

Within the Haul Road, no priority lichen species are anticipated to be directly impacted. One occurrence of southern twayblade within Wetland 161, is found withing the proposed alignment and is expected to be directly impacted.

Potential indirect impacts to vascular plants and lichens surrounding Project infrastructure will be reduced through best management strategies and mitigation measures.

Indirect effects to habitat and flora described in Section 6.10 are relevant to priority flora species as well. Lichens are sensitive to changing environmental conditions, particularly air quality. As such, Project activities may indirectly affect priority lichen species which have been avoided but exist near Project infrastructure. As mentioned, a draft Lichen Mitigation and Monitoring Plan (Appendix P.6) has been developed to monitor for changes in lichen health attributed to the Project.

Terrestrial fauna priority species of conservation interest and species at risk (SOCI/SAR) observed during field surveys within the PA include the mainland moose and the snapping turtle.

Development of the Beaver Dam Mine Site and associated upgrades to the Haul Road will result in direct impacts to habitat used by terrestrial fauna, including wetlands with suitable hibernacula for snapping turtles, and those with abundant submergent and emergent vegetation for mainland moose. A Preliminary Wetland Compensation Plan (Appendix H.3) has been developed to restore wetland habitat and snapping turtle and landbird SAR habitat. Sensory disturbance to terrestrial fauna would result from rock blasting, clearing and grubbing, infrastructure construction during the construction phase and, overall increased traffic, blasting, mining activities and trucking during operations within the PA. This may result in localized wildlife avoidance of the PA, including moose and snapping turtle. Direct mortality of priority fauna species could result from Project activities, particularly due to the increase in traffic during construction and operation of the facility. Increased traffic poses a risk to wildlife such as the mainland moose and snapping turtle along the entire length of the Haul Road between the Beaver Dam Mine Site and the Touquoy Mine Site. Indirect mortality to these species could also occur from exposure to contaminants or spills from unplanned incidents.

With appropriate mitigation and monitoring, no direct mortality of priority bird species is anticipated, with the exception of the low potential for a bird strike with a haul truck. Avian usage of the PA during construction and operation of the Beaver Dam Mine Site will largely be driven by changes to habitat, resulting in localized avoidance of the PA by some species. Some priority species may avoid the PA in favor of undisturbed habitat in the surrounding landscape. Other priority species are anticipated to be attracted to the mine infrastructure and newly created habitat.

Most direct and indirect impacts on birds, including SAR, are accounted for in general mitigation/monitoring for all birds, since many have legislated protection under the *Migratory Birds Convention Act* (primarily through avoiding clearing/grubbing during nesting season, and conducting detailed pre-construction nest searches if clearing or grubbing must occur during nesting season). These pre-construction nest searches are particularly important in wetlands which provide suitable breeding habitat for the Olive-sided Flycatcher, Canada Warbler and Rusty Blackbird. A draft Wildlife Mitigation and Monitoring Plan (Appendix P.7) and associated Landbird SAR Mitigation and Monitoring Plan has been developed (Appendix A of Appendix P.7).

6.17.3 Environmental Effects on Federal or Transboundary Lands

There are no federal or transboundary lands located within or adjacent to the PA. Given the distance from the Project site to federal lands and the analysis completed in Section 6, the Project has limited potential to result in a change to the environment on federal lands. The nearest federal lands to the PA are the Beaver Lake IR 17, located approximately 5 km from the Beaver Dam Mine Site and 3 km from the nearest point of the Haul Road.

6.17.4 Environmental Effects on Indigenous Peoples

Beaver Lake IR 17 is located approximately 5 km from the Beaver Dam Mine Site and 3 km from the nearest point of the Haul Road.

The Confederacy of Mainland Mi'kmaq (CMM) was retained in 2009 by GHD Limited on behalf of the AMNS to complete a Mi'kmaq Ecological Knowledge Study (MEKS) for the proposed Beaver Dam Mine Project. In 2015, CMM was retained to update the MEKS, due to changes in the Haul Road to include approximately 4 km of new construction. CMM was then retained again in 2016 to finalize the MEKS to include the revised PA and any additional information.

In addition to the MEKS cited above, in 2018, a Traditional Land and Resource Use Study (TLRUS; MFC 2019) was undertaken by Millbrook First Nation to document historical and current use of the Project Area and surrounding areas by the Millbrook First Nation. This document was shared with AMNS under a confidentiality agreement. AMNS has integrated information obtained from the TLRUS, with permission from Millbrook First Nation, in appropriate sections of the EIS.

There are several activities associated with the harvest and use of plants, animals and fish within the PA and in the LAA that relate to historical traditions and customs of the Mi'kmaq that are still practiced today. As described, the TLRUS (MFC 2019), the MEKS and residents of the Beaver Lake IR 17 identify trapping and hunting activities, plant and berry gathering, and fishing in, near and surrounding the PA for purposes of sustenance, spiritual and cultural practice. The TLRUS (MFC 2019) described the frequency of use within the LAA which can be summarized as regular: weekly to annually across all seasons. This means the area was, and still is, an important resource area for the Millbrook First Nation community members and by extension, all Mi'kmaq of Nova Scotia, and any Project activities may have potential impacts on the ability of the Mi'kmaq of Nova Scotia to access certain areas to practice their rights where species with important cultural relevance may be found. Wild meat was traditionally a staple of the Millbrook First Nation diet, and a few of the harvesters interviewed for the TLRUS (MFC 2019) indicated they rely mainly on this food source and they share their food with other community members, rather than purchase their meat at a local supermarket.

Some Mi'kmaq community members have camps on Crown land where they go to enjoy peaceful recreational and traditional activities with family and community members. There are five camps documented within 1 km of the Haul Road and multiple other camp locations throughout the LAA (MFC 2019).

Additional details on potential impacts to traditional harvesting is provided in Section 6.14 and the Human Health Risk Assessment (Appendix C.2).

There will be a reduction in area available for hunting, trapping, gathering, fishing, spiritual ceremonies and other Millbrook and broader Mi'kmaq traditional activities within the Beaver Dam Mine Site and Haul Road. The infrastructure footprint (mine site and haul road) will result in direct habitat loss and the Project will restrict access within a proposed property boundary/compliance boundary for a period of eight years.

Additionally, due to the proximity of the Beaver Dam Mine Site and Haul Road to traditional harvesting areas as discussed in the TLRUS (MFC 2019) and MEKS, there will potentially be an area outside of the Beaver Dam Mine Site and Haul Road where Millbrook community members and other Mi'kmaq hunters may observe a changed pattern of wildlife movement. This area has been identified as a potential wildlife environmental effects zone. Within close proximity to the proposed property boundaries of the Beaver Dam Mine Site and Haul Road, there is the potential for sensory disturbance to wildlife and birds from noise and light above background conditions resulting in potential changes to wildlife patterns and by extension, hunting practices for the Mi'kmaq of Nova Scotia. There are limited Project effects expected to hunting, gathering and trapping activities beyond the potential Wildlife Environmental Effects Zone.

The Mi'kmaq may experience hunting limitations near the Beaver Dam Mine Site and Haul Road for the use of firearms. Participants in the TLRUS described how they might be displaced along the Haul Road and in proximity to the Beaver Dam Mine Site where they "may feel uncomfortable using their firearms for safety reasons" (MFC 2019, p. 54). This limited firearms zone is shown on Figure 6.14-5 and demonstrates the maximum potential "loss of harvesting area for those individuals who do not feel comfortable shooting towards an active mine or haul road" (MFC 2019).

These impacts are predicted to be low magnitude, as defined in Section 6.14.6.2 and in consideration of mitigation and accommodation. A low magnitude change is defined (in part) by an observable change in the availability and baseline condition of the lands and resources for traditional purposes for a short temporal window (<20 years) and with commitment to appropriate and negotiated accommodation and compensation with the affected Mi'kmaq community(s).

6.17.5 Power or Duty by Federal Authority

Should the Project require a federal authority to exercise a power or perform a duty, Section 5(2)(b) of *CEAA, 2012* requires the following environmental effects to be considered:

a) *a change, other than those referred to in paragraphs (1)(a) and (b) [of Section 5, CEAA 2012], that may be caused to the environment and that is directly linked or necessarily incidental to a federal authority's exercise of a power or performance of a duty or function that would permit the carrying out, in whole or in part, of the physical activity, the designated Project or the Project; and*

b) *an effect, other than those already described related to aboriginal peoples, of any change referred to in paragraph (a) on*

   i. *health and socio-economic conditions;*

   ii. *physical and cultural heritage; or*

   iii. *any structure, site or thing that is of historical, archaeological, paleontological or architectural significance.*

Any physical activities in wetlands, watercourses or waterbodies may require authorization in accordance with the *Fisheries Act*.

For the Beaver Dam Mine Project, within the Beaver Dam Mine Site, the project team has conservatively calculated a maximum HADD of 415.75 HEU of fish habitat to support the mine development (direct and indirect impact to confirmed fish habitat based on watercourse and wetland characterization, electrofishing and manual fish collection results).

There is also potential for indirect impacts to additional fish habitat surrounding the Project. However, with proper mitigation and monitoring techniques employed (Section 6.9.8 and 6.9.10), the likelihood of this occurring is low.

The predicted residual environmental effects of Project development, operations and active clos on fish and fish habitat are determined to be adverse, but not significant. The overall residual effect of the Project on fish and fish habitat is assessed as not significant after mitigation measures have been implemented, including proposed offsetting measures. During permitting, detailed design will focus on reduction of impact to fisheries resources as much as is possible. A *Fisheries Act* Authorization will be required, based on confirmed direct impacts to fish and fish habitat associated with the mine development infrastructure, and the upgrade and new construction associated with the Haul Road.

6.17.6 Environmental Effects Incidental of Decisions Made by a Federal Authority

Section 5(2)(b) of *CEAA, 2012* identifies that if the Project requires a federal authority to exercise a power or perform a duty or function required by an Act to allow the Project to proceed, environmental effects must be taken into account, including effects on the following:

a) Health and socio-economic conditions;

b) Physical and cultural heritage; or

c) Any structure, site or thing that is of historical, archaeological, paleontological or architectural significance.

As a result of the predicted residual environmental effects on fish and fish habitat, associated changes to the environment are described in accordance with 5(2) of *CEAA 2012*. Table 6.17-2 described the linkages to relevant VCs (if any), where the related effects assessment is present within the EIS, and additional effects assessment, if necessary.

Table 6.17-2: Linkages to Environmental Effects Assessment for Relevant Valued Components

Federal Permit/Decision Required	Project Component(s)	Linkage to Other Valued Component	Effects Evaluation Location in EIS	Additional Evaluation Needed
Fisheries Act Authorization	Waste Rock Storage Area, Stockpiles and Open Pit within mine footprint. Haul Road upgrades and new construction	Wetlands	Section 6.8	none
		Surface Water	Section 6.7	none
		Groundwater	Section 6.6	none
		Habitat/Flora	Section 6.10	none
		Terrestrial Fauna	Section 6.11	none
		Birds	Section 6.12	none
		Species at Risk	Section 6.13	none

Note: EIS = Environmental Impact Statement.

The Beaver Dam Mine Site is currently accessible through a network of existing forestry access roads, and small truck/ATV trails. Several camps and site of community importance have been identified through engagement efforts. The mine site land is owned either by Northern Timber or the Crown. Land directly adjacent to the mine site is leased by the Nova Scotia Salmon Association for a lime doser and the Proponent has committed to work with the NSSA to provide access to this site. Forestry activity surrounding the PA has been significant. The Haul Road has multiple owners , which the two largest being the Crown and Northern Timber. Prest Bros Ltd and Musquodoboit Lumber company own lands near the entrance to the Haul Road from Mooseland Road, but AMNS has secured a lease with both companies. The Proponent also owns a small piece of land within the PA, along the Haul Road.

The PA is located outside a populated centre, with the nearest locality being the small community of Mooseland located at the intersection of the Mooseland Road and the Haul Road. There is significant recreational activity in and around the PA, both from

organized recreational groups and from permanent and seasonal residents of the area. The Mi'kmaq also use the area for traditional activities, such as harvesting, hunting and fishing . Through engagement, the Proponent has been informed that the area near the mine site and haul road is popular for hunting and fishing. The trail system that crosses both the mine site and the haul road is used by owners of camps for access and forms part of the provincial snowmobile/ATV network.

Loss of fish habitat within the mine footprint will result from the development of the open pit, waste rock storage areas and other temporary stockpiles. First order stream habitat and associated headwater and throughflow wetland habitat will be directly disturbed and/or altered to support the development of the mine, which is described in Section 6.9. Wetland habitat that will be altered has been determined to support passage for fish, refuge habitat for fish, and feeding habitat for fish. Several wetlands also have sufficient depth to potentially support overwintering populations of fish. These wetland habitats do provide some hiking, berry picking, bird watching, hunting and recreational opportunities, but provide limited to no fishing opportunities. As a result, the potential effect of a *Fisheries Act* Authorization on Indigenous and non-Indigenous health and socio-economic conditions (e.g., reduction of fishing activity) is expected to be very low due to the loss of fish habitat associated with the mine development.

6.18 Accidents and Malfunctions

6.18.1 Summary of Accidents and Malfunctions Before the Updates

Accidents and malfunctions have the potential to occur through every phase of the Project. To decrease the likelihood of occurrence and level of magnitude should these accidents and malfunctions occur, AMNS will implement a preventative system approach to environmental protection, and worker health and safety. Contractors will be subject to the same health, safety, and environment policies and procedures, and all personnel (employees and contractors) will receive site specific training to prevent and mitigate workplace accidents and malfunctions. The health, safety, and environment policies and procedures implemented for the Touquoy Project will be extrapolated to the Beaver Dam Mine Project and made site specific, where required.

Accidents and malfunctions that have the potential to occur through every phase of the Project were described and an analysis of the risks/hazard assessment was applied to determine effects. The assessment focused on the following:

- Structural Failures (i.e., slope failures);
- Settling Pond Failure;
- Infrastructure Failure;
- Accidents (i.e., fuel and other spills);
- Unplanned Explosive Events;
- Mobile Equipment Accident; and
- Other Malfunctions (i.e., forest fires).

The effects assessment is based on risk/hazard matrix to likelihood of occurring an event occurring. The key is the implementation of design criteria and emergency response planning necessary to prevent accidents and malfunctions from occurring. The emphasis is placed on design criteria as well as emergency preparedness and response.

6.18.2 Summary of Updates to Accidents and Malfunctions

The Accident and Malfunctions section is updated to reflect changes in the Project Description, including advancement of detailed engineering as well as responses to Round 2, Information Requests (IR2s) (e.g., CEAA 2-15 to CEAA 2-18). The IR2s requested additional information on settling pond failures, fuel spills associated with transport and other accidents. Updates to the Accident and Malfunctions Sections are summarized in Table 6-18-1.

Engineering of the settling ponds have been advanced since the Revised 2019 EIS (AMNS 2019) to include design criteria that addresses both major storm events and climate change. In addition, there is contingency planning that includes additional spillways, shut off valves to stop discharge to Cameron Flowage and pumping system to direct water to the north settling pond or open pit. Engineering has also been advanced for permanent (e.g., non-acid generating [NAG] and potential acid generating [PAG]) and temporary stockpiles (e.g., topsoil, till and organic). A geotechnical assessment of stockpile designs has been undertaken by Golder (2021; included as Appendix A.2a) to review potential for slope failures, safety factors, stability, and susceptibility to other risks (i.e., seismic). The assessment concluded that the design parameters are within acceptable safety factor and will be stable. Currently a geotechnical assessment by Golder (In Progress) of the open pit design to evaluate safety factor, stability and risk and hazards associated with the overall design.

Accidents and Malfunctions has been updated to consider design and operations environmental protections as well as contingencies and emergency response planning. The methods have been adjusted slightly from the Revised 2019 EIS to provide more clarity however accidents and malfunctions lends itself to a risk hazard assessment, which is standard practice in assessing potential accidents and malfunctions in mining (Tubis et al. 2020, Asgarian et al. 2017, Bach et al. 2016). The emphasis is on prevention, environmental controls and procedures and contingency to mitigate the risk.

Table 6.18-1: Updated Subsections from the 2019 Revised Environmental Impact Statement – Accidents and Malfunctions

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
-	-	6.18.1 Summary of Accidents and Malfunctions Before the Updates	• New • Summary of Revised 2019 EIS results

Numbered heading title was not used immediately after the main section heading (i.e., 6.18 Accidents and Malfunctions)	Yes	6.18.3 Introduction	• Minor updates to provide additional context and reference to IR2s
6.18.1 Assessment Methodology	Yes	6.18.4 Assessment Methodology	• Minor updates to indicate standard practices for assessment of accident and malfunctions in Environmental Assessment (CEAA 2-15)
6.18.2 Hazard Identification	Yes	6.18.5 Hazard Identification	• Minor updates to hazard classification to be in line with industry standards
6.18.3 Structural Failures	Yes	6.18.6 Structural Failures	• Updates based on design criteria and environmental considerations (CEAA 2-15, CEAA 2-16,
6.18.4 Accidents	Yes	6.18.7 Accidents	• Updates to Address CEAA 2-15, CEAA 2-16, CEAA 2-17, and CEAA 2-18, expanded discussion to include additional details to address slope failures fuel transport and potential release of fuels from storage facilities
6.18.5 Other Malfunctions	Yes	6.18.8 Other Malfunctions	• Minor Updates (CEAA 2-18)
6.18.6 Risk Assessment	Yes	6.18.9 Risk Assessment	• Updates to risk assessment criteria to be in line with industry practices
6.18.7 Discussion	Yes	6.18.10 Discussion	• Minor updates to conclusion

6.18.3 Introduction

Accidents and malfunctions, Section 19(1) of the Canadian *Environmental Assessment Act, 2012* (CEAA 2012) states:

> *"The environmental assessment of a designated project must take into account the following factors:*
>
> a) *the environmental effects of the designated project, including the environmental effects of malfunctions or accidents that may occur in connection with the designated project and any cumulative environmental effects that are likely to result from the designated project in combination with other physical activities that have been or will be carried out;*

b) *the significance of the effects referred to in paragraph (a)".*

Accidents and malfunctions refer to events that are not part of any planned activity or normal operation of a project that is proposed by a proponent. Many accidents and malfunctions are preventable, and their consequences can be severely limited by applying a precautionary approach during planning and design, establishing environmental controls and standard operating procedures, applying mitigation measures and developing a comprehensive emergency response. Accidents and malfunctions, however, still have the potential to occur and create adverse effects to the environment and worker health even with the implementation of best management practices and preventative measures. Identifying likely worst-case accidents and malfunctions and assessing their effects should they occur, AMNS can develop preventative and responsive procedures to reduce or control adverse effects caused by unplanned events resulting from accidents and malfunctions. Preventative and responsive procedures will be developed via the following principles:

- worker health and safety will be the central focus of process and mine safety management;
- best management practices and proven technologies will be utilized to undertake the Project and all planned releases to the environment and their effects will be properly managed;
- implement environmental protections and controls as well as planned contingencies to address unplanned events;
- undertake reviews of engineered structures to ensure they achieve safety and stability requirements;
- develop and apply procedures and training that will aim to promote safe operation of mining equipment and facilities; and
- develop and implement emergency response procedures that will reduce and control the adverse effects of an accident or malfunction.

The Project will be designed to implement preventative (i.e., environmental protection and controls as well as contingency as part on mine planning) and mitigation procedures throughout life of mine that will minimize the potential for accidents and malfunctions to occur. Should those accidents or malfunctions occur, emergency response procedures would be implemented to, reduce or control the resulting adverse effects. Control and contingency measures are included in the design of the Project.

6.18.4 Assessment Methodology

The assessment of effects from potential accidents and malfunctions were based on a credible worst-case scenario, which employs a risk-based approach that involves identifying hazards associated with Project infrastructure and activities, as well as the consequences should those hazards create an accident and malfunction. The identification of hazards was completed utilizing the operational expertise, best management practices, and consulting other projects similar to the Project. The identification of worst-case scenarios/consequences were determined using a qualitative risk assessment to determine the likelihood that hazards would create an accident and malfunction and determining the level of magnitude of those accidents and malfunctions should they occur.

Accidents and malfunctions that are considered either likely to occur, or have a significant effect should they occur, are included in this assessment. For each potential accident and malfunction, the following details will shape the effects assessment:

- a threshold for determination of significance is provided to set a benchmark for significance of an accident and malfunction;
- the interactions between the accident and malfunctions and specific VCs and the resulting effects are discussed in reference to their significance.
- mitigation measures are presented and designed to prevent the occurrence of accidents and malfunctions; and

- preliminary emergency response measures are discussed to lessen the magnitude of accidents and malfunctions should they occur.

Accidents and malfunctions have the potential to occur through every phase of the Project. To decrease the likelihood of occurrence and level of magnitude should these accidents and malfunctions occur, AMNS will implement a preventative system approach to environmental protection and worker and health and safety. Contractors will be subject to the same health, safety, and environment policies and procedures, and all personnel will receive site specific training to prevent and mitigate accidents and malfunctions. AMNS has developed an Environmental Management System and Health and Safety Plans at the fully approved and operating Touquoy Gold Project. These Plans will extend to the activities at the Beaver Dam Mine for all phases of the processing of ore from the Project. These plans will be examined and refined where needed to reflect BMP prior to the time that the Beaver Dam ore is processed at the Touquoy Mine Site. Revised versions of these Plans will also be developed specific to the Beaver Dam Mine Site and operations.

This methodology has also been utilized for a number of other mining-related undertakings which were subject to a proponent environmental assessment that were reviewed by Federal and Provincial government agencies in other jurisdictions including but not limited to *Ontario Environmental Assessment Act, BC Environmental Assessment Act*, Mackenzie Valley *Resource Management Act* and other stakeholders.

6.18.5 Hazard Identification

Nearly all Project components and activities outlined in Sections 2 of this EIS, including the processing activities at the Touquoy mine of ore from Beaver Dam Mine Site, have the potential to create accidents and malfunctions give ideal conditions; however, the likelihood is often extremely low. Those hazards considered to have the greatest likelihood to create an accident and malfunction, or have a significant effect should those accidents and malfunctions occur are outlined by phase in Table 6.18-2.

Table 6.18-2: Summary of Potential Accidents and Malfunctions

Hazard Categories	Potential Accidents and Malfunctions Scenarios	Site Preparation and Construction	Operation and Maintenance	Active Closure and Monitoring
Structural Failures	Open Pit Mine Slope Failure	○	●	○
	Stockpile Slope Failure	○	●	○
	Settling Pond Failure	○	●	○
	Infrastructure Failure	○	●	○
Accidents	Fuel and/or Other Spills	●	●	○
	Fuel Release during Truck Transportation	●	●	○
	Fuel Release from Storage Facilities and Dispensing Areas	●	●	○
	Transportation Accident – Hazardous Materials (excluding fuel)	●	●	○
	Transportation Accident –Non-hazardous Materials	●	●	○
	Unplanned Explosive Event	○	●	N/A -
	Mobile Equipment Accident	●	●	○

Table 6.18-2: Summary of Potential Accidents and Malfunctions (continued)

Hazard Categories	Potential Accidents and Malfunctions Scenarios	Site Preparation and Construction	Operation and Maintenance	Active Closure and Monitoring
	Tailings and Reclaim Water pipeline Spills at Touquoy	N/A	●	N/A
	Cyanide Spills at Touquoy	N/A	●	N/A
Other Accidents and/or Malfunctions	Forest and/or Site Fires	●	●	○

Notes: Potential for Adverse Effects: ● = High potential for adverse effects; ○ = Low potential for adverse effects; N/A = not applicable.

6.18.6 Structural Failures

6.18.6.1 Open Pit Mine Slope Failure

All phases of the Project have the potential for structural failures of slopes within the footprint of the open pit. The potential slope failures are as follows:

- failure of overburden slopes caused by erosion from vegetation stripping and surface water runoff; and
- failure of bedrock faces caused by improperly designed benches and erosion/fracturing from groundwater inflow.

A worst-case scenario is the severe collapse of areas directly adjacent to the open pit and ground surface slump of the surrounding area possibly affecting the site's infrastructure, Haul Roads, and on-site access roads and worker safety. However, the site's components and infrastructure have been designed as far from the perimeter of the open pit as possible so it is not expected that slope failure would affect the site's components and infrastructure.

During the initial stages of site preparation and construction, potential slope failures caused by erosion from vegetation stripping and surface water runoff will be limited to overburden; however, as blasting, and ore and non-ore bearing waste rock extraction commences, bedrock faces have the potential to fail if not properly designed and groundwater inflow is not properly managed. Based on the current delineation of ore, the mine will be excavated through bedrock to an end depth of approximately 170 m below ground surface. Currently, bench heights of 10 m are designed with 8 m wide berms placed every two benches. Actual bench face angles will be implemented for specific depths and zones of the open pit as prescribed by a qualified professional based upon a geotechnical study (Golder 2021, In Progress).

Geotechnical work has been completed at the Touquoy site and the expertise gained from working with these materials will be applied to the final design of the Beaver Dam disturbed areas using actual geotechnical data collected at Beaver Dam to supplement the abundant public information available. The soil and bedrock at the site are well understood from a geotechnical and construction standpoint including extreme conditions such as drought, freeze-thaw cycles, and weather (high rainfall events or storm events and wind). All of these "extreme" factors have been accounted for in the design of the Project and will be for all phases of the Project.

A geotechnical assessment on slope stability is currently being undertaken by Golder (2021, In Progress). The assessment will determine safety factor among other variables of the overall stability of the pit slopes. The design of the open pit may be modified based on this assessment.

6.18.6.1.1 Threshold for Determination of Significance

The criteria that would determine a significant effect should an overburden or bedrock slope fail, is based primarily on worker health and safety, and secondarily on property damage. Should a slope failure result in injury or death to a worker, or loss of mobile equipment the event will be considered significant.

6.18.6.1.2 Potential Interactions and Effects

The potential interactions between an open pit mine slope failure and VCs are outlined in Section 5.8, Tables 5.8-1 to 5.8-3. Additional detail by VC is outlined in Table 6.18-3. Only those interactions with a high potential to cause adverse effects should they occur are discussed in detail.

Table 6.18-3: Open Pit Mine Slope Failure Interactions with Valued Components

Valued Component	Potential Open Pit Mine Slope Failure and Valued Component Interaction	Potential for Adverse Effects
Noise	No potential interaction anticipated	-
Air	Failure of overburden slopes could potentially cause temporary dust generation	Low
Light	No potential interaction anticipated	-
Greenhouse Gases	No potential interaction anticipated	-
Geology, Soil, and Sediment Quality	No potential interaction anticipated	-
Surface Water Quality and Quantity	No potential interaction anticipated	-
Groundwater Quality and Quantity	No potential interaction anticipated	-
Wetlands	No potential interaction anticipated	-
Fish and Fish Habitat	No potential interaction anticipated	-
Habitat and Flora	No potential interaction anticipated	-
Avifauna	No potential interaction anticipated	-
Terrestrial Fauna	No potential interaction anticipated	-
Species of Conservation Interest and Species at Risk	No potential interaction anticipated	-
Mi'kmaq of Nova Scotia	No potential interaction anticipated	-
Physical and Cultural Heritage	Failure of overburden slopes could potentially cause destruction of archaeological, historical, and paleontological sites	Low
Socio-economic Conditions	Failure of overburden slopes and bed rock faces could potentially result in injury or death to mine workers	High

Note: - = not applicable.

Dust generated from the failure of an open pit slope would be temporary and localized to the area directly around the slope failure. In addition, the physical and cultural heritage artifacts in the area of any open pit slope failure are likely to be identified during mine development. As a result, potentially adverse effects to the atmospheric environment and physical and cultural heritage are considered low.

Surface mines with improperly designed benches and slopes and poor surface water and groundwater management pose a health and safety risk to workers during the site preparation and construction, and operation and maintenance phases, as well as a financial liability risk related to mobile equipment damage or loss.

The maximum effect of an overburden or bedrock face slope failure as it relates to worker health and safety would be a death caused by falling objects. The maximum effect of an overburden or bedrock face slope failure as it relates to financial liability would be a total loss of one or more pieces of mobile equipment.

Overburden or bedrock face slope failure may also occur during the decommissioning and reclamation/closure phase of the Project as the open pit fills with water via surface water runoff and groundwater inflow. Surface water runoff may erode overburden to a point of failure, while groundwater inflow may weaken major bedrock joints or discontinuities and cause a failure. However, as this decommissioning activity is passive, it will not involve direct interaction between workers and slopes and given a lack of environmental receptors in the open pit and that all effects from a slope failure will be contained to the open pit, potential adverse effects to other VCs from an overburden slope failure or bedrock face failure are anticipated to be non-existent.

6.18.6.1.3 Mitigation and Emergency Response

Regional and site-specific drilling has encountered bedrock materials that consist mainly of metamorphosed sedimentary rocks of the Goldenville Group. These materials are very stable and widely used in Nova Scotia for road materials and situations where erosion resistant materials are needed. Abundant highway construction projects leave these strata at vertical or near vertical with limited issues of stability.

A daily inspection of pit slopes by qualified personnel will be undertaken for any work area within the pit prior to employees or machinery entering. It is proposed to have an independent qualified professional review the slopes on a quarterly basis. Pit slopes are based on recommendations of the qualified professional with appropriate design safety factors applied. Slopes will be monitored throughout the life of the operation.

A berm surrounding the open pit will direct surface water runoff into a water diversion channel that discharges to the settling pond to the west. The berm will be keyed into the bedrock to prevent shallow groundwater flow and/or surface water originating in Cameron Flowage from entering the open pit. An in-mine water diversion ditch will be established along the top bench of the mine to intercept any surface water that infiltrates the berm and flows into the mine. This ditch will direct water to in-mine sumps where it will be pumped out of the mine.

Based on the current delineation of ore, the open pit will be excavated through bedrock to an end depth of approximately 170 m below ground surface. Bench heights and bench face angles prescribed by a geotechnical study (Golder *In Progress*) will be implemented for specific depths and zones of the open pit.

If slope failure were to occur, emergency procedures would be implemented that will be outlined in the site emergency response plan. Generally, slope failure emergency response includes evacuation of all equipment and personnel from the area and areas up-slope and down-slope from the slope failure area. An assessment is then made using on-site staff and possibly external resources (geotechnical specialists) to make a determination if the area can be accessed to make repairs, what repairs are needed and actions to prevent future incidents. This will be detailed in a recovery plan. Depending on the regulator involvement there may be a requirement to file incident reports with certain regulatory agencies prior to initiating the repairs and return to work in the area; these are very case specific and often dependent on whether personnel were injured or equipment damaged as a result of the slope failure.

6.18.6.2 Stockpile Slope Failure

All phases of the Project have the potential for structural failures of topsoil, till, and waste rock stockpile slopes. Failure of these slopes may be caused by improperly designed lifts, and erosion from surface water runoff.

Worst-case scenario resulting from stockpile slope failure would be disturbance to surrounding area, including the potential for mine rock and low-grade ore to enter nearby watercourses, damage to infrastructure and worker safety. As discussed below, stockpiles will be constructed in a way to reduce the consequences of the worst-case scenarios.

Topsoil stockpiles will be constructed to completion in single lifts of 10 m with 1.5:1 active slopes during the preparation and construction phase. They will be removed through use in progressive reclamation of the till and waste rock stockpiles during operation and maintenance and will have no significant presence prior to or shortly after decommissioning and reclamation commences.

Till stockpiles will be constructed to completion in single lifts of 15 m with 1.5:1 active slopes during the preparation and construction phase. They will be progressively capped with topsoil excavated from the open pit area and hydro seeded at the end of operations. This should allow for revegetation to being prior to or shortly after the decommissioning and reclamation commences.

The waste rock stockpile will be constructed in multiple lifts of 10 m with each lift having an active slope of 2:1. Construction of the waste rock stockpile will begin during the site preparation and construction phase and will be completed prior to or shortly after the decommissioning and reclamation phase commences. The waste rock stockpile will be progressively capped with topsoil excavated from the open pit area and hydro seeded during the decommissioning and reclamation phase.

Ore stockpiles will be constructed in 15 m lifts with 1.5:1 active slopes during the operation and maintenance phase. High-grade ore will be stockpiled near the crusher on the ROM and facilities pad. The high-grade ore stockpiles will be continually added to by mine trucks and subtracted from by front end loaders. Low-grade ore will be stockpiled east of this area and will remain until near the end of the operation and maintenance phase. All ore stockpiles will be removed prior to the decommissioning and reclamation phase.

Slope failures from stockpiles including waste rock, ore and till stockpiles have been considered and assessed. The stockpiles are situated at least 30 m away from the Cameron Flowage. The stockpiles have been designed to consider climate changes and seismic conditions and are engineered to a recognized industry standard. A geotechnical stability assessment has been undertaken by Golder (2021; included as Appendix A.2a) to evaluate the design criteria for waste rock, till and organic stockpiles. The results of the assessment indicate that they do not represent a safety risk or stability risk. The following provides a summary of description of design considerations and operations environmental protections that will be established to manage slope failures during construction and operations.

6.18.6.2.1 Design and Operation Environmental Protections

A number of design and operation environment protection have been considered to prevent a slope failure these include but not limited to the following:

- Waste rock and stockpile slopes are designed to meet a safety factor of at least 1.5.
- Internal roads will be designed to provide internal drainage and help dissipate construction induced pore pressure within the pile.
- If appropriate during final design, instrumentation may be installed to record pore pressures and deformation of the underlying ground and mineral waste in order to provide an early warning of potential failure.

- Daily inspections, at a minimum, will be undertaken to check for slumping and instability.
- The perimeter runoff collection ditches and sedimentation ponds will allow runoff management by capturing stockpile runoff in ditches and allowing it to settle in ponds prior to discharge to the environment.

6.18.6.2.2 Contingency and Emergency Response Procedures

In the unlikely event of a slope failure, an emergency response action plan will be implemented. Once the failure area is secured, and depending on the scale of the failure, the stockpile slope will be recontoured in place. If any material migrated as far as the perimeter ditch, it would be excavated and returned to the stockpile and if required the drainage ditches repaired. If the slope failure caused effluent in the perimeter ditching to spill, silt fencing could be deployed downstream of the spill to prevent sediment laden waters from entering a watercourse.

6.18.6.2.3 Threshold for Determination of Significance

The criteria that would determine a significant effect should a stockpile slope fail, is based primarily on worker health and safety, and secondarily on property damage and environmental effects. Should a slope failure result in injury or death to a worker, a loss of mobile equipment, or a release of low pH surface water to the environment the event will be considered significant.

6.18.6.2.4 Potential Interactions and Effects

The potential interactions between a stockpile slope failure and the VCs are outlined in Section 5.8, Tables 5.8-1 to 5.8-3. Additional detail by VC is outlined in Table 6.18-4. Only those interactions with a high potential to cause adverse effects should they occur are discussed in detail.

Table 6.18-4: Stockpile Slope Failure Interactions with Valued Components

Valued Component	Potential Stockpile Slope Failure and Valued Component Interaction	Potential for Adverse Effects
Noise	No potential interaction anticipated	-
Air	Failure of overburden slopes could potentially cause temporary dust generation	Low
Light	No potential interaction anticipated	-
Greenhouse Gases	No potential interaction anticipated	-
Geology, Soil, and Sediment Quality	Failure of waste rock and ore stockpile slopes could potentially alter acid rock drainage (ARD) mitigation measures and discharge to settling ponds	Low
Surface Water Quality and Quantity	Failure of waste rock stockpile and ore slopes could potentially alter ARD mitigation measures and discharge to settling ponds	Low
Groundwater Quality and Quantity	No potential interaction anticipated	-
Wetlands	Failure of waste rock and ore stockpile slopes could potentially alter ARD mitigation measures and discharge to settling pond	Low
Fish and Fish Habitat	Failure of waste rock stockpile slopes could potentially alter ARD mitigation measures and discharge to settling ponds	Low
Habitat and Flora	No potential interaction anticipated	-
Avifauna	No potential interaction anticipated	-
Terrestrial Fauna	No potential interaction anticipated	-

Table 6.18-4: Stockpile Slope Failure Interactions with Valued Components (continued)

Valued Component	Potential Stockpile Slope Failure and Valued Component Interaction	Potential for Adverse Effects
Species of Conservation Interest and Species at Risk	No potential interaction anticipated	-
Mi'kmaq of Nova Scotia	No potential interaction anticipated	-
Physical and Cultural Heritage	No potential interaction anticipated	-
Socio-economic Conditions	Failure of stockpile and ore slopes could potentially result in injury or death of mine workers	High

Note: - = not applicable.

Dust suspended from the failure of a stockpile slope would be temporary and localized to the area directly around the slope failure. In addition, production and discharge of ARD to receiving watercourses in the area is unlikely due to all surface water runoff being directed to settling ponds for treatment and monitoring prior to discharge to the environment. As a result, potentially adverse effects to the atmospheric environment, geology, soil, and sediment, surface water quality and quantity, wetlands, and fish and fish habitat are considered low.

Improperly designed stockpiles with poor surface water management pose a health and safety risk to workers and a financial liability risk related to mobile equipment damage or loss through all phases of the Project.

The maximum effect of a stockpile slope failure as it relates to worker health and safety would be a death caused by falling objects. The maximum effect of a stockpile slope failure as it relates to financial liability would be damage to or a total loss of one or more pieces of mobile equipment.

Given proper stockpile design and surface water management, as well as progressive reclamation practices for the till and waste rock stockpiles, stockpile slope failure is most likely to occur during the operation and maintenance phase of the Project when stockpiles are being continually acted upon either through loading, unloading, or shaping of material. Surface water runoff may erode topsoil, till, and waste rock to a point of failure as well.

Given surface water runoff from all stockpiles will be directed to settling ponds for treatment and a slope failure would likely not result in disturbance to environment, potential adverse effects to other VCs from a stockpile slope failure are anticipated to be non-existent.

6.18.6.2.5 Mitigation and Emergency Response

Design and Operation Environmental Protections

A number of design and operation environment protection have been considered to prevent a slope failure these include but not limited to the following:

- Waste rock and stockpile slopes are designed to meet a safety factor of at least 1.5.
- Internal roads will be designed to provide internal drainage and help dissipate construction induced pore pressure within the pile.
- If appropriate during final design, instrumentation may be installed to record pore pressures and deformation of the underlying ground and mineral waste to provide an early warning of potential failure.
- Daily inspections, at a minimum, will be undertaken to check for slumping and instability.

- The perimeter runoff collection ditches and sedimentation ponds will allow runoff management by capturing stockpile runoff in ditches and allowing it to settle in ponds prior to discharge to the environment.

Stockpile slopes will be designed at an angle determined by geotechnical analysis and acceptable safety factors, thereby reducing the likelihood of a slope failure. Placement of materials in the stockpiles would follow a plan developed for the stockpile that would consider thickness of the lift, compaction - if needed, load size, start and stockpile physical limits. Slopes will be monitored throughout the life of the operation with routine inspections by qualified staff and repairs made if warranted.

Surface water run-off from the non-ore bearing waste rock stockpile, Mine Site roads, and till stockpiles will flow by gravity, with the aid of berms and channels, to a settling pond located west of the open pit. Water will be gradually decanted to Cameron Flowage by gravity via a water diversion structure that runs northeast from the settling pond.

6.18.6.2.6 Contingency and Emergency Response Procedures

In the unlikely event of a slope failure, an emergency response action plan will be implemented. Once the failure area is secured, and depending on the scale of the failure, the stockpile slope will be recontoured in place. If any material migrated as far as the perimeter ditch, it would be excavated and returned to the stockpile and if required the drainage ditches repaired. If the slope failure caused effluent in the perimeter ditching to spill, silt fencing could be deployed downstream of the spill to prevent sediment laden waters from entering a watercourse.

6.18.6.3 Settling Pond Failure

All phases of the Project have the potential for a settling pond failure. A failure of the settling pond is defined as a breach of the banks through overflow or bank structure failure resulting in the release of sediment laden water to the environment. A worst-case scenario would be complete failure of the settling pond, resulting in uncontrolled discharge of sediment laden water into the surrounding environment. The capacity demand of the settling pond will increase as open pit depth increases and more infiltrated groundwater is pumped out of the mine.

Surface water run-off from the non-ore bearing waste rock stockpile, Mine Site roads, topsoil stockpiles, and till stockpiles will flow by gravity, with the aid of berms and channels, to a settling pond located west of the open pit. This settling pond will also receive water from the open pit dewatering program. Treatment of surface water runoff and mine infiltration groundwater will be passive. Water will eventually decant to Cameron Flowage through a fringe wetland and by gravity via a water diversion structure that runs northeast from the settling pond.

Surface water runoff from the Beaver Dam Mine Site ROM and facilities pad will flow by gravity, with the aid of berms and channels, to a collection pond located between the crushing operation and water storage tanks. A culvert located beneath the mine entrance road will facilitate decant overflow from the pond to a water diversion structure that splits the two ore stockpiles. The water diversion structure will discharge to a channel that will run down gradient to the northeast and ultimately discharge to Cameron Flowage. The discharge point will be equipped with a concrete flow-control structure with the ability to be shutoff allowing no flow to leave if needed.

The updated Beaver Dam Mine Project Mine Water Management Plan is summarized below. Additional detail is presented in Appendix P.4 (Mine Water Management Plan) and Appendix C (draft Erosion and Sediment Control Plan) of Appendix P.4.

The Beaver Dam Mine Site has a network of drainage ditches and ponds supporting onsite water management including:

- North Settling Pond;
- East Settling Pond;
- South Settling Pond;
- West Settling Pond; and
- Evaporation Pond.

6.18.6.3.1 Potential Concern

Environmental concerns relate to failure of settling ponds may contain elevated levels of water quality parameters (e.g., total suspended solids [TSS]) can be toxic to aquatic life and could harm local fish, amphibian and benthic invertebrate populations. Suspended solids can interfere with aquatic life, particularly during periods of egg incubation. Sediments can damage fish gills, interfere with feeding or if they are deposited, they can smother eggs by preventing oxygen exchange.

6.18.6.3.2 Designs and Environmental Protections

- **A:** The likelihood of failure of the North Settling Pond is expected to be low. There are two potential pathways for pond failure: overtopping and piping. With respect to overtopping failure, the pond will be designed to control site runoff up to and including the 100-year storm event, with a minimum freeboard of 0.3 m above the 100-year water level. Larger flow events will be controlled through one of two emergency spillways (two-way pump and overflow spillway weir) that will be directed to the sump within the open pit. Water collected in the pit will be pumped back into the pond after the storm event, as storage becomes available. As a result, pond failure by overtopping will not impact fish or fish habitat in the Killag River. The North Settling Pond will be designed to mitigate failure of the containment berm by piping. The operating water level (permanent pool) of the pond will be below the ground elevation on the downstream side of the berm. Only the active storage portion of the pond has potential for piping failure. In addition, the pond will be lined with an impermeable geosynthetic liner to prevent seepage through the pond berms. Further, due to the temporary nature of water storage in this part of the settling pond (only after a storm event and for approximately 24 hours afterwards) there is low risk for piping failure to form.

  The East, West and South Settling ponds will also be designed to control site runoff generated from the 100-year storm event, with the 0.3 m freeboard above the 100-year water level. Both ponds will also be lined with an impermeable geosynthetic liner to prevent seepage through the pond berms and minimizing the potential for piping failure. Larger events will be controlled through the emergency spillways. With planned site erosion and sediment controls in place, discharge via the emergency spillway is anticipated to have diluted total suspended solids (TSS) concentrations.

  All pond berms and outlet structures will be monitored regularly to detect any deficiencies that may result in failure. In addition, all ponds will have short service lives as they will be decommissioned post-closure. As a result, all discharge from the Site Settling Ponds to Cameron Flowage will be treated and overflow will not negatively impact fish or fish habitat in Cameron Flowage.

- **B:** The settling pond systems will be monitored regularly during mine operations to ensure the water levels are within the operational range, and the active and passive flood control infrastructure is in good working order, so that they perform as intended during major storm events. The North Settling Pond will be designed with a multi-level approach to flood control. A two-way pump will be installed to pump water between the pond and the pit. If a large storm event is anticipated, pond water can be pumped to the pit in advance of a storm event to increase the active storage volume of the pond. The pumps will run over the duration of the storm event. The pond will also include an emergency spillway, which will be designed to passively

control larger than the 100-year storm event (designed to the Hurricane Beth historical storm) discharge toward the pit, in the event the pumps become overwhelmed or inoperable. The emergency response plan will include evacuation of all equipment and site personnel downstream of the settling ponds and within the pit in anticipation of a major storm event.

- **C:** The North, East, West and South Settling Ponds will be designed to control site runoff generated up to and including the 100-year storm event through passively controlled primary outlet structures. Each pond will be equipped with an emergency spillway, sized to control the Hurricane Beth discharge. The North Settling Pond emergency spillway will be directed into the open pit, which will be dewatered back into the North Settling Pond when storage becomes available.
- **D:** The North, East, West and South Settling Ponds will be designed to control site runoff generated up to and including the 100-year storm event through passively controlled primary outlet structures. Each pond will be equipped with an emergency spillway, which will be activated during events in exceedance of the 100-year storm. The emergency spillways will be sized to control the Hurricane Beth discharge. Climate change impacts were incorporated (approximately 6% increase in IDF 100-year 24-hour rainfall depths) into the pond design as the ponds will only be in service during the mine operations, which is projected to be 7 years. The ponds will be decommissioned post-mine closure.
- **E:** The likelihood of failure of the North Settling Pond is expected to be low. The pond will be designed to control site runoff generated from the 100-year storm event. Larger flow events will be controlled through an emergency spillway that will be directed to the sump within the open pit. Water collected in the pit will be pumped back into the pond after the storm event, as storage becomes available. As a result, pond failure by overtopping will not impact fish or fish habitat in the Killag River. In addition, the North Settling Pond will be designed to mitigate failure of the containment berm by piping. The operating water level (permanent pool) of the pond will be below the ground elevation on the downstream side of the berm.

The predictive water quality analysis demonstrates that discharge from the East and South Settling Ponds does not require treatment for metals; as such, these ponds will provide TSS removal only. With the planned site erosion and sediment controls in place, discharge via the emergency spillway would have low and significantly diluted TSS concentrations compared to the runoff generated from more frequent storm events. As a result, the spillway discharge is expected to have minimal negative impacts to fish communities.

6.18.6.3.3 Threshold for Determination of Significance

The criteria that would determine a significant effect should a settling pond fail, is based primarily on environmental protection. Should a settling pond failure result in an uncontrolled discharge of sediment laden water to Cameron Flowage the event will be considered significant.

Comparison of surface water samples to CCME FWAL TSS guidelines and MMER TSS guidelines will be utilized to determine if sediment laden water will have an impact on surface water quality in Cameron Flowage and subsequently on fish and fish habitat.

6.18.6.3.4 Potential Interactions and Effects

The potential interactions between settling pond failure and the VCs are outlined in Section 5.8, Tables 5.8-1 to 5.8-3. Additional detail by VC is outlined in Table 6.18-5. Only those interactions with a high potential to cause adverse effects should they occur are discussed in detail.

Table 6.18-5: Settling Pond Failure Interactions with Valued Components

Valued Component	Potential Settling Pond Failure and Valued Component Interaction	Potential for Adverse Effects
Noise	No potential interaction anticipated	-
Air	No potential interaction anticipated	-
Light	No potential interaction anticipated	-
Greenhouse Gases	No potential interaction anticipated	-
Geology, Soil, and Sediment Quality	Failure of settling pond could potentially cause contaminated suspended solids to settle in Cameron Flowage and effect sediment quality	Low
Surface Water Quality and Quantity	Failure of settling pond could potentially cause sediment laden water to discharge to Cameron Flowage via the fringe wetland around Mud Lake	High
Groundwater Quality and Quantity	No potential interaction anticipated	-
Wetlands	Failure of settling pond could potentially cause sediment laden water to discharge to fringe wetlands around Mud Lake	High
Fish and Fish Habitat	Failure of settling pond could potentially cause sediment laden water to discharge to Cameron Flowage via the fringe wetland around Mud Lake	High
Habitat and Flora	No potential interaction anticipated	-
Avifauna	No potential interaction anticipated	-
Terrestrial Fauna	No potential interaction anticipated	-
Species of Conservation Interest and Species at Risk	Failure of settling pond could potentially cause sediment laden water to discharge to Cameron Flowage via the fringe wetland around Mud Lake	High
Mi'kmaq of Nova Scotia	No potential interaction anticipated	-
Physical and Cultural Heritage	No potential interaction anticipated	-
Socio-economic Conditions	No potential interaction anticipated	-

Note - = not applicable.

The degree to which suspended solids are expected to settle out of solution in a concentrated area should a settling pond failure occur is considered minimal. As a result, potentially adverse effects to the sediment quality portion of the geology, soil, and sediment quality VC are considered low.

Inadequate settling pond capacity and water level monitoring, combined with a significant precipitation event may cause a settling pond failure and thus, pose a risk to surface water quality, wetlands, fish and fish habitat, and SOCI/SAR through all phases of the Project.

The maximum effect of a settling pond failure as it relates to VCs above would be heavy siltation of wetlands and Cameron Flowage and subsequent stresses on fish and other aquatic species.

Given inputs for the settling pond would originate partially from the open pit dewatering program, settling pond failure is more likely to occur as development of the open pit progresses. Extracting waste rock and ore from the open pit will increase the potential for groundwater infiltration, thus increasing the amount of water that needs to be pumped from the open pit to the settling pond. As a result, the capacity requirements of the settling pond will increase the further the open pit is advanced and the potential for settling pond failure through bank overflow and structure failure increases as well.

Given the settling pond is a passive treatment process and it will not provide habitat for terrestrial species, adverse effects to other VCs from a settling pond failure are anticipated to be non-existent.

6.18.6.3.5 Mitigation and Emergency Response

The water diversion structure leading from the collection pond will discharge to a channel that will run down-gradient to the northeast and ultimately discharge to Cameron Flowage. The discharge point will be equipped with a concrete flow-control structure. Sediment laden water from the settling pond will be gradually decanted to Cameron Flowage via a water diversion structure that runs northeast from the settling pond.

The settling pond will be lined with suitable materials, such as clay or a plastic liner. In the event of a 1 in 100-year precipitation event that creates volumes in excess of the capacity available in ponds and ditching, or infrastructure failure, a spillway into the water diversion structure will be used for overflow. In the case of a storm event or infrastructure failure, settling ponds will be monitored regularly.

If settling pond failure were to occur, emergency procedures would be implemented that will be outlined in the site emergency response plan. Generally, settling pond failure emergency response includes raising the alarm and evacuation of all equipment and personnel from the area. If settling pond contents encroach on neighbouring properties or public roadways, appropriate authorities will be notified and construction of bunds and/or diversion drains may be required to contain settling pond contents on-site. An assessment is then made using on-site staff and possibly external resources (surface water specialists) as to what repairs are needed and actions to prevent future incidents. This will be detailed in a recovery plan. Depending on the regulator involvement there may be a requirement to file incident reports with certain regulatory agencies prior to initiating the repairs and return to work in the area, these are very case specific and often dependent on whether personnel were injured or equipment damaged as a result of the settling pond failure.

6.18.6.4 Infrastructure Failure

All phases of the Project have the potential for failures of infrastructure. Failure of these structures may be caused by improper design and construction, or natural causes such as hurricanes or earthquakes. A worst-case scenario would be failure of multiple operational components as a result of a natural cause impacting worker health and safety and the surrounding environment. The following operational facilities will be installed or constructed to support the Project:

- septic tanks and leach drains;
- raw water and potable water tank;
- diesel fuel storage and distribution system;
- diesel generators and power distribution overhead transmission lines;
- pole mounted lighting;
- vehicle washdown facility;
- pre-fabricated office facility and workshop building; and
- fire protection systems.

All infrastructure will be located on a central operational and ROM facilities pad that will provide quick access to the Haul Road and open pit. These components are described in detail in Project Description Section 2 of this EIS.

6.18.6.4.1 Threshold for Determination of Significance

The criteria that would determine a significant effect should an infrastructure failure occur is based primarily on worker health and safety and environmental impact, and secondarily on property damage. Should an infrastructure failure result in injury or death to a worker or a loss of infrastructure the event will be considered significant.

Should an infrastructure failure event result in the loss of any quantity of fuel, oil, lubricant, or other Project related raw materials to the environment such that a measurable contamination of soil, surface water, or groundwater results, the event will be considered significant.

Contamination is defined as the following:

- Soil:
  - when concentrations of any contaminant exceed the guidelines provided in the Nova Scotia Contaminated Sites Regulations - Tier 1 Environmental Quality Standards for Soil at a Non- potable Site, Section 1, Table 1B.
- Surface Water:
  - when concentrations of any contaminant exceed the guidelines provided in the Nova Scotia Contaminated Sites Regulations - Tier 1 Environmental Quality Standards for the Protection of Freshwater Aquatic Life in Surface Water, Section 1, Table 3.
- Groundwater:
  - when concentrations of any contaminant exceed the guidelines provided in the Nova Scotia Contaminated Sites Regulations - Tier 1 Environmental Quality Standards for Groundwater at a Non-potable Site, Section 1, Table 4.

6.18.6.4.2 Potential Interactions and Effects

The potential interactions between infrastructure failure and VCs are outlined in Section 5.8, Tables 5.8-1 to 5.8-3. Additional detail by VC is outlined in Table 6.18-6. Only those interactions with a high potential to cause adverse effects should they occur are discussed in detail.

Table 6.18-6: Infrastructure Failure Interactions with Valued Components

Valued Component	Potential Infrastructure Failure and Valued Component Interaction	Potential for Adverse Effects
Noise	No potential interaction anticipated	-
Air	An infrastructure failure event could potentially cause a fuel oil spill or small fire and release particulate matter, carbon monoxide, sulphur dioxide, nitrous oxides, and volatile organic compounds to the atmosphere	Low
Light	No potential interaction anticipated	-
Greenhouse Gases	An infrastructure failure event could potentially cause a fuel oil spill or small fire and release particulate matter, carbon monoxide, sulphur dioxide, nitrous oxides, and volatile organic compounds to the atmosphere	Low
Geology, Soil, and Sediment Quality	An infrastructure failure event could potentially cause a release of fuel oil to soil if released to the terrestrial environment	Low
Surface Water Quality and Quantity	No potential interaction anticipated	-

Table 6.18-6: Infrastructure Failure Interactions with Valued Components (continued)

Valued Component	Potential Infrastructure Failure and Valued Component Interaction	Potential for Adverse Effects
Groundwater Quality and Quantity	No potential interaction anticipated	-
Wetlands	No potential interaction anticipated	-
Fish and Fish Habitat	No potential interaction anticipated	-
Habitat and Flora	No potential interaction anticipated	-
Avifauna	No potential interaction anticipated	-
Terrestrial Fauna	No potential interaction anticipated	-
Species of Conservation Interest and Species at Risk	No potential interaction anticipated	-
Mi'kmaq of Nova Scotia	No potential interaction anticipated	-
Physical and Cultural Heritage	No potential interaction anticipated	-
Socio-economic Conditions	Failure of infrastructure could potentially cause injury or death to mine workers	High

Note: - = not applicable.

The emissions produced through volatilization of fuel oil or through a small fire from an infrastructure failure event would be temporary and localized to the area directly around the failure. In addition, a release of fuel oil, lubricants or other Project related raw materials would be minor in volume and likely contained and cleaned up prior to significantly effecting soil. As a result, potentially adverse effects to the atmospheric environment, and geology, soil, and sediment quality are considered low.

Infrastructure that is improperly designed and constructed poses a health and safety risk to workers during the site preparation and construction, and operation and maintenance phases, as well as a financial liability risk related to infrastructure damage or loss.

The maximum effect of an infrastructure failure as it relates to worker health and safety would be a death caused by falling objects or collapsing structures. The maximum effect of an infrastructure failure as it relates to financial liability would be damage to or a total loss of one or more pieces of infrastructure.

Given proper design and construction of infrastructure, failure will most likely to occur during the operation and maintenance phase of the Project when infrastructure is being worn and torn through operational processes. Infrastructure with moving components, such as the crusher and conveyor, are more likely to fail than static infrastructure, such as the office and workshop facilities.

Given infrastructure failure would likely not result in disturbance to a greenfield environment, potential adverse effects to other VCs from an infrastructure failure occurrence are anticipated to be non-existent.

6.18.6.4.3 Mitigation and Emergency Response

Infrastructure at the Beaver Dam Mine Site will be minimal and given the short life of the Project, failure should not occur without being acted upon by extreme natural causes, such as a hurricane or earthquake, or human error.

On-site infrastructure would be informally inspected by site personnel for signs of premature failure through the normal course of the working shift. More rigorous inspection would occur with routine maintenance. Existing legislation is well established and understood by the Proponent personnel through the development and future operation of the Touquoy Mine Site.

A Health and Safety Plan will be developed and implemented for the Beaver Dam Mine Site, which will include evacuation procedures, proper housekeeping procedures for the storage and use of small equipment, and materials.

6.18.7 Accidents

6.18.7.1 Fuel and/or Other Spills

All phases of the Project have the potential for fuel and/or other spills to occur. The perceived risk of a spill is most logical during the operation and maintenance phase when the following is occurring at the Beaver Dam Mine Site:

- bulk storage of diesel fuel is present on-site;
- frequent transfer and handling of diesel fuel is occurring;
- mobile equipment is operating and being maintained; and
- waste fluids such as oils, lubricants, and antifreeze are produced.

The site preparation and construction, and decommissioning and reclamation phases of the Project will have reduced risk due to a number of these activities not yet occurring or ceasing once the operation and maintenance phase is over.

Spills associated with these activities may occur through failure of storage tanks, improper fuel transfer procedures, fuel/hydraulic line breaks or leaks, spillage or failure of storage containers, and/or mobile equipment and refueling truck accidents.

A worst-case scenario would be a transportation collision causing the entire amount of material being transported to be spilled into a water body. The effects of the spill would vary depending on the material spilled; diesel fuel and gasoline are toxic to aquatic life and would have the greatest impact to the environment.

Diesel fuel will be delivered to double-walled aboveground storage tanks via licensed tanker trucks and be used in all mobile equipment and to power on-site generators. Other petroleum based and non-petroleum-based liquids will be used for equipment maintenance.

Diesel fuel and lubricant storage will be located away from wetlands and watercourses to the extent practical and a dedicated refueling truck will deliver these materials to the mine and maintenance mobile fleet, as well as diesel powered generators. The fleet of Haul Road trucks required to transport crushed ore from the Beaver Dam Mine Site to Touquoy Mine Site will be refueled at the Beaver Dam Mine Site as needed using the fuel and lube truck noted above.

6.18.7.1.1 Fuel Transport

In response to CEAA 2-17, the following provides additional details on the following transport of fuels and potential effects fish as well as key mitigations.

AMNS intent is to address the potential impact of fuel spills through project design and operational performance to ensure a safe and environmentally mine site. The response, therefore, is focused on the environmental designs and protections that that will be in place to address potential fuel spills before there is an impact to fish and fish habitat.

Fuel Release during Transport

Fuel will be transported to the proposed Beaver Dam Mine Site along the regional road network by tanker trucks. The tanker trucks will consist of single units that typically have a capacity of 30,000 L. Dual trailer units (B-trains) will not be used. Tanker trucks are generally compartmentalized, such that if there were to be an accident, only a portion of the load will be lost except in a catastrophic incident. The principal type of fuel used at the site will be diesel for generators and propane for power during the construction and operation phases as well as heavy equipment operation during construction, operation and closure.

The average fuel consumption of is approximately 3 million L/a during operations and approximately 500,000 L/a during the construction. Fuel is transported safely throughout the local region and across Canada on a routine basis, by licenced and trained drivers, and the risk of incident involving a serious collision where fuel is released into the environment is small.

Smaller quantities of gasoline will be trucked to site by tanker truck or container on truck, also using licenced and trained drivers.

Potential Environmental Concerns

Despite all reasonable safeguards, there is a small potential for spills from tanker trucks due to collisions, accidents related to poor weather conditions, or other mishaps. A diesel spill from a truck travelling to site could affect the soil (or snow in winter) in the vicinity of the spill, and could potentially enter a waterbody if the accident occurred on or near a water crossing.

Diesel fuel and gasoline is toxic to aquatic life when spilled in fresh water. A tanker truck spill will have the greatest environmental impact if the spill reached a major watercourse that supports aquatic life. The diesel slick will move downstream, potentially impacting riverbanks over the length of the watercourse until the spill could be contained or it naturally degrades. A spill on land will be comparatively easy to contain and clean up, particularly under frozen ground conditions.

Design and Operations Environmental Protections

Regular maintenance of fuel trucks can significantly reduce the chance of an equipment failure caused accident. The need for compliance with the Transportation of Dangerous Goods Act and associated Regulations will be reinforced in all applicable contracts and vendor agreements.

The potential for environmental impacts associated with malfunction and accidents on the trucking route will be minimized by the following operational procedures which will be incorporated into the environmental management system as possible and into trucking / supply contracts as reasonable:

- speed limits are to be strictly adhered to;
- strict adherence to national trucking hour limits and other applicable requirements;
- drivers will be required to meet all applicable regulatory training requirements, be trained in spill response procedures for the materials they transport, and carry the appropriate Material Safety Data Sheets;
- all vehicles transporting materials to site will be required to maintain a supply of basic emergency response equipment, including communication equipment, first aid materials and a fire extinguisher; and
- penalties for operational violations.

6.18.7.1.2 Threshold for Determination of Significance

The criteria that would determine a significant effect should a fuel and/or other spill occurs is based primarily on environmental protection. Should a spill result in the loss of any quantity of fuel, oil, lubricant, or other Project related raw materials to the environment such that a measurable contamination of soil, surface water, or groundwater results, the event will be considered significant.

Contamination is defined as the following:

- Soil:
  - when concentrations of any contaminant exceed the guidelines provided in the Nova Scotia Contaminated Sites Regulations - Tier 1 Environmental Quality Standards for Soil at a Non- potable Site, Section 1, Table 1B.
- Surface Water:
  - when concentrations of any contaminant exceed the guidelines provided in the Nova Scotia Contaminated Sites Regulations - Tier 1 Environmental Quality Standards for the Protection of Freshwater Aquatic Life in Surface Water, Section 1, Table 3.
- Groundwater:
  - when concentrations of any contaminant exceed the guidelines provided in the Nova Scotia Contaminated Sites Regulations - Tier 1 Environmental Quality Standards for Groundwater at a Non-potable Site, Section 1, Table 4.

6.18.7.1.3 Potential Interactions and Effects

The potential interactions between fuel and/or other spills and VCs are outlined in Section 5.8, Tables 5.8-1 to 5.8-3. Additional detail by VC is outlined in Table 6.18-7. Only those interactions with a high potential to cause adverse effects should they occur are discussed in detail.

Table 6.18-7: Fuel and/or Other Spills Interactions with Valued Components

Valued Component	Potential Fuel and/or Other Spills and Valued Component Interaction	Potential for Adverse Effects
Noise	No potential interaction anticipated	-
Air	Fuel and/or other spills could potentially volatilize into the atmosphere	Low
Light	No potential interaction anticipated	-
Greenhouse Gases	Fuel and/or other spills could potentially volatilize into the atmosphere	Low
Geology, Soil, and Sediment Quality	Fuel and/or other spills could potentially contaminate bedrock and soil if released to the terrestrial environment Fuel and/or other spills could potentially contaminate sediment if released to the aquatic environment along the Haul Road	High
Surface Water Quality and Quantity	Fuel and/or other spills could potentially contaminate surface water if released to the aquatic environment	High
Groundwater Quality and Quantity	Fuel and/or other spills could potentially contaminate groundwater if released to the terrestrial environment and soil/bedrock conditions allow vertical migration	High
Wetlands	Fuel and/or other spills could potentially contaminate wetlands if released to the aquatic or terrestrial environment	High
Fish and Fish Habitat	Fuel and/or other spills could potentially adversely affect fish and fish habitat if released to the aquatic environment	High

Table 6.18-7: Fuel and/or Other Spills Interactions with Valued Components (continued)

Valued Component	Potential Fuel and/or Other Spills and Valued Component Interaction	Potential for Adverse Effects
Habitat and Flora	No potential interaction anticipated	-
Avifauna	Fuel and/or other spills could potentially adversely affect birds	Low
Terrestrial Fauna	Fuel and/or other spills could potentially adversely affect fauna	Low
Species of Conservation Interest and Species at Risk	Fuel and/or other spills could potentially adversely affect species of conservation interest and species at risk if released to the terrestrial environment and/or aquatic environment	High
Mi'kmaq of Nova Scotia	Fuel and/or other spills could potentially adversely affect Indigenous Peoples	High
Physical and Cultural Heritage	No potential interaction anticipated	-
Socio-economic Conditions	No potential interaction anticipated	-

Note: - = not applicable.

Volatilization of fuel oil and/or other substances should they be spilled would be localized to the area directly around the spill. In addition, only a minor portion of diesel fuel oil, the most widely used substance for the Project, is considered volatile. Adverse effects to birds and fauna are considered low due to the developed nature and lack of habitat in areas (Beaver Dam Mine Site) considered being at the greatest risk for fuel and/or other spills. As a result, potentially adverse effects to the atmospheric environment, birds, and fauna are considered low.

Accidents that cause a fuel and/or other spill pose an environmental risk to the following VCs:

- geology, soil, and sediment;
- surface water quality and quantity;
- groundwater quality and quantity;
- wetlands;
- fish and fish habitat; and
- SOCI/SAR; and
- Indigenous Peoples.

Indigenous Peoples' use of land and resources for traditional purposes has the potential to be adversely affected from the underlying changes to other VCs that a fuel and/or other spill would cause. Depending on the location and timing of a potential fuel and/or other spill both groundwater and surface water quality could be affected, which in turn could directly affect traditional practices and drinking water of Indigenous people. There also could be potential indirect effects as a result of a spill event to the current land and resource use due to potential adverse effects to fish, fish habitat, wetlands and terrestrial habitats and species.

The greatest potential for a fuel and/or other spills to occur is during the site preparation and construction, and operation and maintenance phases when the greatest amount of fuel is being stored, handled, and transferred on-site.

Small spills like those seen due to improper transfer procedures during refueling of equipment will likely have negligible environmental effects, while larger spills like those seen due to equipment/storage tank failures and mobile equipment accidents may have significant environmental effects.

The location of the spill will also determine the magnitude of effects. A spill occurring within the Beaver Dam Mine Site is unlikely to cause significant environmental effects as the area will be largely devoid of ecological receptors and the presence of hundreds of workers will likely lead to quick and efficient containment and cleanup efforts. The primary receiver for spills in this area is the soil portion of the geology, soil, and sediment quality VC. Spills are unlikely to reach surface water, sediment, groundwater, wetlands, and fish habitat due to anticipated spill response times, as well as containment and cleanup efforts. A spill occurring due to an accident along the Haul Road may have more significant environmental effects if the accident occurs in close proximity to a watercourse or wetland. If not, the primary receiver for spills along the Haul Road is the soil portion of the geology, soil, and sediment quality VC.

6.18.7.1.4 Mitigation and Emergency Response

The source of greatest risk for potential spills and releases of diesel fuel relates to the improper execution of procedures for transfer and handling to and from stationary and mobile tankage. Other sources of potential spills and releases of diesel fuel relate to equipment failures, damage to storage or piping systems, mobile equipment accidents, and mobile refueling truck accidents. Releases of maintenance fluids pose a lesser risk in terms of magnitude, but can still occur due to equipment failures, damage to storage containers, and mobile equipment accidents. A release of these fluids may result in soil, groundwater, and/or surface water contamination that may adversely ecological receptors through absorption, and/or ingestion of contaminated media.

An Emergency Response Plan, including a Spill Contingency Plan, forms part of the environmental management system that will address the primary hazardous materials on site including procedures for spill response on the trucking route to the site. Materials to be maintained in vehicles will be identified in the draft Emergency Response Plan (Appendix P.1) and are likely to include absorbent materials and equipment to contain spilled material.

At the Beaver Dam Mine Site, the following additional controls will be in place to reduce the potential for or the severity of accidents involving hazardous materials:

- speed limits, to be posted and enforced by RRP security personnel;
- right of way procedures will be defined and haul trucks and loaded vehicles will be given preference;
- traffic will be required to yield to wildlife as observed; and
- where possible, heavy traffic will be limited to site haul roads and other traffic limited to site access roads.

Preventative procedures will be also be undertaken and fuel storage and transfer areas will be designed to accommodate these procedures and controls, such as limiting areas of fuel transfer. Staff will be trained in spill response measures and spill response kits will be accessible in areas of fuel transfer. A spill response plan, noted above, will be developed. The contingency measures developed as part of the spill response plan will be focused on areas of high ecological importance and areas used by Indigenous Peoples and will provide a plan on how such areas could/would be protected in the event of a spill. AMNS has committed to keep fuel storage on site

If a spill were to occur, emergency procedures would be implemented that will be outlined in the site emergency response plan. Generally, spill response includes raising the alarm, evacuation of all equipment and personnel from the area and possibly the area up wind, away from any vapour cloud, and establishment of a 500 to 1000 m radius exclusion zone from the spill location. An assessment is then made using on-site staff and possibly external resources (air quality specialists) to determine the type, quantity and source of the spill and whether Emergency Services are required. If required, Emergency Response Team will be contacted. The safety data sheet for the spilled material will be reviewed and will be made available to Emergency Response Team. A plan to contain and clean up the spill, as well as actions to prevent future incidents, will be detailed in a recovery plan. If it is safe to do

so, the spill source will be shut down and any ignition sources will be isolated. Barriers and signs to prevent access to the affected area may be required until the spill is completely contained and cleaned up. AMNS will file appropriate incident reports with regulatory agencies and will provide details, as required in an Industrial Approval.

6.18.7.2 Unplanned Explosive Event

An unplanned explosive event is limited to the site preparation and construction, and operation and maintenance phases of the Project. The worst-case scenario would be bodily harm as a result of improperly handling explosives.

Explosives will be supplied by an off-site contractor and there will be no requirement for an on-site magazine.

6.18.7.2.1 Threshold for Determination of Significance

The criteria that would determine a significant effect should an unplanned explosive event occur is based primarily on worker health and safety and secondarily on property damage and environmental protection.

Should an unplanned explosive event result in injury or death to a worker or a loss of infrastructure or mobile equipment the event will be considered significant.

Should an unplanned explosive event result in the loss of any quantity of fuel, oil, lubricant, or other Project related raw materials to the environment such that a measurable contamination of soil, surface water, or groundwater results, the event will be considered significant.

Contamination is defined as the following:

- Soil:
  - concentrations of any contaminant exceed the guidelines provided in the Nova Scotia Contaminated Sites Regulations - Tier 1 Environmental Quality Standards for Soil at a Non- potable Site, Section 1, Table 1B.
- Surface Water:
  - concentrations of any contaminant exceed the guidelines provided in the Nova Scotia Contaminated Sites Regulations - Tier 1 Environmental Quality Standards for the Protection of Freshwater Aquatic Life in Surface Water, Section 1, Table 3.
- Groundwater:
  - concentrations of any contaminant exceed the guidelines provided in the Nova Scotia Contaminated Sites Regulations - Tier 1 Environmental Quality Standards for Groundwater at a Non-potable Site, Section 1, Table 4.

6.18.7.2.2 Potential Interactions and Effects

The potential interactions between an unplanned explosive event and VCs are outlined in Section 5.8, Tables 5.8-1 to 5.8-3. Additional detail by VC is outlined in Table 6.18-8. Only those interactions with a high potential to cause adverse effects should they occur are discussed in detail.

Table 6.18-8: Unplanned Explosive Event Interactions with Valued Components

Valued Component	Potential Unplanned Explosive Event and Valued Component Interaction	Potential for Adverse Effects
Noise	No potential interaction anticipated	-
Air	An unplanned explosive event could potentially cause suspension of dust particles into the atmosphere	Low
Light	No potential interaction anticipated	-
Greenhouse Gases	An unplanned explosive event could potentially cause suspension of dust particles into the atmosphere	Low
Geology, Soil, and Sediment Quality	An unplanned explosive event could potentially cause a release of fuel oil and/or ammonium nitrate to soil	Low
Surface Water Quality and Quantity	No potential interaction anticipated	-
Groundwater Quality and Quantity	No potential interaction anticipated	-
Wetlands	No potential interaction anticipated	-
Fish and Fish Habitat	No potential interaction anticipated	-
Habitat and Flora	No potential interaction anticipated	-
Avifauna	An unplanned explosive event could potentially cause behavioral effects to birds in the area	Low
Terrestrial Fauna	An unplanned explosive event could potentially cause behavioral effects to fauna in the area	Low
Species of Conservation Interest and Species at Risk	An unplanned explosive event could potentially cause behavioral effects to species of conservation interest and species at risk in the area	Low
Mi'kmaq of Nova Scotia	No potential interaction anticipated	-
Physical and Cultural Heritage	An unplanned explosive event could potentially destroy undiscovered archaeological, historical, and/or paleontological artifacts	Low
Socio-economic Conditions	An unplanned explosive event could potentially cause injury or death to mine workers	High

Note: - = not applicable.

Dust suspended from an unplanned explosive event would be temporary and localized to the area directly around the explosion. In addition, a release of ammonium nitrate or fuel oil to the environment is considered unlikely as the majority of these substances will be consumed should an explosion occur.

Effects to birds, fauna, and SOCI/SAR will likely be minimal due to the Beaver Dam Mine Site being devoid of habitat once blasting commences. Effects to physical and cultural heritage will likely be minimal as well; it is anticipated that anywhere an unplanned explosive event as the potential to occur, the ground will already be disturbed by site preparation and construction activities. As a result, potentially adverse effects to the atmospheric environment, birds, fauna, SOCI/SAR, and physical and cultural heritage are considered low.

Explosives that are improperly handled pose a health and safety risk to workers during the site preparation and construction, and operation and maintenance phases of the Project, as well as a financial liability risk related to infrastructure and mobile equipment damage or loss.

The maximum effect of an unplanned explosive event as it relates to worker health and safety would be a death caused by direct interaction or from falling objects or collapsing structures damaged from the explosion. The maximum effect of an unplanned explosive event as it relates to financial liability would be damage to or a total loss of one or more pieces of infrastructure or mobile equipment.

Explosives will be supplied and managed by a licensed contractor.

6.18.7.2.3 Mitigation and Emergency Response

Blasting will be undertaken by a qualified contractor and explosives who will be responsible for all licensing and approvals as required by Natural Resources Canada for this Project. Transportation, storage and handling of explosives will be carried out in compliance with the *Explosives Act* and any other relevant legislation. If an unplanned explosive event were to occur, emergency procedures would be implemented that will be outlined in the site emergency response plan. Generally, unplanned explosive event response includes raising the alarm and evacuation of all equipment and personnel from the area. No attempt to approach or extinguish any fire should be made. An assessment is then made using on-site staff to determine whether Emergency Services are required. If required, Emergency Services will be contacted. A safe zone around the affected area will be established, the size of which will be determined by on-site staff and possibly external resources (explosive specialists). Barriers and signs to prevent access to the affected area may be required until clean-up is complete. Depending on the regulator involvement there may be a requirement to file incident reports with certain regulatory agencies prior to initiating the clean-up and return to work in the area, these are very case specific and often dependent on whether personnel were injured or equipment damaged as a result of the unplanned explosive event.

6.18.7.3 Mobile Equipment Accident

All phases of the Project will have the potential for vehicular accidents to occur. A worst-case scenario would be a severe accident-causing injury or death.

The majority of mobile equipment traffic will be limited to the Beaver Dam Mine Site where guided traffic patterns, speed limits, right-of-way signage, and training will minimize the risk of vehicular accidents. The remaining mobile equipment will include haul trucks, which will transport crushed ore 30 km from the Beaver Dam Mine Site to the Touquoy Mine Site. The number of return truck trips per day will be an annual average of approximately 185 for 12 or 16 hours per day, 350 days per year for the anticipated duration of the mine Project (3.3 years). During construction and pre-production (8 months), the number of trips will be less and required for moving material from Touquoy to Beaver Dam and construction and upgrade of the Haul Roads.

The Haul Road will be dual lane and designed to facilitate the safe passage of two-way truck traffic at 70 km/h. Speed limit and Right-of-way signage will be installed and all haul truck operators will receive operator training to minimize the risk of haul truck collisions. All intersections will be designed to NSTIR Standards.

6.18.7.3.1 Threshold for Determination of Significance

The criteria that would determine a significant effect should a mobile equipment accident occur is based primarily on worker health and safety and secondarily on property damage and environmental protection.

Should a mobile equipment accident result in injury or death to a worker or a loss of infrastructure or mobile equipment the event will be considered significant.

Should a mobile equipment accident result in the loss of any quantity of fuel, oil, lubricant, or other Project related raw materials to the environment such that a measurable contamination of soil, surface water, or groundwater results, the event will be considered significant.

Contamination is defined as the following:

- Soil:
  - concentrations of any contaminant exceeding the guidelines provided in the Nova Scotia Contaminated Sites Regulations - Tier 1 Environmental Quality Standards for Soil at a Non- potable Site, Section 1, Table 1B.
- Surface Water:
  - concentrations of any contaminant exceeding the guidelines provided in the Nova Scotia Contaminated Sites Regulations - Tier 1 Environmental Quality Standards for the Protection of Freshwater Aquatic Life in Surface Water, Section 1, Table 3.
- Groundwater:
  - concentrations of any contaminant exceeding the guidelines provided in the Nova Scotia Contaminated Sites Regulations - Tier 1 Environmental Quality Standards for Groundwater at a Non-potable Site, Section 1, Table 4.

6.18.7.3.2 Potential Interactions and Effects

The potential interactions between a mobile equipment accident and VCs are outlined in Section 5.8, Tables 5.8-1 to 5.8-3. Additional detail by VC is outlined in Table 6.18-9. Only those interactions with a high potential to cause adverse effects should they occur are discussed in detail further.

Table 6.18-9: Mobile Equipment Accident Interactions with Valued Components

Valued Component	Potential Mobile Equipment Accident Interactions with Valued Component	Potential for Adverse Effects
Noise	No potential interaction anticipated	-
Air	A mobile equipment accident could potentially cause a fuel oil spill or small fire and release particulate matter, carbon monoxide, sulphur dioxide, nitrous oxides, and volatile organic compounds to the atmosphere	Low
Light	No potential interaction anticipated	-
Greenhouse Gases	A mobile equipment accident could potentially cause a fuel oil spill or small fire and release particulate matter, carbon monoxide, sulphur dioxide, nitrous oxides, and volatile organic compounds to the atmosphere	Low
Geology, Soil, and Sediment Quality	A mobile equipment accident could potentially cause a release of fuel oil to soil if released to the terrestrial environment A mobile equipment accident could potentially cause a release of fuel oil to sediment if released to the aquatic environment.	Low
Surface Water Quality and Quantity	A mobile equipment accident could potentially cause a release of fuel oil to watercourses	High
Groundwater Quality and Quantity	No potential interaction anticipated	-
Wetlands	A mobile equipment accident could potentially cause a release of fuel oil to wetlands	High
Fish and Fish Habitat	A mobile equipment accident could potentially cause a release of fuel oil to fish habitat	High

Table 6.18-9: Mobile Equipment Accident Interactions with Valued Components (continued)

Valued Component	Potential Mobile Equipment Accident Interactions with Valued Component	Potential for Adverse Effects
Habitat and Flora	No potential interaction anticipated	-
Avifauna	A mobile equipment accident could potentially cause bird mortality through direct strikes	Low
Terrestrial Fauna	A mobile equipment accident could potentially cause fauna mortality through direct strikes	Low
Species of Conservation Interest and Species at Risk	A mobile equipment accident could potentially cause a release of fuel oil to watercourses along the haul road A mobile equipment accident could potentially cause aquatic based species of conservation interest and species at risk mortality through direct strikes	High Low
Mi'kmaq of Nova Scotia	No potential interaction anticipated	-
Physical and Cultural Heritage	No potential interaction anticipated	-
Socio-economic Conditions	A mobile equipment accident could potentially cause injury or death to mine workers	High

Note: - = not applicable.

The emissions produced from a mobile equipment accident would be temporary and localized to the area directly around the accident. In addition, a release of fuel oil, lubricants or other Project related raw materials would be minor in volume and likely contained and cleaned up prior to significantly effecting soil or sediment quality. Effects to birds, fauna, and SOCI/SAR would be limited to death by direct strike, which would be limited to individuals rather than species populations. As a result, potentially adverse effects to the atmospheric environment, geology, soil, and sediment quality, birds, fauna, and SOCI/SAR are considered low.

Mobile equipment accidents pose an environmental risk to the following VCs:

- surface water quality and quantity;
- wetlands;
- fish and fish habitat; and
- SOCI/SAR.

The greatest potential for a mobile equipment accident to occur and cause adverse environmental effects is during the site preparation and construction, and operation and maintenance phases when the largest amount of mobile equipment is in use. The primary risk for the VCs listed above is associated with the release of fuel oil to the environment.

The magnitude of a release from mobile equipment is dependent on the severity and type of accident that occurs. A large spill can occur if an accident results in the complete destruction of a storage tank, or a small spill can occur if an accident results in a fuel line leak.

The location of the mobile equipment accident will also determine the magnitude of effects. An accident occurring within the Beaver Dam Mine Site boundaries is unlikely to cause significant environmental effects as the area will be largely devoid of ecological receptors and the presence of hundreds of workers will likely lead to quick and efficient containment and cleanup efforts. The primary receiver for spills as a result of accidents in this area is the soil portion of the geology, soil, and sediment quality VC. Spills are unlikely to reach surface water, sediment, groundwater, wetlands, and fish habitat due to anticipated spill response times, as

well as containment and cleanup efforts. A spill occurring due to an accident along the Haul Road may have more significant environmental effects if the accident occurs in close proximity to a watercourse or wetland. Should this occur, the effects to surface water quality, wetland health, fish and fish habitat, and SOCI/SAR may be more pronounced.

A mobile equipment accident may pose a health and safety risk to workers during all phases of the Project, as well as a financial liability risk related to mobile equipment damage or loss. The risk of a mobile equipment accident may decrease once the operations and maintenance phase ceases, as decommissioning and reclamation will likely require fewer pieces of mobile equipment.

The maximum effect of a mobile equipment accident as it relates to worker health and safety would be a death caused by a collision of two pieces of mobile equipment, a single equipment crash, or a direct strike from mobile equipment. The maximum effect of a mobile equipment accident as it relates to financial liability would be damage to or a total loss of one or more pieces of mobile equipment.

6.18.7.3.3 Mitigation and Emergency Response

The majority of mobile equipment traffic will be limited to the Beaver Dam Mine Site where guided traffic patterns, speed limits, right-of-way signage, and training will minimize the risk of vehicular accidents. The remaining mobile equipment will include haul trucks, which will transport crushed ore 30 km from the Beaver Dam Mine Site to the Touquoy Mine Site. The Haul Road will be dual lane and designed to facilitate the safe passage of two-way truck traffic at 70 km/h. Speed limits will be enforced on the Mine Site and Haul Road.

Speed limit and right-of-way signage will be installed and all haul truck operators will receive operator training to minimize the risk of haul truck collisions. All intersections will be designed to NSTIR Standards. Communications will be maintained between vehicles using radios so that adverse conditions or collisions may be reported immediately. The operators training will include proper procedures for daily travel to minimize the risk of vehicular accidents, as well as procedures related to emergency response should there be a vehicular accident.

Good maintenance practices for equipment and vehicle maintenance will be undertaken, including regular maintenance as specified by suppliers.

An emergency response plan will be developed for the Project and will include procedures to be followed in the event of a mobile equipment accident. The legislation is well established and understood by the Proponent's staff and will be conveyed to any contractors at the site so that all know of actions to take and reporting requirements.

If a mobile equipment accident were to occur, emergency procedures would be implemented that will be outlined in the site emergency response plan. Generally, mobile equipment accident response includes raising the alarm, providing first aid to any injured persons, and securing all equipment in the area. An assessment is then made using on-site staff to determine whether Emergency Services are required and the cause of the accident. If required, Emergency Services will be contacted. A plan to determine what repairs are needed and actions to prevent future incidents will be detailed in a recovery plan. Depending on the regulator involvement there may be a requirement to file incident reports with certain regulatory agencies prior to initiating the clean up and return to work in the area, these are very case specific and often dependent on whether personnel were injured or equipment damaged as a result of the mobile equipment accident.

6.18.7.4 Touquoy Mine

The Project will utilize the existing processing facility at the Touquoy Mine Site to process Beaver Dam ore. The Touquoy Mine Site is a fully permitted and approved facility currently operating as part of the Touquoy Gold Mine Project in Moose River, Halifax County, Nova Scotia.

Only minor changes to the existing works will be necessary to modify the Touquoy Mine Site to process Beaver Dam ore. The minor modifications to the processing facility can be accommodated within the existing footprint and do not result in a change the processing flowsheet. Beaver Dam tailings will be stored in the exhausted Touquoy open pit as opposed to the Touquoy tailings management facility. The tailings and reclaim water lines will be re-routed in order to transport Beaver Dam tailings to the exhausted Touquoy pit and return process water to the mill. The Touquoy Mine Site footprint will, as a result, be maintained as originally permitted.

An amendment to the Touquoy IA will be sought as necessary to accommodate these changes. As well, the currently approved Reclamation Plan will be updated to reflect the above changes and re-submitted.

The continued operation of the Touquoy processing plant and the use of the open pit mine for tailings storage will create the potential for accidents and malfunctions to occur at the Touquoy Mine Site for an additional four years. The potential for accidents and malfunctions at the Touquoy Mine Site will continue to be mitigated through the application of existing environmental management plans, operating procedures and monitoring programs.

6.18.7.5 Tailings and Reclaim Water Pipelines Spills

Prior to the completion of mining operations at the Touquoy Mine Site, a tailings line will be routed to the exhausted Touquoy pit in preparation to receive Beaver Dam tailings. Tailings will flow by gravity from the mill to the open pit. Initially, reclaim water will continue to be withdrawn from the supernatant pond in the existing TMF via the existing reclaim works to supply processing water needs for Beaver Dam ore. A reclaim water pump and barge, with a new pipeline to the process water tank, will be installed when process water accumulation from the tailings slurry deposited in the open pit is adequate. The transition from the TMF to the open pit reclaim water system is expected to be smooth, requiring minimal downtime and no expected extra freshwater requirements beyond what is currently permitted from Scraggy Lake under Touquoy's water withdrawal approvals. The existing TMF will only be used for initial process water requirements and will not be used for tailings storage in the processing of Beaver Dam ore.

Supernatant water collected in the open pit will be pumped to the process water tank located next to the pre-leach thickener. The sections of the tailings and reclaim pipelines between the plant site and open pit will be double-walled and run in HDPE lined trenches to an adequately sized lined collection ponds capable of containing the volume of the pipeline. Monitoring systems will be installed on the pipelines for leak detection and triggering shutdown procedures.

The Touquoy Project currently employs an Operation, Maintenance and Surveillance (OMS) Manual for the existing TMF. This manual will be updated in advance of using the open pit for storage of Beaver Dam tailings in order to reflect changes in operating conditions and environmental factors. As well, Touquoy also currently employs an Emergency and Spill Response Plan which will also be updated, Environmental monitoring will continue as prescribed under the Touquoy IA which will be amended as necessary to reflect the changes in processing of Beaver Dam ore and storage of Beaver Dam tailings in the exhausted pit.

6.18.7.5.1 Threshold for Determination of Significance

The criteria that would determine a significant effect should a tailings or reclaim water pipeline fail, is based primarily on environmental protection. Should a pipeline failure result in an uncontrolled discharge of tailings and/or process water to the receiving surface water environment the event will be considered significant.

Comparison of receiving surface water samples to CCME FWAL TSS guidelines and MMER TSS guidelines will be utilized to determine if tailings/process water will have an impact on surface water quality and subsequently on fish and fish habitat.

6.18.7.5.2 Potential Interactions and Effects

The potential interactions between a tailings or reclaim water pipeline accident and VCs are outlined in Section 5.8, Tables 5.8-1 to 5.8-3. Additional detail by VC is outlined in Table 6.18-10. Only those interactions with a high potential to cause adverse effects should they occur are discussed in detail further.

Table 6.18-10: Unplanned Tailings/Reclaim Water Line Event Interactions with Valued Components

Valued Component	Potential Unplanned Tailings/Reclaim Water Line Event and Valued Component Interaction	Potential for Adverse Effects
Noise	No potential interaction anticipated	-
Air	No potential interaction anticipated	-
Light	No potential interaction anticipated	-
Greenhouse Gases	No potential interaction anticipated	-
Geology, Soil, and Sediment Quality	No potential interaction anticipated	-
Surface Water Quality and Quantity	Failure of a tailings or reclaim water pipeline could potentially cause tailings solids and/or contaminated process water to discharge to surface waters	Low
Groundwater Quality and Quantity	No potential interaction anticipated	-
Wetlands	No potential interaction anticipated	-
Fish and Fish Habitat	Failure of a tailings or reclaim water pipeline could potentially cause tailings solids and/or contaminated process water to discharge to surface waters	Low
Habitat and Flora	No potential interaction anticipated	-
Avifauna	No potential interaction anticipated	-
Terrestrial Fauna	No potential interaction anticipated	-
Species of Conservation Interest and Species at Risk	No potential interaction anticipated	-
Mi'kmaq of Nova Scotia	No potential interaction anticipated	-
Physical and Cultural Heritage	No potential interaction anticipated	-
Socio-economic Conditions	No potential interaction anticipated	-

Note: - = not applicable.

6.18.7.5.3 Mitigation and Emergency Response

The sections of the tailings and reclaim pipelines between the plant site and open pit will be double-walled and run in HDPE lined trenches to an adequately sized lined collection pond capable of containing the volume of the pipeline. The catchment pond will be lined with suitable materials, such as clay or a plastic liner.

Process controls will be in place to detect a pipeline leak or spill and initiate shutdown procedures.

The potential for accidents and malfunctions at Touquoy mine will continue to be mitigated through the application of existing environmental management plans, operating procedures and monitoring programs, including the OMS Manual and Emergency and Spill Response Plan.

Given the location of the pipelines, trench and catchment pond within the mine production area and in close proximity to other facilities and personnel, detection and response to any spill would be expected to be rapid and confined to the mine footprint area and not result in significant release to the receiving environment.

If a tailings and/or reclaim water pipelines spill were to occur, emergency procedures would be implemented that will be outlined in the site emergency response plan. Generally, tailings and/or reclaim water pipelines emergency response includes evacuation of all equipment and personnel from the area. If tailings and/or reclaim water encroach on neighbouring properties or public roadways, appropriate authorities will be notified and construction of bunds and/or diversion drains may be required to contain tailings and/or reclaim water on-site. Other immediate responses may include lowering tailing pond levels, stopping the inflow into the tailings pond from the mill, stabilizing unstable slopes, and mitigating downstream consequences. An assessment is then made using on-site staff and possibly external resources (surface water specialists) as to what repairs are needed and actions to prevent future incidents. This will be detailed in a recovery plan. Depending on the regulator involvement there may be a requirement to file incident reports with certain regulatory agencies prior to initiating the repairs and return to work in the area, these are very case specific and often dependent on whether personnel were injured or equipment damaged as a result of tailings and/or reclaim water pipelines spill.

6.18.7.6 Cyanide Release

Cyanide Handling

Sodium cyanide (NaCN) is a key reagent used in the Carbon-In-Leach (CIL) process to leach gold from a sold matrix to form a gold cyanide complex that can be extracted from the slurry by adsorption onto activated carbon.

NaCN is delivered to Touquoy in the form of in dry briquettes from an approved supplier as per International Cyanide Management Code (ICMC) standards. NaCN deliveries are made by truck in one tonne secured (strapped) wooden crates. Within the crates the NaCN is double wrapped and sealed closed. Upon receipt at Touquoy, the sodium cyanide is stored in a locked, fenced area within the secure reagent building and kept under camera surveillance.

Prior to use, NaCN is mixed with water and sodium hydroxide (NaOH) for dilution and pH control within a mixing tank. Prior to mixing, operators suit up in full personnel protective equipment (PPE) including Tyvek suits and powdered air purifying respirators (PAPR). Water and NaOH are added to the cyanide mix tank. The wooden crates are opened, and a gantry crane lifts the bags out and transports them to the mix tank. The bags are lifted by crane into the bag cutter on top of the mix tank and the door is shut to enclose the bag. The bag is slowly lowered onto the bag cutter and the dry solids are emptied into the mix tank. The bag cutter has water sprays to clean the cyanide bags prior to removing from the enclosure. This process is repeated for 4 cyanide (NaCN) bags to achieve a mix concentration of ~22%. Once the NaCN storage tank level drops below 20% the contents of the mix tank are then transferred to the storage tank for distribution throughout the plant.

Cyanide is added into three areas; Leach tank #1, Intensive Leach Reactor (ILR) and Barren Eluate tank #12. Leach tank #1 is a continuous addition whenever the leach circuit is being fed with ore. It is controlled based on constant cyanide titrations throughout the leach/CIL circuit. The ILR and Barren Eluate tank are dosed based on a batch process. When a batch is ready, the dosage is

controlled based on a flowmeter to a targeted concentration. All these addition points have pH control reagents (NaOH or Lime) with automated interlocks that will not permit NaCN addition until a suitable pH is achieved to avoid the formation of hydrogen cyanide (HCN) gas.

Cyanide target concentrations are as follows:

- Leach tank # 1 = 50 ppm (0.005%). By the end of the CIL circuit (CIL tank #6), the remaining cyanide is about 30 ppm (0.003%).
- ILR = 14,000 ppm (1.4%). Once the process is complete, this small volume (5.2 m^3) is transferred and diluted in the much larger Leach/CIL circuit (9,100 m^3) for consumption.
- Barren Eluate Tank #12 = 1,000 ppm (0.1%). Once the process is complete, the remaining cyanide stays in the tank to be re-used during the next batch. Each new batch, the cyanide is just topped up to the target concentration.

6.18.7.6.1 Cyanide Detoxification

Cyanide detoxification occurs within the cyanide destruction circuit. Slurry passing through the carbon safety screen gravitates to two 300 m^3 cyanide detoxification tanks which are designed on the conventional air-SO_2 process and can operate in series or parallel for operational flexibility. The average slurry residence time at 250 t/h is 1.5 hours.

The tanks utilize high shear agitators and air injection to enhance high oxygen dissolution in the slurry to meet the high oxygen demand of the cyanide destruction process. Sodium metabisulphite and copper sulphate solutions are dosed into either tank providing the oxidizing agent and catalyst respectively for the cyanide destruction. Acid generation is neutralized by the addition of lime slurry to the detox tanks via a ring main.

The detoxified slurry stream gravitates to the tailings hopper from where it is pumped through a single pipeline to the TMF by variable speed tailings pumps (1 duty/1 standby). The tailings slurry is then discharged at selected outlet points around the periphery of the facility. Pipe runs are designed to be self- draining to avoid dead legs.

Contingency measures for cyanide detoxification include primary linear and secondary rotary vezin tailings samplers taking representative tailings samples after the slurry has been detoxified and prior to entering the tailings hopper. The cyanide destruction and tailings hopper area has a dedicated bunded concrete area for collecting spillage. A local sump pump returns any spillage to the carbon safety screen. The area is enclosed for cold weather protection. A CNWAD analyzer automatically monitors slurry levels and a HCN detector provides monitoring for airborne gas.

Shutdown procedures are in place in the event of process upsets including cyanide detoxification.

6.18.7.6.2 Threshold for Determination of Significance

The criteria that would determine a significant effect should an unplanned cyanide release occur is based primarily on worker health and safety and environmental impact. Should an unplanned cyanide release result in injury or death to a worker or contamination of the receiving environment the event will be considered significant.

6.18.7.6.3 Potential Interactions and Effects

The potential interactions between an unplanned cyanide release and VCs are outlined in Section 5.8, Tables 5.8-1 to 5.8-3. Additional detail by VC is outlined in Table 6.18-11. Only those interactions with a high potential to cause adverse effects should they occur are discussed in detail further.

Table 6.18-11: Unplanned Cyanide Event Interaction with Valued Components

Valued Component	Potential Unplanned Cyanide Event and Valued Component Interaction	Potential for Adverse Effects
Noise	No potential interaction anticipated	-
Air	An unplanned cyanide release event could potentially cause short term toxic effects within the localized area	Low
Light	No potential interaction anticipated	-
Greenhouse Gases	No potential interaction anticipated	-
Geology, Soil, and Sediment Quality	No potential interaction anticipated	Low
Surface Water Quality and Quantity	An unplanned cyanide release event could potentially cause toxic effects within the localized area	Moderate
Groundwater Quality and Quantity	An unplanned cyanide release event could potentially affect groundwater within the localized area	Low
Wetlands	No potential interaction anticipated	-
Fish and Fish Habitat	An unplanned cyanide release event could potentially cause toxic effects within the localized area	Moderate
Habitat and Flora	An unplanned cyanide release event could potentially cause toxic effects within the localized area	Low
Avifauna	An unplanned cyanide release event could potentially cause toxic effects within the localized area	Low
Terrestrial Fauna	An unplanned cyanide release event could potentially cause toxic effects within the localized area	Low
Species of Conservation Interest and Species at Risk	An unplanned cyanide release event could potentially cause toxic effects within the localized area	Low
Mi'kmaq of Nova Scotia	An unplanned cyanide release event could potentially affect land use in short or long term	Low
Physical and Cultural Heritage	No potential interaction anticipated	-
Socio-economic Conditions	An unplanned cyanide release event could potentially cause effects to safety and land use	Moderate

Note: - = not applicable.

6.18.7.6.4 Mitigation and Emergency Response

Cyanide handling and use is highly regulated and subject to strict practices and procedures. Cyanide as delivered in dry briquette form is relatively safe from spills and easy to clean up in the event of a transportation or handling incident. Cyanide in solution is restricted to use within the processing facility with an abundance of design and process controls, as well as occupational health and safety practices, to prevent release of cyanide solution or gas within and without the building structure. Cyanide solution is detoxified by a proven and efficient process and tested by an automated in-line sampler prior leaving the processing facility, making the release of a high concentration (i.e., non-detoxified) cyanide solution outside the confines of the process facility a highly unlikely event.

If cyanide exposure were to occur, emergency procedures would be implemented that will be outlined in the site emergency response plan. Generally, cyanide exposure response includes raising the alarm, contacting Emergency Services, evacuation of all personnel from the area to fresh air, removal of contaminated clothing, washing of cyanide residue from affecter personnel, administering oxygen, and securing the area. A plan to determine what repairs are needed and actions to prevent future incidents will be detailed in a recovery plan. Depending on the regulator involvement there may be a requirement to file incident reports with certain regulatory agencies prior to initiating the clean-up and return to work in the area, these are very case specific and often dependent on whether personnel were injured as a result of the cyanide exposure.

6.18.8 Other Malfunctions

6.18.8.1 Forest and/or Site Fires

All phases of the Project will have the potential for forest and/or site fires to occur. A worst-case scenario is an extreme fire that results in worker injury or death or that causes significant damage to the environment. A forest fire may occur through human or natural causes, while a site fire may occur due to an equipment failure and/or human error. Forest fires have the potential to affect the Project at the Beaver Dam Mine Site and at the Touquoy Mine Site; however, due to a lack of vegetation at the Beaver Dam Mine Site and Touquoy Mine Site, it is unlikely that a site fire could spread to and affect the surrounding forest. Forest fires along the Haul Road have the potential to affect Haul Road operations and likewise, site fires along the Haul Road could spread to and affect the surrounding forest.

6.18.8.1.1 Threshold for Determination of Significance

The criteria that would determine a significant effect should a forest and/or site fire occur is based primarily on worker health and safety and secondarily on property damage and environmental protection.

Should a forest and/or site fire result in injury or death to a worker or a loss of infrastructure or mobile equipment the event will be considered significant.

Should a forest and/or site fire result in the loss of any quantity of fuel, oil, lubricant, or other Project related raw materials to the environment such that a measurable contamination of soil, surface water, or groundwater results, the event will be considered significant.

Contamination is defined as the following:

- Soil:
  - concentrations of any contaminant exceed the guidelines provided in the Nova Scotia Contaminated Sites Regulations - Tier 1 Environmental Quality Standards for Soil at a Non- potable Site, Section 1, Table 1B.
- Surface Water:
  - concentrations of any contaminant exceed the guidelines provided in the Nova Scotia Contaminated Sites Regulations - Tier 1 Environmental Quality Standards for the Protection of Freshwater Aquatic Life in Surface Water, Section 1, Table 3.
- Groundwater:
  - concentrations of any contaminant exceed the guidelines provided in the Nova Scotia Contaminated Sites Regulations - Tier 1 Environmental Quality Standards for Groundwater at a Non-potable Site, Section 1, Table 4.

Potential Interactions and Effects

The potential interactions between a forest and/or site fire and VCs are outlined in Section 5.8, Table 5.8-1 to 5.8-3. Additional detail by VC is outlined in Table 6.18.12. Only those interactions with a high potential to cause adverse effects should they occur are discussed further.

Table 6.18-12: Forest and/or Site Fire Interactions with Valued Components

Valued Component	Potential Forest and/or Site Fire and Valued Component Interaction	Potential for Adverse Effects
Noise	No potential interaction anticipated	-
Air	A forest and/or site fire could potentially release particulate matter, carbon monoxide, Sulphur dioxide, nitrous oxides, and volatile organic compounds to the atmosphere	Low
Light	No potential interaction anticipated	-
Greenhouse Gases	A forest and/or site fire could potentially release particulate matter, carbon monoxide, Sulphur dioxide, nitrous oxides, and volatile organic compounds to the atmosphere	Low
Geology, Soil, and Sediment Quality	No potential interaction anticipated	Low
Surface Water Quality and Quantity	A forest and/or site fire could potentially cause surface water runoff to erode and entrain suspended solids for deposition into water courses A forest and/or site fire could potentially reduce surface water quantity through extraction to extinguish the fire	Low
Groundwater Quality and Quantity	No potential interaction anticipated	-
Wetlands	A forest and/or site fire could potentially cause wetland destruction through burning of vegetation	Low
Fish and Fish Habitat	A forest and/or site fire could potentially cause surface water quality and quantity issues that may indirectly effect fish and fish habitat	Low
Habitat and Flora	A forest and/or site fire could potentially cause destruction of habitat and flora	High
Avifauna	A forest and/or site fire could potentially cause destruction of bird habitat and/or direct mortality	High
Terrestrial Fauna	A forest and/or site fire could potentially cause destruction of fauna habitat and/or direct mortality	High
Species of Conservation Interest and Species at Risk	A forest and/or site fire could potentially cause destruction of species of conservation interest and species at risk	High
Mi'kmaq of Nova Scotia	A forest and/or site fire could potentially cause effects to the current use or land and resources for traditional purposes by Indigenous Peoples	Low
Physical and Cultural Heritage	No potential interaction anticipated	-
Socio-economic Conditions	A forest and/or site fire could potentially result in injury or death of mine workers	High

Note: - = not applicable.

The topographic profile of the region allows for precipitation to be retained in soil and numerous watercourses and wetlands to form. As a result, large forest and/or site fires are unlikely to occur. In the unlikely event a forest and/or site fire occurs, the following adverse effects to VCs are considered low:

- emissions produced from a forest and/or site fire would be temporary; however, may adversely affect ambient air quality in the area;
- surface water run-off created from extinguishing the fire may transport sediment and potential contaminants towards watercourses along the Haul Road; thereby affecting surface water quality;
- surface water quantity in watercourses near the Beaver Dam Mine Site may be slightly affected through extraction and use of surface water for extinguishing the fire; however, these watercourses will only be utilized to aid in extinguishing small localized fires;
- effects to wetlands and fish and fish habitat are expected to be minimal due to the presence of water and saturated soils and flora; and
- unless a forest and/site fire extends to the Beaver Lake IR 17, it is unlikely that Indigenous Peoples will be adversely affected by forest and/or site fires.

As a result, potentially adverse effects to the atmospheric environment, surface water quality and quantity, wetlands, fish and fish habitat, and Indigenous Peoples are considered low.

The greatest potential for a forest and/or site fire to occur as a result of the Project is during the site preparation and construction, and operation and maintenance phases when the greatest amount of physical activity is occurring at the at the Beaver Dam Mine Site and along the Haul Road. The primary risk for the environment is associated with physical habitat destruction and death of terrestrial species.

A forest and/or site fire caused by the Project has the potential to modify terrestrial habitat and cause direct mortality to wildlife populations, especially during the breeding season when the mobility of immature individuals is limited. The destruction of habitat may result in the loss of breeding, nesting, rearing, and/or other habitat for birds, fauna, and SOCI/SAR. Habitat fragmentation created by a fire may cause potential adverse effects for species that migrate throughout a landscape based on resources that are seasonally available.

Although a forest and/or site fire caused by the Project is likely to be extinguished before it creates a significant effect to the local area, it is unlikely that terrestrial habitat loss or direct individual mortality would create population viability issues if an uncontrollable fire was allowed to burn. It is likely that mobile terrestrial species will move to adjacent areas and any habitat loss would lead to regrowth within a few generations. In addition, habitat types in the area of the Project are not unique and would be easily supplanted with minor migration efforts by terrestrial species.

A forest and/or site fire created by the Project would likely result from a structural failure or accident identified in Sections 6.18.4 and 6.18.5 of this EIS. Should the mitigation measures for these structural failures or accidents be implemented, it is extremely unlikely that a forest and/or site fire created by the Project would occur.

6.18.8.1.2 Mitigation and Emergency Response

Fire protection for the plant site will be via a "wet system" with hydrants located around the plant site area. The water contained within the lower portion of the raw water tank will be reserved for fire protection. Fire detection systems will be installed in all buildings and in key areas of the Mine Site.

In each area, a combination of heat and smoke detectors will be provided with break-glass units mounted externally to the buildings. The large primary mining fleet including excavators, front end loader, haul truck, dozers and drills will be fitted with fire suppression systems in case of fire.

The water truck will be fitted with a pump and 2.5-inch hydrant hose reel for firefighting. Supplementary hand-held fire extinguishers, each suitable for its specific area, will be mounted in all buildings and vehicles. The site will have fire-fighting and fire-suppression capabilities that will be supplemented by support from the local community.

Fire response training and fire extinguisher training will be provided to all staff. An emergency response plan will be developed for the site, which will include fire response.

The site will be staffed to varying levels 24 hours a day with personnel in all areas of the Beaver Dam Mine Site. Fires, if they occur, would be quickly detected and emergency procedures able to be acted on. The availability of water, equipment and nearby personnel from volunteer fire departments and NSL&F staff with expertise in forest fire control are all benefits to the Project and greatly reduce the possibility of fires that would not be able to be quickly controlled, and damage limited.

If a forest fire were to occur, emergency procedures would be implemented that will be outlined in the site emergency response plan. Generally, forest fire response includes raising the alarm and evacuation of all personnel from the area. If required, Emergency Services will be contacted.

6.18.9 Risk Assessment

Each potential accident and malfunction identified in the previous sections was assessed considering the likelihood of occurrence and the level magnitude should these accidents and malfunctions occur.

The likelihood of occurrence is given a score of 1 to 5 with an associated rating as defined below:

1. **Negligible:**

- Accident or malfunction not likely to occur with a less than 1 in 10,000 probability of occurrence per year.

2. **Low:**

- Accident or malfunction unlikely to occur with a less than 1 in 1,000 probability of occurrence per year.

3. **Moderate:**

- Accident or malfunction has potential to occur with a less than 1 in 100 probability of occurrence per year.

4. **High:**

- Accident or malfunction may occur with a less than 1 in 10 probability of occurrence per year.

5. **Extreme:**

- Accident or malfunction is likely to occur with a greater than 1 in 10 probability of occurrence per year.

The level of magnitude should these accidents and malfunctions occur is also given a score of 1 to 5 with an associated rating as defined below:

1. **Negligible:**

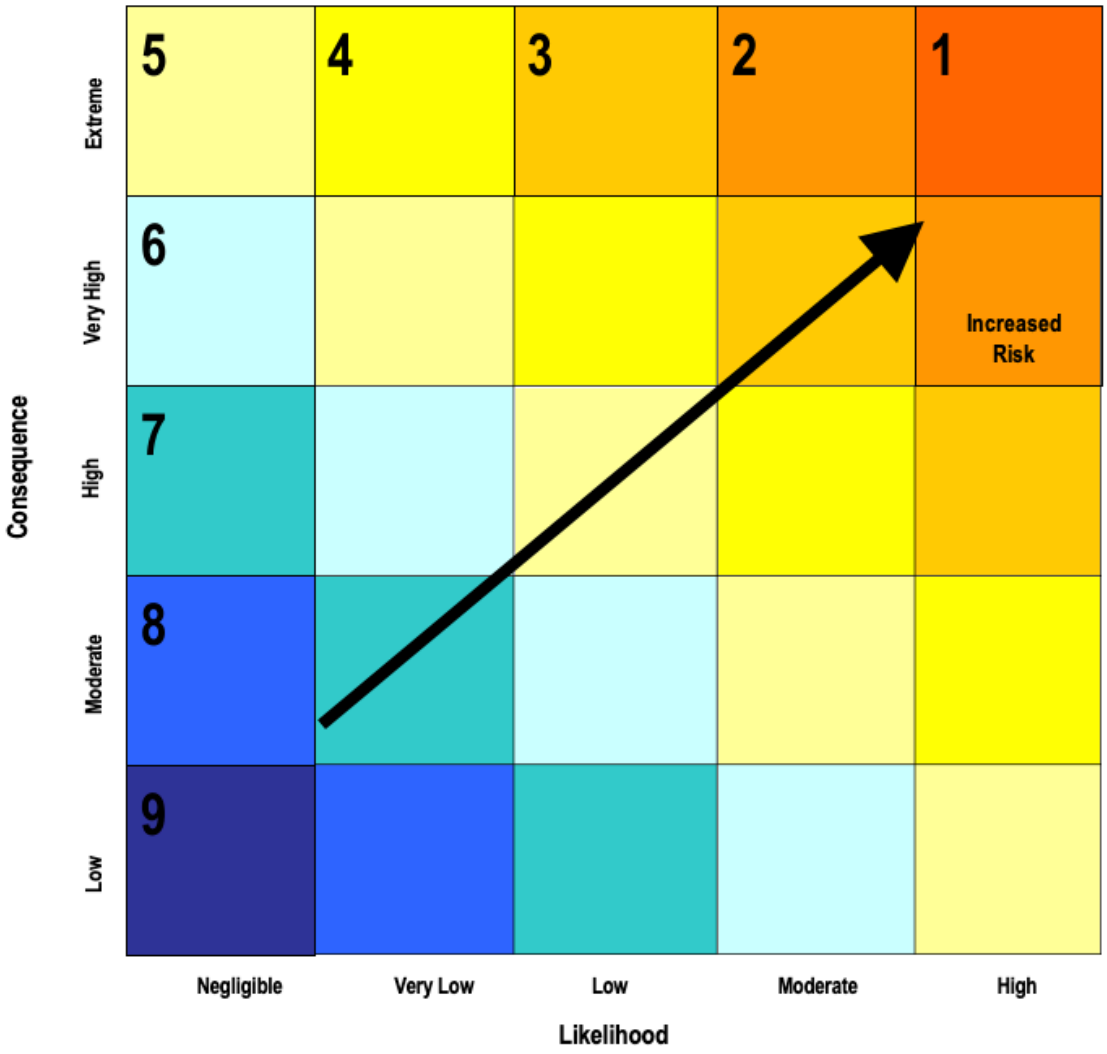
- preventative requirements are minimal,
- no long-term effects are expected, and
- readily remediated with funds in the $0 to $10,000 range.

2. **Low:**

- preventative requirements are minimal,
- limited long-term effects are expected, and
- limited remediation required with funds in the $10,000 to $100,000 range.

3. **Moderate:**

- preventative requirements are moderate,
- moderate long-term effects are expected, and
- moderate remediation required with funds in the $100,000 to $1,000,000 range.



4. **High:**

- preventative requirements are high,
- significant long-term effects are expected, and
- significant remediation required with funds in the $1,000,000 to $10,000,000 range.

5. **Extreme:**

- Preventative requirements are very high,
- permanent effects are expected, and
- highly significant remediation required with funds in the $10,000,000 plus range.

Figure 6.18-1: Risk Ranking Matrix

Each credible potential accident and malfunction discussed was assessed according to likelihood of occurrence and magnitude / consequence of occurrence, and given a risk ranking of between 1 (highest) and 9 (lowest). Each risk ranking refers to a diagonal row of cells within a risk matrix shown in the same colour (Table 6.18-13). As shown in the risk matrix, increased risk is associated with malfunctions and accidents having a greater likelihood of occurrence and increased level of consequence, as is intuitively true. The breakdown of ratings each accident and malfunction, as well as summarizes the key VCs that would likely be affected is provided in Table 6.18-13.

Table 6.18-13: Accident and Malfunction Characterization Criteria for Risk Rating Matrix

Accident / Malfunction	Concerns	Key Valued Components Potentially Affected	Likelihood	Consequence	Risk Ranking
Slope Failures	Ground surface slump of the surrounding area affecting the site's infrastructure, Haul Roads and onsite access roads and worker safety	Socio-economic Conditions	Low	Moderate	6
Open Pit Slope Failure	Affects to habitat and limited flooding of open pit	Socio-economic Conditions Physical and Cultural Heritage	Low	Moderate	6
Waste Rock Stockpile Slope Failure	Affects to Terrestrial habitat and aquatic life	Surface Water Quality and Quantity Wetlands Fish and Fish Habitat Species of Conservation Interest/Species at Risk	Very Low	High	6
Till/Organic Stockpile Slope Failure	Affects to terrestrial habitat and aquatic life	Surface Water Quality and Quantity Wetlands Fish and Fish Habitat Species of Conservation Interest/Species at Risk	Very Low	Moderate	7
Settling Pond Failure	Affects to aquatic life	Surface Water Quality and Quantity Wetlands Fish and Fish Habitat Species of Conservation Interest/Species at Risk	Negligible	Moderate	7

Table 6.18-13: Characterization Criteria for Risk Rating Matrix (continued)

Accident / Malfunction	Concerns	Key Valued Components Potentially Affected	Likelihood	Consequence	Risk Ranking
Infrastructure Failures	Failure of multiple operational components as a result of a natural cause impacting worker health and safety and surrounding environment	Socio-economic Conditions Surface Water Quality and Quantity Wetlands Fish and Fish Habitat Species of Conservation Interest/Species at Risk	Negligible	Moderate	7
Explosives Accident	Human environment	Socio-economic Conditions Fish and Fish Habitat	Negligible	Low	9
Fuel Release during Truck Transport	Affects to aquatic life and downstream human environment	Socio-economic Conditions Surface Water Quality and Quantity Wetlands Fish and Fish Habitat Species of Conservation Interest/Species at Risk	Very Low	High	6

Table 6.18-13: Characterization Criteria for Risk Rating Matrix (continued)

Accident / Malfunction	Concerns	Key Valued Components Potentially Affected	Likelihood	Consequence	Risk Ranking
Fuel Release from Storage Facilities and Dispensing Area	Affects to habitat	Socio-economic Conditions Surface Water Quality and Quantity Wetlands Fish and Fish Habitat Species of Conservation Interest/Species at Risk	Low	Low	7
Transportation Accident – Hazardous Materials (excluding fuel)	Affects to habitat, aquatic life and downstream human environment	Socio-economic Conditions Human Environment Surface Water Quality and Quantity Wetlands Fish and Fish Habitat Species of Conservation Interest/Species at Risk	Very Low	High	6
Transportation Accident – Non-hazardous Materials	Affects to local terrestrial environment	Socio-economic Conditions Habitat and Fauna Wetlands Species of Conservation Interest/Species at Risk	Low	Low	7

Table 6.18-13: Characterization Criteria for Risk Rating Matrix (continued)

Accident / Malfunction	Concerns	Key Valued Components Potentially Affected	Likelihood	Consequence	Risk Ranking
Mobile Equipment Accident	Severe accident-causing injury or death, property damage and environmental impacts	Surface Water Quality and Quantity Wetlands Fish and Fish Habitat Species of Conservation Interest/Species at Risk Socio-economic Conditions	Very Low	High	6
Tailings/Reclaim Water Pipeline Spill	Uncontrolled discharge of tailings and/or contaminated water into the surrounding environment	Surface Water Quality and Quantity Fish and Fish Habitat	Negligible	Moderate to Very High	6 to 8
Cyanide Release	Uncontrolled release of cyanide into the workplace and/or surrounding environment resulting in worker injury or death and/or causing significant damage to the environment		Negligible	Moderate to Very High	6 to 8
Project-related Fires	Affects Human environment, local terrestrial habitat loss	Habitat and Flora Avifauna Terrestrial Fauna Species of Conservation Interest/Species at Risk Socio-economic Conditions	Negligible	Moderate to Very High	6 to 8

6.18.10 Discussion

Potential accidents and malfunctions assigned a risk rating of 1 to 5 are considered low risk, those assigned a risk rating of 6 to 15 are considered moderate risk, and those assigned a risk rating of 16 to 25 are considered high risk. If an accident or malfunction is assigned a risk rating of 16 or higher, it is considered significant and requires further consideration during the Project's detailed design phase. The results of this qualitative analysis indicate that a mobile equipment accident and fuel and/or other spill are considered the most risky; however, all identified accidents and malfunctions have a low or moderate risk rating and are therefore considered not significant.

7 EFFECTS OF THE ENVIRONMENT ON THE BEAVER DAM MINE PROJECT

7.1 Introduction

7.1.1 Summary of Effects of the Environment on the Beaver Dam Mine Project Before the Updates

Section 7 described the effects of the environment on the Project that includes how local conditions, natural hazards, climate change and external events could affect the Project.

The Beaver Dam Mine Site infrastructure are designed to accommodate the conditions imposed by the natural environment and to accommodate the effects of external events on the Project, as much as possible. Climate change is not anticipated to have a significant effect on the Project, based on the relatively short duration of the Project.

There are no significant adverse environmental effects anticipated due to the changing environmental conditions. Potential effects of the environment on the Project will be reduced as much as practicable through proper design and planning and mitigation measures. Extreme weather events cannot be predicted, but through proper design and planning the majority of the effects of these events on the Project may be minimized.

7.1.2 Summary of Updates to Effects of the Environment on the Beaver Dam Mine Project

The effects of the environment on the Project has been updated to reflect updates of the Project Description (Section 2) and to address Round 2, Information Requests (IR2) issued by the Impact Assessment Agency of Canada (IAAC, formerly the Canadian Environmental Assessment Agency [CEAA 2019]) and Nova Scotia Environment (NSE 2019). This includes:

- Update of the data set that was used for the precipitation and temperature profiles at Middle Musquodoboit Station
- Updated the climate data set to include lake evaporation climate normals (1981–2010) which were taken from the Truro climate station
- Effects of the environment, specifically climate change, was considered in the design of settling ponds and ditches that were designed as a result of the update of the Project Description

The changing environment is not an assessment endpoint in themselves but rather an assessment of how these conditions have been considered in project design, predictive modelling, mitigation, monitoring and management plans.

An outline of updates to the effects of the environment on the Beaver Dam Mine Project are summarized in Table 7.1-1.

Table 7.1-1: Updated Subsections from the 2019 Revised Environmental Impact Statement – Effects of the Environment on the Beaver Dam Mine Project

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
-	-	7.1 Introduction	• New
7.1 Environmental Considerations	No	7.2 Environmental Considerations	• N/A
7.1.1 Climate	Yes	7.2.1 Climate	• Updated to reflect changes in data set. Lake evaporation climate normal data (1981 – 2010) was used in the assessment which was taken from the Truro climate station (ID#8205990). • Temperature and Precipitation subsections and tables updated to reflect changes in data set.
7.1.2 Extreme Weather	Yes	7.2.2 Extreme Weather	• Flood and Drought Conditions and Extreme Temperatures, Storms, and Wind subsections updated to reflect changes in data set.
7.1.3 Climate Change	Yes	7.2.3 Climate Change	• Regional Future Projections subsection Updated to reflect changes in data set. • Climate Change Mitigation and Adaptation subsection updated to reflect contingency to water management facility and collection ponds designs.
7.1.4 Slope Stability	Yes	7.2.4 Slope Stability	• Updated to reflect information from the geotechnical stability of permanent and temporary stockpiles undertaken by Golder (Appendix A.2a).
7.1.5 Seismic Events	Yes	7.2.5 Seismic Events	• Updated to reflect information from the geotechnical stability of permanent and temporary stockpiles undertaken by Golder (Appendix A.2a).
7.2 Mitigations	No	7.3 Mitigation	• Updated to include monitoring to be conducted during construction, operations, and active closure of engineered structures.
7.3 Residual Effects	Yes	Section removed	• N/A
-	-	7.4 Summary	• New

7.2 Environmental Considerations

The changing environment is not an assessment endpoint in themselves but rather an assessment of how these conditions have been considered in project design, predictive modelling, mitigation, monitoring and management plans.

Environmental conditions include, natural hazards, climate change and external events could affect the Project. Additionally, the accidents or malfunctions (Section 6.18) considers these conditions when developing mitigation measures and contingencies in the event of upset conditions.

The natural environment has the ability to potentially adversely impact the Project through events which may include the following:

- flooding;
- drought;
- extreme temperatures;
- severe weather events, including snow, ice, rain, and windstorms;
- lightning strikes;
- landslides, erosion, or subsidence;
- fire; and
- seismic events.

The Beaver Dam Mine Site infrastructure will be designed to accommodate the conditions imposed by the natural environment and to accommodate the effects of external events on the Project, as much as possible.

7.2.1 Climate

Climate refers to average long-term (typically minimum 30-year record) weather patterns within a particular area (NASA, 2005). Average weather patterns that define a climate include measures of temperature, humidity, precipitation, evaporation and wind velocity. Phenomena such as frost, fog and hail storms are also considered when defining the climate of an area (NASA, 2005).

As stated in Section 6.2.4 (Air – Baseline Conditions), the nearest climate station with historical data is the Middle Musquodoboit climate station (ID# 8203535) operated by the Co-operative Climate Network (CCN). The station is located approximately 15 km northwest of the Mine Site, near Middle Musquodoboit (45° 04'N, 63° 06'N). The following is a summary of average climate conditions at the Middle Musquodoboit station, based daily rainfall, snowfall and mean temperature data published by Environment and Climate Change Canada for the 41 year period of record including 1968 to 2005, 2009, 2014 and 2016. Wind data is taken from the Halifax Airport climate station (MSC ID# 202250), which is located approximately 45 km west of the Mine Site. This is the closest station to the site for which wind data exists. Lake evaporation climate normals (1981–2010) are taken from the Truro climate station (ID# 8205990), the closest climate station to the site which collects lake evaporation data.

7.2.1.1 Temperature

Temperature data for the Middle Musquodoboit Station is provided in Table 7.2-1. The annual mean temperature is estimated as 6.4ºC. The mean summer high temperature is 18.5ºC for July, while the winter mean low temperature is -6.2ºC in January. The lowest extreme minimum temperature was -34.0ºC January 1993 and December 1989, and the highest extreme maximum was in August of 1976 at 35.6ºC (Table 7.2-2) There is an average of 312 days per year with an average temperature above 0ºC.

7.2.1.2 Precipitation

The mean climate normal monthly precipitation data are provided in Table 7.2-3. The mean annual average precipitation is 1,356 mm. Approximately 87.5% of the total precipitation was in the form of rain and 12.5% as snowfall. The extreme daily precipitation amounts are shown in Table 7.2-4. The highest rainfall experienced was 172.2 mm in 1971 and the highest snowfall experienced was 70.0 cm in 1981. The highest precipitation generally occurs in the months of November and December, with lowest precipitation in the month of June. Measurable precipitation occurs on an average of 164 days per year, with 141 days of

measurable rainfall and 31 days of measurable snowfall. Hurricanes are also possible in this region. The largest hurricane on record, recorded at Halifax International Airport (approximately 80 kilometres [km] west of the Site), was Hurricane Beth in 1971 with 296.4 mm of rainfall over 48 hours.

7.2.1.3 Wind

Wind direction is generally westerly to northerly in November through April and southerly in May through October. Wind speeds average approximately 16.5 km/h, with an average range of 13.3 km/h in August to 18.5 km/h in March.

7.2.2 Extreme Weather

7.2.2.1 Flood and Drought Conditions

Flooding or drought conditions may occur during the lifespan of the Project. These events can generally be accommodated in the Project design and construction. As stated above, the historical mean annual total precipitation for the Middle Musquodoboit climate station is 1,356 mm. Approximately 87.5% (1,186 mm) falls as rain, while 12.5% (170 cm) falls as snow. Although extreme precipitation events may occur at any time during the year, rainfall in the Project area is generally highest during autumn months (September to November). The largest historical extreme one- day precipitation events recorded at the Middle Musquodoboit station includes 173 mm of rainfall on August 15, 1971 and 70 cm of snowfall on February 8, 1981 (Table 7.2-4).

The effects of a drought or flood on the Project may include increased dust and decreased availability of water for site operations or an excess of water on the Mine Site and Haul Road. Potable groundwater will be brought to the site and therefore a reduction in the availability of potable groundwater is not anticipated to be an adverse effect. Minimal volumes of water from the settling ponds are anticipated to be re-used on Site for dust suppression purposes, as required. The majority of water collected in the settling pond will be released to Cameron Flowage. A reduction in water being collected by the settling ponds will result in less water being released to Cameron Flowage and is not anticipated to affect site operations. Should a storm event larger than 1 in 100-year precipitation occur that creates volumes in excess of the capacity available in ponds and ditching, or infrastructure failure, a spillway into the pit will be used for overflow. In the case of a storm event or infrastructure failure, settling ponds will be monitored regularly. The Haul Roads could also become flooded and the transportation of ore may temporarily be suspended.

7.2.2.2 Extreme Temperatures, Storms, and Wind

Air temperatures vary seasonally. As stated above, average local temperatures range between from -6.2ºC to 18.5ºC. Temperature extremes can range between -34ºC to 35.6ºC (Table 7.2-2). The Project will be designed to accommodate these temperature ranges.

Extreme temperatures and storms (ice, snow) could cause damage to site infrastructure or could directly impact site workers. An Occupational Health and Safety Plan will be implemented to ensure worker safety during extreme temperature events and storm events.

Maximum hourly speeds can range from 56 km/h in August to 89 km/h in February, with maximum gusts of up to 132 km/h recorded. The Project will be designed to accommodate these wind speed ranges.

7.2.2.3 Lighting Strikes

Thunderstorms are not overly common in the Project area. In Nova Scotia, cloud to ground lightning typically occurs between the months of March to November (ECCC 2016e). The average number of days with lightning (years 1999 to 2013) was 12.1 days in Halifax, and 12.6 days in Truro.

In the event of a lightning strike, damage to site infrastructure or injury to site workers could occur. A power surge or outage could also occur. Designing infrastructure with proper grounding circuits, as per standard practice, would help to prevent damage or injury.

7.2.3 Climate Change

Climate change is anticipated to cause an increase in frequency and intensity of extreme weather events, warmer average temperatures, higher sea levels, and more extreme rainfall and flooding events (DeRomilly and DeRomilly Limited et al. 2005). More frequent and intense extreme weather events could cause an increased risk of flooding and snow and ice storms. Increased flood events would also increase the risk of erosion. Existing infrastructure in Canada was generally not intended to withstand the more extreme and frequent storms that may be experienced in coming years; however, new construction, such as the construction of the Project is designed for these changing weather patterns and extreme events into consideration. In particular, Nova Scotia Environment's *Guide to Considering Climate Change in Environmental Assessments in Nova Scotia* states the importance of environmental assessments as planning tools for the consideration of climate change into project planning, development, operation and decommission (NSE, 2011c).

Over the last several decades, Nova Scotia has already experienced a significant number of adverse impacts of extreme weather events and is experiencing changes in its historical climate. It is very likely that a further increase in temperature, precipitation and other climate drivers will continue to occur throughout the 21st century. It is forecasted that temperature will rise by 2ºC to 4ºC and that storm surges that happened only once in the 20th century could happen up to ten times in the 21st century (NSE, 2009a).

To prepare for adaption to climate change, the NSE Climate Change Unit has published scenarios of possible future climate for 13 regions within Nova Scotia. For each region, historical climate data (1961-1990) and future projections generated using the statistical downscaling method are available. Climate data provided in future projections includes minimum and maximum temperatures, precipitation, extreme precipitation and growing season length. Although advancements in climate modelling projections have occurred over the last decade, the results are not meant to be interpreted as absolutes, but rather used as guidance in the design and planning stages to facilitate climate change adaptation (W. Richards Climate Consulting, 2011).

7.2.3.1 Regional Future Projections

The closest of the 13 regions to the Project is the HRM. Future projections are provided for 2020s, 2050s and 2080s. Since the duration for the Project is relatively short, approximately 8 years including active reclamation but excluding passive pit-refilling and ongoing monitoring) the future climate projections for the 2020s were used for the assessment of the effects of climate change on the Project.

While a significant change in the range of average monthly temperatures is not anticipated for the HRM, it is very likely average temperatures will increase by a maximum of approximately 1.5ºC on average across all seasons in the 2020s (W. Richards Climate Consulting, 2011). Approximately 2 days a year are projected to be over 30ºC with no days reaching a temperature higher than 35ºC. Approximately 243 days a year are projected to have daily mean temperature is greater than 0ºC and two days a year are projected to be less than -10ºC compared to the historical average of 224 days and 3 days respectively (W. Richards Climate Consulting, 2011). The average growing season length in the 2020s is projected to be approximately 209 days, which is 11 days longer than the average historical growing season (W. Richards Climate Consulting, 2011).

Annual precipitation amounts are projected to be 1,453 mm a year, which is a 97 mm increase from the historical average (W. Richards Climate Consulting, 2011). Warmer winter temperatures (14 more days with a daily mean temperature is greater than 0°C) will lead to more precipitation falling as rain instead of snow. Rainstorm events are projected to be more extreme with a 5 percent change in the current 20-year return value of the 24-hour precipitation rate used in building design (W. Richards Climate Consulting, 2011).

7.2.3.2 Effects of Climate Change on the Project

Key potential effects of climate change that could impact the Project include:

- Increasing frequency of unusually high or low daily temperature extremes.
- Long-term increasing or decreasing mean annual temperatures and/or precipitation.
- Increasing or decreasing frequency of storm events (e.g., rainfall, snowfall, extreme wind).

Although the Project is relatively short in duration (approximately 8 years including construction, operations and active closure and not including ongoing monitoring [post-closure]) and therefore the effects of climate change on the Project will likely be insignificant, climate change was still considered for each phase of the Project: construction, operations, and active closure.

7.2.3.2.1 Construction – 1 Year

Since site construction will occur during the first year of the Project and is planned to commence within the near future, rather than considering long term effects of climate change it is more appropriate to consider the potential effects of current weather extremes and variabilities during construction. For the effects of extreme weather events on the Project (Section 7.2.2).

7.2.3.2.2 Operations – 5 Years

Average temperatures and precipitation amounts and intensities projected in the future climate scenario for the 2020s as described above is unlikely to impact the operation of the Beaver Dam Mine as mines are successful operated in areas with higher/lower mean and extreme temperatures and more frequent precipitation than is outlined in this scenario. However, the Project may be affected by climate change-induced events, such as extreme precipitation events. The Project will be designed to withstand these events, including effects of these events such as flooding and erosion. For details of the effects of extreme weather events on the Project (Section 7.2.2).

7.2.3.2.3 Active Closure – 2 Years

The Active Closure of the mine is not anticipated to be affected by higher or lower mean and extreme temperatures or more frequent precipitation. However, the removal of equipment and infrastructure has the potential to be delayed as a result of periods of high precipitation and extreme weather events. The re-vegetated area could be affected from periods of drought, flooding or erosion.

7.2.3.3 Forest Fires

Since the limited duration of the Project on a whole indicates that warming air temperatures will not affect the Project, and as the Beaver Dam Mine Site will be primarily cleared land, the potential for forest fires is considered to be low.

7.2.3.4 Climate Change Mitigation and Adaptation

7.2.3.4.1 Mitigation

To minimize or offset the effects of the Project on climate change, in particular to reduce the greenhouse gas (GHG) emissions associated with the construction, operation and active reclamation of the mine, mitigation measures will be implemented. The federal guidance document *Incorporating Climate Change Considerations in Environmental Assessment: General Guidance for*

Practitioners defines mitigation measures as "Measures to eliminate, reduce or control the adverse environmental effects of a project, including restitution for any damage to the environment caused by such effects through replacement, restoration, compensation or any other means" (CCCEAC, 2003, Page 23). Mitigation measures include actions such as utilizing different technologies and construction materials. Impact Management Measures and BMPs to reduce the Project's effect on the environment will be determined and implemented at the onset of each stage of the Project. Possible BMP/ Mitigation measures include:

- Implement and enforce an anti-idling policy for all vehicles and machinery on-site during the construction and operations;
- Try to utilize materials that have a lower carbon footprint and a long lifespan; and,
- Replace and plant additional native vegetation to create a carbon sink.

Further mitigation measures to reduce the potential effects of the environment on the Project are discussed in Section 7.3.

7.2.3.4.2 Adaptation

Climate change adaptation is focused on addressing effects of climate change on the Project. The federal guide defines adaptation as an "Adjustment in natural or human systems in response to actual or expected climatic stimuli or their effects, which moderates harm or exploits beneficial opportunities" (CCCEAC, 2003, Page 23). Although it was determined that climate change will have no significant adverse effects on the Project due to the relatively short duration of the Project, the identification of possible adaptation measures was undertaken to increase both Project and ecosystem resilience to climate change.

Adaptation measures, as noted in the Mine Water Management Plan (Appendix P.4) are strengthen and increase the resilience of the Project and include:

- designing comprehensive water management measures;
- to add contingency to the water management facility designs, the impacts due to climate change were considered in the development of the settling ponds and drainage system. As such, a 5% increase to the historic IDF curve was incorporated to account for potential impacts due to climate change.
- collection ponds have been designed with the capacity to convey runoff from Hurricane Beth, modelled as a 48-hour storm event, through an emergency spillway.
- choosing vegetation known to withstand erosion and climatic stressors such as extreme heat, drought tolerance, and flood resistance; and
- planting additional vegetation as required.

The above is not a comprehensive list of the additional adaption measures that will be considered. The development of Best Management Practices will be implemented at the mine to prepared for a changing climate.

7.2.4 Slope Stability

All phases of the Project have the potential for slope failures within the footprint of the open pit, the topsoil, till, organics, and waste rock stockpiles. The slopes are designed at an angle determined by geotechnical analysis and acceptable safety factors. However, in the event of an extreme weather event or seismic event, slope failure may be possible.

Features constructed from site materials such as permanent waste rock stockpiles and temporary (i.e., till, organic and topsoil) stockpiles will stored at the mine site. The temporary stockpiles will be used as part of final reclamation. A geotechnical stability assessment of permanent and temporary stockpiles has been undertaken by Golder (2021; included as Appendix A.2a) with the exception of the topsoil stockpile because of the small size and height. The assessment undertaken by Golder (2021; included as Appendix A.2a) evaluated the design by assessing the following:

- Seismic site classification and seismic hazard parameters;
- Liquefaction potential;
- Design parameters for foundation and stockpiled materials;
- Equilibrium slope stability (static and seismic) load conditions, and
- Assessment on site preparation and placement.

Recommendations have been incorporated into the final design and operational procedural manual/work instructions will be developed before construction. The outcomes of the assessment is that the design are within an appropriate safety factor. Monitoring will be undertaken during construction, operation and active closure to ensure slope stability is maintained.

7.2.5 Seismic Events

Although seismic activity is unpredictable, the Province of Nova Scotia as a whole is located in a next-to-lowest hazard zone, with moderate to high-hazard zones located offshore in the southern Bay of Fundy and along the Laurentian Slope (NRCAN 2015).

The Northern Appalachians Seismic Zone is located in southwest Nova Scotia. The Beaver Dam Mine Project is located east of this zone. The nearest earthquake to Marinette, Nova Scotia was recorded with a magnitude of 2.7 in 1999 and was located northeast approximately 20 km north of the Project area. If an earthquake occurs, seismic activity may affect the Beaver Dam Mine Project through primary impacts such as slope and mine wall failures, and infrastructure damage facilitated by ground vibrations and secondary impacts such as fires facilitated by damaged infrastructure. In the unlikely event that a Tsunami occur in relation to offshore earthquakes, impacts to the Project are highly unlikely. The Project is approximately 30 km from the coast and at an elevation of 140 masl. Given that Nova Scotia is located in a low-hazard zone, and given the limited extent and duration of the Project, the potential risk of seismic activity affecting the Project is very low and not considered significant.

Site infrastructure will be built to National Building Code of Canada standards to aid in mitigating damage to infrastructure or injury to site workers in the event of an earthquake in the Project area.

A geotechnical stability assessment (Golder 2021; included as Appendix A.2a) has been undertaken on stockpile design that considered potential exposure to seismic event on slope stability. The assess indicated that the design is with in professional safety standards (Appendix A.2c). A similar stability assessment is in Progress for the open pit and recommendations will be integrated into the final design.

7.3 Mitigation

The Beaver Dam Mine Site will be designed to use commonly utilized infrastructure which will be designed to consider extreme weather events. Climate change is not anticipated to have a significant effect on the Project, based on the relatively short duration of the Project and on the climatic scenarios and events outlined above.

The following mitigation measures will be applied to reduce the potential effects of the environment on the Project:

- Project design considers potential flood or drought conditions to minimize the impacts of these events on mine infrastructure.
- Project design accommodates temperature extremes, storms, and wind speed ranges identified for the Beaver Dam Mine Site.
- Project design will follow industry standards, including the National Building Code of Canada, to prevent damage to equipment or injury to site workers.
- Topsoil, till, and waste rock stockpiles will be designed with slopes designed at an angle determined by geotechnical analysis and acceptable safety factors. Stockpiles will be constructed using collected geological data for final design and reduce the possibility of landslides, slope erosion, and subsidence.
- An Emergency Response Plan will be implemented for the Mine Site and will consider measures that may be required during an extreme weather event to secure site infrastructure, mobile equipment, stockpiles, fuel storage, and electrical equipment.
- An Occupational Health and Safety Plan will be implemented for the Mine Site and will consider measures that may be required during an extreme weather or temperature event, flood or drought, or storm event.
- Ongoing monitoring will be undertaken during construction, operations and active closure of engineered structures.

Table 7.3-1: Mitigation for Effects of the Environment on the Beaver Dam Mine Project

Project Phase	Mitigation Measures
C	• Project design to consider extreme weather events, temperature extremes, wind speed ranges, flood or drought conditions, lightning strikes. • Project design will follow industry standards, including the National Building Code of Canada. • An Emergency Response Plan will be implemented during the construction phase. • An Occupational Health and Safety Plan will be implemented to protect worker health and safety
C	• Stockpile design will consider collected geological data and will be designed with slopes at the angle determined by geotechnical analysis and acceptable safety factors. • An Emergency Action Plan will be implemented during the construction phase
O	• An Emergency Action Plan will be implemented during the operations phase. • An Occupational Health and Safety Plan will be implemented to protect worker health and safety
O	• Stockpile design will be re-assessed following material placement to ensure slopes are geotechnical stable and within acceptable safety factors • An Emergency Action Plan will be implemented during the operation phase
CL	• Stockpile design will consider collected geological data and will be designed with slopes at the angle determined by geotechnical analysis and acceptable safety factors.

Note: C = Construction Phase, O = Operations Phase, CL = Active Closure Phase

7.4 Summary

As noted above, consideration of environmental conditions is not a Value Component or an assessment end point. These conditions considered in the design, mitigation, monitoring and management of the Project.

8 CUMULATIVE ENVIRONMENTAL EFFECTS ASSESSMENT

8.1 Introduction

8.1.1 Summary of the Cumulative Effects before Updates

A Cumulative Effects Assessment was carried out in order to meet the general requirements of the CEAA 2012, as well as the specific requirements laid out in the Guidelines for the Preparation of *an Environmental Impact Statement pursuant to the Canadian Environmental Assessment Act, 2012 and Nova Scotia Registration Document pursuant to the Nova Scotia Environment Act – Beaver Dam Mine – Atlantic Gold Corporation*. A 35 km radius of the PA was used to identify 'other projects' with potential cumulative effects for all VCs.

Through the scoping methodology, the following VCs were selected for evaluation of cumulative effects: air, surface water quality and quantity, wetlands, fish and fish habitat, birds, species of conservation interest and species at risk, and Indigenous Peoples. Once the mitigation measures are taken into account, there are no significant residual cumulative effects anticipated for air, surface water, wetlands and fish and fish habitat.

Historical and current land use within the region has undeniably affected the local habitats in ways that have affected the local distribution and abundance of several species of flora terrestrial fauna and birds, including SOCI and SAR. However, the mitigation of the effects originating from regional forestry and land management practices falls outside the scope of the project proponent's authority and responsibility.

The predicted residual cumulative effects on Indigenous Peoples with regards to indirect effects from impacts to water quality, wetland habitats, and road safety, are assessed to be adverse, but not significant. The significant residual effects of historical and current land use within the region to the local distribution and abundance of several species of flora and fauna has presumably affected there use for traditional purposes.

8.1.2 Summary of Updates to the Cumulative Effects

The Cumulative Effects Assessment (CEA) has been revised for all Valued Components (VCs), to ensure consistency with the Cumulative Effects Assessment Methodology Interim Technical Guidance document (version 2), prepared by CEAA (2018), and in response to the second round of information requests related to the 2019 EIS Submission. This evaluation includes clearly defined determinations of Projects and spatial boundaries for each VC, which demonstrates the decision-making process for inclusion and exclusion of particular projects for each VC. The component specific criteria for significance thresholds have been revised through each VC chapter, and carried forward through the CEA, in response to CEAA-2-02. Specific to the Mi'kmaq of Nova Scotia, the spatial boundary has been updated to reflect the Eskikewa'kik territory, as requested in CEAA-2-51.

The Proponent has determined that an ecosystem-based approach to the spatial boundary determination is the most appropriate to identify cumulative effects of the Project. The spatial boundary determination is based on the VC geographic range and the zone of influence (ZOI) for that VC. The ZOI sets a spatial limit beyond which the residual effects of the Project on a VC are not detectable. Through the CEA, it has been determined that the RAA for each respective VC is the appropriate spatial boundary for this assessment, rather than a 35 km radius of the PA for all VCs.

The residual environmental effects for each VC have been updated throughout the CEA, based on the results presented in each updated VC chapter (CEAA IRs 2-05, 2-07, 2-08, 2-09, 2-10, 2-13, 2-14, 2-16, 2-17, 2-26, 2-27, 2-28 and 2-53). Furthermore, the

list of 'other projects' included in the CEA has been updated to reflect all Projects registered or proposed within the RAA for the Mi'kmaq of Nova Scotia since the 2019 EIS submission.

Through the scoping of valued components for inclusion in the CEA, it was determined that further evaluation was warranted for cumulative effects to noise, air, light, surface water quality and quantity, fish and fish habitat, species of conservation interest and species at risk, and the Mi'kmaq of Nova Scotia.

8.1.3 Summary of Approach to Cumulative Effects Assessment

Section 19(1)(a) of the *Canadian Environmental Assessment Act, 2012* (CEAA 2012) requires that an EA of a designated project take into account any cumulative environmental effects that are likely to result from the designated project in combination with the environmental effects of other physical activities that have been or will be carried out[1]

This section presents methodology of the Cumulative Effects Assessment (CEA) that was carried out to meet the general requirements of the *CEAA 2012*, as well as the specific requirements laid out in the *Guidelines for the Preparation of an Environmental Impact Statement pursuant to the Canadian Environmental Assessment Act, 2012* and *Nova Scotia Registration Document pursuant to the Nova Scotia Environment Act – Beaver Dam Mine – Atlantic Gold Corporation* (CEAA 2016) and the second round of information requests (AMNS 2021).

8.2 Types of Cumulative Effects

When considering possible cumulative effects on VCs it is important to understand how the effects may interact and manifest in order to make reasonable and technical sound predictions about the significance of the cumulative effects[2].

There are four main ways that cumulative effects can interact, additive, synergistic, compensatory and masking. The definitions as presented in the draft Technical *Guidance for Assessing Cumulative Environmental Effects under the Canadian Environmental Assessment Act, 2012* (2018) are as follows:

> *"An **additive cumulative effect** is the sum of individual effects of two or more physical activities" (page 42).*
>
> *"A **synergistic cumulative effect** occurs as a result of the interaction between two or more effects, when the resultant combination is greater or different than the simple addition of the effects" (page 42).*
>
> *"**Compensatory cumulative effects** are effects from two or more physical activities that "offset" each other" (page 43).*
>
> ***Masking cumulative effects** are "the effects of one project might mask the effects of another in the field" (page 44).*

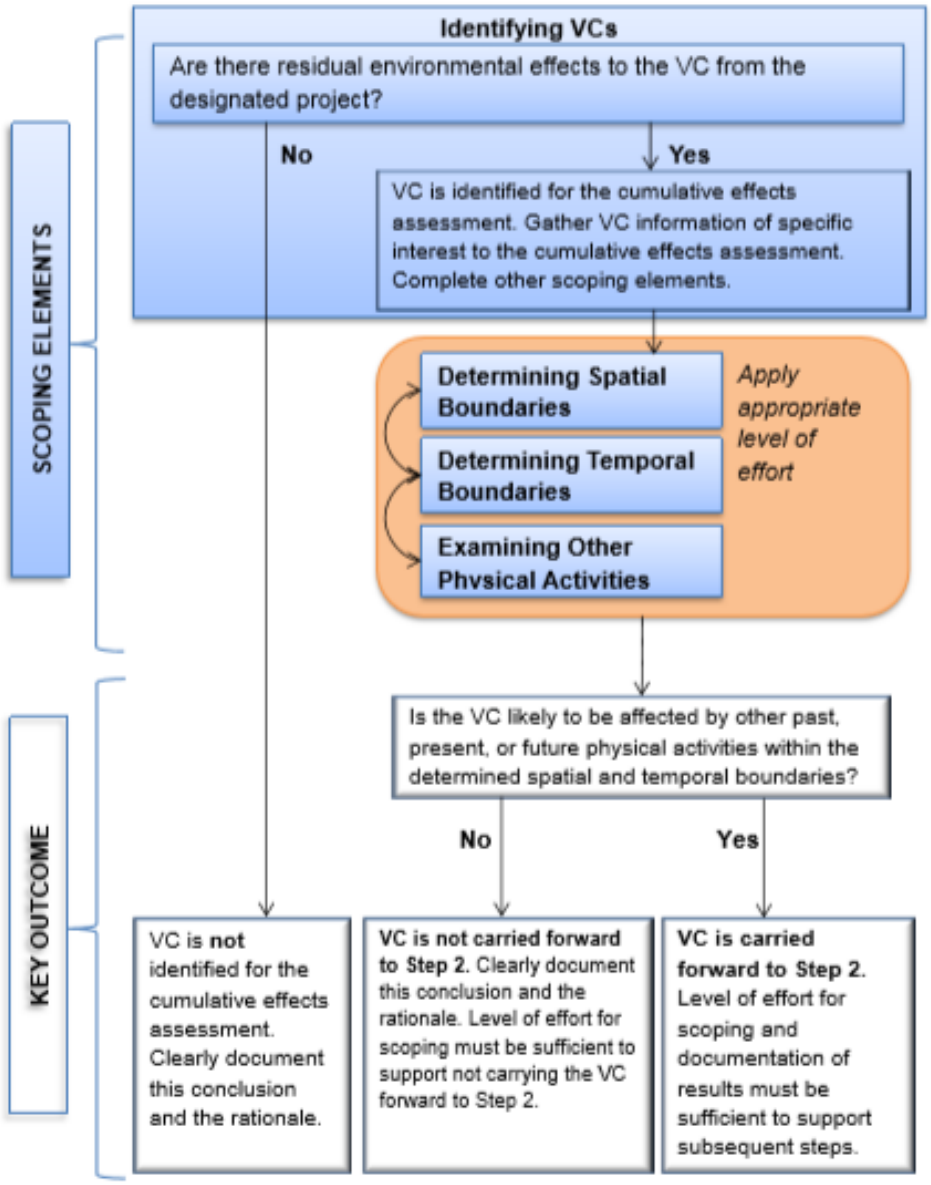
1 *Assessing Cumulative Environmental Effects under the Canadian Environmental Assessment Act, 2012*. https://www.canada.ca/en/environmental-assessment-agency/news/policy-guidance/assessing-cumulative-environmental-effects-under-canadian-environmental-assessment-act-2012.html

2 Ibid

8.3 Cumulative Assessment Methodology

The general approach of the cumulative impact assessment is based on the Agency's Operational Policy Statement entitled Addressing Cumulative Environmental Effects under the *Canadian Environmental Assessment Act*, 2012 and the guide entitled Cumulative Effects Assessment Practitioners' Guide, 1999 (Hegmann et al., 1999).

The main steps involved in this approach are as follows:



- The initial steps cover the scoping of the Cumulative Effects Assessment and include:
  - Identification of the VCs that will constitute the focus of the Cumulative Effects Assessment.
  - Determining the spatial and temporal boundaries for each VC.
  - Identification, selection and description of physical activities (projects) in the area.
  - Confirmation of the VCs to be carried forward to the assessment stage.
- The following steps constitute the analysis of the CEA and are presented separately for each VC selected at the scoping stage:
  - Description of the baseline conditions.
  - Description of the residual effects of the proposed Project.
  - Description of the effects of other projects in the area.
  - Description of the cumulative effects.
  - Proposed mitigation and monitoring.
  - Residual Cumulative Effects and Significance Assessment.
  - Follow-up.
  - Scoping Approach

8.3.1 Scoping Approach

The scoping methodology as depicted in the draft Technical Guidance for Assessing Cumulative Environmental Effects under the *Canadian Environmental Assessment Act*, 2012 (2018)[3] is presented in Figure 8.3-1 below.

3 Canadian Environmental Assessment Agency. (2014). *Technical Guidance for Assessing Cumulative Environmental Effects under the Canadian Environmental Assessment Act, 2012*

Figure 8.3-1: Generic Approach to Scoping for Cumulative Effects Assessment Adapted from the Technical Guidance for Assessing Cumulative Environmental Effects under the *Canadian Environmental Assessment Act,* 2012

The methodology followed for the four main steps associated with scoping or CEA is described below:

Step 1 - Identification of the Valued Components (VCs) That Will Constitute the Focus of the Cumulative Effects Assessment.

In order to identify the VCs that are likely to be affected by cumulative effects resulting from the proposed Project and other projects in the area, each of the VCs taken into account in the environment effects assessment of the proposed Project (Section 6) was analyzed. In order to be included in the CEA, adverse residual effects must have been identified for the VC. As per the Agency's *Guidelines for the Preparation of an Environmental Impact Statement pursuant to the Canadian Environmental Assessment Act,*

2012 and *Nova Scotia Registration Document pursuant to the Nova Scotia Environment Act – Beaver Dam Mine – Atlantic Gold Corporation* (EIS Guidelines, 2016) the following valued components at a minimum must be considered:

- fish and fish habitat;
- birds (including migratory birds);
- species at risk; and
- Mi'kmaq of Nova Scotia.

As stated in the EIS Guidelines "Valued components that would not be affected by the project or would be affected positively by the project can therefore, be omitted from the cumulative effects assessment" (Section 6.7.3 of the EIS guidelines, CEAA 2016). As such, if any VCs were only positively affected, or if it was determined through the EIS that a particular VC had no residual effects, they were not carried forward to the assessment phase. Documentation of the step is provided in Section 8.4.1.

Step 2- Determining the Spatial and Temporal Boundaries for Each VC.

The spatial and temporal boundaries to be considered in the cumulative effects assessment are determined individually for each selected VC. The Regional Assessment Area (RAA) outlined in each VC section is used as the basis for the cumulative effects assessment. The RAA for each VC was determined based on the potential for cumulative effects.

The main points taken into consideration in determining spatial boundaries were:

- Whether the effects of different projects to a VC could be additive if felt at separate locations; and
- The expected geographical extent of the project effects on the VC.

The determination of the appropriate geographic scale required to assess the effects on a biological population. In most cases, a broad, regional area was considered appropriate, though the existence of physical boundaries between populations was taken into account. For example, effects to fish populations were considered cumulative within a watershed.

In the determination of temporal boundaries, the following points were taken into account:

- Duration of the expected environmental effects;
- The timing of the expected environmental effects; and
- Whether or not the effects are only additive if felt simultaneously.

For example, it was considered for most physical VCs that effects could only be cumulative if the effects of two projects overlap in time and space. For instance, cumulative effects on water quality that exceed those assessed for an individual project are only possible if two projects affect the same body of water. However, for other VCs, such as wildlife or bird populations, effects from projects that do not overlap in space or time may have cumulative effects if their effects reach the same population. The spatial cumulative effects boundaries for such VCs may therefore be wider than those used to assess the effects of an individual project and should generally be determined in a way that is ecologically defensible.

Temporal cumulative effect boundaries take into account the timing at which a type of effect has occurred, is occurring or is expected to occur in the future, as well the expected duration of the effect. For example, the cumulative effects of habitat loss could start with the first historical effects on the habitat in question and end with the recovery of the lost habitat. Documentation of the step is provided in Section 8.4.2.

Step 3 - Identification, Selection and Description of Projects in the Area.

Information regarding upcoming and past projects (also referred to as physical activities under CEAA guidance) was obtained from a review of new and existing projects listed on the NSE Environmental Assessment Division website as well as the CEAA's online registry. In addition, a generalized internet search was used to identify other anticipated or ongoing projects.

A search was conducted to identify all major projects within the region with a potential to have cumulative effects with the Project. Each VC's RAA was used to determine which projects were included in the CEA. Each VC's RAA is considered appropriate for this analysis, because the effects will be assessed within a boundary that is relevant to that particular VC. The Project is not expected to have any direct effects on any VCs outside of their RAA. The RAAs used for the cumulative effects assessment were determined given the social and ecological context of each VC (i.e., the RAA and pursuant cumulative effects assessment for socio-economic impacts is based on municipal boundaries, whereas effects to aquatic ecosystems are based on watershed boundaries). Identified projects in the RAAs were included in the evaluation, regardless of their respective temporal boundaries. Documentation of this step is provided in Section 8.4.3.

Step 4 - Confirmation of the VCs to be Carried Forward to the Assessment Stage.

Upon completion of the three steps listed above, the residual effects to VCs that would likely interact with the effects from other past, present, or future physical activities within the spatial and temporal boundaries of each VC were determined through the application of screening criteria.

The following screening criteria were used:

- level of concern noted during engagement;
- current state of the VC (health/status/condition);
- potential for significant cumulative effects;
- uncertainty in predictions of cumulative effects; and
- potential for follow up or additional mitigation.

The results of the application of the screening criteria for each VC were documented along with a rationale for each VC, which describes whether the VC was carried forward to the CEA or not with an accompanying rationale. Where significant adverse effects are identified, the EIS will discuss the likelihood or probability that the effect will occur.

8.3.2 Assessment Approach

8.3.2.1 Baseline Conditions

A description of the baseline conditions is given for each of the selected VCs through the scoping phase carried forward for analysis within their designated spatial and temporal boundaries. Emphasis is put on aspects of the VC that are likely to be affected by cumulative effects between the Project and the other identified projects in the area.

8.3.2.2 Identification and Assessment of the Cumulative Effects

The first step in the assessment of the cumulative effects is to describe the residual effects of the Project, based on the results of the environmental effects assessment presented in Section 6. The environmental effects assessment methodology used for the Project is presented in Section 5.

This is followed by the identification of any effects of the other projects identified in the area that may act in combination with the residual effects of the Project. If available, environment impact statements or environmental assessments for identified projects with potential cumulative effects were consulted. In addition, information contained in the baseline conditions for a VC often included a description of the effects of past and ongoing activities as these have left their mark on the current conditions.

In the case of past activities, their effects can be used to contextualize the current state of the VC as described in the baseline conditions. Taking this information into consideration, the total cumulative effects of all projects having an effect on the selected VC is then described as to their nature, scope and intensity. An assessment of the relative contribution of the Project on the overall cumulative effects is given by comparing these effects with and without the inclusion of the proposed project.

As indicated in the EIS Guidelines (CEAA 2016), the assessment of cumulative effects on current use of lands and resources for traditional purposes by Mi'kmaq of Nova Scotia focusses on the effects on specific activities such as hunting, fishing, trapping and plant harvesting.

8.3.2.3 Mitigation

As a first step, an assessment of whether any additional mitigation measures beyond those proposed in the environmental effects assessment of the Project (Section 6) is made. If additional technically and economically feasible measures are warranted to reduce the cumulative effects, these are proposed.

Given the large spatial and temporal cumulative effects boundaries of certain VCs, the implementation of mitigation measures may exceed the scope of the Proponent's responsibility. In such cases the parties that have the authority to act are identified and any discussions that have taken place in order to implement the necessary measures over the long term are summarized.

8.3.2.4 Residual Cumulative Effects and Significance Assessment

The residual cumulative effects, taking into account the implementation of the mitigation measures, are described in Section 8.5. These are then compared to the significance thresholds identified for each VC in order to determine if they are significant.

8.3.2.5 Follow-up and Monitoring

If it is considered warranted, after taking into account the confidence level of the predictions of the residual cumulative effects and the expected scale of the effects, a follow-up program is proposed to verify the accuracy of the assessment or to address the uncertainty concerning the effectiveness of mitigation measures for certain cumulative effects.

8.3.3 Consideration of Engagement Results and Indigenous Traditional Knowledge

Key issues raised during public and Mi'kmaq engagement relating to Mi'kmaq of Nova Scotia include: potential habitat loss and effects on individual flora and fauna used in traditional hunting, fishing and trapping activities and medicinal food and plants; loss of access to traditional areas; potential impact to traditional foods from dust deposition; potential impact to surface water and groundwater; and potential impacts to fish and wildlife.

8.4 Scoping of the Valued Components

8.4.1 Identification of the Valued Components

All of the VCs (as listed below) included in the environmental effects assessment of the Project (Section 6) were taken into consideration in the scoping exercise for the CEA.

- Physical Environment:
  - Noise;
  - Air;
  - Light;
  - GHGs
  - Geology, Soil and Sediment;
  - Groundwater Quality and Quantity; and
  - Surface Water Quality and Quantity.
- Biophysical Environment:
  - Wetlands;
  - Fish and Fish Habitat;
  - Habitat and Flora;
  - Terrestrial Fauna;
  - Avifauna; and
  - Species of Conservation Interest and Species at Risk.
- Socio-Economic Environment:
  - Mi'kmaq of Nova Scotia;
  - Physical and Cultural Heritage; and
  - Socio-Economic Conditions.

The initial screening of the VCs listed above is based on the outcome of the environmental effects assessment (Section 6) and is summarized in Table 8.4-1. The table provides the possible pathways for VCs to cause cumulative effects as well as possible linkages of the residual effects on a VC to other VCs. Both the pathway of an effect and possible linkages of the residual effect to other VCs are important to consider from a cumulative effects perspective, specifically when determining the possible interaction of the Project's residual effects with the effects from other activities in the area.

The residual effects of 15 of the 16 identified VCs for the Project were determined not to be significant but were assessed as adverse. The Projects' effects to Socioeconomic Condition are determined to be positive. As described above, VCs with positive residual impacts are not carried forward through the CEA exercise. All other VCs were carried forward for additional consideration in the scoping process.

8.4.2 Determining the Spatial and Temporal Boundaries

8.4.2.1 Spatial Boundaries

Spatial boundaries for cumulative effects assessment are based on setting adequate spatial boundaries that represent anticipated geographic limits that will aid in defining the scale and range of interactions between Project activities and VCs.

A map of the PA is presented in Section 5.5, Figure 5.5-1. The PA used for the environmental effects assessment for all VCs and the LAA and RAA used for each specific VC, as described in Section 6, were established to capture areas broader than the expected Project impacts in considerations of other project boundaries as per cumulative effects methodology. Therefore, the spatial boundaries (PA, LAA, and RAA), established for the environmental effects assessment are appropriate for determining potential cumulative effects. Each boundary is discussed below and presented on a figure in each per VC in Section 6 of this EIS.

8.4.2.1.1 Project Area (PA)

The PA encompasses the immediate area in which direct Project activities may occur and are likely to cause direct and indirect effects to VCs. The PA consists of the three components: the Beaver Dam Mine Site, the Beaver Dam Haul Road, and the Touquoy Mine Site, extending from Marinette to Moose River Gold Mines, Halifax County, NS (Section 5.5, Figure 5.5-1). The PA is the same for each VC.

8.4.2.1.2 Local Assessment Area (LAA)

The LAA encompasses adjacent areas outside of the PA where Project related direct and indirect effects to VCs are reasonably expected to occur. Generally, the LAA is limited to the area in which Project activities are likely to have indirect effects on VCs; however, the size of the LAA can vary depending on the VC being considered, and the biological and physical variables present. The LAA for each VC is defined in Table 8.4-1 and are described in detail in relevant VC sections in Section 6 of this EIS.

8.4.2.1.3 Regional Assessment Area (RAA)

The RAA encompasses all Project and VC interactions and are defined intending to be spatially larger than expected for direct and indirect Project interactions, with the exception of VCs that may have diffuse or longer-range effects such as those from Project activities on socio-economic environments. The RAA varies in size depending on the VC being considered, and the biological and physical variables present. The RAA for each VC is defined in Table 8.4-1 and are described in detail in relevant VC sections in Section 6 of this EIS.

8.4.2.2 Temporal Boundaries

The Project has three distinct phases - Construction (1 year), Operations (5 years), and Active Closure (2 years) with post-closure monitoring proposed for 10 years after the active closure, dependent on water quality and monitoring requirements. These phases define the maximum temporal boundary for assessment of impacts on each VC. The maximum Project life is 8 years for the construction, operation and active closure phases. Monitoring and water treatment, as required, is expected be required for longer during the post-closure stage.

Table 8.4-1: Initial Screening of the Valued Components based on the Outcome of the Environmental Effects

Project VC	EIS Section	Spatial Boundaries		Temporal Boundaries	Summary of A Significant Effect*	Pathway	Adverse Residual Effects			Include in Scoping Exercise	Rationale
		Local Assessment Area (LAA)	Regional Assessment Area (RAA)				Summary	Significance	Linkages to Other VCs (If Applicable)		
PHYSICAL ENVIRONMENT											
Noise	6.1	The LAA for Noise encompasses adjacent areas outside of the PA where Project related effects to Noise are reasonably expected to occur. The LAA constitutes the noise modelling domain based on the location of the Project noise emission sources and predicted noise levels for Project Constriction and Operations phases, as well as the location of potential sensitive receptors. The Noise modelling domain was established so that it would be inclusive of, at minimum, any predicted noise contours above 35 dBA, a threshold value criterion for baseline nighttime noise levels adopted from the Alberta Energy and Utilities Board. See Figure 6.1-2.	The Regional Assessment Area (RAA) extends beyond the LAA as to encompass potential indirect effects of Noise with other related VCs, such as human health and wildlife. See Figure 6.1-2.	The temporal boundary for the assessment of effects to air quality includes the construction, operation and closure (active reclamation and decommissioning) phases.	Significant residual effects for the Noise VC would be defined as having high magnitude (i.e., an exceedance of the maximum noise or vibration limits), occur beyond the PA and LAA, be of long-term to permeant duration, occur at regular intervals or be continuous throughout the Project, and be only partially reversible to irreversible.	Atmospheric	Increased ambient noise.	Adverse, not significant	Fauna, Birds, SAR/SOCI, Mi'kmaq of Nova Scotia	Yes	Adverse residual effects were identified within VC evaluation
Air	6.2	The LAA encompasses a 15 km zone in all directions from the PA. (Figure 6.2-1).	The RAA encompasses 35 km buffer from the PA, which represents the maximum zone of influence. The RAA covers the anticipated maximum extent of particulate deposition under worst case scenarios (Figure 6.2-1).	The temporal boundary for the assessment of effects to air quality includes the construction, operation and closure (active reclamation and decommissioning) phases.	Significant residual effects for the Air VC is defined as having high magnitude (i.e., an exceedance of applicable criteria), occur beyond the LAA, be of long-term to permeant duration, occur at regular intervals or be continuous throughout the Project, and be only partially reversible to irreversible.	Atmospheric	Increased ambient dust.	Adverse, not significant	Flora, SAR/SOCI, and Mi'kmaq of Nova Scotia	Yes	Adverse residual effects were identified within VC evaluation
Light	6.3	The LAA for light variable based on a 1 LUX threshold. Preliminary modelling and evaluation of light has determined this to be the maximum distance of light propagation to a 1 LUX threshold. See Figure 6.3-1.	The RAA for light encompasses a distance defined by 0.1 lux surrounding the PA. This is based on the maximum extent of light propagation. See Figure 6.3-1.	The temporal boundary for the assessment of effects to air quality includes the construction, operation and closure (active reclamation and decommissioning) phases.	Direct light trespass that meets 1 lux light trespass into windows at the nearest receptor. This was determined as a result of the baseline environmental light classification of E2 at the Beaver Dam Mine Site.	Atmospheric	Increased ambient light.	Adverse, not significant	Fauna, birds, SAR/SOCI, Mi'kmaq of Nova Scotia	Yes	Adverse residual effects were identified within VC evaluation
GHG	6.4	The Local Assessment Area (LAA) encompass a 15 kilometre (km) zone in all directions from the PA, based on the expected maximum extent of potential ground level emissions (Figure 6.4-1).	The Regional Assessment Area (RAA) encompasses the province of Nova Scotia. GHG emissions will be compared to Nova Scotia targets and totals (Figure 6.4-1)	The temporal boundaries used for the assessment of effects to GHGs are the construction phase, operational phase, and active closure phase.	An increase in GHG greater than 0.2% pf NS 2018 (CO_2e) levels at the regional scale.	Atmospheric	Increased greenhouse gas emissions	Adverse, not significant	NA	Yes	Adverse residual effects were identified.
Geology, Soil and Sediment	6.5	There is no LAA or RAA for geology, soil and sediment, as impacts to this VC are only expected to occur within the PA.		Project-related impacts may occur during construction, operation, and closure (active reclamation and decommissioning stage) phases of the Project.	There are no regulated or proposed thresholds for geology and soils effects for this site and Project. Both sediment and soils that become mobilized have a linkage with surface water and quality that have regulated thresholds and can be assessed through predictive efforts for the Surface Water VC (Section 6.7 and 6.9) or through the monitoring program proposed.	Soils and Sediment	Erosion, soil and sediment quality	Adverse, not significant	Surface Water, Wetlands, Fish Groundwater, Flora, Fauna.	Yes	Adverse residual effects were identified within VC evaluation

Table 8.4-1: Initial Screening of the Valued Components based on the Outcome of the Environmental Effects (continued)

Project VC	EIS Section	Spatial Boundaries		Temporal Boundaries	Summary of A Significant Effect*	Pathway	Adverse Residual Effects			Include in Scoping Exercise	Rationale
		Local Assessment Area (LAA)	Regional Assessment Area (RAA)				Summary	Significance	Linkages to Other VCs (If Applicable)		
Groundwater	6.6	The LAA for Groundwater Quality and Quantity encompasses an 800 m buffer from the Beaver Dam Mine Site, an 800 m buffer along the portion of the Haul Road that will be upgraded where receptors are present, and the portion of down-gradient habitat from the Touquoy Mine Site. See Figure 6.6-7.	The RAA for Groundwater Quality and Quantity encompasses tertiary watersheds intersecting the PA. See Figure 6.6-7.	The temporal boundary for the assessment of effects to Groundwater Quality and Quantity includes the Construction, Operation and Closure Phases.	A significant adverse effect from the Project on groundwater quality is defined as an effect that results in groundwater quality exceeding the NSE Tier 1 EQS for potable groundwater, GCDWQ or NSE Tier 2 PSS for groundwater discharge to surface water (>10 m). Detailed definition provided in Section 6.6	Groundwater	Disturbance to groundwater quality and quantity	Adverse, not significant	Surface Water, fish, wetlands, SAR/SOCI, Mi'kmaq of Nova Scotia	Yes	Adverse residual effects were identified within VC evaluation
Surface Water	6.7	The LAA is defined by the tertiary watersheds that encompass or intersect the PA, and contains surface water features upstream, downstream and within the PA. The lakes and watercourses that are included as part of the baseline programs and/or predictions of effects are located within the LAA boundary. See Figure 6.7-11.	The RAA in the context of surface water quality and quantity encompasses Secondary Watersheds (East River Sheet Harbour and Fish River), see Figure 6.7-11.	The temporal boundary for the assessment of effects to Surface Water Quality and Quantity includes construction, operation and closure phases.	A repeated or sustained change in water flows that differ substantially from baseline flow conditions (15%); and/or an indicator is predicted to be greater than guidelines and differ substantially from baseline water quality (outside of the 75th to 95th baseline water quality), resulting in a detectable change beyond the range of natural variation. Detailed definition provided in Section 6.7.	Surface Water	Change in Water Quality and Quantity Habitat Loss and disturbance	Adverse, not significant	Fish, Wetlands, SAR/SOCI, Mi'kmaq of Nova Scotia	Yes	Adverse residual effects were identified within VC evaluation
BIOPHYSICAL ENVIRONMENT											
Wetlands	6.8	The LAA is defined by the tertiary watersheds that encompass or intersect the PA (Beaver Dam Mine Site, Haul Road and Touquoy Mine Site), and contains surface water features upstream, downstream and within the PA. The lakes and watercourses that are included as part of the baseline programs and/or predictions of effects are located within the LAA boundary. See Figure 6.7-11.	The RAA encompasses three Secondary Watersheds: West River Sheet Harbour, Tangier River and Fish River-Lake Charlotte). See Figure 6.7-11.	The temporal boundary for the assessment of effects to wetlands includes the construction, operation, closure (active reclamation and decommissioning) and post-closure phases.	A significant adverse effect from the Project on wetlands is defined as an effect that results in an unmitigated or uncompensated net loss of wetland habitat as defined under the NSE Wetland Conservation Policy, and its associated no-net loss policy, or an effect that is likely to cause a permanent loss of >10% wetland habitat for a SAR species identified in the PA within the LAA.	Vegetation, Hydrology	Habitat loss and disturbance	Adverse, not significant	Habitat and flora, fauna, avifauna, fish, SAR/SOCI, surface water, groundwater, Mi'kmaq of Nova Scotia	Yes	Adverse residual effects were identified within VC evaluation
Fish and Fish Habitat	6.9	The LAA is defined by the tertiary watersheds that encompass or intersect the PA (Beaver Dam Mine Site, Haul Road and Touquoy Mine Site), and contains surface water features upstream, downstream and within the PA. The lakes and watercourses that are included as part of the baseline programs and/or predictions of effects are located within the LAA boundary. See Figure 6.7-11.	The RAA encompasses three Secondary Watersheds: West River Sheet Harbour, Tangier River and Fish River-Lake Charlotte). See Figure 6.7-11.	The temporal boundary for the assessment of effects to wetlands includes the construction, operation, closure (active reclamation and decommissioning) and post-closure phases.	A significant adverse effect from the Project on fish and fish habitat is defined as an effect that results in an unmitigated or uncompensated net loss of fish habitat as defined under the *Fisheries Act*, and its associated no-net loss policy.	Aquatic Resources	Habitat loss and disturbance Increased habitat connectivity Decreased water quality	Adverse, not significant	SAR/SOCI, Mi'kmaq of Nova Scotia	Yes	Adverse residual effects were identified within VC evaluation

Table 8.4-1: Initial Screening of the Valued Components based on the Outcome of the Environmental Effects (continued)

Project VC	EIS Section	Spatial Boundaries		Temporal Boundaries	Summary of A Significant Effect*	Pathway	Adverse Residual Effects			Include in Scoping Exercise	Rationale
		Local Assessment Area (LAA)	Regional Assessment Area (RAA)				Summary	Significance	Linkages to Other VCs (If Applicable)		
Habitat and Flora	6.10	The LAA includes a 2 km buffer around the Beaver Dam Mine Site and a 500 m buffer surrounding the Haul Road (excluding Mooseland Road). See Figure 6.10-7.	The RAA encompasses portions of Ecodistrict 440 within Halifax Regional Municipality (HRM), east and north of Lake Charlotte. Where the Ecodistrict boundary approached the northern extent of the Beaver Dam Mine Site, the RAA was enlarged to include a 5 km buffer around the PA. See Figure 6.10-7.	The temporal boundary for the assessment of effects to habitat and flora includes the construction, operation, closure (active reclamation and decommissioning) and post-closure phases.	A significant adverse effect from the Project on habitat is defined as an effect that is likely to cause a permanent, unmitigated, alteration to habitat that supports flora species distribution. For the purposed of this analysis, habitat is defined as: A **natural** environment composed of both living organisms (biotic) and non-living components (abiotic) which function together as an ecological unit and includes managed forests (e.g. treated stands, cutblocks, plantations). Urban and industrial developments (e.g. roads, houses, quarries etc.) are excluded from this definition.	Vegetation	Disturbance and loss of habitat	Adverse, not significant	Fauna, avifauna, SAR/SOCI, wetlands, Mi'kmaq of Nova Scotia	Yes	Adverse residual effects were identified within VC evaluation
Terrestrial Fauna	6.11	The LAA includes a 5 km buffer around the Beaver Dam Mine Site and a 500 m buffer surrounding the Haul Road and Touquoy Mine Site. See Figure 6.11-3.	The RAA encompasses portions of Ecodistrict 440 within Halifax Regional Municipality (HRM), east and north of Lake Charlotte. Where the Ecodistrict boundary approached the northern extent of the Beaver Dam Mine Site, the RAA was enlarged to include a 5 km buffer around the PA. See Figure 6.11-3.	The temporal boundary for the assessment of effects to terrestrial fauna includes the construction, operation, closure (active reclamation and decommissioning) and post-closure phases.	A significant adverse effect from the Project on terrestrial fauna is defined as an effect that is likely to cause a permanent, unmitigated, alteration to habitat that supports fauna species distribution.	Wildlife	Disturbance and loss of habitat	Adverse, not significant	Habitat and flora, SAR/SOCI, wetlands, Mi'kmaq of Nova Scotia	Yes	Adverse residual effects were identified within VC evaluation
Avifauna	6.12	The LAA includes a 5 km buffer around the Beaver Dam Mine Site and a 500 m buffer surrounding the Haul Road and Touquoy Mine Site. See Figure 6.12-2.	The RAA encompasses portions of Ecodistrict 440 within Halifax Regional Municipality (HRM), east and north of Lake Charlotte. Where the Ecodistrict boundary approached the northern extent of the Beaver Dam Mine Site, the RAA was enlarged to include a 5 km buffer around the PA. See Figure 6.12-2.	The temporal boundary for the assessment of effects to avifauna includes the construction, operation, closure (active reclamation and decommissioning) and post-closure phases.	A significant adverse effect from the Project on avifauna is defined as an effect that is likely to cause a permanent, unmitigated, alteration to habitat that supports avian species distribution.	Wildlife	Disturbance and loss of habitat	Adverse, not significant	Habitat and flora, SAR/SOCI, wetlands, Mi'kmaq of Nova Scotia	Yes	Adverse residual effects were identified within VC evaluation

Table 8.4-1: Initial Screening of the Valued Components based on the Outcome of the Environmental Effects (continued)

Project VC	EIS Section	Spatial Boundaries		Temporal Boundaries	Summary of A Significant Effect*	Pathway	Adverse Residual Effects			Include in Scoping Exercise	Rationale
		Local Assessment Area (LAA)	Regional Assessment Area (RAA)				Summary	Significance	Linkages to Other VCs (If Applicable)		
Species at Risk (SAR) /Species of Conservation Interest (SOCI)	6.13	The LAA for SAR and SOCI is equivalent to those described for Habitat and Flora, Terrestrial Fauna, Fish and Fish Habitat, and Avifauna.	The RAA for SAR and SOCI is equivalent to those described for Habitat and Flora, Terrestrial Fauna, Fish and Fish Habitat, and Avifauna.	The temporal boundary for the assessment of effects to SAR and SOCI includes the construction, operation, closure (active reclamation and decommissioning) and post-closure phases.	A significant adverse effect from the Project on SAR and SOCI is defined as an effect that is likely to cause a permanent, unmitigated, alteration to habitat that supports a species' distribution, or alteration of critical habitat. An adverse effect that does not cause a permanent alteration to habitat of SAR or SOCI species is not considered to be significant. Sedentary species such as vascular and non-vascular flora do not have the opportunity to move to avoid direct or indirect impact. For these species, the loss of an individual or individuals of a SAR species that is important in the context of the province, or that species' overall abundance or distribution, may be considered significant, if appropriate mitigation measures are not implemented. Mortality of a single SAR could, under some circumstances, be considered a significant effect.	Wildlife, Vegetation, Aquatic Resources	Disturbance and loss of habitat	Adverse, not significant	Wetlands, Mi'kmaq of Nova Scotia	Yes	Adverse residual effects were identified within VC evaluation
SOCIO-ECONOMIC ENVIRONMENT											
Mi'kmaq of Nova Scotia	6.14	The LAA encompasses a 5 km radius from the PA. The LAA includes the maximum extent of physical disturbance from project and interactions with expected Mi'kmaq current use of lands and resources, and physical and cultural heritage (Figure 6-14.1).	The RAA for the assessment of the Mi'kmaq of Nova Scotia is defined as the territorial boundaries of the *Eskikewa'kik* (meaning 'skin dressers territory'). See Figure 6.14-1.	The temporal boundary for the assessment of effects to the Mi'kmaq of Nova Scotia includes construction (one year), operations (five years), and active closure (two years) phases.	An effect that results in long-term (greater than 20 years) loss of the availability of, or access to, land and resources currently relied upon for traditional use practices or the permanent loss of traditional use areas within a large portion of the PA; an effect on health identified through conclusions of the Human Health Risk Assessment, and/or an unmitigated loss of a physical or cultural structure, site or thing that is of historical, archaeological, paleontological or architectural significance to the Mi'kmaq A detailed definition is provided in Section 6.14.6.2.	Physical and Biophysical pathways and Socio-economic conditions	Loss of plant specimens and habitat Loss of fish habitat Change in species movement pattern Sensory disturbance Visual change Increased Traffic Loss of Access	Adverse, not significant	NA	Yes	Adverse residual effects were identified within VC evaluation
Physical and Cultural Heritage	6.15	There is no LAA or RAA for physical and cultural heritage, as the loss or destruction of heritage or archaeological resources could occur only within the disturbed footprint of the Project (PA).		The temporal boundaries used for the assessment of effects to physical and cultural heritage are limited to the construction phase of the Project. Construction is estimated to take approximately one year.	A significant adverse effect is an uncontrolled (without appropriate study, analysis and mitigation measures in conjunction with the Province and Mi'kmaq archaeologists as required) disturbance to, or destruction of, any unassessed historical or cultural resource of importance in context of the *Special Places Act*.	Cultural Heritage	Loss of archaeological features Site 6 and Areas 2 and 3 will be impacted by the Project. Additional shovel tests were completed within Site 6, Area 2 and Area 3 in fall 2020. No Pre-contact Mi'kmaq archaeological resources were encountered.	Adverse, not significant	Mi'kmaq of Nova Scotia	Yes	Adverse residual effects were identified within VC evaluation

Note: A summary of each VCs threshold for determination of a significant effect is presented herein. For the full definition of a significant effect, including determination of the magnitude, see the effects assessment methodology for each VC in Section 6.

8.4.3 Identification, Selection and Description Past, Present and Future Physical Activities

Major industrial projects that have taken place, are taking place or are known to potentially take place in the future within the RAA for each VC are described in the following sections. Projects were identified as per the methods described in Section 8.3.1 and consider major industrial projects (i.e. those requiring federal or provincial environmental assessment) as well as projects that are known to be present in the area from engagement efforts, common knowledge, aerial imagery review of the local area, or other methods as available. This list is meant to be inclusive, but the Proponent acknowledges the limitations of these methods of project identification; some projects may have been excluded due to ignorance on the part of the EIS team and limited publicly available data. This list of physical activities is current as of April 2021.

The ability to draw conclusions from publicly available data is a considerable limitation for the cumulative effects assessment. The best source of publicly available data for other projects being considered lies in the provincial and federal environmental assessment websites. Some of the projects identified below do not trigger an EA process, but would be regulated under provincial Approvals (i.e. Water Approvals, Integrated Resource Management approvals, or Industrial Approvals). These approval documents, and the supporting information are not readily publicly available. Projects which do trigger a formal environmental assessment process have EARDs or EISs available online, but they do not necessarily follow consistent methodology in the assessment or determination of effects. Furthermore, the details associated with information requests or insufficient information requests are not readily publicly available. Some projects may be currently in review so the outcome of that decision is unknown. As such, there is a risk in using conclusions presented in environmental assessments, because the Proponent is unable to confirm whether the effects assessment determinations presented therein were satisfactory, rigorous or appropriate. Furthermore, some projects (such as timber harvesting on private land, or the Nova Scotia Salmon Association's Acid Mitigation project) relevant to the evaluation of cumulative effects, do not trigger regulatory approvals or an EA process. As a result, publicly available information is limited.

A preliminary assessment of the potential cumulative effects of these projects with the Project is presented. A summary of the identified projects and their potential cumulative effects can be found in Section 8.4.3.1. Where possible the distance of the identified projects from the FMS Mine Site and the Touquoy Mine Site were determined along with the anticipated duration of the identified projects to determine potential interaction of the effects of those projects with the Project's adverse residual effects.

If a project falls within a particular VCs RAA, it is considered in that VCs cumulative effects assessment. As such, within each Project listed below, a list of relevant VCs is provided based on the RAA spatial boundary for each VC. Socioeconomic effects have already been screened out of the CEA, based on predicted residual positive effects.

There is a direct spatial overlap with the Project PA and several projects. These include:

- Historic and current mining activity at the Touquoy Mine Site;
- Historic mining activity at the Beaver Dam Mine Site;
- Proposed usage of the Haul Road for transportation of concentrate from the proposed Fifteen Mile Stream Project;
- Regional forestry operations within the PA; and
- Terrestrial liming within Tent Lake Watershed.

As a result of the direct spatial overlap with the Project PA, these projects are considered in the CEA for all VCs.

8.4.3.1 Current and Past Projects

8.4.3.1.1 Fifteen Mile Stream Historic and Proposed Mining Operations (Past and Future)

Gold mining is known to have occurred in the Fifteen Mile Stream (FMS) Study Area near Trafalgar, NS, since 1874, when development along the Jackson Lead took place, approximately 300 m south of the Egerton-MacLean area). Between 1874 and 1893, a number of different companies were active in the Old Egerton and MacLean Shaft area. At this time, small mines were worked from various shafts with the deepest recorded workings located on the Egerton Lead. In 1879, gold was discovered in the Hudson area, west of Egerton-MacLean, and some mining took place here until 1887, when a fire destroyed the mill and hoist. Mining operations appear to have stopped between 1903-1938. Very little, if any work, occurred between 1941-1980, with the exception of a tailings sampling program which occurred at the Egerton Stamp Mill in 1973. Exploration activities recommenced in the 1980's, but little activity occurred between 1990-2008.

In 2009, Acadian Mining started re-examining some of the historic drill core and in 2010, Acadian took 2,139 samples representing previously unsampled intervals from 22 of the historic drill holes. They demonstrated that much of the previously unsampled core was mineralized and that mineralization was more extensive than had been recognized. In 2011, Acadian drilled 29 diamond holes for 3,741 m. Twenty holes were drilled in the Egerton – MacLean area, ten holes in the Hudson area and the remaining hole in the 149 East Zone. This new information was used, together with the historic drill data by Snowden Consulting for a 2012 estimate of resources.

In 2014, Acadian Mining was acquired by Atlantic Gold Corporation. FSSI Consultants completed a resource update using the same database as that used by Snowden Consulting in the 2012 estimate. In 2016, Atlantic Gold commenced an exploration drilling program to determine mineralization extents at the FMS site. A total of 11 holes were drilled for 945 m. The program was continued in 2017 with a further 180 holes drilled for 23,044 m. In the same year Atlantic Gold commenced infill drilling to improve resource confidence and supplement drilling completed in the early 1980s. A total of 186 holes were drilled for 26,062 m. These additional holes were used, together with the historical drill data, by FSSI Consultants to complete a 2017 resource update. Historic mining activities within the FMS Study Area resulted in some habitat fragmentation and general disturbance, in addition to deposition of tailings along Seloam Brook.

The FMS Gold Project EIS has been submitted to IAAC for review. Upon approval of the proposed Project, extraction will commence in 2024. Concentrate from FMS will be hauled to the Touquoy Mine Site for processing. Tailings from FMS concentrate will be deposited into the exhausted Touquoy pit. The FMS Mine Site is in Trafalgar, Halifax County, Nova Scotia. It is located on land owned partially by MacGregor Properties Ltd, with whom the Proponent has a lease, and the remainder is owned by the Crown and access to the land will be granted by a Crown land lease.

Upon approval and the commencement of mining operations, concentrate from the FMS Gold Project will be transported and processed at the existing plant at the Touquoy Mine Site. The FMS Gold Project is anticipated to commence construction in 2022, come into production in 2023, cease operations in 2027, and then be reclaimed. From 2024 to 2030, concentrate from FMS Gold Project will be processed at the Touquoy Facility along with ore from the Project and concentrate from the Cochrane Hill Gold Project.

As part of the Beaver Dam Mine Project, a Haul Road will be constructed to transport ore to the Touquoy Mine Site. The effects assessment for construction and operation of the Haul Road are presented in this EIS. However, when this haul road is completed, the proposed FMS Gold Project and the proposed Cochrane Hill Gold Project will use the Haul Road to transport gold concentrate to the Touquoy Mine Site. The cumulative effects of increase traffic levels on the Haul Road are assessed herein as a stand-alone

project. The Fifteen Mile Stream site is located approximately 19 km northeast of the Beaver Dam Mine Site, and 38 km northeast of the Touquoy Mine Site.

Spatial overlap with the following RAAs: All VCs

8.4.3.1.2 Beaver Dam Mining Operations (Past)

The area has been subject to exploration and mining activity since gold was first discovered in 1868. Between 1871 and 1949, there were intermittent attempts to develop and mine the area, initially focused on the Austen Shaft area and later on the Mill Shaft area located approximately 1.2 km west of the Austen Shaft. The small Papke Pit located approximately 400 m west of the Austen Shaft was excavated in 1926; however, the majority of development was focused on a belt of quartz veins in greywacke and slates that was approximately 23 m wide where intersected from the Austen Shaft. Approximately 967 ounces of gold production is recorded for Beaver Dam gold deposit between 1889 and 1941. From 1978 until 1988, several companies drilled a combined 251 diamond drill holes for 47,935 m. Some of these drill holes were completed underground via an exploration decline that reached a maximum depth of 100 m below surface. In 1987, a small open pit was also excavated in the Austen Shaft zone. Approximately 2,445 ounces of gold production was also recorded for Beaver Dam gold deposit between 1986 and 1989. Between 2005 and 2009 two companies drilled a combined 153 diamond drill holes for 22,010 m and also completed several other exploration programs including an aeromagnetic survey, a till survey, and a follow-up reverse circulation drilling program for geochemical purposes.

Spatial overlap with the following RAAs: All VCs

8.4.3.1.3 Touquoy Mining Operations (Past, Present and Future)

The Touquoy Mine Site is a fully permitted and approved gold mine in Moose River, Halifax County, Nova Scotia. It is located on land owned by the Proponent and NSL&F. This area has a long history of gold mining, with mining activities occurring periodically since the 1890's. Further details related to the Touquoy Mine Site are presented in Section 2. The Touquoy Gold Project has been fully operational since October 2017 and is described in detail in the Project Description as it relates to the current Project. The current proposed Project involves a temporal extension of the operation of the Touquoy Processing Facility as part of its project description and the effects of the temporal extension are evaluated as effects of the proposed Project.

In the future, it is proposed that the Touquoy pit be expanded to extract additional high grade ore (Appendix F.10). To support cumulative effects assessment for the Project, this expansion is considered herein.

In the future, it is currently proposed that tailings from the processing of ore or ore concentrates from four deposits at the Touquoy mill will be disposed of in the Touquoy pit. These tailings include the processing of lower grades of ore stockpiled for the Touquoy Project, processing of ore transported from the Beaver Dam Project, and processing of ore concentrates from the Fifteen Mile Stream Gold Project and Cochrane Hill Gold Project. Each of these proposed tailings depositions into the Touquoy pit are being evaluated separately as required to reach regulatory approvals. However, to support this cumulative effects assessment for the Project, the cumulative effects from the disposal of tailing from all four projects on Water Resources are assessed in (Appendix F.7). This cumulative assessment memo also considers the proposed expansion of the Touquoy pit.

Possible cumulative effects on the VCs are summarized in Table 8.4-2.

Spatial overlap with the following RAAs: All VCs

8.4.3.1.4 Regional Forestry Operations (Past, Present and Future)

The PA is located on a combination of lands owned by the Crown, and by Northern Timber Nova Scotia Corp. Leases allow forestry to occur on Crown land. In addition to the current forestry activity in the area, evidence of historical forestry is present; clearcutting is a widespread practice throughout the region. The PA contains a diversity of habitat types and landscape features but has experienced a considerable amount of disturbance and habitat fragmentation as a result of historic mine operations, and current and historic timber harvesting practices.

Forestry activities occur in the region surrounding the PA. Due to these operations, the regional area spanning between the Beaver Dam Mine Site and the Touquoy Mine Site is a mosaic of forested habitats at different stages of regeneration, including some relatively undisturbed mature forest. Harvested wood in this area is transported from the area by road. Regional forestry operations are likely to continue into the future following current forest management practices. Forest harvesting may also contribute to traffic on the Beaver Dam Haul Road during the life of the mine projects.

MEL consulted the Nova Scotia Harvest Map Plan Viewer (NSL&F, 2021) and NSL&F to attempt to quantify timber harvesting activity on Crown Lands, to help advise the assessment of potential cumulative effects. NSL&F confirmed that the Harvest Map available to view online identifies forest patches that are proposed or approved for timber harvesting on crown land. This tool has limited application in quantifying harvest operations, because its' intention is for public consultation purposes, and NSL&F does not use this tool to confirm if and when any approved forest patch has been actually harvested. As such, the total area of past, current and proposed crown land timber harvesting within the RAA could not be quantified. Furthermore, this layer applies to crown lands only, and there is no equivalent tracking system for timber harvesting operations on private land (which accounts for approximately 67% of the RAA). As such, timber harvesting operations cannot be discussed in any meaningful, quantitative way. Given the limitations of available data, discussions related to timber harvesting are qualitative in nature. Timber harvesting practices and standards are currently being reviewed under recommendations provided in the Leahy Report (2018). The details associated with which recommendations will be implemented are unknown at this time, though the general intent is to promote more ecologically driven timber harvesting. As a result, the implementation of recommendations outlined in the Leahy report are only anticipated to reduce residual effects of timber harvesting moving into the future, rather than increase residual effects.

Spatial overlap with the following RAAs: All VCs

8.4.3.1.5 Nova Scotia Salmon Association – Acid Mitigation Project

The WRSH watershed is home to one of the largest and longest Atlantic salmon restoration projects in Canada – the WRSH Acid Mitigation Project. Like most watersheds in the SU region, the WRSH has experienced acidification, reducing the habitat quality for spawning Atlantic salmon. Before intervention, the pH range of the main WRSH and Killag River was approximately 4.3 to 5.5 and 4.7 to 5.5, respectively (Halfyard, 2013). In an effort to improve the quality of fish habitat, the Nova Scotia Salmon Association (NSSA) with support from the Atlantic Salmon Federation and numerous other organizations has operated a continuous lime dosing station in the West River since 2005 (6 km southwest of the Beaver Dam Mine Site, and 13 km northeast of the Touquoy Mine Site). A second lime dosing station was installed on the Killag River in 2017. The Killag River dosing station is located approximately 500 m east and downstream of the Beaver Dam Mine Site, and 13 km northeast of the Touquoy Mine Site. Their purpose is to increase the pH of the water to a range that is more suitable for juvenile Atlantic salmon (approximate pH levels of 5.5). As a result of the Acid Mitigation Project, treated river pH within the WRSH has increased to 5.5 to 7.5 (Halfyard, 2013).

In addition to the operation of two lime dosing stations, the NSSA has implemented a terrestrial liming program, to remediate effects of chronic acidification in the watershed, and to complement the ongoing aquatic liming programs. Terrestrial liming involves deposition of dolomitic limestone across the catchment by helicopter, while lime dosers add a slurry of limestone directly into the

watercourse on a continuous basis. To date, terrestrial liming has occurred within the Keef Brook, Paul Brook and Tent Brook tertiary watersheds (Rotteveel, 2018; DFO, 2020; NSSA, 2017).

Spatial overlap with the following RAAs: All VCs

8.4.3.1.6 Goldboro Gas Plant – Sable Offshore Energy Project (Past)

The Goldboro Gas Plant was built to collect and distribute natural gas from the Sable Offshore Energy Project in 1999. The gas plant completed initial processing to prepare natural gas to be sent via pipeline to the Point Tupper Fractionation Plant for additional processing. The gas plant operated for more than ten years, and decommissioning studies and planning commenced in 2012. Well plug and abandonment commenced in 2017. This site is approximately 87 km northeast of the Beaver Dam Mine Site, and 105 km northeast of the Touquoy Mine Site.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.1.7 Port of Sheet Harbour (Present)

The Port of Sheet Harbour is a deep-water port located 25 km southeast of the Beaver Dam Mine Site and 35 km southeast of the Touquoy Mine Site on the coast of the Atlantic Ocean. The terminal consists of a 152 m wharf with a minimum draft of 10 m and is capable of handling ships of up to 214 m (Port of Sheet Harbour, 2017).

This facility has the capacity to handle aggregates and dry bulk, scrap metal and a variety of large bulky equipment such as neobulk marshalling and load out, fabrication modules including construction equipment and heavy lift project cargo, pipes and tubulars, boilers and transformers, and wind turbines (Port of Sheet Harbour, 2017).

Spatial overlap with the following RAAs: Air, Mi'kmaq of Nova Scotia

8.4.3.1.8 Cook's Brook Sand and Gravel Pit (Present and Future)

Gallant Aggregates Limited operates a sand and gravel pit in Cooks Brook, located approximately 46 km west of the Beaver Dam Mine Site and 30 km west of the Touquoy Mine Site. An eastward extension of the site was approved in 2013 and scheduled to commence that same year. The sand and gravel pit is approximately 500 m long by 250 m wide.

Spatial overlap with the following RAAs: Air, Mi'kmaq of Nova Scotia

8.4.3.1.9 ScoZinc Ltd. Mine (Past and Future)

ScoZinc Limited owns and operates a zinc/lead operation in Cooks Brook, approximately 49 km west of the Beaver Dam Mine Site and 33 km west of the Touquoy Mine Site. The footprint of this mine is approximately 160 hectares. An EARD for the project was approved in 2011; and several temporal extensions of the Approval have been granted as the Project did not commence within the approved timelines. According to the EARD (CRA, 2010), the project includes mineral extraction, milling and reclamation activities.

Spatial overlap with the following RAAs: Air, Mi'kmaq of Nova Scotia

8.4.3.1.10 National Gypsum Quarry (Present)

National Gypsum operates a large quarry in Milford Station, approximately 55 km west of the Beaver Dam Mine Site and 38 km west of the Touquoy Mine Site. It is the largest gypsum quarry in the world and was first constructed in 1955 (National Gypsum 2015). The footprint of the quarry is approximately 2.5 km by 1.1 km. It is anticipated to be in operation for the next 40 plus years.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.1.11 Murchyville Gypsum Mine (Past)

A small, approximately 275 m by 200 m, gypsum quarry is located in Murchyville, 35 km southwest of the Beaver Dam Mine Site and 18 km west of the Touquoy Mine Site. This quarry is not currently operational and is currently on care and maintenance.

Spatial overlap with the following RAAs: Air, Mi'kmaq of Nova Scotia

8.4.3.1.12 Tangier Gold Mine (Past and Future)

The Tangier Gold Mine is located approximately 29 km south of the Beaver Dam Mine Site, and approximately 28km southwest of the Touquoy Mine Site. The footprint of this mine is approximately 500 m by 150 m, as measured on Google Earth.

The area of the Tangier Gold Mine has seen mining activity since the 1860s. The existing mine began its activities in the 1980s and is currently inactive. According to a press release dated January 29, 2019, the proponent had filed a Notice of Intention to make a proposal under the *Bankruptcy and Insolvency Act* (Resource Capital Gold Corp. 2017), and was deemed officially bankrupt on July 13, 2019 (PwC Canada, 2021).

Spatial overlap with the following RAAs: Air, Mi'kmaq of Nova Scotia

8.4.3.1.13 Dufferin Gold Mine (Past, Present and Future)

The Dufferin Gold Mine is located approximately 27 km southeast of the Beaver Dam Mine Site, and 42 km east of the Touquoy Mine Site. The footprint of this mine is approximately 375 m by 150 m.

Mining has been active in this area for more than a century. The site of the Dufferin Gold Mine began activity in the 1980s and has had sporadic development over the years. In 2014, the mine operated for a short period of time before closing. It is currently under the same ownership as Tangier Gold Mine and there were plans for re-opening to begin in 2017. A bulk sampling program and associated milling was completed in 2018, but in 2019 the proponent (Resources Capital Gold Corporation) filed a Notice of intention to make a proposal under the *Bankruptcy and Insolvency Act* so future plans for this Project are uncertain.

Spatial overlap with the following RAAs: Air, Habitat and Flora, Terrestrial Fauna, Avifauna, SAR and SOCI, Mi'kmaq of Nova Scotia

8.4.3.1.14 Great Northern Timber Wood Chipping and Shipping (Present)

Great Northern Timber owns and operates a chipping and ship loading facility in Sheet Harbour, approximately 25 km southeast of the Beaver Dam Mine Site. Great Northern Timber procures wood chips and roundwood fibre from industrial landowners, sawmills, Crown lands, Private land contractors and Private woodlot management organizations in Nova Scotia, Prince Edward Island, New Brunswick and Quebec.

Spatial overlap with the following RAAs: Air, Mi'kmaq of Nova Scotia

8.4.3.1.15 Taylor Lumber Co. Ltd. Mill (Present)

Taylor Lumber Co. Ltd. has operated a mill in Middle Musquodoboit since 1945. This site, located approximately 30 km west of the Beaver Dam Mine Site and 17 km northwest of the Touquoy Mine Site, includes a saw mill, a finishing plant, a pallet plant, a power plant, a dry-kiln, and a chipping plant. The power plant is a co-generation facility that burns biomass produced from their operation that provides power to their operation as well as to homes and businesses within a 30 km radius (Taylor Lumber, 2017).

Spatial overlap with the following RAAs: Air, Mi'kmaq of Nova Scotia

8.4.3.1.16 Regional Wind Power Projects (Present)

A total of at least five Wind Power Projects (WPP) are present within the broadest RAA (Mi'kmaq of Nova Scotia) to be considered in the cumulative effects assessment. Wind power Projects within this RAA range from single turbines projects with a 1.5 MW capacity to projects with 6 turbines with a capacity of 13.8 MW. The closest WPP to the Study Area is the Sheet Harbour WPP, 24 km southeast of the Beaver Dam Mine Site. The projects reviewed include the Mulgrave WPP, Chebucto – Pockwock WPP, Sable WPP, Gaetz Brook WPP, and Chebucto Terence Bay WPP.

Given the distance between regional WPPs and the proposed Project, and the comparatively small scale of WPPs, and the limited expected residual effects of these wind projects post mitigation efforts, these projects are determined to be unlikely to contribute to cumulative effects with the Project. As such, they are not discussed in any further detail in this Cumulative Effects Assessment. These WPPs fall within the RAA for Mi'kmaq of Nova Scotia, and except at the sites of the turbines themselves, they are not believed to limit land and resource use by the Mi'kmaq of Nova Scotia.

Wind Power Projects spatially overlap with the RAA for Mi'kmaq of Nova Scotia, however these projects are not specifically considered in any VCs, based on justification provided above.

8.4.3.1.17 Porcupine Mountain Quarry (Present)

Porcupine Mountain Quarry is a large aggregate quarry located at Porcupine Mountain, near Mulgrave, Guysborough County. This aggregate quarry exceeds 200 hectares in disturbed area. It has been in operation for more than 70 years, having been used as the source of rock for construction of the Canso Causeway in the 1950s. This site is 119 km northeast of the Beaver Dam Study Area and 138 km northeast of the Touquoy Mine Site.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.1.18 Mosher Lake Limestone Co. (Present)

Mosher Limestone processing facility is located approximately 20 km northwest of the beaver Dam Mine Site Dam Mine and 16 km north of the Touquoy Mine Site. Mosher Limestone processes and sells limestone products in Nova Scotia and Atlantic Canada. Products include pelletized limestone, powdered limestone, granular limestone, powdered gypsum, pelletized gypsum, and traction sand. The processing facility crushes, packages and ships product.

Spatial overlap with the following RAAs: Air, Mi'kmaq of Nova Scotia

8.4.3.1.19 Great Northern Timber Pellet Facility (Present)

Great Northern Timber Group owns and operates a wood pellet manufacturing facility at Upper Musquodoboit – Great Northern Pellets, since 2017, located approximately 21 km northwest of the Beaver Dam Mine Site and 16 km north of the Touquoy Mine Site. The plant has had a capacity for processing 60,000 tons of wood pellets per year. Past operators shipped product to Europe through the Port of Halifax.

Spatial overlap with the following RAAs: Air, Mi'kmaq of Nova Scotia

8.4.3.1.20 Goff's Quarry Expansion (Present and Future)

Scotian Materials currently operates a quarry on private land, approximately 70 km southwest of the Beaver Dam Mine Site and 52 km southwest of the Touquoy Mine Site. Currently, the quarry is permitted under an industrial approval, as it operates under 4.00 ha. Scotian Materials has submitted an EA registration document to expand the quarry to approximately 41 hectares, extending the life of the quarry by an estimated 25-50 years.

A provincial EA was registered August 7th, 2018 for the proposed undertaking. The Minister released a decision on September 25th, 2018 requesting additional information. On 25 October 2019, the Minister granted Approval for a 14-ha expansion (Phase 1 and Phase 2) of the Project described in the registration document, to ta total quarry footprint of 18 hectares. Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.1.21 Lake Major Dam Replacement (Present)

On December 16, 2016, Halifax Water submitted a provincial Environmental Assessment Registration Document for the replacement of a dam on Lake Major in Halifax County. The Project is located 55 km southwest of the Touquoy Mine Site and 70 km southwest of the Beaver Dam Mine Site. The Minister approved the Project on February 9th, 2017, subject to a number of conditions.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.1.22 Loch Katrine Quarry (Present and Future)

On November 2nd, 2016, Dexter Construction Company Limited submitted a provincial Environmental Assessment Registration Document. The proposed undertaking involves an expansion of the existing 3.94 ha aggregate quarry in Loch Katrine, Guysborough County. The expanded quarry will occupy a maximum footprint of 27.3 ha, providing aggregate for road and local construction industries for up to 40 years. This site is located 73 km northeast of the Beaver Dam Mine Site and 90 km northeast of the Touquoy Mine Site. This project was granted ministerial approval on December 22nd, 2016.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.1.23 Chedabucto Aggregates Quarry (Present and Future)

On September 17th, 2014, Chedabucto aggregates Limited submitted a provincial Environmental Assessment Registration Document. The proposed undertaking involves an expansion of the existing hectares aggregate quarry in Queensport, Guysborough County to a maximum size of 11.4 ha. This site is located 113 km northeast of the Beaver Dam Mine Site and 130 km northeast of the Touquoy Mine Site. This project was granted ministerial approval on November 6th, 2014.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.1.24 Highway 107 – Bedford to Burnside (Present)

In June of 2017, Nova Scotia Transportation and Infrastructure Renewal submitted a provincial Environmental Assessment Registration Document for the construction of an extension to Highway 107, from Bedford to Burnside. The Project involves construction of a four-lane highway, approximately 9km in length, connecting Akerley Boulevard and Burnside Drive to the west end of Duke Street. This project also proposes to widen approximately 1.5 km of Duke Street in Bedford which leads to Highway 102. On August 25th, 2017, the Minister released a decision requesting supplemental information. This was provided on June 18, 2018, and the Project was approved on August 7th, 2018.The registration document submitted in June 2018 proposed a construction schedule of 5 years (2018-2022). The project lies approximately 63 km southwest of the Touquoy Mine Site and 80 km southwest of the Beaver Dam Mine Site. Construction commenced on this project in September 2019.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.2 Future Physical Activities (Certain, Reasonably Foreseeable or Hypothetical)

It is expected that the forestry industry will continue into the foreseeable future throughout the RAA for Mi'Kmaq of Nova Scotia (the largest RAA). The mining industry could become more active if the price of minerals, notably gold, increases. This could hypothetically lead to the expansion of existing projects or the proposal of other new mining projects as exploration for mining is active in the region.

In addition to the ongoing forestry industry and the potential increase in general mining activities, two projects proposed by the Proponent, the Fifteen Mile Stream Mine Project and the Cochrane Hill Gold Project that are associated with the Touquoy Mine Site were identified as potential future projects. Neither project has been approved, as they are both currently undergoing federal environmental assessments; they are therefore determined as reasonably foreseeable projects for the purpose of this CEA.

8.4.3.2.1 Cochrane Hill Gold Project (Future)

The proposed Cochrane Hill Gold Project comprises of the development, operation, closure and reclamation of a surface gold mine in association with the Touquoy mine, which would produce approximately two million tonnes of gold-bearing ore a year. The Cochrane Hill surface mine is located within Guysborough County, in central Nova Scotia, approximately 145 km northeast of Halifax, and 62 km northeast of the Beaver Dam Mine Project. The property covers the historic Cochrane Hill Gold District located on NTS sheets 11E01/D, 11E08/A, and 11E05/B. Concentrate from Cochrane Hill Mine Site will be trucked to the Touquoy Mine Site for processing, along with FMS concentrate and ore from Beaver Dam. This proposed transportation route includes the use of the Beaver Dam Haul Road.

Processing the gold concentrate produced the Cochrane Hill Gold Project at the Touquoy facility will eliminate the need for a separate processing facility at the Cochrane Hill Mine Site. It is anticipated that 350,000 tonnes of tailings would be deposited into the Touquoy exhausted pit as a result of processing the gold concentrate from the Cochrane Hill Gold Project.

To facilitate the processing of the gold concentrate produced at the Cochrane Hill Mine Site, minor changes to the Touquoy facility would be needed. Additional concentrate storage and the addition of a second gravity concentrate leach reactor and a gravity electrowinning cell would have to be added. However, all of these items can be accommodated within existing footprint at the Touquoy mine.

There is also potential for cumulative effects associated with the effects resulting from the continued use of the Touquoy Mine Site. The residual effects for the Cochrane Hill Gold Project resulting from use of the Touquoy Mine Site would be a temporal extension

of the residual effects defined for the Touquoy Gold Project. The cumulative impacts of the addition of the Cochrane Hill Gold Project must take into account the extension of the temporal boundaries for the effects at the Touquoy Mine Site, alongside the same extension from the Project and the Beaver Dam Mine Project. Also, any such effects that are lasting could accumulate over time. Possible cumulative effects on the VCs are summarized in Table 8.4-2.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.2.2 Beaver Dam Haul Road use by the Project, Cochrane Hill (Future), Beaver Dam Mine Project, and Forestry Activities (Future)

The gold concentrate from the Cochrane Hill Mine Site and FMS Mine Site as well as ore from the Beaver Dam Mine Site will be transported to the Touquoy Mine Site for processing. The Beaver Dam Haul Road is proposed for construction as part of the Beaver Dam Mine Project, at which point, it will be used to transport ore and concentrate from the Project to the Touquoy Mine Site. A total of 190 return trips are expected to travel on the Beaver Dam Mine Haul Road to facilitate transportation of Beaver Dam ore to the Touquoy Mine Site. Both Cochrane Hill and FMS Projects will contribute an additional 11 return trips each per day.

In addition, the Haul Road may also occasionally be used by forestry harvesters in the local area. In addition to 7 return trips by forestry trucks estimated per day, it is estimated 3/4-ton service trucks would make up to approximately 20 round trips per day on the haul roads.

The Project Team was unable to ascertain specific data regarding schedule or frequency of cutting within this area, or the resulting number of trucks that could be present from harvesting activities in the same temporal boundary as the projects as the Beaver Dam, Fifteen Mile Stream and Cochrane Hill Projects. As a result, this activity has been evaluated in a qualitative way as part of this cumulative effects assessment, where possible, given the data limitations.

The possible cumulative effect includes an expected increase in traffic on the Beaver Dam Haul Road between Highway 224 and the Mooseland Road, and the small contribution of each project to the overall disturbance of natural habitats at the regional scale for both humans (traditional usage and local residents) and flora and wildlife.

Spatial overlap with the following RAAs: All VCs

8.4.3.2.3 Goldboro Gold Mine (potential Future)

In August 2018, Anaconda Mining Inc. submitted a provincial Environmental Assessment Registration Document for construction and operation of a gold mine in Goldboro, Guysborough County. This site is approximately 86 km east of the Beaver Dam Mine Site, and 100 km east of the Touquoy Mine Site. Based on the project description available in the 2018 EARD, the proposed Project would involve operation of surface and underground mine facility producing 575 tonnes per day, 24 hours/day, 7 days/week, within a project footprint of approximately 126 ha. An on-site concentrator and tailings facility would be built as well. The proposed Project timeline involved production commencing in 2020, with project completion occurring in 2029, pending approval. On September 19th, 2018, the Minister released a decision, indicating that additional information would be required before approval could be granted. The Minister released terms of reference for a Focus Report to be submitted by the Proponent. The proponent withdrew their Environmental Assessment Registration Document on September 16, 2019.

The Goldboro area has been an active and productive mining area around the turn of the century from 1893-1910. There are historic mine workings as well as contamination throughout the area due to this history of mining.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.2.4 Sheet Harbour Quarry (Future)

On January 31st, 2019, Dexter Construction registered an Environmental Registration Document with Nova Scotia Environment. The Minister released a decision on November 8th, 2019, approving the proposed undertaking. It is unknown whether the project has commenced. The Project is located in the community of Mushaboom, Halifax, County, Nova Scotia, approximately 26 km south of the Beaver Dam Mine Site, 6.6 km south of the community of Sheet Harbour, and 4 km southwest of the Port of Sheet Harbour. The total infrastructure footprint of the project is approximately 85 ha.

The purpose of the undertaking is to meet local and regional aggregate demand for projects carried out by Dexter Construction in the Sheet Harbour regional area. There is future potential for aggregate material to be sold offshore using the Port of Sheet Harbour as a shipping point. This quarry will replace existing smaller quarries in the region that are nearly exhausted and will be reclaimed. The extractable reserves in the quarry as designed is anticipated to be 50 plus years with production commencing at approximately 50,000 tonnes per year and increasing to 500,000 tonnes per year by Year 16 depending on markets.

Site activities will include the drilling, blasting, crushing, stockpiling, and transporting by trucks of aggregate for sale or for use in projects that are contracted to Dexter Construction. The operation will consist of a lay down area for the portable crushing equipment and screens, various aggregate stockpiles, and weigh scales, as well as the physical features of the site such as the quarry floor and active working faces, and site settling pond(s).

Assuming the mitigation, monitoring, and progressive reclamation measures specified in this report are implemented, and the quarry is operated according to provincial guidelines and approvals, no significant adverse residual environmental or socio-economic effects are likely. Effects are expected to be of small spatial magnitude, low frequency, short duration, and/or limited geographical extent. Operation of the quarry will result in economic benefits, including employment and an economic source of quality aggregates to local demand markets.

Environmental effects will include the loss of some habitat within the proposed quarry property area. The property has been the subject of past forestry- activities.

Localized impacts on air quality can be expected through the formation of airborne particulate matter. These impacts are readily controlled through standard mitigation measures (e.g., dust suppression) and follow-up monitoring as necessary to ensure compliance with the Pit and Quarry Guidelines at the property boundaries.

Spatial overlap with the following RAAs: Air, Mi'kmaq of Nova Scotia

8.4.3.2.5 Black Point Quarry (Future)

On March 4th, 2014, Black Point Aggregates Inc. submitted a Provincial Environmental Assessment Registration Document and federal EIS for the operation of a granite quarry in Guysborough County. It is located 180 km east of the Beaver Dam Mine Site and 143km northeast of the Touquoy Mine Site. On April 26, 2016 federal and provincial approval was granted for this project to proceed. On March 29th, 2018, the Minister authorized an extension for the commencement of work. The Proponent must commence work on or before April 26th, 2020 unless granted an extension by the Minister. It is uncertain whether an extension was sought, or has been granted by the minister; so this Project will remain in this list as reasonably foreseeable in an effort to be conservatively inclusive.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.2.6 Bearpaw Pipeline (Future)

On March 30th, 2016, Bear Paw Pipeline Corporation Inc. submitted a provincial Environmental Assessment Registration Document for the construction and operation of a 62.5 km high pressure steel natural gas pipeline from Goldboro to the future location of the Bead Head LNG liquefied natural gas export facility in Richmond County, Nova Scotia. The project will include a compressor facility to deliver natural gas pressure to Bear Had LNG. On November 2nd, 2016, the Proponent submitted an addendum to the Registration Document. The Minister granted approval to this project on December 22nd, 2016. The western extent of this proposed pipeline in in Goldboro, approximately 86 km east of the Beaver Dam Mine Site, and approximately 100 km northeast of the Touquoy Mine Site. The proposed pipeline route runs northeast across Guysborough County towards the Strait of Canso.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.2.7 Goldboro LNG Facility (Future)

In September 2013, Pieridae Energy (Canada) Ltd. submitted a provincial Environmental Assessment Registration Document for the construction and operation of a Natural Gas Liquefaction Plant and Marine Terminal in Goldboro, Guysborough County. The Project received ministerial approval on March 21, 2014, and an extension for the commencement of work on October 24, 2017. The proponent must commence work on or before March 21, 2019, unless granted an extension by the Minister. This site is approximately 86 km east of the Beaver Dam Mine Site, and 100 km east of the Touquoy Mine Site.

Associated with this project, Pieridae Energy (Canad) Ltd. submitted a provincial Environmental Assessment Registration Document for the Realignment of Marine Drive (Highway 316) project on March 10, 2021. The purpose of this project is to permanently re-align approximately 3.5 km of the existing Marine Drive (Highway 316) around the proposed Goldboro LNG Project site. This project is pending a decision from the Minister.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.2.8 Canso Spaceport Facility (Future)

Maritime Launch Services Ltd. (MLS) has proposed to construct and operate a private commercial space launch site near the communities of Little Dover, Hazel Hill, and Canso, within the Municipality of the District of Guysborough (MODG) of Nova Scotia. The purpose of the Project is to establish a commercially-controlled, commercially-managed, launch site that would provide launch site options in North America, in support of the growing commercial space transportation industry. The site location is approximately 140 km northeast of the Beaver Dam Mine Site and 155 km northeast of the Touquoy Mine Site.

The Project will be situated on a portion of Crown Land designated by Property Identification Number (PID) 35096320 and consist of three components; the Launch Control Center (LCC), the Horizontal Integration Facility (HIF), and the Vertical Launch Area (VLA) connected by a transportation route. Access to the Project site is expected to coincide, in part, with the access road to the Sable Wind Farm, owned and operated by the MODG, in partnership with Nova Scotia Power.

A provincial EA was registered in June of 2018 for the proposed undertaking. The Minister released a decision in August 2018 requesting additional information. A focus report was submitted on March 11th, 2019, and Minister issued an Approval for the Project on June 4, 2019.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.2.9 Waste Dangerous and Non-Dangerous Goods Temporary Storage Facility (Future)

On August 7 2019, Envirosystems Incorporated (Envirosystems) registered an environmental assessment for the Waste Dangerous and Non-Dangerous Goods Temporary Storage Facility at 11 Brownlow Avenue in Burnside, NS. The Minister decided additional information was required to make a decision on this Project. On 11 February 2020, the Minister decided to approve the undertaking. The project lies approximately 63 km southwest of the Touquoy Mine Site and 78 km southwest of the Beaver Dam Mine Site. The Project involves construction and operation of a new waste dangerous and non-dangerous goods temporary storage facility (Storage Facility) at their existing site at 11 Brown Avenue, a fully permitted Used Oil Collection and Storage operation (Approval No. 2001-024626-R10). The existing site is approximately 20,940 square metres (m^2) in size with the proposed facility occupying roughly 1.55% of the site.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.2.10 Liquid Asphalt Storage Facility (Future)

On 1 May 2020, General Liquids Canada and the municipal Group of Companies registered an environmental assessment document for a proposed Liquid Asphalt Storage Facility Project. This facility is proposed to be located on Pleasant Street in Dartmouth, which is approximately 61 km southwest of the Touquoy Mine Site and 76 km southwest of the Beaver Dam Mine Site. This facility would allow transferring, storage and preparation of liquid asphalt for shipment. On 22 June 2020, the Minister decided to approve the undertaking, subject to a number of conditions.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.3.2.11 Highway 102 Aerotech Connector Road Project (potential Future)

On 20 September 2019, Nova Scotia Transportation and Infrastructure Renewal submitted a provincial Environmental Assessment Registration Document for the construction of a connector road from Highway 102 Aerotech Interchange (Exit 5A) to Trunk 2 in Wellington. This 5km connector road is designed as a four-lane road. According to the registration document, the project may commence in 2020 and is expected to take 5 years to complete. The Minister of Environment approved this undertaking on January 5, 2021. The project lies approximately 52 km southwest of the Touquoy Mine Site and 68 km southwest of the Beaver Dam Mine Site.

Spatial overlap with the following RAAs: Mi'kmaq of Nova Scotia

8.4.4 Confirmation of Valued Components to be Carried Forward Cumulative Effects Assessment

The three steps listed above include identification of the valued components, determination of spatial and temporal boundaries, and identification of past, present and future physical activities or projects relevant to the selected VCs based on identified RAAs for each VC. This exercise allowed for the identification of pathways for potential cumulative effects per VC based on:

- The extent of predicted Project effects on each VC;
- Potential extent of other Projects' impacts based on publicly available or published data;
- The timeframe of Project impacts;
- The timeframe of other Projects potential impacts, based on publicly available or published data; and,
- Types of potential cumulative effects (additive, synergistic, compensatory and masking).

This fourth step takes these confirmed pathways and potential intersections with other Projects, and then identifies which VCs will be brought forward to the CEA, based on the following criteria:

- level of concern noted during engagement;
- current state of the VC (health/status/condition);
- potential for significant cumulative effects with other projects as identified for each VC; and
- uncertainty in predictions of cumulative effects especially project knowledge and data limitations.

As described in Table 8.4-2 the following VCs warrant further assessment:

- Physical Environment:
  - Air;
  - Noise;
  - Light; and
  - Surface Water Quality and Quantity.
- Biophysical Environment:
  - Fish and Fish Habitat; and
  - Species of Conservation Interest and Species at Risk.
- Socio-Economic Environment:
  - Mi'kmaq of Nova Scotia.

Noise and light VCs associated with the defined Beaver Dam Project do not trigger evaluation of cumulative effects based on confirmed Project Areas and VC spatial boundaries (RAAs) and locations of other identified projects. However, due to the proposed interactions of the Fifteen Mile Stream Project with the Project and Cochrane Hill Gold Project, as well as forestry trucking activities, relating to the use of the Beaver Dam Haul Road for transportation of gold concentrate from the Project, the noise and light VCs are carried forward to evaluation for cumulative effects herein only in consideration of the plan to use the Beaver Dam Haul Road for transportation of gold concentrate to the Touquoy Mine Site. Trucks associated with the transportation of this concentrate have additive cumulative potential for increased dust, light intrusion into the forest, and noise when considered with the Beaver Dam Haul Road truck traffic, and also the truck traffic associated with the proposed Cochrane Hill Gold Project (additional transportation of gold concentrate using this Haul Road) and potential forestry traffic.

SAR/SOCI is being evaluated with regards to cumulative effects for rare species, including Avifauna. As such, cumulative effects to migratory birds more generally will be addressed through the effects assessment for Avifauna SAR.

Table 8.4-2: Selection of Valued Components for the Cumulative Effects Assessment

Project VC	Residual Adverse Effects	EIS Finding	Boundaries		Criteria for Determining Whether Further Assessment Is Required			Carried Forward to Cumulative Effects Assessment		
			Spatial – Geographical Extent of Residual Effects	Temporal - Timeframe Associated with Residual Effects	Level of Concern Noted During Engagement	Current State of The VC (Health/Status/ Condition)	Potential for Cumulative Effects: Screening Evaluation Summary	Uncertainty in Prediction of Cumulative Effects	Yes/No	Rationale
Noise	Increased ambient noise	Not Significant	Residual effects related to ambient noise levels are not anticipated to extend outside the LAA	Residual effects to ambient noise levels may occur throughout the duration of the project including Construction, Operation and Active Closure	Medium. Local residents and Mi'kmaq are concerned with potential noise from the mine. Noise along the Beaver Dam Haul Road is a concern for the Millbrook First Nation and local residents.	Good. Project noise is predicted to be in compliance with the Pit and Quarry Guideline nighttime guideline of 55 dBA at the proposed property boundaries for the Beaver Dam Mine Site, the Haul Road and the Touquoy Mine Site.	No. It is likely that forestry operations will occasionally coincide with those of the Beaver Dam Mine Project within the RAA and cause increased ambient noise levels, compared to the levels that these operations produce individually. However, such additive periods are likely to be limited in duration and frequency and are not expected to be significant. The NSSA AMP overlaps with the Noise RAA, however with the exception of annual helicopter deposition of limestone over a several week period, the project does not generate noise. No other projects were identified within the RAA for noise. Cumulative effects of transportation of gold concentrate from Fifteen Mile Stream Gold Project, the Cochrane Hill Gold Project and forestry activity, together with the Project, is possible (trucking on Beaver Dam Haul Road)	Moderate. The principal assumption behind the potential of significant cumulative effects is that local forestry practices will not change in any substantial, meaningful way throughout the Project. This assumption is considered as having a moderate uncertainty. No data was available to confirm this statement.	Yes.	The predicted cumulative effects are not anticipated to be significant and the residual effects of the Project are anticipated to revert back to baseline conditions upon completion of the project. However, due to potential for cumulative effects of trucking on the Beaver Dam Haul Road, further evaluation is warranted specific to this location only.
Air	Increased ambient dust	Not Significant	Residual effects related to air quality are not anticipated to extend outside the LAA.	Residual effects to ambient air quality levels may occur throughout the duration of the project including Construction, Operation, and Active Closure	Medium to high. Concerns were specifically expressed by the Mi'kmaq relating to atmospheric environment include potential dust from mining operations at the Beaver Dam Mine Site and Touquoy Mine Site for traditional practices Dust along the Beaver Dam Haul Road is a concern for the Millbrook First Nation and local residents.	Good. Concentrations of all parameters are predicted to be in compliance with appropriate regulatory criteria at the proposed property boundaries for the Beaver Dam Mine Site and Haul Road. Compliance will be reached through the application of chemical dust suppressants along the Haul Road (proposed 80% dust suppression). There are no predicted impacts from the Project at the Touquoy Mine Site.	No. It is likely that forestry operations will occasionally coincide with those of the Beaver Dam Project and cause increased ambient dust levels, compared to the levels that these operations produce individually. However, such additive periods are likely to be limited in duration and frequency and are not expected to be significant. Cumulative effects of transportation of gold concentrate from Fifteen Mile Stream Gold Project, the Cochrane Hill Gold Project and forestry activity, together with the Project, is possible (trucking on Beaver Dam Haul Road)	Moderate. The principal assumption behind the potential of significant cumulative effects is that local forestry practices will not change in any way throughout the Project. This assumption is considered as having a moderate uncertainty. No data was available to confirm this statement.	Yes.	Further assessment is required to determine if there is the possibility of significant residual cumulative effects to Air at the Beaver Dam Mine Site. Also, due to potential for cumulative effects of trucking on the Beaver Dam Haul Road, further evaluation is warranted specific to this location.
Light	Increased ambient light	Not Significant	Residual effects related to ambient light levels are not anticipated to extend outside the RAA.	Residual effects to ambient light levels may occur throughout the duration of the project including Construction, Operation and Active Closure.	Medium. Local residents and Mi'kmaq are concerned with potential light from the Beaver Dam Mine Site Light intrusion into the forest along the Beaver Dam Haul Road is a concern for the Millbrook First Nation and local residents.	Good. The RAA is a rural area and is mostly wooded. Ambient nighttime light conditions would be minimal and typical of an undeveloped rural area. There are no predicted impacts from the Project at the Touquoy Mine Site	No. It is likely that forestry operations will occasionally coincide with those of the Beaver Dam Mine Project and cause increased ambient light levels, compared to the levels that these operations produce individually. However, such additive periods are likely to be limited in duration and frequency and are not expected to be significant. Cumulative effects of transportation of gold concentrate from Fifteen Mile Stream Gold Project, the Cochrane Hill Gold Project and forestry activity, together with the Project, is possible (trucking on Beaver Dam Haul Road)	Moderate. The principal assumption behind the potential of significant cumulative effects is that local forestry practices will not change in any way throughout the Project. This assumption is considered as having a moderate uncertainty. No data was available to confirm this statement.	Yes.	The predicted cumulative effects are not anticipated to be significant and the residual effects of the Project are anticipated to revert back to baseline conditions upon completion of the project. However, due to potential for cumulative effects of trucking on the Beaver Dam Haul Road, further evaluation is warranted specific to this location only.
GHG	Increased greenhouse gas emissions	Not significant	Residual effects related to GHG emissions are anticipated to extend throughout the RAA (the Province of Nova Scotia)	Residual effects to GHGs may occur throughout the duration of the project including Construction, Operation and Active Closure.	Limited concern has been noted specific to greenhouse gas emissions associated with the Project	Good. The total GHG emissions from Nova Scotia were identified to be 17,000 kilotonnes CO_2e during 2018, which achieved the legislated reduction goal of 10% below 1990 levels by 2020	No. All phases from this project would represent approximately 0.128% of the total GHG emissions for Nova Scotia. It is therefore considered that the proposed project contributes very little to the overall cumulative effects of regional industry to GHG emissions.	Low. Although there is some uncertainty in levels of GHG emissions, there is good confidence in the fact that the Beaver Dam Mine will only contribute a small percentage for Nova Scotia.	No.	As the predicted cumulative effects are not anticipated to be significant and given the small contribution of the Beaver Dam Project to total GHG emissions, the effects with and without the project are very similar. Therefore, no further assessment is warranted.

Table 8.4-2: Selection of Valued Components for the Cumulative Effects Assessment (continued)

Project VC	Residual Adverse Effects	EIS Finding	Boundaries		Criteria for Determining Whether Further Assessment Is Required			Carried Forward to Cumulative Effects Assessment		
			Spatial – Geographical Extent of Residual Effects	Temporal - Timeframe Associated with Residual Effects	Level of Concern Noted During Engagement	Current State of The VC (Health/Status/ Condition)	Potential for Cumulative Effects: Screening Evaluation Summary	Uncertainty in Prediction of Cumulative Effects	Yes/No	Rationale
Geology, Soil and Sediment Quality	Erosion, soil and sediment quality, (i.e. flora and fauna/habitat, etc.)	Not Significant	Residual effects related to erosion, soil and sediment quality are not anticipated outside of the Beaver Dam Study Area.	Residual effects to Geology, Soil and Sediment Quality may occur throughout the duration of the project including Construction, Operation and Active Closure.	Medium. Concerns were expressed relating to potential ARD, suspended solids and mobilization of historical tails from the Beaver Dam Mine Site, which may affect receiving water and its fish habitat.	Good. Based on a number of conservative assumptions, the results indicate that there is very low potential for acidic conditions to occur during operations. During closure phase, there is potential for acidic conditions to occur, however, through mitigation these conditions can be mitigated. Historical tailings present at Beaver Dam Mine Site will be delineated, tested and managed on site before new mining activities commence. Options for disposal on-site or off-site are being considered in conjunction with regulatory consultation.	No. Potential cumulative effects related to sediment release are not anticipated. Historic Beaver Dam mining operations, forestry, haul road usage and the NSSA AMP are the only activities identified within the RAA for Soil, Sediment and Geology. Effects of historic tailings will be mitigated during construction including "working in the dry" and effective water management. Effects of forestry on sediment transport are expected to be minimal, providing forestry operators adhere to Provincial Wildlife Habitat and Watercourse Protection Regulations. Furthermore, FMS Mine Site erosion and sedimentation control measures will have a localized compensatory effect of any sediment release from local forestry activities. Therefore, it is unlikely that other projects would interact with this VC.	Low. Based on the residual effects being confined to the Beaver Dam Mine Site and Haul Road, with proper mitigation, it is unlikely that other projects would interact with this VC. This assumption is considered as having a low uncertainty.	No.	As the predicted cumulative effects are not anticipated to be significant with only two projects overlapping spatially with the Project, and the residual effects of the Project are anticipated to limited to the Beaver Dam Mine Site and Haul Road, no further assessment is warranted.
Groundwater Quality and Quantity	Disturbance to groundwater quality and quantity	Not Significant	The potential for residual groundwater quality effects are limited to the PA.	Residual effects to groundwater quality and quantity may occur throughout the duration of the project including Construction, Operation and Active Closure.	Medium. Concerns were expressed regarding groundwater drawdown and potential effects on surface water and potential impacts to potable wells at the Beaver Lake IR. The nearest potable well is 5km south of the Beaver Dam Mine Site (drilled well Beaver Lake IR).	Good. Maximum radius of influence (groundwater drawdown) is predicted at 1000 m (to the south) from the pit during operations, and less that this during closure, when the pit is re-filling with water. The nearest potable well is 5 km south of the Project. Groundwater seepage has been predicted through modelling efforts and these seepage rates have been included in operational and closure surface water modelling efforts to understand potential effect of groundwater seepage on surrounding surface water features for both the Beaver Dam Mine Site and the Touquoy Mine Site.	No. Historic mining activities within the PA, haul road usage, forestry and the NSSA AMP are the only projects within the RAA for groundwater quantity and quality. Potential cumulative effects on groundwater are not anticipated at the mine site because of the lack of other activities affecting this VC at this location. Furthermore, the potential groundwater seepage at the Touquoy site has been evaluated as part of the surface water VC.	Low. Uncertainty will be addressed through the monitoring and follow-up programs established for the Project.	No.	The predicted cumulative effects are not anticipated to be significant due to the spatial boundaries of the residual effects (zone of influence for groundwater interactions). Therefore, no further assessment is warranted.
Surface Water Quality and Quantity	Change in Water Quality and Quantity Habitat Loss and disturbance	Not Significant	The potential for residual surface water quality and quantity effects are limited to the PA and LAA.	Residual effects to surface water quality and quantity may occur throughout the duration of the project including Construction, Operation and Active Closure phases, along with the Post Closure phase when water monitoring and possible treatment is on-going.	Moderate to high. Key issues raised during stakeholder engagement was the concern about effect on water quality and quantity in downstream receiving environments and associated potential effect on fish.	Moderate. All mine contact water during operations will be directed to the North Settling Pond for treatment as required prior to release. Discharge water will meet MDMER at the end of pipe. There is a 100 m modelled mixing zone from the water discharge point within Cameron Flowage/Killag River at which point, water quality will meet CCME/Tier I, background and/or Site Specific Criteria. During closure, a cover planned for the PAG stockpile to improve water quality.	Yes. Historic mining activities within the PA, timber harvesting, Haul Road usage and the NSSA Acid Mitigation Projects are located within the RAA for surface water. Cumulative impacts based on forestry are expected to be low, providing forestry operators adhere to Wildlife Habitat and Watercourse Protection legislation. There is potential for cumulative effects between the Project and NSSA Acid Mitigation Project. The Project will adhere to all applicable water quality guidelines. However, the use of the Touquoy processing plant and deposition of tails into the exhausted pit at Touquoy extends the temporal scale of potential effects to surface water. Deposition of tails into the exhausted pit must be considered for cumulative effects. Also, the Project may require an extension to the use of Scraggy Lake as one of the sources of fresh water to process concentrate. The cumulative effect of the combined projects could mean a reduction in the streamflow from Scraggy Lake to the Fish River system. In addition, subsequent deposition of tails into the exhausted Touquoy Pit will result in release of discharge into the Moose River once the pit has filled.	Low. Uncertainty will be addressed through refinement of modelling, and the monitoring and follow-up programs established for the Project.	Yes	Further assessment is required to determine if there is the possibility of significant residual cumulative effects to Surface Water Quality and Quantity at both the FMS Mine Site and the Touquoy Mine Site.

Table 8.4-2: Selection of Valued Components for the Cumulative Effects Assessment (continued)

Project VC	Residual Adverse Effects	EIS Finding	Boundaries		Criteria for Determining Whether Further Assessment Is Required			Carried Forward to Cumulative Effects Assessment		
			Spatial – Geographical Extent of Residual Effects	Temporal - Timeframe Associated with Residual Effects	Level of Concern Noted During Engagement	Current State of The VC (Health/Status/ Condition)	Potential for Cumulative Effects: Screening Evaluation Summary	Uncertainty in Prediction of Cumulative Effects	Yes/No	Rationale
Wetlands	Habitat loss and disturbance	Not Significant	The potential for residual effects to wetlands are limited to the PA and LAA. No change in footprint at the Touquoy Mine Site is required for the Project.	Residual effects to wetlands may occur throughout the duration of the Project including Construction, Operation and Active Closure.	Low-moderate. Key issues raised during stakeholder engagement was the concern about wetlands being impacted at the Project and future compensation, and potential reduction in habitat, water quality and flood control due to loss of wetlands.	Good. Wetlands within the PA generally offer high quality wildlife habitat and water quality and quantity functions. 95% of all wetlands assessed were determined to provide moderate-high plant community integrity with a diversity of species generally composed of native species characteristic of the wetland type. Wetlands within the PA, have experienced disturbance from historic mining activity and timber harvesting in adjacent uplands.	No. The loss of wetlands from the PA results in a direct loss of 31.8 ha of wetlands which will require compensation under the Nova Scotia Wetland Conservation Policy. A cumulative wetland loss assessment exercise was carried out in Section 6.8.7.2, which determined that there was no expected significant effect on wetland loss within the LAA. Within the RAA, other activities are limited to historic mining and forestry. Effects of historic tailings will be mitigated. Effects of forestry on sediment transport are expected to be minimal, providing forestry operators adhere to Provincial Wildlife Habitat and Watercourse Protection Regulations and the Nova Scotia Wetland Conservation Policy. No additional wetland impacts are proposed at the Touquoy Mine Site.	A moderate level of uncertainty exists in the potential effect of Project changes to local hydrology and resultant impacts to wetlands. Little to no uncertainty exists related to direct wetland impacts. The potential cumulative effects (loss of wetlands within the Project footprint) is based on the planned footprint of the Project which is unlikely to change.	No.	The predicted cumulative effects are not anticipated to be significant due to the limited spatial boundaries of the residual effects (LAA) and the magnitude of these effects (Moderate). Therefore, no further assessment is warranted
Fish and Fish Habitat	Habitat loss and disturbance Decreased water quality and quantity	Not Significant	The potential for adverse residual effects to fish and fish habitat is limited to the PA and LAA.	Residual effects to fish and fish habitat may occur throughout the duration of the project including Construction, Operation and Active Closure along with the Post Closure phase when water monitoring and possible treatment is on-going.	Moderate to High. Key issues raised during public and Mi'kmaq engagement relating to fish and fish habitat include potential impacts to the Nova Scotia Southern Uplands population of Atlantic Salmon; based on proximity of the Project to the Killag River, and Acid Mitigation Projects being completed by the Nova Scotia Salmon Association, and potential indirect effects from wetland alteration or changes to surface water and groundwater quality and quantity on fish and fish habitat.	Moderate. Habitat quality within the areas proposed for direct impact do not provide suitable habitat for coldwater species and comprise anthropogenically altered habitat within the proposed open pit. High temperatures and low pH are limiting factors to fish habitat quality. Suitable habitat for a variety of species including Atlantic Salmon is present within the Killag River, immediately downstream of the proposed Project.	Yes. Within the RAA, other activities are limited to historic mining and forestry, and the ongoing Acid Mitigation Project operated by the Nova Scotia Salmon Association. Effects of historic tailings will be mitigated. Effects of forestry on sediment transport are expected to be minimal, providing forestry operators adhere to Provincial Wildlife Habitat and Watercourse Protection Regulations. Potential interaction between the Project and the NSSA works require further evaluation of cumulative effects. Site infrastructure has been micro-sited for fish habitat avoidance wherever practicable Development of the Beaver Dam Pit and associated mine infrastructure will require direct impact to fish habitat. A Fish Habitat Offset Plan has been developed to facilitate compensation for direct and indirect impacts to fish habitat (Appendix J.3)	Moderate. The uncertainty of cumulative effects to fish habitat will correspond with the level of detailed information available from the Nova Scotia Salmon Association. The uncertainty as to the Project effects on fish and fish habitat would be addressed through monitoring and follow-up programs established for the Project.	Yes.	Although the potential for significant cumulative effects to fish and fish habitat is not anticipated given appropriate mitigation, the VC was carried forward due to the concern expressed relating to fish and fish habitat including the proximity to the Killag River, and its population of southern uplands Atlantic Salmon.
Habitat and Flora	Habitat loss and disturbance	Not Significant	The potential for adverse residual effects to habitat and flora is limited to the PA and LAA. No change in footprint at the Touquoy Mine Site is required for the Project.	Residual effects to habitat and flora may occur throughout the duration of the Project including Construction, Operation and Active Closure phases.	Low-moderate. Concerns were raised during public and Mi'kmaq engagement relating to habitat and flora include potential effect on biodiversity and loss of habitat associated within the PA.	Moderate. Ecosites are predominantly poor to medium nutrient regimes with acidic soils and dominated by mixedwood and conifer forest stands. Historical mining and disturbances from timber harvesting have affected the habitat and flora communities with the PA.	No. Projects which lie within the RAA for Habitat and Flora include current and proposed mining activities at Touquoy Gold Project, historic mining at the Beaver Dam Mine Project and Dufferin Gold Mine, future mining activities at Fifteen Mile Stream, Nova Scotia Salmon Association's Acid Mitigation project (3 components), along with various regional forestry activities. Project effects on Habitat and Flora for the Beaver Dam Mine Site are limited to the LAA, which does not overlap the LAA for the proposed Project. While spatial boundaries for potential residual effects for the Dufferin Project were not available, it is expected that effects to habitat and flora would occur on a similar spatial scale to the proposed Project (2km buffer of the Study Area). Provided this is a reasonable assumption, project effects to Habitat and Flora would not overlap spatially. The Dufferin Project is not expected to overlap temporally with the proposed Project either, as the Proponent for the Dufferin Project has declared bankruptcy. The lime dosing stations operated by the Nova Scotia Salmon Association are not expected to have a significant interaction with terrestrial flora and habitat; however, the potential interaction between the terrestrial liming and flora is unknown. Any interaction between terrestrial liming and rare flora will be discussed in the cumulative effects assessment for SAR and SOCI. Forestry activities within the RAA could result in a cumulative impact to habitat and flora.	Moderate uncertainty. The generalized disturbance of the landscape by forestry on crown land is well documented in the NSL&F Forest Inventory. However, timber harvesting on private land, and potential effects of terrestrial liming on flora has a moderate level of uncertainty.	No.	Overall, the generalized disturbance of the landscape by forestry activities, past, present and future are the main source of cumulative effects of habitats throughout the area. Without the Project, the loss of habitat in the Beaver Dam Mine Site during the construction and operation phases would be avoided, however the current observed generalized disturbance of the landscape would be unaffected. Any potential significant cumulative effect based on habitat fragmentation will be discussed in the context of SAR and SOCI.

Table 8.4-2: Selection of Valued Components for the Cumulative Effects Assessment (continued)

Project VC	Residual Adverse Effects	EIS Finding	Boundaries		Criteria for Determining Whether Further Assessment Is Required			Carried Forward to Cumulative Effects Assessment		
			Spatial – Geographical Extent of Residual Effects	Temporal - Timeframe Associated with Residual Effects	Level of Concern Noted During Engagement	Current State of The VC (Health/Status/ Condition)	Potential for Cumulative Effects: Screening Evaluation Summary	Uncertainty in Prediction of Cumulative Effects	Yes/No	Rationale
Terrestrial Fauna	Habitat loss and disturbance	Not Significant	The potential for adverse residual effects terrestrial fauna occurs within the LAA and possibly may extend into the RAA when considering habitat fragmentation.	Residual effects to terrestrial fauna may occur throughout the duration of the Project including Construction, Operation and Active Closure.	Low. Concerns raised during public and Mi'kmaq engagement relating to terrestrial fauna include potential for direct mortality and indirect effects of other VCs, such as dust, noise and light, as well as potential effects on avifauna associated with loss of habitat from construction of the Project.	Moderate. The PA was evaluated for bat hibernacula potential through both desktop and field evaluations. A single abandoned mine opening was identified as a potential bat hibernaculum, however no bat species were observed, nor evidence found that indicates any usage of the PA by priority bat species. Three set of moose tracks were observed incidentally and during targeted moose surveys between 2015 and 2021. One female snapping turtle and nest was observed within the Beaver Dam Mine Site. Three snapping turtles were observed incidentally along the Haul Road and at the Touquoy Mine Site.	No. Projects which lie within the RAA for Terrestrial Fauna include current and proposed mining activities at Touquoy Gold Project, historic mining at the Beaver Dam Mine Project and Dufferin Gold Mine, future mining activities at Fifteen Mile Stream, Nova Scotia Salmon Association's Acid Mitigation project (3 components), along with various regional forestry activities. Project effects on Terrestrial Fauna from the Fifteen Mile Stream Gold Project are limited to the LAA, which does not overlap the LAA for the proposed Project. While spatial boundaries for potential residual effects for the Dufferin Project were not available, it is expected that effects to habitat and flora would occur on a similar spatial scale to the proposed Project (2km buffer of the Study Area). Provided this is a reasonable assumption, project effects to Terrestrial Fauna would not overlap spatially, and given the proponents bankruptcy declaration, the projects are not likely to overlap temporally. No significant cumulative effect is expected from the Nova Scotia Salmon Associations' Acid Mitigation Project on terrestrial fauna. Although both the Beaver Dam Project and the Touquoy Gold Project will cause the loss and disturbance of habitats within the PA, these effects are relatively small given the fact that most of the affected areas are already disturbed.	Low. The main assumption behind this assessment is that the overall patterns of land use in the region will remain unchanged in the foreseeable future.	No.	As the potential cumulative effects are not anticipated to be significant and loss of habitat will be restored during the reclamation stage no further assessment is warranted. SAR/SOCI is being evaluated with regards to cumulative effects for rare species, including Mainland Moose and Snapping Turtle. As such, cumulative effects to terrestrial fauna more generally will be addressed through the effects assessment for Mainland Moose and Snapping Turtle.
Avifauna	Habitat loss and disturbance Decreased surface water quality (Touquoy Mine Site)	Not Significant	The potential for adverse residual effects to avifauna is limited to the PA and LAA.	Residual effects to avifauna may occur throughout the duration of the Project including Construction, Operation and Active Closure.	Low. Concerns raised during public and Mi'kmaq engagement relating to avifauna include potential for direct mortality and indirect effects of other VCs, such as dust, noise and light, as well as potential effects on avifauna associated with loss of habitat from construction of the Project.	Good. Abundance and diversity of avian species observed was moderate to high based on observer experience in the geographic area. The common species assemblage of forest birds was observed, along with many priority species.	No. Projects which lie within the RAA for Avifauna include current and proposed mining activities at Touquoy Gold Project, historic mining at the Beaver Dam Mine Project and Dufferin Gold Mine, future mining activities at Fifteen Mile Stream, Nova Scotia Salmon Association's Acid Mitigation project (3 components), along with various regional forestry activities. Project effects on Avifauna from the Fifteen Mile Stream Gold Project are limited to the LAA, which does not overlap the LAA for the proposed Project. While spatial boundaries for potential residual effects for the Dufferin Project were not available, it is expected that effects to habitat and flora would occur on a similar spatial scale to the proposed Project (2km buffer of the Study Area). Provided this is a reasonable assumption, project effects to Avifauna would not overlap spatially. The temporal scale of the Dufferin project is not expected to overlap either, as the Proponent has declared bankruptcy. The lime dosing stations operated by the Nova Scotia Salmon Association are not expected to result in any negative effects to avifauna, nor is the terrestrial liming activities as liming typically occurs in the fall outside of the active nesting season. Within the RAA, there is some potential additive cumulative effects with respect to habitat loss on the broad scale. Overall habitat loss and potential additive cumulative effects will be addressed in SAR-SOCI cumulative effects. Although both the Beaver Dam Project and the Touquoy Gold Project will cause the loss and disturbance of habitats within the PA, these effects are relatively small given the fact that most of the affected areas are already disturbed.	Low. The main assumption behind this assessment is that the overall patterns of land use in the region will remain unchanged in the foreseeable future.	No.	The predicted cumulative effects are not anticipated to be significant and loss of habitat will be restored during the reclamation stage. As such, the VC was not carried forward to the Cumulative Effects Assessment. SAR/SOCI is being evaluated with regards to cumulative effects for rare species, including Avifauna. As such, cumulative effects to avifauna more generally will be addressed through the effects assessment for Avifauna SAR.

Table 8.4-2: Selection of Valued Components for the Cumulative Effects Assessment (continued)

Project VC	Residual Adverse Effects	EIS Finding	Boundaries		Criteria for Determining Whether Further Assessment Is Required			Carried Forward to Cumulative Effects Assessment		
			Spatial – Geographical Extent of Residual Effects	Temporal - Timeframe Associated with Residual Effects	Level of Concern Noted During Engagement	Current State of The VC (Health/Status/ Condition)	Potential for Cumulative Effects: Screening Evaluation Summary	Uncertainty in Prediction of Cumulative Effects	Yes/No	Rationale
Species of Conservation Interest (SOCI) and Species at Risk (SAR)	Habitat loss and disturbance	Not Significant	The potential for adverse residual effects to SOCI and SAR is limited to the PA and LAA, with the exception of Moose, which is evaluated at the RAA level relating to potential habitat fragmentation.	Residual effects to avifauna may occur throughout the duration of the Project including Construction, Operation and Active Closure.	High. Key issues raised during public and Mi'kmaq engagement relating to SAR and SOCI include potential direct effects on priority flora and fauna, particularly Atlantic Salmon, associated with construction of the Project and potential indirect effects associated with changes to other VCs, such as air, wetlands, surface water and groundwater.	Good. Evidence of Mainland Moose and Snapping Turtle was recorded within the Beaver Dam Mine Site. Thirty-two priority avifauna species were recorded, including nine SAR. Six priority vascular species were recorded. No SAR were observed. Eleven priority lichen species were recorded, including three SAR. Three priority fish species were observed. No SAR were observed. Direct habitat loss is expected as a result of the Project. Direct priority vascular plant loss includes one observation of southern twayblade. Direct priority lichen loss includes two observations of blue felt lichen, six observations of salted shell lichen three observations of slender monk's hood lichen and one observation of eastern candlewax lichen.	Yes. Projects overlapping the RAA for SAR fish, flora, terrestrial fauna and avifauna, and potential interactions therein, are discussed in respective VCs above.	Low. The main assumption behind this assessment is that the overall patterns of land use in the region will remain unchanged in the foreseeable future.	Yes.	Although, the potential for significant cumulative effects to SOCI and SAR is not anticipated, the VC was carried forward due to the concern expressed by the Mi'kmaq of Nova Scotia and the Nova Scotia Salmon Association relating to SAR and SOCI, and as required by the per the EIS guidelines (See 8.3.1). Concerns included the potential direct effects on rare flora, fish, and terrestrial fauna associated with construction of the Project and the potential indirect effects associated with changes to other VCs, such as wetlands, surface water and groundwater.
Mi'kmaq of Nova Scotia	Loss of plant specimens Habitat loss Sensory Disturbance Visual Change Aesthetics effect Loss of Access	Not Significant	The potential for adverse residual effects to Mi'kmaq of Nova Scotia are limited to the PA and LAA.	Residual effects to Mi'kmaq of Nova Scotia may occur throughout the duration of the project including Construction, Operation and Active Closure.	High. Key issues raised during public and Mi'kmaq engagement relating to Mi'kmaq of Nova Scotia include concerns related to pathways of adverse effects, primarily related to access and resources and harvesting, from Project activities during construction and operation.	Moderate. The nearest Mi'kmaw community is the Beaver Lake IR 17, located approximately 5km southwest of the Beaver Dam Mine Site; followed by the Sheet Harbour IR, located approximately 21km southeast of the Beaver Dam Mine Site.	Yes. Potential significant adverse cumulative effects to surface water, could cause effects on the use of surface water bodies and the fish inhabiting them by the Mi'kmaq of Nova Scotia. There is also the potential for cumulative effects on habitats, flora, terrestrial fauna and birds to lead to effects on current use of land and resources for traditional purposes.	Moderate. Effects are linked to a number of VCs and therefore can be more difficult to predict.	Yes.	Further assessment is required to determine if there is the possibility of significant residual cumulative effects to Mi'kmaq of Nova Scotia.
Physical and Cultural Heritage	Loss of archaeological features	Not significant	The potential for adverse residual effects to Physical and Cultural Heritage are limited to the PA	Residual effect to Physical and Cultural Heritage are anticipated to occur through the Construction phase.	Low. Concern was noted during Mi'kmaq engagement regarding areas of elevated potential for Mi'kmaq resources (near Crusher Lake, Killag River and Cameron Flowage).	Good. Thirteen sites/areas with elevated archaeological potential were identified with the Beaver Dam Mine Site. Most sites are associated with historical mining activities and Euro-Canadian archaeological resources. Three sites were identified as having elevated potential for historic Mi'kmaw archeological resources. Three sites will be impacted by the Project. No direct or indirect impacts to Mi'kmaq archaeological features are expected. Additional shovel tests were completed within Site 6 and Areas 2 and 3 in 2020. No Pre-contact Mi'kmaq archaeological resources were encountered, and CRM Group recommends these areas be cleared of requirements for further investigation.	No. While other archaeological features may be present in the LAA or RAA, there is no pathway for disturbance of these features outside of the PA.	Low. The expected disturbance to archeological features is assessed and well understood. Chance find protocols for archaeological resources will be implemented as part of the Project Environmental Protection Plan (EPP). Personnel will receive the appropriate level of EPP training to properly implement the chance find protocol.	No	As the potential cumulative effects are not anticipated to be significant no further assessment is warranted.
Socio-Economic Conditions	Disturbance to recreational usage of site.	Not Significant	Positive residual effects are expected to occur through the RAA.	Residual effects to socio-economic conditions may occur throughout the duration of the project including Construction, Operation and Active Closure.	Medium. Concern about volumes of truck traffic in context of safety on public roadways and recreational access to the areas surrounding the Project to fish, hunt and for ATV access and throughflow access.	Good. The area sees public use for access to hunting, fishing and ATV activity. Between 2014-2018, 93 jobs were created for exploration. An estimated 289 jobs will be created during construction and operation.	No. Disturbance to recreational usage is restricted to the PA so, with proposed mitigation and bypass roads, no cumulative effects are anticipated. The overall effect of the Project on Socio-economic Conditions is positive.	Low. Prediction made on the assumption that the local road usage will not change, with proposed mitigation measures in place.	No.	As the overall potential effect of the Project on Socio-economic Conditions is positive, no further assessment is warranted.

8.5 Cumulative Effects Assessment of the Valued Components

Using appropriate data and information is critical to the analysis of cumulative effects. Exhaustive baseline studies have been completed to characterize the environment within the PAA, LAA and RAA for the Project. Baseline information for all VC's is described in detail in Section 6 of the EIS, and for the reader, has also been summarized in the subsequent sections for those VC's that have been carried forward for the cumulative effects assessment. Baseline information provided for each valued component is limited by the evaluation methods and frequency of surveys. It is representative of the current status of the Project footprint. However, there are limitations to this data collection and analysis.

The following VCs have been carried forward for cumulative effects assessment based on the parameters and screening tools described in the previous sections:

- Noise (Beaver Dam Haul Road component of the Beaver Dam Mine Project only- qualitative);
- Air;
- Light (Beaver Dam Haul Road component of the Beaver Dam Mine Project only- qualitative);
- Surface Water;
- Fish and fish habitat;
- Species at Risk (SAR) and Species of Conservation Interest (SOCI); and
- Mi'kmaq of Nova Scotia.

Data and information for the other projects considered in the cumulative effects section is provided from public sources of information only. Data is collected from environmental assessment websites (both federal and provincial) and review of publicly available documents. There are significant limitations in this approach. Environmental assessments do not follow a standard methodology so often the data available is not in a format that can be directly comparable to the data available for the Project, or the same level of data analysis was not completed (air dispersion modelling for example, or quantitative predictive water quality modelling). Past projects can be devoid of published information (historical tailings for example) limiting the ability to quantitatively evaluate the potential cumulative impact of this project with the Project. Furthermore, projects that do not require environmental assessment (timber harvesting, or the NSSA Acid Mitigation Project, for example) have very limited data available for review and inclusion in these cumulative effects analyses. The EIS team has attempted to avoid sweeping qualitative statements and conclusions and has acknowledged data limitations where necessary in this section and in some instances, these data limitations limit conclusions.

8.5.1 Noise Cumulative Effects Assessment

8.5.1.1 Baseline Conditions

8.5.1.1.1 Baseline Noise Levels

Ambient noise has been sampled at several representative locations. Noise data was recorded in A-weighted decibels (dBA) and presented as equivalent continuous noise level (Leq) averaged over a time period and compared to Nova Scotia Environment criteria by time of day. Sound level measurements for all sample locations, except for Location #1 at the Beaver Dam Mine Site, met NSE Pit and Quarry criteria for all time intervals.

At the measurement locations around the Beaver Dam Mine Site, based on the 2014 values, the average value is 33 dBA ±. The dominant noise sources noted are natural, including birds, the movement of leaves, and possibly the odd vehicle on a logging road. The measurement locations at Beaver Dam Mines Road and Mooseland Road would be mostly from natural sources. Mooseland Road measurements are comparable to the Beaver Dam Mine Site. It is located on a little used gravel road. The Beaver Dam Mines Road is elevated and is near a paved highway with regular traffic. This road also passes through Beaver Dam IR and ambient sound will be the same as at the measured location.

Potential Noise interactions and effects for Construction and Operations are quantitatively assessed by acoustic modelling. The technical reports documenting the updated approach and inputs for Noise modelling (Construction, Operations) are provided in Appendix B.1 and Appendix B.2, and are summarized in this section.

The updated noise analysis results include all identified worst-case human receptor locations (R1 to R9, Figure 6.1-3). Specific non-residential locations of traditional land use and recreation have not been identified for inclusion in the analysis; however, it is understood that traditional and recreational uses such as hunting may occur in areas close to the Project Area.

In summary, an updated acoustical model was undertaken to provide an order of magnitude estimation of the estimated noise from the crushing operations at the Beaver Dam Mine Site and haul truck travel along the Haul Road. The noise sources and topography were input into an industry standard acoustic model. Computer Aided Noise Abatement Acoustical Modeling Software (Cadna A), version 4.6, is based on the ISO 9613-2 standard "Acoustics - Attenuation of Sound During Propagation Outdoors - Part 2: General Method of Calculation." The Cadna A model is the industry standard for environmental noise modeling in Canada. The nearest receptor considered in the preliminary acoustical model included Beaver Lake IR 17, located approximately 5 km from the Mine Site and 3 km from the nearest point of the Haul Road.

To predict the future worst-case noise impacts from the Project activities, representative octave band noise data was used, measured from processing equipment similar to what is noted to be required for the Project. This data was obtained from the Department of Environment Food and Rural Affairs (DEFRA) "Update of Noise Database for Prediction of Noise on Construction and Open Sites, 2005 and 2006". The United States Department of Transportation, Federal Highway Administration (FHWA) document "FHWA Roadway Construction Noise Model User's Guide, 2006" was used as a supplemental document to obtain sound level data for equipment not listed by DEFRA.

8.5.1.1.2 Regional baseline Noise conditions

The relatively steady ambient noise of the surrounding area is a conglomeration of distant noise sources including wind in trees, bird and animal noise, rainfall, distant aircraft, logging activities, traffic and all-terrain vehicle use. The acoustic monitoring completed in the vicinity of the Beaver Dam Mine Site and Haul Road is considered representative of the local baseline conditions.

8.5.1.2 Analysis of Effects

8.5.1.2.1 Residual Effects of Proposed Project

The predicted residual environmental effects of Project development and production of noise are assessed to be adverse, but not significant within the PA. During construction, operations and active closure phases, the noise levels defined in the Pit and Quarry Guidelines will be met at the property boundary for both the Beaver Dam Mine Site and Haul Road, while baseline noise levels are met at the RAA boundary.

8.5.1.2.2 Effects of Other Projects in the Area

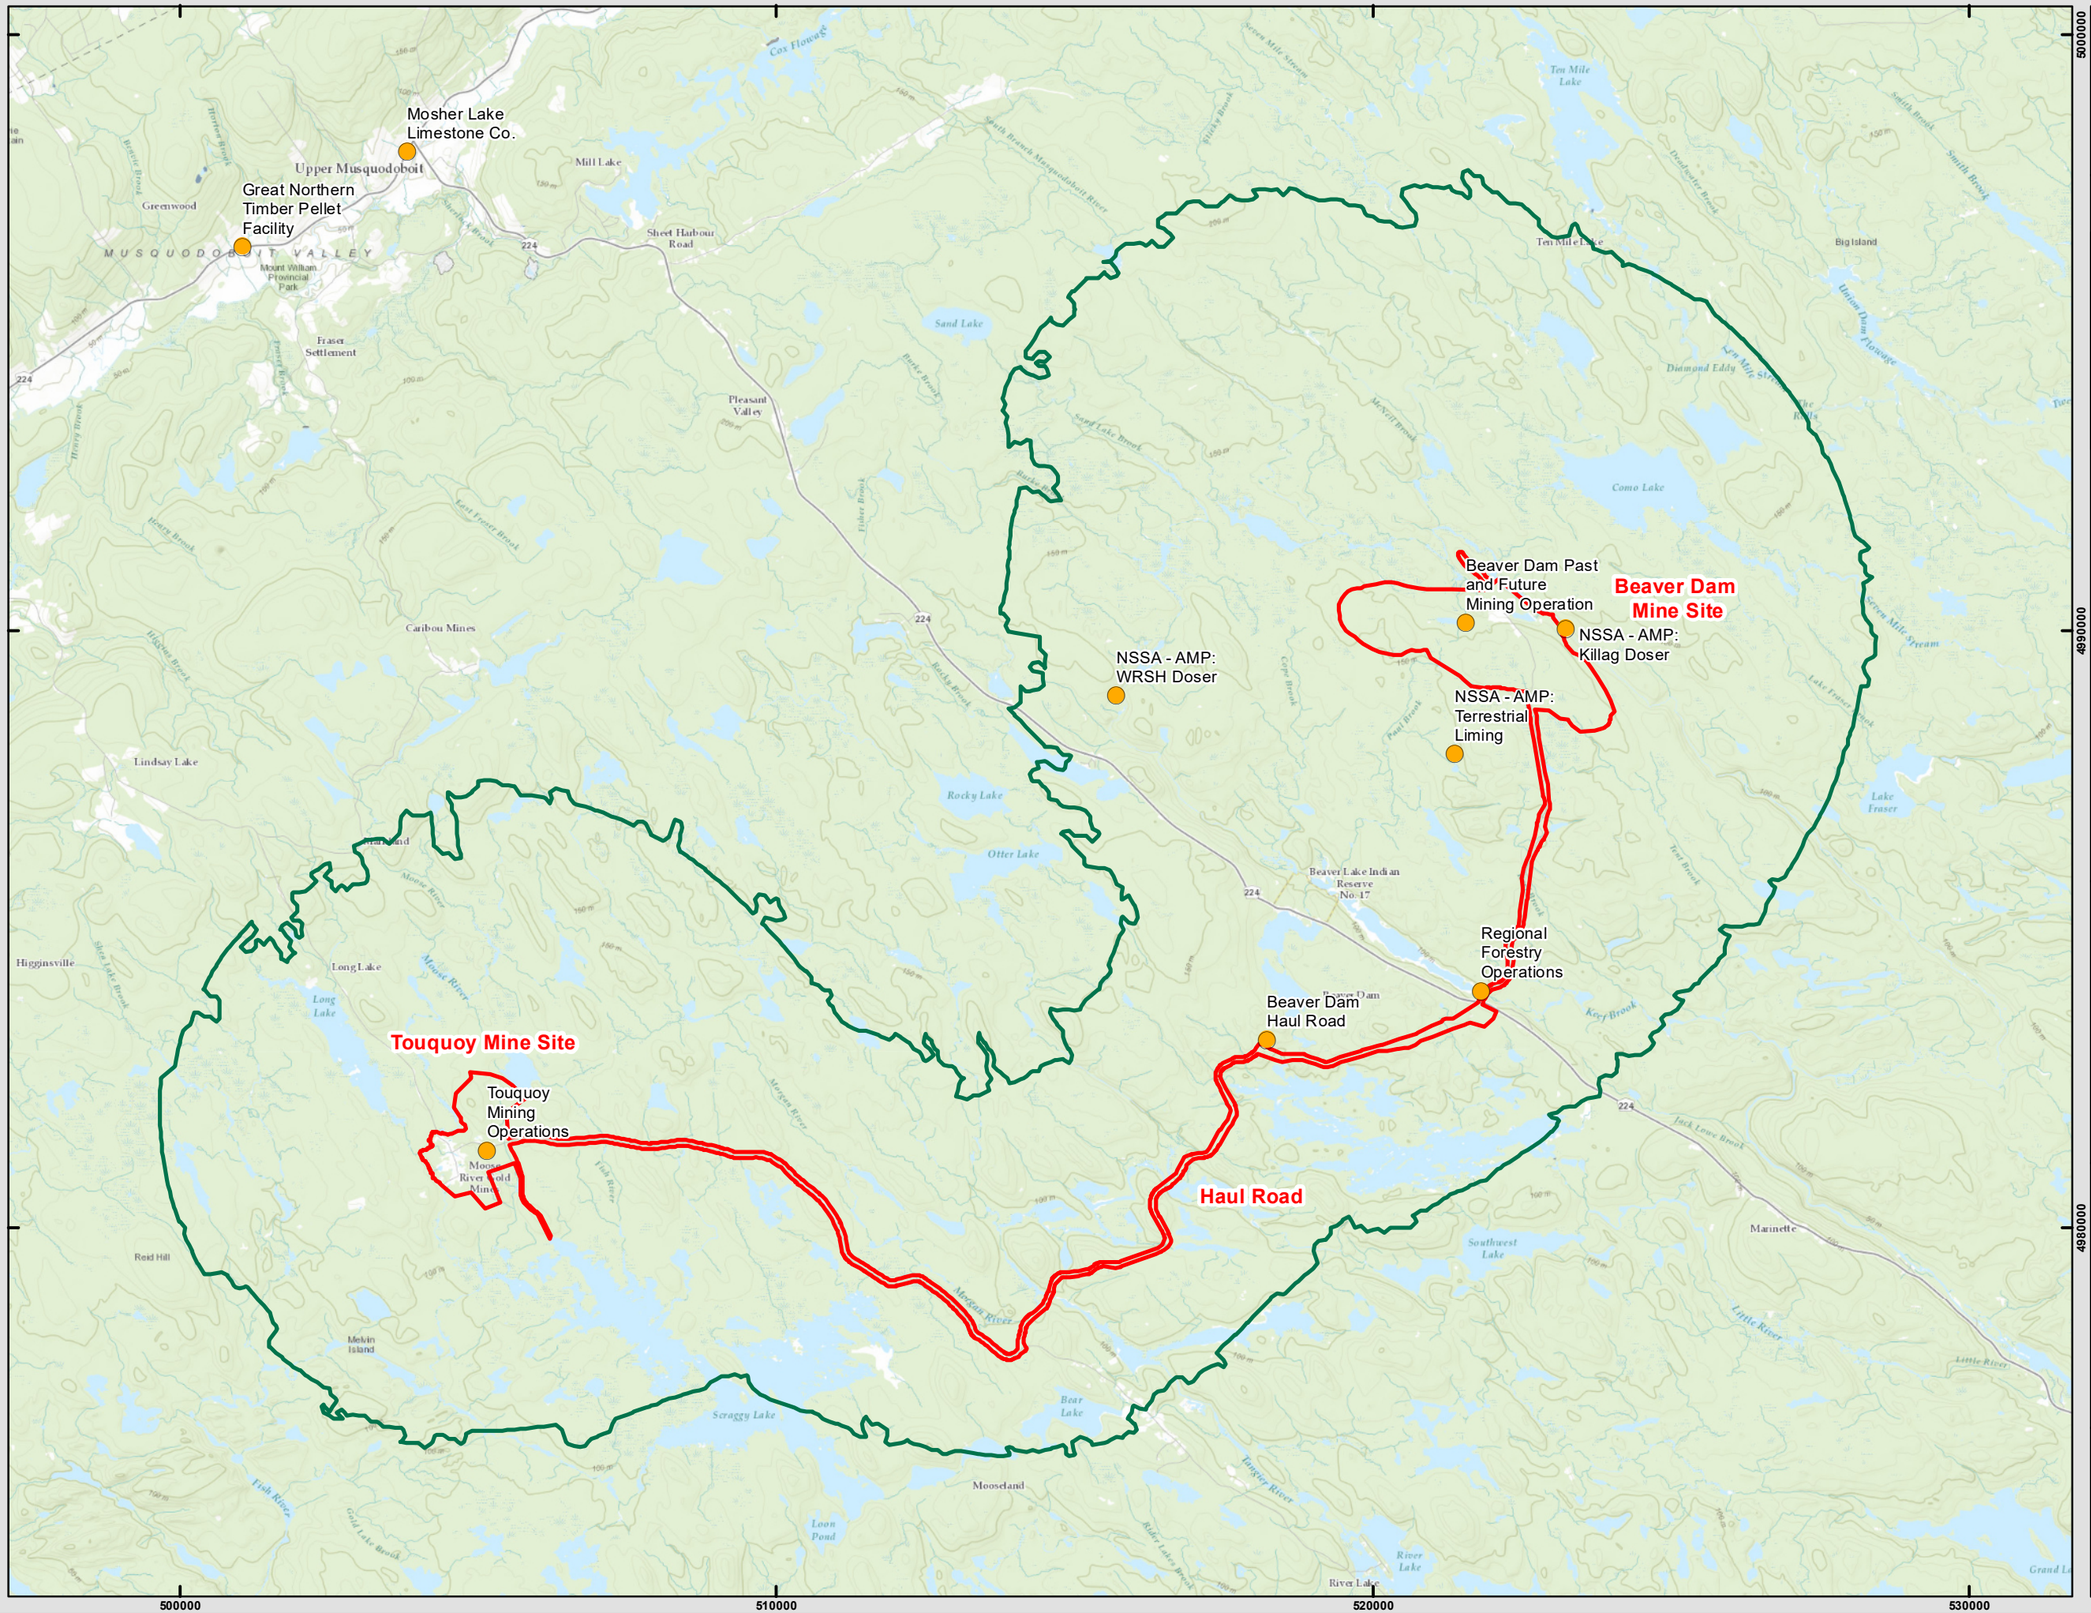
The RAA for noise, and projects which fall within this RAA are shown on Figure 8.5-1. The NSSA Acid Mitigation Project has a spatial and temporal overlap with the Projects' RAA for noise. However, this project is not being discussed in the context of cumulative noise, because aside from several days per year of helicopter flights for terrestrial liming, the NSSA work does not generate additional sources of considerable noise.

Current Regional Forestry Operations

The local forestry industry has the potential to have cumulative effects on noise levels due to timber harvesting and trucking of timber. Anthropogenic sources of noise have been excluded from noise modelling calculations. Data is publicly unavailable to quantify the level of noise expected from timber harvesting and trucking due to regional forestry operations. However, the baseline forestry activity on the Haul Road has been considered in this cumulative effects assessment (Section 8.5.1.2.2.3). However, noise associated with timber harvesting is likely to be relatively seasonal and sporadic, and not likely to affect regional noise levels in any significant or sustained manner.

Touquoy Mine Site

The Noise Impact Study (Appendix B.2) shows that the predicted levels for sound propagation from the Touquoy Mine Site for the Project will be below the Pit and Quarry Guidelines noise thresholds (day/evening/night) at the property boundaries. As indicated in the EARD, the maximum sound generated at the processing plant is 80 dBA, which attenuates to the background of 40 dBA over a distance of 500 m.



The Touquoy Mine Site is in production. The primary effect of the continued use of the Touquoy Mine Site is the continued generation of noise due to haul truck traffic on the site, processing of Beaver Dam ore. There are no new or additional effects from noise anticipated to be caused by the processing of ore and the management of tailings (exhausted pit) from the Project, as no new construction or disturbance is required at the Touquoy Mine Site related to the processing of Beaver Dam ore.

Beaver Dam Haul Road Use by the Project, the Fifteen Mile Stream Project, Cochrane Hill Gold Project and Regional Forestry

Trucks from other projects and forestry operations on the Haul Road have the potential to increase the cumulative effect of noise at the receptors. Noise levels due to cumulative effects of trucks on the Haul Road were assessed, and the predicted noise levels remain within the applicable NSEL sound level limits at all identified residential receptors. Details of this assessment are provided in Appendix B.2 and summarized below.

A cumulative effects analysis has been conducted to determine the potential effects of truck traffic from the proposed Fifteen Mile Stream Gold Project, Cochrane Hill Gold Project and Forestry operations that may use the Haul Road concurrently with trucks from the Beaver Dam Mine Site. Truck traffic volumes used in the direct (i.e., Project only) and cumulative effects analysis are summarized in Table 8.5-1.

Truck traffic from the Project will operate on the Haul Road 16 hours per day, during day and evening time periods only (7:00 AM to 11:00 PM). It is assumed that trucks originating from the other projects and industries will operate during the same hours for the purposes of the cumulative effects analysis.

In addition to the heavy truck traffic summarized above, it is estimated 3/4-ton service trucks would make up to approximately 20 round trips per day on the haul roads. Noise emissions from these service trucks have also been included in the cumulative effects noise model.

Table 8.5-1 shows the predicted cumulative effects of truck traffic for noise during the Operation Phase of the Project are within the applicable sound level limits at all of the identified residential receptors and the property boundary for the Beaver Dam Mine Site and Haul Road, including noise emissions from equipment and activities at the Beaver Dam Mine Site, Touquoy Mine Site, and Haul Road.

Table 8.5-1: Operation Phase Predicted Cumulative Effects

Receptor ID	Receptor Description	Noise Level (dBA) (Day/Evening/Night)	Sound Level Limit [(a)] (dBA) (Day/Evening/Night)	Compliance
R1	9 Beaver Dam Mine Road (Marlborough Property)	50 / 50 / 27	65 / 60 / 55	Yes
R2	4112 Highway 224 (Beaver Lake IR 17)	31 / 31 / 28	65 / 60 / 55	Yes
R3	4115 Highway 224 (Cottage on Crown Land)	33 / 33 / 28	65 / 60 / 55	Yes
R4	3492 Highway 224 (Hobbs Property)	56 / 56 / 27	65 / 60 / 55	Yes
R5	3379 Highway 224 (McLeod Property)	51 / 51 / 27	65 / 60 / 55	Yes
R6	3373 Highway 224 (Smith Property)	51 / 51 / 27	65 / 60 / 55	Yes
R7	Tangier River (Deepwood Estates Property)	55 / 55 / 20	65 / 60 / 55	Yes
R8	Tanger River (Musqudoboit Lumber Co. Ltd. Property/John Dickson Lease)	44 / 44 / 20	65 / 60 / 55	Yes
R9	5579 Mooseland Road (Lloy Property)	52 / 52 / 27	65 / 60 / 55	Yes

Notes: Truck traffic used in the noise assessment and related modelling has been adjusted to a 16-hour shift, including the nighttime hour of 6:00 AM to 7:00 AM
(a) NSEL 1999.

Overall, the findings summarized in the Noise Impact Study, and the EIS for Beaver Dam Mine Project will remain valid, and the cumulative effects of noise along the Haul Road are predicted to remain within the guideline limits specified by Nova Scotia Environment and Labour (NSEL) at all of the identified receptors, and with consistent conclusions relating to the property boundary along the Haul Road. Based on those predictions, noise levels at all nearby residential receptors are anticipated to be within the NSEL noise level limits with the additional vehicles included in the assessment. Speed limits would be implemented as a part of each of these projects will mitigate the potential increase in ambient noise from the associated trucking operations.

8.5.1.2.3 Cumulative Effects on Noise Levels

It is likely that forestry operations will occasionally coincide with activities at the Beaver Dam Mine Site and cause greater disturbance to noise levels that these operations produce individually. However, such additive periods are likely to be limited in duration and frequency and are not expected to be significant. This cannot be quantified for the purpose of this CEA due to a lack of available data relating to forestry activities and future plans for harvesting. The principal assumption behind this assessment is that local forestry practices are not expected to change in any important way during the life of the Project. Data to support the quantification of timber harvesting is limited, particularly related to noise levels.

The gold concentrate transportation and processing activities associated with the Fifteen Mile Stream Gold Project and the Cochrane Hill Gold Project overlap in both time and space with the Project. Therefore, the potential effects from the transportation

and processing from the three projects, along with forestry activities on the Beaver Dam Haul Road, have the potential to act in an additive and cumulative nature. The additive cumulative effects on noise from transportation to the Touquoy Mine Site from the cumulative projects are not expected to be significant, provided mitigation measures for noise are implemented.

The processing of Beaver Dam ore and deposition of tails is not expected to affect noise levels at the Touquoy Mine Site in any noticeable way. This will be confirmed through monitoring.

8.5.1.3 Mitigation

Standard mitigation measures for noise generated by the Project at the Beaver Dam Mine Site, Haul Road and Touquoy Mine site are presented in Section 6.1.8, and mitigation measure associated with use of the Beaver Dam Haul Road are described in the Beaver Dam Mine Project EIS. As no pathway for significant cumulative effects are identified, no additional mitigation measures are warranted.

8.5.1.4 Residual Cumulative Effects and Significance Assessment

A significant adverse effect to noise at the Beaver Dam Mine Project is defined as having high magnitude (i.e., an exceedance of the maximum noise or vibration limits), occurring beyond the PA and LAA, of long-term to permeant duration, occurring at regular intervals or be continuous throughout the Project, and be only partially reversible to irreversible. The cumulative effects to noise are predicted to be low, diverging from existing conditions but in compliance with appropriate guidelines; these effects do not extend into the RAA, are long-term, and are considered reversible. The overall residual cumulative effects on noise is assessed as not likely to have significant adverse effects after mitigation measures have been implemented. Thus, predicted residual environmental effects of Project development and production on Noise are assessed to be not significant (Table 8.5-2).

Table 8.5-2: Residual Cumulative Environmental Effects for Noise

Residual Adverse Cumulative Effects (After Mitigation)	Significance Levels						Overall Significance of Residual Adverse Effects (and Rationale)
	Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility	
Cumulative increased noise levels (Noise from construction, operation, reclamation, and operation of mining, haul trucks, forestry activities and haul road usage)	L Noise levels are expected to be less than or equal to appropriate guidelines or threshold values at the Beaver Dam Mine Site and Haul Road property boundary. Additive cumulative effects may occur when forestry operations occasionally coincide with Project activities and hauling ore from FMS and Cochrane Hill to Touquoy Mine Site for processing	LAA The cumulative effects causing increased background noise levels will not extend beyond the LAA.	A VC is expected to be affected by timing, with sporadic nature of timber harvesting.	LT Effects may extend beyond 8 years.	R Additive periods of potential effects from the Project and forestry operations are likely to be limited in frequency. However, cumulative effects to baseline noise levels from the use of the Beaver Dam Haul Road by Beaver Dam, Fifteen Mile Stream and Cochrane Hill Gold Projects will occur regularly throughout the operational phase of the Project.	R VC will recover to baseline conditions once operations have stopped.	Low Adverse Effect (Not Significant) Effects are limited to the LAA based on Project interactions and usage of the Beaver Dam Haul Road by various activities. Furthermore, the VC is anticipated to recover to baseline conditions once the operation of the mine has stopped. Effects would be confirmed through monitoring.

Legend (refer to Section 5.11, Table 5.11-1 for definitions)

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	PR	Partially reversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	IR	Irreversible
H	High					P	Permanent	C	Continuous		

8.5.1.5 Follow-up and Monitoring Programs

No additional follow-up or monitoring beyond that presented in Section 6.1.10 is warranted.

8.5.2 Air Cumulative Effects Assessment

8.5.2.1 Baseline Conditions

8.5.2.1.1 Baseline Air Quality Monitoring Program

Preliminary baseline particulate monitoring was undertaken for TSP and PM_{10}. Baseline air quality measurements were obtained from nine locations near the Beaver Dam Mine Site and along the proposed Haul Road, five locations on the Touquoy Mine Site, two locations near the proposed Fifteen Mille Stream Gold Project, and two locations near the proposed Cochrane Hill Gold Project.

Baseline TSP concentrations ranged from 1.7 to 41.7 micrograms per cubic metre (µg/m³), with the highest value obtained at Location #2 during monitoring in June 2008. Results for PM_{10} concentrations ranged from 7.1 to 13.1 µg/m³, with the highest value also obtained at Location #2 during monitoring in June 2008. This monitoring station was located in a recently clear-cut area, which may have contributed to higher particulate levels in comparison to the other locations. This area was resampled in 2014 (AN#2). The 2014 results for that area were 4.6 µg/m³. All samples collected were below the NSAQS for TSP, there is no NSAQS for PM_{10}.

The data obtained as part of the baseline program reported herein provides a preliminary snapshot of air quality in the area of the Beaver Dam Mine Site and Haul Road, and a general understanding of local air quality. Due to a lack of other sources of data for ambient TSP, the background concentration for TSP is based on the maximum measured 24-hour TSP concentration (there are insufficient data to provide a meaningful 90^{th} percentile value), and the average of all the TSP measurements. There is uncertainty in how representative these values might be for background, but they represent the best available data at this time.

To support the effects assessment of the Air VC, air dispersion modelling was performed. Emission rates from the Project-related sources were calculated using USEPA AP-42 (5th Edition) emission factors for the Beaver Dam Mine Site and Haul Road dust emissions, and MOBILE6.2 (M6.2) for Haul Road vehicle emissions. There is currently no guidance on the use of models in Nova Scotia, and therefore the O.Reg. 419/05 requirements were used as a framework. The version of the air dispersion model used in this project is currently accepted in Ontario, and AERMOD is used across Canada and throughout the United States as a regulatory model of choice. AERMOD is an advanced steady state plume model that has the ability to incorporate building cavity downwash, actual source parameters, emission rates, terrain and historical meteorological information to predict ground level concentrations (GLCs) at specified locations.

Air compounds evaluated included TSP, PM_{10}, $PM_{2.5}$, NO_X, SO_2 and VOC.

Haul Road emissions calculations assume that the roads are unpaved, and a dust management plan (targeting 80-90 %percent dust suppression efficiency). This will be achieved through the implementation of a fugitive dust control plan that includes the use of dust suppressant (Section 6.2.8 and Appendix C.3).

The Beaver Dam Mine Site mining, crushing, and transfer operations will primarily operate from adjacent to the open pit. Although vehicle traffic is also expected, it was assumed that most of these operations also occur adjacent to the open pit. Therefore, the Beaver Dam Mine Site emissions were modelled using as an open pit source such that all emissions from mining operations were summed and attributed to the pit source. As discussed in Project Description (Section 2) the Beaver Dam Mine site may not rely

on a primary crusher if the ore can be broken using jawbreaker and other mining equipment. For the purposes of this air assessment, a conservative assessment approach has been applied and assumed that a primary crusher would be in use.

The Touquoy Mine Site consists of crushers and mining sources as volume sources. These sources were previously modelled in AERMOD for an Emissions Summary and Dispersion Modelling Assessment (CRA 2007a). As the Beaver Dam Mine Site will use the Touquoy Mine Site for its refining capabilities, the crushing and mining operations remained unchanged.

8.5.2.1.2 Regional ambient air quality

Ambient air quality in Nova Scotia is monitored using a network of 10 sites operated by NSE and Environment and Climate Change Canada (ECCC) through the NAPS. Common air pollutants monitored at these stations include the following:

- SO_2;
- $PM_{2.5}$;
- ozone (O_3); and
- oxides of nitrogen (NO_2, NO, and total NO_X).

Data collected at these stations is used by NSE to report the Air Quality Index (AQI) and by ECCC to report the Air Quality Health Index (AQHI). There are currently no permanent air monitoring stations within the vicinity of the PA. The Beaver Dam Mine Site is located in a relatively undeveloped rural region of Nova Scotia with infrequent industrial operations that would affect air quality. As the NAPS monitoring stations are typically located in areas with local industry, measured concentrations of indicators are likely lower at the Beaver Dam Mine Site than at NAPS stations.

The nearest representative stations which report concentrations for the air quality parameters assessed include:

- Lake Major, Nova Scotia (Station ID 030120) – $PM_{2.5}$, NO_2, and SO_2;
- Port Hawkesbury, Nova Scotia (Station ID 030201) – $PM_{2.5}$, NO_2, and SO_2;
- Aylesford Mountain, Nova Scotia (Station ID 030701) – $PM_{2.5}$, and NO_2; and
- Pictou, Nova Scotia (Station ID 030901) – $PM_{2.5}$, and NO_2.

VOCs are not measured at these stations. PM_{10} are not measured in many areas in Canada. Of the locations which do measure PM_{10}, most are in British Columbia urban centres, four are in Manitoba cities, one is in Regina, Saskatchewan, and four are in the Northwest Territories. In terms of locations that are somewhat comparable to the Project site (human habitation, regional activities that may generate airborne particulate, etc.), Norman Wells, NWT Regional Office (Station ID 129102) appears the most appropriate location that has recent data available (Appendix C.1).

8.5.2.2 Analysis of Effects

8.5.2.2.1 Residual Effects of Proposed Project

The Project will result primarily in the generation and airborne transport of fugitive dust particles and exhaust emissions from equipment. Fugitive dust typically refers to small particles of geological or other origin that are moved into the atmosphere from non-ducted, open sources. Fugitive dust sources can originate from both stationary and mobile sources such as open fields, open

burning, agricultural activity, construction sites, logging road traffic, vehicle traffic on paved and unpaved roads, aggregate pits and storage piles, as well as open pit mines.

Airborne particulate matter will be generated during construction and operation of the proposed Haul Road. Sources of project-related particulate matter would include upgrading the existing road to be suitable for the mine traffic, and truck traffic hauling ore from Beaver Dam Mine to the Touquoy Mine Site for processing. Dust can be generated from mine haul truck tires interacting with gravel surfaced Mine Haul Roads and Beaver Dam Haul Roads. Dust is also generated during the truck loading and dumping activities. Dust is not expected from uncovered trucks because the ore material is of a size that is unlikely to generate dust. Dust can be tracked across asphalt roads and re-entrained by traffic or by the wind.

Results of air dispersion modelling for maximum predicted concentrations of emitted particulate species from the Beaver Dam Mine Site are presented in Table 6.2-7 in Section 6.2.7. This table summarizes the particulate size fraction considered, the averaging period, the assessment criteria against which the results are compared, the maximum predicted concentration from the modelling, the ambient background concentration, the combined effect (the modelled concentration from the site added to the assumed existing background concentration for that averaging period), and the percentage of the assessment criteria for the site modelling results alone and the cumulative effects.

For this site, maximum predicted concentrations occurred at the property boundary. Predicted concentrations for all indicator compounds and averaging periods were lower than existing background concentrations, and well below relevant assessment criteria.

Results of air dispersion modelling for maximum predicted concentrations of emitted particulate species from the Haul Road are presented in Table 6.2-10 in Section 6.2.7. This table summarizes the particulate size fraction considered (i.e., TSP, PM_{10} and $PM_{2.5}$), the averaging period, the assessment criteria against which the results are compared, the maximum predicted concentration from the modelling, the ambient background concentration, the combined effect (the modelled concentration from the site added to the assumed existing background concentration for that averaging period), and the percentage of the assessment criteria for the site modelling results alone and the cumulative effects.

For this site, maximum predicted concentrations occurred within 30 m of the road, and predicted concentrations decreased, with increasing distance from the road. The maximum predicted concentrations for all compounds occurred in close proximity to the road, in areas that are not continuously occupied. Maximum predicted concentrations presented occur at 30 m from the road and decrease rapidly with distance.

Maximum predicted concentrations of emitted particulate species from the Touquoy Mine Site are presented in Table 6.2-13 in Section 6.2.7. This table summarizes the particulate size fraction considered, the averaging period, the assessment criteria against which the results are compared, the maximum predicted concentration from the modelling, the ambient background concentration, the cumulative effect (the modelled concentration from the site added to the assumed existing background concentration for that averaging period), and the percentage of the assessment criteria for the site modelling results alone and the cumulative effects.

For this site, maximum predicted concentrations occurred at the property boundary. Predicted concentrations for all indicator compounds and averaging periods were lower than existing background concentrations, and well below relevant assessment criteria.

Modelling of sources at the Beaver Dam Mine Site and the Touquoy Mine Site showed maximum predicted concentrations at their respective fencelines well below applicable air quality criteria, which are unlikely to cause adverse effects. The Haul Road between

the proposed Beaver Dam and the Touquoy Mine Sites is the source primarily responsible for the maximum predicted concentrations at both the gridded receptors and the sensitive receptors identified for this assessment.

Maximum predicted $PM_{2.5}$ concentrations did not exceed the CAAQS for either the 24-hour or annual averaging periods at any of the sensitive receptor locations, based on Project alone predictions, or Project plus background. PM_{10} was predicted to exceed the Ontario Interim 24-hour guideline at Deepwood Estates up to 2% of the time without background) and up to 57% of the time with background concentration included. PM_{10} was also predicted to exceed the Ontario Interim 24-hour guideline at 9 Beaver Dam Mines Road up to 13% of the time with background concentration included but met the guideline without background. TSP was predicted to exceed the 24-hour Nova Scotia Air Quality Standard up to 0.3% of the time with background included at the Deepwood Estates receptor. There is uncertainty in the presented background concentrations of both PM_{10} and TSP. The Deepwood Estate property, the most impacted, has been acquired by AMNS so there will be no permanent or seasonal resident at this property. In addition, this property will likely be used as part of the monitoring to confirm impact predictions and assess the effectiveness of the mitigations.

8.5.2.2.2 Effects of Other Projects in the Area

The RAA for air, and other projects which fall within this RAA are shown on Figure 8.5-2. The NSSA Acid Mitigation Project has a spatial and temporal overlap with the Projects' RAA for air. However, this project is not being discussed in the context of cumulative air impacts, because aside from several days per year of helicopter flights for terrestrial liming, the NSSA work does not generate air emissions. The Gaetz Brook Wind Power Project is within the RAA for Air; however, this project is not anticipated to generate emissions. The existing Touquoy project lies within he RAA for air; however, it is an integral component of the Beaver Dam Project and air emissions from the Touquoy project are considered in the modelling for the Beaver Dam Project. As a result, this project is not being described further in the cumulative effects assessment for Air.

Current Regional Forestry Operations

The local forestry industry has the potential to have cumulative effects on air quality. As the forestry industry is ongoing in the region and has been for many decades, its effects on air quality are already accounted for in the local baseline conditions. The largest effect noted from the baseline data was the measurement of the highest suspended particulate concentrations from a monitoring station located in a recently clear-cut area. As a result of the expected inclusion of forestry contributions to air quality in baseline data, no additional analysis for cumulative effects of this industry related to air is necessary.

Beaver Dam Haul Road Use by the Project, Fifteen Mile Stream Project, Cochrane Hill Gold Project and Regional Forestry

During the operation phase of the Project and the Cochrane Hill Gold Project, gold concentrate from each surface mine will be transported to the Touquoy processing site for final processing into gold doré bar. The proposed haul route for each of these projects is proposed to overlap with the Beaver Dam Haul Road west of the Highway 224, along with potential trucking activity associated with the forest industry. Eleven round-trips are proposed to carry gold concentrate from each of the Cochrane Hill and the FMS Projects per day (totaling 22 vehicle round-trips per day or 11 1-way trips), plus 190 round-trips per day (or 95 1-way trips) between Beaver Dam Mine Site and Touquoy Mine Site. This could be further compounded by forestry truck activity (approximately 7 return trips per day plus 20 round trip service trucks). The total number of trucks for cumulative effects assessment is 288 trucks round trip (Appendix C.1). Mitigation measures proposed in the Beaver Dam Mine Project EIS will result in an 80 to 90% targeted dust suppression efficiency.

The modelled particulate concentration results of the Cumulative Haul Road emissions scenario for the four road sections modelled (Figure 3 in Appendix C.1) are summarized in Table 7A for the 80% road dust mitigation scenario. All predicted Cumulative maximum concentrations are well below the air quality assessment criteria with background added, as shown in Table 7A in Appendix C.1. The maximum particulate deposition along the Haul Road for the Cumulative truck traffic scenario ranged from 78.9 to 81.6 g/m^2/year. Table 7B in Appendix C.1 summarizes the predicted maximum concentrations of the gaseous species (NO_2, SO_2 and VOCs). There are no exceedances of the air quality criteria for NO_2 and SO_2. There are no criteria applicable for total VOCs. The predicted concentrations of VOCs as presented in Table 7B show that the VOC concentrations are very low (less than 1 microgram per cubic metre) and are provided for reference only.

The maximum concentrations for all contaminants occur at 30 m from the Haul Road centerline, which is the project boundary for the Haul Road. Figures 4A to 4E in Appendix C.1 show the 30 km haul road contour plots for TSP, PM_{10} and $PM_{2.5}$ modelled for the 80% dust mitigation scenario. As shown on these figures, there are no exceedances of the applicable criteria along the haul road.

Sheet Harbour Quarry (Future)

On January 31, 2019, Dexter Construction Company Limited submitted an Environmental Assessment Registration Document for the Sheet Harbour Aggregate Quarry Project, located approximately 26 km southeast of the Beaver Dam Mine Site, and 35 km southeast of the Touquoy Mine Site. According to the EARD, Project activities will result in release of dust and exhaust type emissions through construction, operation, and reclamation phases of this proposed quarry. Mitigation measures proposed include wet suppression of unpaved surfaces, equipment maintenance, and the use of low-sulphur fuel. Assuming appropriate mitigation measures are employed, the EARD indicates that the effect of the Project on air quality are minor. The EARD does not predict air quality concentrations from the project, nor does it predict the spatial extent of this potential dust deposition.

The spatial boundaries used to make this determination are not provided in the EARD. However, the Projects' effects on air is not expected to spatially overlap with the proposed Beaver Dam Project, based on the distance between the two sites. The EARD was determined to provide insufficient information for the Minister to grant approval to the Project. On March 22, 2019, the Minister requested submission of additional information. The Minister approved this undertaking on November 8, 2019, but it is unclear in the public records whether operation has commenced. As such, there is additional uncertainty in the potential temporal overlap between this project and the Project.

Great Northern Timber Pellet Facility (Present)

The Great Northern Timber Pellet Facility is located approximately 22 km northwest of the Beaver Dam Mine Site, and 16 km north of the Touquoy Mine Site. This facility produces chips for pulp and paper, MDF, and biomass, in addition to selling whole birch logs.

Data to support conclusions about residual effects of this project on Air quality is unavailable, however it is not expected that this project would result in a significant additive effect to Air quality with the Project. Neither of these projects triggered provincial or federal environmental assessment processes. As such, no air dispersion modelling was completed for either of these activities, and neither is expected to result in cumulative effects with the Project. There is some uncertainty in this conclusion, however, due to lack of available data.

Murchyville Gypsum Mine (Past)

This small gypsum mine is located approximately 36 km west of the Beaver Dam Mine Site and 18 km west of the Touquoy mine Site. As a small extraction mine with no processing of materials on site (beyond crushing), air emissions are not expected to be generated at this location. This project is not currently operational; therefore, there is no expectation of cumulative effects to Air between the Murchyville Gypsum Mine and the Project.

Dufferin Gold Mine (Historic and Proposed)

The Dufferin Gold Mine is located approximately 26 km southeast of the Beaver Dam Mine Site, and 43 km west of the Touquoy Mine Site. The footprint of this mine is approximately 375 m by 150 m. A bulk sampling program and associated milling was completed in 2018, but in 2019 the proponent (Resources Capital Gold Corporation) filed a Notice of intention to make a proposal under the Bankruptcy and Insolvency Act so future plans for this Project are uncertain. As such, the potential temporal overlap of this project and the Beaver Dam Project are unknown. Should the project proceed and overlap with the beaver Dam Project temporally, the potential spatial overlap of effects to Air needs to be considered. Details associated with the effects of the Dufferin project on air are limited. Considering the Beaver Dam Project is able to mitigate residual effects on Air and meet applicable guidelines within the Property boundary, the relatively small size of the proposed operation at the Dufferin site, and the distance

between the two (26 km), a spatial or temporal overlap between these projects is unlikely. Therefore, there is little potential for cumulative effects on air quality.

Tangier Gold Mine (Historic and Proposed)

The Tangier Gold Mine is located approximately 28 km south of the Beaver Dam Mine Site, and 27 km southwest of the Touquoy Mine. The footprint of this mine is approximately 500 m by 150 m, as measured on Google Earth. The Tangier Gold Mine was purchased by Resource Capital Gold Corp and plans are being developed for re-opening the mine. However, according to a press release dated January 29th, 2019, the proponent had filed a Notice of Intention to make a proposal under the Bankruptcy and Insolvency Act. The planned activities are limited to mining as no processing is planned at this site. Processing would take place at the Dufferin Gold Mine (Resource Capital Gold Corp. 2017). The potential temporal overlap of this project and the Project are unknown. Should the project proceed and overlap with the Project temporally, the potential spatial overlap of effects to Air needs to be considered. Details associated with the effects of the project on air are limited. Considering the Beaver Dam Project is able to mitigate residual effects on Air and meet appropriate air quality guidelines within the property boundary, the relatively small size of the proposed operation at the Tangier site, and the distance between the two (28 km), a spatial or temporal overlap between these projects is unlikely. Therefore, there is little potential for cumulative effects on air quality.

Taylor Lumber Co. Ltd. Mill (Present)

Taylor Lumber Co. Ltd. has operated a mill in Middle Musquodoboit since 1945. This site, located approximately 30 km west of the Beaver Dam Mine Site and 17 km northwest of the Touquoy Mine Site, includes a saw mill, a finishing plant, a pallet plant, a power plant, a dry-kiln, and a chipping plant. The power plant is a co-generation facility that burns biomass produced from their operation that provides power to their operation as well as to homes and businesses within a 30 km radius (Taylor Lumber, 2017).

It is possible that the Taylor Lumber Mill may result in an additive cumulative effect to Air quality, however the extent of the residual impact of the lumber bill on Air quality is unknown. No additional information is available to predict potential cumulative effects in a quantitative manner. Given that the Project is able to meet applicable air quality guidelines at the property boundary, the likelihood of a cumulative effects on air quality is low.

Mosher Lake Limestone Co. (Present)

Mosher Limestone processing facility is located approximately 21 km northwest of the Beaver Dam Mine Site and 16 km north of the Touquoy Mine Site. As such, the project lies within the RAA for Air for the Project, and there is a potential spatial overlap of residual effects. Mosher Limestone processes and sells limestone products in Nova Scotia and Atlantic Canada. Products include pelletized limestone, powdered limestone, granular limestone, powdered gypsum, pelletized gypsum, and traction sand. The processing facility crushes, packages and ships product. While very little data is publicly available, the Moser Lake Limestone Quarry is expected to generate dust and exhaust type emissions similar to other construction projects. This site has the potential for an additive cumulative effect on air quality with the Project, though it is expected to be minor given the distance between the two projects. No additional information is available to predict potential cumulative effects in a quantitative manner. This project did not trigger an environmental assessment and no publicly available data was found to provide air quality results associated with this project.

Fifteen Mile Stream Past and Proposed Mining Operations (proposed)

The Fifteen Mile Stream Gold Project is located approximately 17 km northwest of the Beaver Dam Mine Site, and 37 km northwest of the Touquoy Mine site. Residual effects on air quality from operation of the proposed Fifteen Mile Stream Mine Project include dust from onsite activities, vehicle travel, material handling and crushing of ore prior to transportation to the Touquoy Mine Site for processing. Residual effects are expected to be adverse, but not significant, and limited to the LAA, which represents a 1.5 km buffer of the PA. These effects will be mitigated through equipment maintenance, dust suppression, enforcement of speed limits, stabilization of stockpile slopes, covering of haul trucks and minimizing blasting events. There is no spatial overlap of residual effects between the FMS and Beaver Dam Gold Projects, as such, there is no expectation of additive cumulative effects. There is little uncertainty in this determination, given the clear definition of the spatial and temporal extent of residual impacts to Air presented in the EIS for the Fifteen Mile Stream Project.

ScoZinc Ltd. Mine (Past and Future)

ScoZinc is a proposed future (and past) zinc mine located approximately 50 km west of the Beaver Dam Mine Site, and 32 km west of the Touquoy Mine Site. While this Project is not currently in operation, it has an approved EARD and is expected to commence operation in the near future, so a temporal overlap of the Projects is possible. The ScoZinc Mine is expected to generate emissions related to trucking primarily. The spatial extent of impacts of the ScoZinc Mine on air quality has been defined as a 5 km zone of influence surrounding the Project. As such, there is no expectation for spatial overlap of residual effects between the ScoZinc Mine and the Beaver Dam Project, and no pathway for cumulative effects.

Cooks Brook Sand and Gravel Pit (Present)

This sand and gravel pit is located 47 km west of the Beaver Dam Mine Site and 29 km west of the Touquoy Mine Site. The primary operation at this facility is extraction and crushing of sand and gravel; air emissions are not expected to be generated at this location. Given that the spatial extent of residual effects of the Project on Air quality are limited to the LAA, there is no expectation of additive cumulative effects of these two facilities, given the distance between the sites.

Port of Sheet Harbour and Great Northern Timber Wood Chipping and Shipping (Present)

The Port of Sheet Harbour is a deep water port located 23 km southeast of the Beaver Dam Mine Site and 35 km southeast of the Touquoy Mine Site on the coast of the Atlantic Ocean. The terminal consists of a 152 m wharf with a minimum draft of 10 m and is capable of handling ships of up to 214 m (Port of Sheet Harbour, 2017).

At this same location, Great Northern Timber owns and operates a chipping and ship loading facility in Sheet Harbour, approximately 25 km southeast of the Beaver Dam Mine Site. Great Northern Timber procures wood chips and roundwood fibre from industrial landowners, sawmills, Crown lands, Private land contractors and Private woodlot management organizations in Nova Scotia, Prince Edward Island, New Brunswick and Quebec.

Data to support conclusions about residual effects of these projects on Air quality is unavailable, however it is not expected that either of these projects would result in a significant additive effect to Air quality with the Project. Neither of these projects triggered provincial or federal environmental assessment processes. As such, no air dispersion modelling was completed for either of these activities, and neither is expected to result in cumulative effects with the Project. There is some uncertainty in this conclusion, however, due to lack of available data.

8.5.2.2.3 Cumulative Effects on Ambient Air Quality

It is likely that forestry operations will occasionally coincide with those of the Project and cause greater disturbance to air quality that these operations produce individually. However, such additive periods are likely to be limited in duration and frequency and are not expected to be significant.

The gold processing and transportation activities associated with the Fifteen Mile Stream Mine Project, the Cochrane Hill Gold Project and the Project overlap in both time and space, with additional consideration to potential forestry activities that could also overlap spatially and temporally. Therefore, effects from the transportation and processing of gold from the three projects and forestry activities have the potential to act in an additive and cumulative nature. The operation of Beaver Dam Mine Project, the Project and the Cochrane Hill Gold Project are proposed roughly to occur during the same timeframe, with all three mines operating at the same time from 2023 to 2027. During this time all three projects will use the portion of the Beaver Dam Haul Roads west of the Highway 224 to transport gold concentrate to the Touquoy Mine Site resulting in potential additive cumulative effects to air quality through increased ambient dust levels along the Beaver Dam Haul Road. The addition of trucking from the two projects and forestry activity will not result in a significant cumulative effect (Appendix C.1).

The principal assumptions behind this assessment is that local forestry practices will not change in any important way during the Project, the Fifteen Mile Stream Project or the Cochrane Hill Gold Project. Limitations related to data availability do not allow us to make meaningful conclusions related to cumulative effects and project interactions for many of the projects listed throughout Section 8.5.2.2.2, however, given the limited spatial scale of the individual project effects, the mitigation measures proposed, and the distance between the projects, it is unlikely that any cumulative effects would be significant.

8.5.2.3 Mitigation

As the cumulative effects are not anticipated to be significant, additional mitigative measures (beyond those proposed to mitigate Project related effects, Section 6.2.7) for cumulative effects to air are not warranted.

8.5.2.4 Residual Cumulative Effects and Significance Assessment

Significant residual effects for the Air VC Are defined as having high magnitude (i.e., an **exceedance** applicable criteria), occur beyond the LAA, be of long-term to permeant duration, occur at regular intervals or be continuous throughout the Project, and be only partially reversible to irreversible, as described in Section 6.2.

The residual cumulative effects on the atmospheric environment are considered to be adverse but not significant (Table 8.5-3).

Table 8.5-3: Residual Cumulative Environmental Effects for Air

Residual Adverse Cumulative Effects (After Mitigation)	Significance Levels						Overall Significance of Residual Adverse Effects (and Rationale)
	Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility	
Increased cumulative dust during operation of the Project (Dust from mining and haul trucks)	M Possible exceedance of guidelines or threshold values when forestry operations occasionally coincide with hauling from the Project to the Touquoy Processing Facility along with ore or concentrate from Fifteen Mile Stream and Cochrane Hill Projects.	LAA The cumulative effects causing increased background air concentrations will not extend beyond the LAA.	A VC will be affected by timing – drier periods will increase fugitive dust emissions relative to wetter times of the year.	LT Effects may extend beyond 7 years.	R Additive periods of potential effects from the Project and forestry operations are likely to be limited in frequency. However, cumulative effects to ambient dust levels from the use of the Beaver Dam Haul Road by the Project, the Fifteen Mile and Cochrane Hill Gold Projects will occur regularly throughout the operational phase of the Project.	R VC will recover to baseline conditions once operations have stopped.	Moderate Adverse Effect (Not Significant) Effects are limited to the LAA where there are limited sensitive receptors, and the use of the Beaver Dam Haul Road. Furthermore, the VC is anticipated to recover to baseline conditions once the operation Project has been completed. Effects would be confirmed through monitoring.

Legend (refer to Section 5.11, Table 5.11-1 for definitions)

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	IR	Irreversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular		
H	High					P	Permanent	C	Continuous		

8.5.2.5 Follow-up and Monitoring Programs

No additional follow-up or monitoring beyond that presented in Section 6.2.10 is warranted.

8.5.3 Light Cumulative Effects Assessment

8.5.3.1 Baseline Conditions

8.5.3.1.1 Baseline Light Levels

As part of the 2007 Focus Report, a background light study was conducted at the Touquoy Mine Site. At all locations where baseline measurements were taken at the Touquoy Mine Site, ambient light measurements were under exposed, indicating ambient light levels were too low (<0.01 lux) to be measured (CRA, 2007). The Touquoy baseline conditions fell under the classification for rural areas, small villages, or relatively dark urban areas: “E2 Low District Brightness Areas”.

The conditions around Beaver Dam Mine Site, Haul Road, and surrounding area are similar to that of the background conditions for Touquoy Mine Site 2007 Focus Report, due to its remote, rural and mostly wooded, location. Ambient nighttime light conditions are minimal and typical of an undeveloped rural area. The largest artificial light sources in the Project Area are from the nearest residences, the Beaver Lake IR, and the occasional all-terrain vehicle. As such additional on-site light monitoring was not required to support the light impact assessment. The Beaver Dam Mine Site, Haul Road and surrounding area also fall under the classification for rural areas, small villages, or relatively dark urban areas: “E2 Low District Brightness Areas”.

A light impact assessment (Appendix D.1) was completed for the Beaver Dam Mine Project and included 9 points of reception (Section 6.3). For the purposes of this assessment, "pre-curfew" was assumed to be before 11 PM, and included road activity, and "post-curfew" was between 11 PM and 7 AM and included only overnight activities at the Beaver Dam Mine Site. The assessment of light impacts along the Haul Road was completed by considering a “worst case” scenario when two trucks are closest to each receptor and shining light towards the receptor. Because receptors along the Haul Road are not located on any road bends, with limited line of site to the travelling trucks, the assessed light impacts to these receptors were likely overestimated (Appendix D.1).

The calculated light levels at all receptors are below the limits recommended by the ILP guidelines during both pre- and post-curfew conditions (i.e., between 11 pm and 7 am and before 11 pm; Table 6.3-6 and Figure 6.3-2). The assessment considers worst-case operating conditions, for example, if all mobile equipment was in use at the same time and illuminating towards the receptors and the potential for light from both the Beaver Dam Mine Site and the Haul Road trucks to affect a receptor in a cumulative way.

The calculated light levels from the Haul Road are also below the limits recommended by the ILP guidelines (Table 6.3-6 and Figure 6.3-2).

Ambient night-time (post-curfew) light levels at the Beaver Dam Mine Site are predicted to meet the 1 lux guideline within 1.6 km from the site and as such not anticipated to affect the Beaver Lake IR or other receptors. The Beaver Lake IR 17 is located approximately 5 km southwest of the Beaver Dam Mine Site and is separated from the Beaver Dam Mine Site by forest and two topographic ridges.

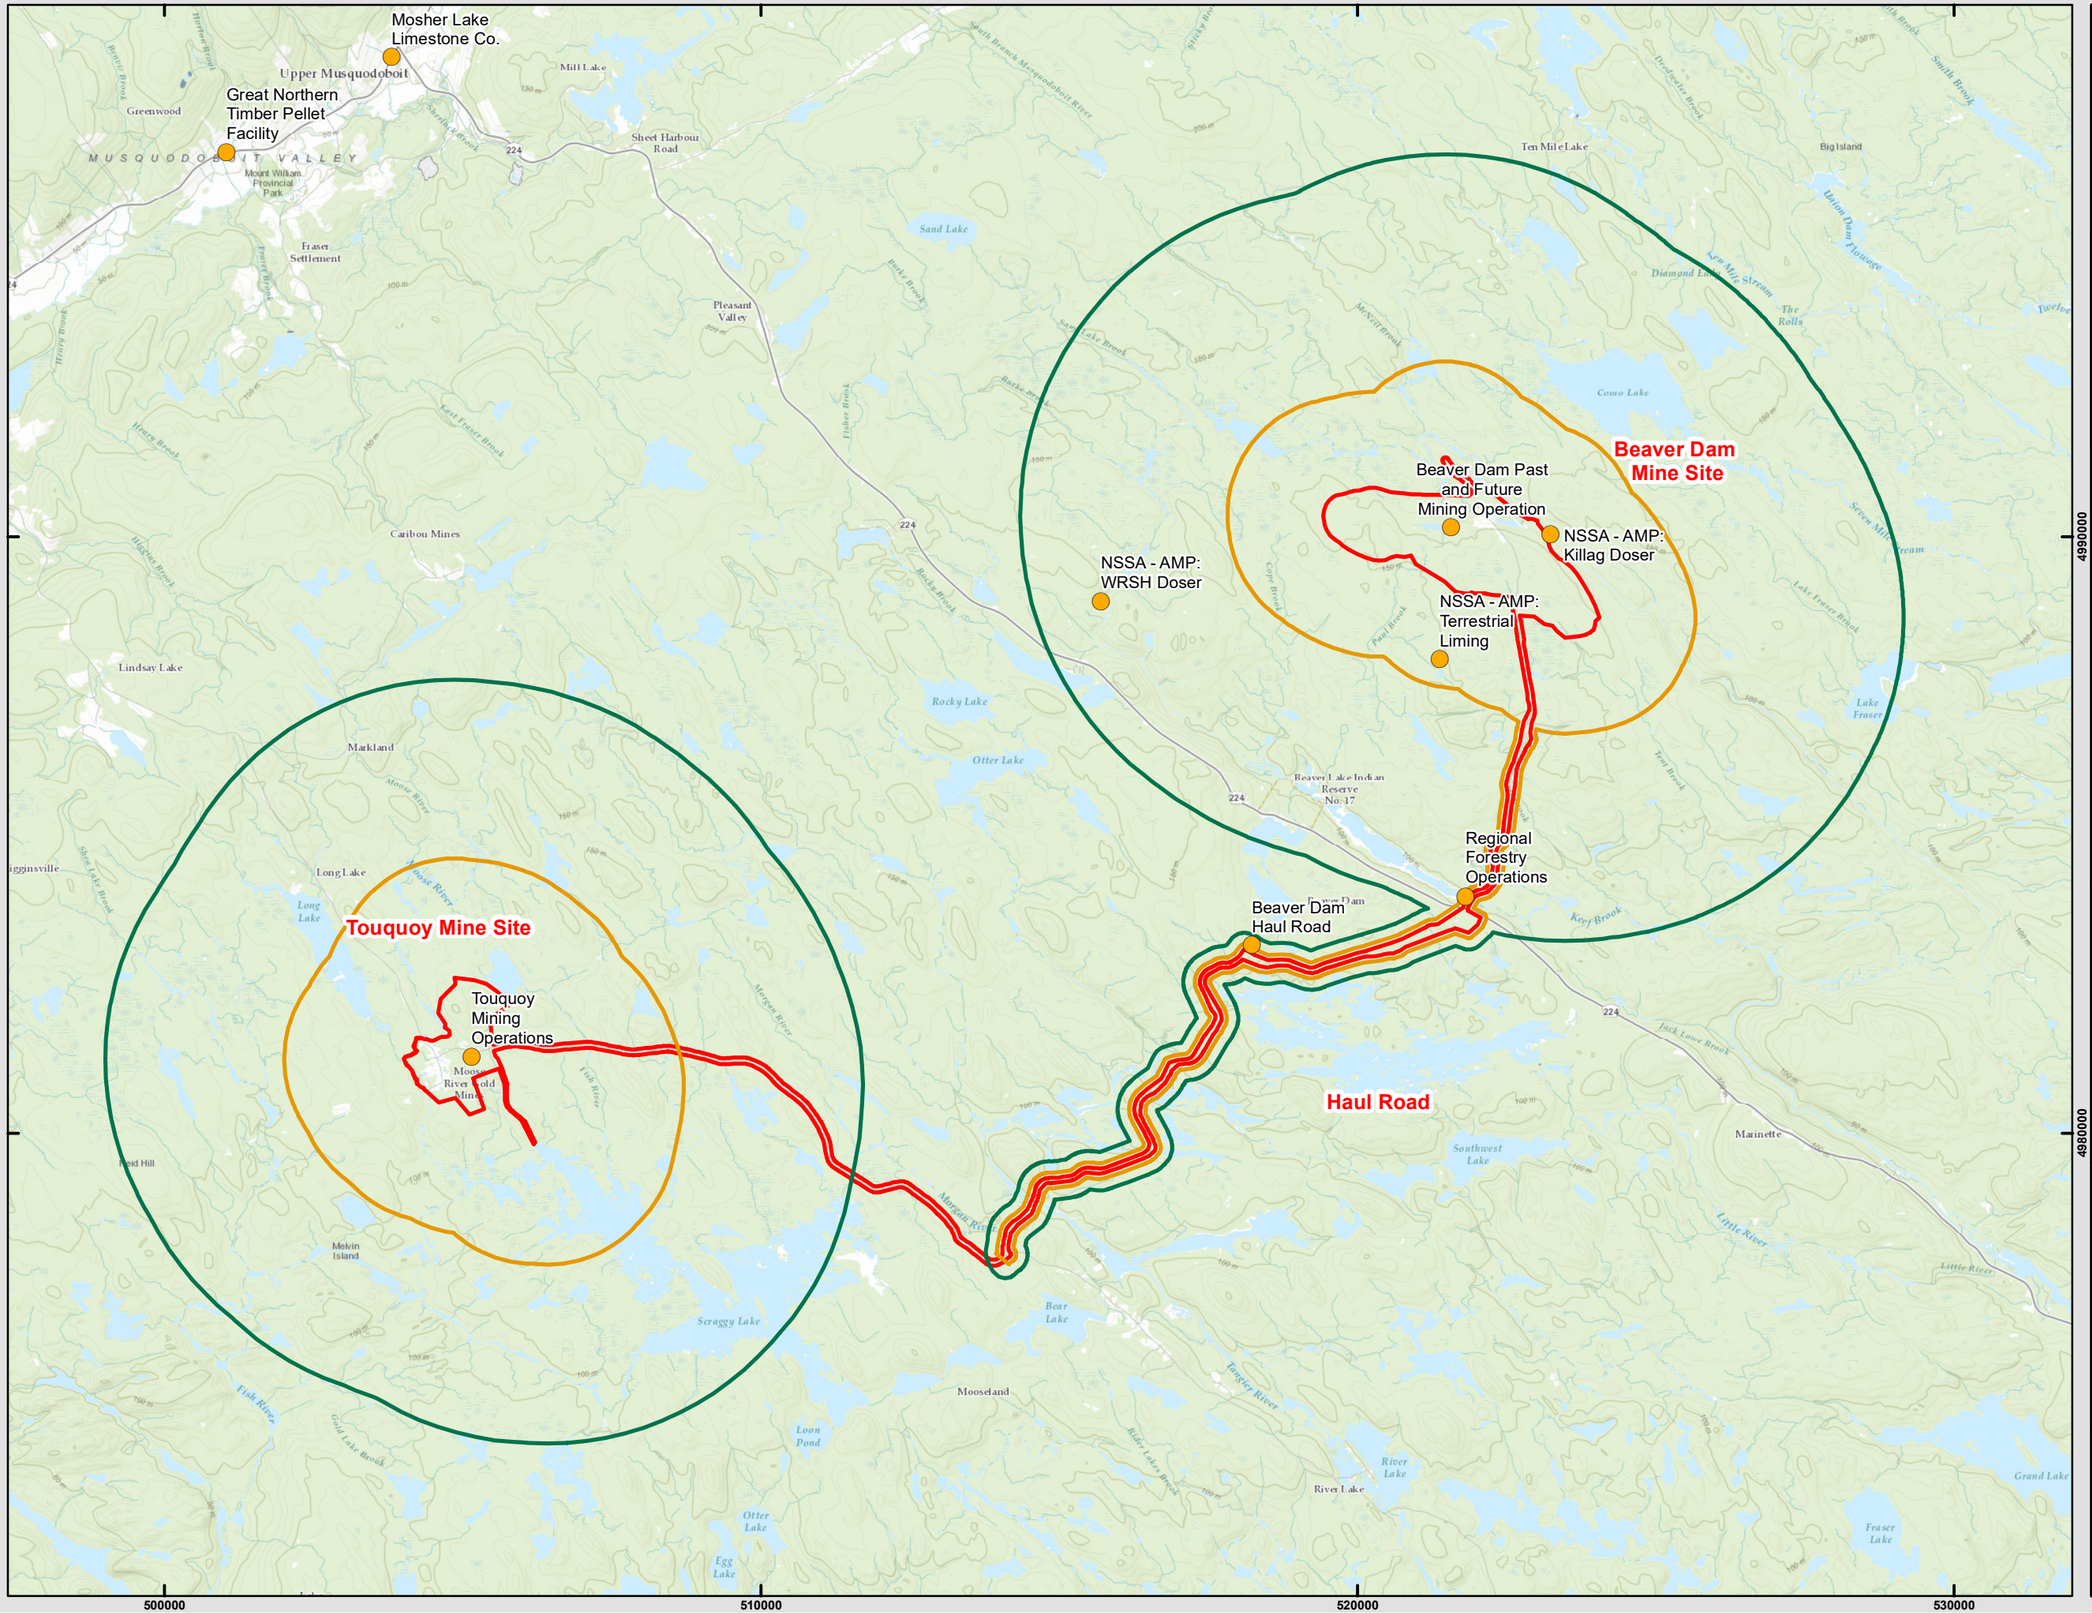
Distance to Sky Glow dissipation is summarized in Table 6.3-7 along with total luminous flux from the Beaver Dam Mine and Haul Road, and distance to the 5.0 lux and 1.0 lux assessment criteria. Table 6.3-7 shows the distance to a maximum 0.1 lux illuminance level which is considered as background light level for this assessment. Figure 6.3-2 shows the Light shed map depicting these

distances. The light shed map (Figure 6.3-2) shows that the light levels from the Beaver Dam Mine Site reach maximum 5 Lux at a distance of 719 m from the source, maximum 1 Lux light level at distance of 1,607 m from the source and maximum 0.1 Lux (background level) at a distance of 5,082 m from the source. Table 6.3-7 and Figure 6.3-2 also show that during Pre-Curfew conditions when the Haul Road is in operation, when two trucks pass the same point simultaneously, the ambient light may be 5 lux or more out to a maximum distance of 39 m from the Haul Road (on an instantaneous basis, this will not be a continuous light level, it will occur only where two trucks are passing each other, and only for the brief period they are both affecting the same receptor). At a distance of 279 m, the light under these same conditions will be less than 0.1 lux (or less than background) (Appendix D.1).

8.5.3.1.2 Residual Effects of Proposed Project

The predicted residual environmental effects of Project development and production of light are assessed to be adverse, but not significant. The calculated light levels at all receptors are below the limits recommended by the ILP guidelines during both pre- and post-curfew conditions. The calculated light levels at all receptors from the Haul Road are also below the limits recommended by the ILP guidelines.

The resulting area of illumination elevated above background conditions (sky glow) from the Beaver Dam Mine Site will be seen within 5,082 m. This encompasses receptors R1, R2, R3, and R4 (Figure 6.3-2). The predicted illuminance levels represent the worst-case operating conditions of the Beaver Dam Mine Site. The assessment considers when all of the mobile equipment at the mine would be in use at the same time, illuminating towards receptors. The areas surrounding the site are wooded with varying topography and inhibit the spread of light. It was conservatively assumed for screening purposes that 50% of the light will not reach the receptors due to directionality and line of sight obstructions. The amount of light blocked by the surrounding woodland and topographic changes, however, will likely be much greater than this (>90%), especially during the seasons when deciduous trees are leaf on (Appendix D.1). It is therefore not expected that the illumination will cause any significant visual impact, due to a combination of distance and the screening effects of topography and vegetative cover.



Beaver Dam ore will be trucked to the operating Touquoy Mine Site for processing. The primary effect of the continued use of the Touquoy Mine Site is the continued lighting of facilities and vehicular traffic during the processing of FMS concentrate. There are no new or additional effects from light anticipated to be caused by the processing of concentrate and the management of tailings from the Project and are therefore not further evaluated in this cumulative effects assessment.

8.5.3.1.3 Effects of Other Projects in the Area

The RAA for light, and projects which fall within this RAA are shown on Figure 8.5-3. The NSSA Acid Mitigation Project has a spatial and temporal overlap with the Projects' RAA for light. However, this project is not being discussed in the context of cumulative light impacts, because aside from several days per year of helicopter flights for terrestrial liming during daytime, the NSSA work does not generate light.

<u>Current Regional Forestry Operations</u>

The local forestry industry has the potential to have cumulative effects on light. As the forestry industry is ongoing in the region and has been for many decades, its effects on light are already accounted for in the local baseline conditions. Impacts on light associated with timber harvesting would be limited to temporary increases in light based on transportation to timber, and cannot be quantified in a meaningful with publicly available data.

McCallum Environmental Ltd.

Document Name: BD_EIS_Figure8-4-X_CEA_Light

Beaver Dam Haul Road Use by the Fifteen Mile Stream Project, Cochrane Hill Gold Project and Regional Forestry

During the operation phase of the Project, ore will be transported to the Touquoy Mine Site for processing. The Fifteen Mile Stream and Cochrane Hill Gold Projects plan to also transport gold concentrate from each surface mine to the Touquoy processing site for final processing into gold doré bar. The proposed haul route for each of these projects is proposed to overlap with the Beaver Dam Haul Road west of the Highway 224, along with potential trucking activity associated with the forest industry. Eleven round-trips are proposed to carry gold concentrate from each of the Cochrane Hill and the FMS Projects per day (totaling 22 vehicle round-trips per day or 11 1-way trips), plus 190 round-trips per day (or 95 1-way trips) between Beaver Dam Mine Site and Touquoy Mine Site. The total number of trucks for cumulative effects assessment is 288 trucks round trip (Appendix C.1).

The assessment of light impacts along the Beaver Dam Haul Road was completed by considering a "worst case" scenario when two trucks are closest to each receptor and shining light towards the receptor. Because receptors along the Beaver Dam Haul Road are not located on any road bends, with limited line of site to the travelling trucks, the assessed light impacts to these receptors were likely overestimated.

The 22 additional vehicle round trips along this Haul Road are not anticipated to change the assessment presented. The worst-case would still occur when two trucks are close to a single receptor and shining lights toward that receptor. As the road is only 2 lanes, only two trucks could approach a receptor at one time (one from each direction). During daylight hours, the truck lights are insignificant compared to ambient light levels, in the dawn, dusk and evening hours (until 11 PM when curfew is implemented), potential light impacts will be as presented in Section 6.3.

Within the Beaver Dam Mine Project EIS, the calculated light levels at all receptors from the Haul Road are also below the limits recommended by the ILP guidelines, as a result of road traffic. This will be unchanged with the additional vehicles from Fifteen Mile Stream and Cochrane Hill and with consideration of baseline forestry activity (Appendix D.1).

8.5.3.1.4 Cumulative Effects on Light

It is likely that forestry operations will occasionally coincide with those of the Beaver Dam Mine Project and cause localized elevated light levels relative to what these operations produce individually, especially along the Beaver Dam Haul Road. However, such additive periods are likely to be limited in duration and frequency and are not expected to be significant. There are no available data to quantify timber harvesting accurately on crown land or on private land. This is a substantial data limitation, which prevents us from making any more meaningful conclusions related to cumulative effects on light from the Project, in the context of a resource driven landscape with unknown amounts of timber harvesting. Based on the current understanding of proposed lumbering operations, it has been assumed that forestry operations may add 7 truck trips per day plus service vehicles (20 trips per day), but it clear that forestry will not be a significant source of traffic on the Haul Road.

The gold concentrate processing and transportation activities associated with the Beaver Dam Mine Project, the Project and the Cochrane Hill Gold Project overlap in both time and space. Therefore, the potential effects from the transportation from the three projects have the potential to act in an additive and cumulative nature. The operation of Beaver Dam Mine Project (2023 to 2027), the Project (2023 to 2029) and the Cochrane Hill Gold Project (2025 to 2030) are proposed roughly to occur during the same timeframe, with all three mines likely operating at the same time from 2025 to 2027. During this time all three projects will use the portion of the Beaver Dam Haul Road west of the Highway 224 to transport gold concentrate to the Touquoy Mine Site resulting in potential additive cumulative effects to light levels from trucking along the Haul Road. Given the limitations of traffic on the Beaver Dam Haul Road (2 lanes, only 2 trucks can be in one place at one time), the increase in volume of traffic will not result in a cumulative impact on light levels, particularly related to light levels at reception points.

The principal assumptions behind this assessment is that local forestry practices will not change in any important way during the Project, the Beaver Dam Mine Project or the Cochrane Hill Gold Project. These assumptions are considered to have a low uncertainty.

8.5.3.2 Mitigation

As the cumulative effects are not anticipated to be significant, additional mitigative measures (beyond those proposed to mitigate Project related effects, Section 6.3.7) for cumulative effects to light are not warranted.

8.5.3.3 Residual Cumulative Effects and Significance Assessment

For the purpose of this assessment, the threshold of determination of significant effects from light at the Beaver Dam Mine Site was determined to be 1 lux light trespass into windows at the nearest receptor. This was determined as a result of the baseline environmental light classification of E2 at the Beaver Dam Mine Project.

The residual cumulative effects on the atmospheric environment are considered to be adverse but not significant (Table 8.5-4).

Table 8.5-4: Residual Cumulative Environmental Effects for Light

Residual Adverse Cumulative Effects (After Mitigation)	Significance Levels						Overall Significance of Residual Adverse Effects (and Rationale)
	Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility	
Increased light levels during operation of the Project (operational light levels and light from transportation of gold concentrate and use of the Beaver Dam Haul Road by other projects)	L Less than or equal to appropriate guidelines or threshold values.	LAA The cumulative effects causing increased background light concentrations will not extend beyond the LAA. Exception to this is the cumulative light along the Beaver Dam Haul Road which is outside of the Project LAA but described herein.	N/A VC is not expected to be affected by timing.	LT Effects may extend beyond 8 years.	R Additive periods of potential effects from the Project and forestry operations are likely to be limited in frequency. However, cumulative effects to ambient light levels from the use of the Beaver Dam Haul Road Use by Fifteen Mile Stream and Cochrane Hill Gold Projects will occur regularly throughout the operational phase of the Project.	R VC will recover to baseline conditions once operations have stopped.	Low Adverse Effect (Not Significant) Effects are limited to the LAA where there are limited sensitive receptors, and the use of the Beaver Dam Haul Road. Furthermore, the VC is anticipated to recover to baseline conditions once the operation of the Beaver Dam Mine SIte has been completed.

Legend (refer to Section 5.11, Table 5.11-1 for definitions)

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	PR	partially reversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	IR	Irreversible
H	High					P	Permanent	C	Continuous		

8.5.3.4 Follow-up and Monitoring Programs

No additional follow-up or monitoring beyond that presented in Section 6.3.10 is warranted.

8.5.4 Surface Water Quality and Quantity Cumulative Effects Assessment

8.5.4.1.1 Baseline conditions

Surface Water Features

Beaver Dam Mine Site and Haul Road

The Beaver Dam Mine Site lies within the West River Sheet Harbour (WRSH) drainage basin, which is directly east of the Musquodoboit River Valley system. The watershed occupies an area of roughly 576 square kilometers (km^2), a moderately sized watershed in the Province. The area is characterized by rolling till plains, drumlin fields, extensive rockland, and numerous freshwater lakes, streams, bogs and wetlands having relatively low relief, hummocky type terrain. This inland area is somewhat removed from the immediate climatic influence of the Atlantic Ocean and is characterized by warmer summers and cooler winters.

The Killag River and Cameron Flowage is the main mapped linear watercourses of the Beaver Dam Mine Site, and Crusher Lake and Mud Lake are the major mapped lakes. The complex system of streams, lakes, bogs, and wetlands is a direct result of the underlying bedrock geology of greywacke and slate found in the region. The basin ultimately drains to the south via the West River Sheet Harbour, and discharge peaks are likely attenuated to a large extent by the numerous lakes and wetlands through which runoff is routed. The West River Sheet Harbour and Tangier River Secondary boundary runs through the center of the Project Area (Section 6.7.3) along the proposed Haul Road. Elevations within the catchment vary from approximately 135 to 165 meters above sea level (masl) in the headwater areas and gradually decrease to sea level at the final outlet located at Sheet Harbour. The headwaters of the drainage basin are located along the topographic divide separating the Musquodoboit River Valley to the northwest.

An inventory of surface water features was undertaken to identify water features may be impacted directly or indirectly by the proposed mine and Haul Road construction and operations. Initially three waterbodies (Crusher Lake, Mud Lake, and an unnamed waterbody in the southwest section of the Project Area) were identified through a desktop review of available mapping as requiring characterization of baseline conditions. During the 2019 field evaluations, 10 additional watercourses were identified within the Beaver Dam Mine Site, totaling 24 watercourses within the mine area. Three additional watercourses outside of the Beaver Dam Mine Site were also delineated (WC-23 [Outlet to Cope Brook], WC-26 [Outlet to Killag], and WC-27 [Outlet of Mud Lake]), due to potential impacts to fish and fish habitat within the LAA (Section 6.9). New watercourses are described in Section 6.7.3 and shown in Figures 6.7-1 and 6.7-2.

Most watercourses within the Beaver Dam Mine Site are first order streams originating within headwater wetland habitat inside of the PA. Many streams across the Beaver Dam Mine Site are generally small with minimal pool/riffle structure and consist of mucky organic substrate. While most are generally perennial in nature, many have intermittent patches, which go dry during prolonged rainless periods when percolation depletes all flow (Alberta Transportation 2009).

Tertiary basins potentially affected by the Project including four within the Beaver Dam Mine Site and six along the Haul Road footprint; were identified as a result of baseline characterizations studies, are listed below and shown on Figure 6.7-4).

The four tertiary basins constituting the PA and LAA identified for the Project:

- Portion of Killag River (1EM-2-D);
- Tent Brook (1EM-2-F);
- Paul Brook (1EM-2-H); and
- Cope Brook (1EM-2-J).

The six tertiary basins affected along the Haul Road:

- Tent Brook (1EM-2-F);
- Keef Brook (1EM-2-G);
- Jack Lowe Brook (1EM-2-N);
- Little River (1EM-2-P);
- Portion of Sandy Pond (1EL-2-C); and
- Portion of Morgan River (1EL-2-H).

Touquoy Mine Site

The Touquoy Mine Site is an active Mine Site that commenced operation on October 11, 2017 and is subject to an Industrial Approval to operate issued by NSE. A Class I Environmental Assessment under the *Nova Scotia Environment Act* and Environmental Assessment Regulations for the Project was reviewed and approved in 2008, subject to Approval conditions. The use of the Touquoy Mine Site for the processing of Beaver Dam Mine ore and deposition of the associated tailings will occur after ore extraction from the Touquoy open pit has ceased. As such, the baseline conditions for the Touquoy Mine Site for the Project operations will be the conditions expected near the end of the Touquoy ore processing operations.

Existing conditions with respect to surface water for the watershed was based on the available data collected as part of the 2007 submission (CRA), 2013 LiDAR (Leading Edge), and Water Management Plan (Stantec 2017a) for operation, the Reclamation Plan (Stantec 2017b) for reclamation and closure, and the 2017 surface water quality/quantity monitoring reports (Stantec 2018b).

The existing Touquoy Mine Site is part of the Moose River drainage basin, which is directly east of the Musquodoboit River Valley system. As described in the Environmental Assessment Registration Document (CRA 2007b), the Moose River watershed can be characterized by rolling till plains, drumlin fields, extensive rock land, and numerous freshwater lakes, streams, bogs and wetlands in the headwaters and the relatively low relief hummocky terrain. Forests are predominantly coniferous of red and black spruce (CRA 2007b). Local ground surface elevations at the Touquoy Mine Site range from 102 to 145 masl. The Touquoy Mine Site is approximately 10 kilometers (km) northwest of the Tangier Grand Lake Wilderness Area. This protected area consists of 16,000 ha of predominantly coniferous forest and has abundant lakes, wetlands, and waterways. The waterbodies within the Wilderness Area are contained within a separate watershed from that of the Touquoy Mine Site, which lies in the Fish River Watershed.

The Moose River drainage basin ultimately drains to the south via Moose River, and runoff through the catchment to Moose River is likely attenuated by the many lakes and wetlands in the catchment thus reducing the peak flow. The catchment area of Moose River is 3,904 ha at surface water monitoring station TQ-SW-2 draining from topographical highs of 180 to 110 masl in elevation (CGVD 2013) at the banks of Moose River. Moose River flows south approximately 2.3 km downstream of SW-2 where it joins the

Fish River. Watercourse No. 4 has a catchment area of 136.3 ha at surface water monitoring station TQ-SW-3 and flows south between the existing open pit and Tailings management Facility (TMF) to Moose River and eventually to the Fish River.

Surface Water Quality

The Killag River, Crusher Lake, Mud Lake, Tent Brook and Cope Brook (Beaver Dam Mine Site area), and Moose River (existing Touquoy Mine) constitute the primary focus of the Project baseline surface water characterization studies, as well as subsequent effects assessment, as these watercourses will receive direct discharge and/or catchment areas have potential to be impacted by Project water management activities.

The Project is in a highly mineralized region and the geology contributes to naturally elevated concentrations of many water quality parameters in the area, including iron, arsenic and aluminum. The occurrence of naturally elevated concentrations in surface waters is commonly observed in regions of planned/proposed mining activities, all over the world (e.g., "Golden Triangle" of northwestern British Columbia, Canada). In such regions, naturally elevated concentrations of certain water quality parameters generally occur where exposure of rock or other geologic materials to oxygen and water results in natural weathering processes, including chemical oxidation and leaching of solid-phase constituents (e.g., metals), which are then transported to surface waters.

Natural exceedances of water quality guidelines in baseline conditions are not a Project effect and, for these parameters, generic water quality guidelines (WQG) such as Canadian Council of Ministers of the Environment Water Quality Guidelines for the Protection of Freshwater Aquatic life (CCME FAL), do not necessarily apply. That is, WQG generally represent generic criteria that are developed by governments or international organizations to identify the concentrations of parameters in the receiving environment that are not expected to cause an adverse effect on various receptors or uses (e.g., aquatic life, wildlife, livestock/agriculture, drinking water. As WQG are intended to apply universally, they do not necessarily account for site-specific factors including the presence/absence of specific species in the receiving environment, or naturally occurring elevated existing water quality due to mineralization of the watershed.

To support baseline characterization for the Project, and subsequent effects assessment, site-specific water quality objectives (SSWQO) have been developed for arsenic (As). SSWQOs are site-specific criteria developed by proponents as part of ESIAs or permit applications in many jurisdictions, for example Canada, on a site-by-site basis to replace the generic WQG guidelines of the receiving environment; take instead, site-specific water quality. Here, arsenic is naturally elevated in Project area-streams and, in this instance, CCME FAL is not appropriate.

Baseline surface water monitoring was conducted at 19 locations around the Beaver Dam Mine Site and 29 locations along the Haul Road and 13 locations at the Touquoy Mine site, to obtain water quality data. The purpose of this program was to establish a baseline for comparison of surface water quality and quantity before site activities for the Beaver Dam Mine site commence.

At the Beaver Dam Mine Site, most nutrients were below or slightly above detectable concentrations, but below available water quality guidelines, indicating little to no influence from agricultural operations in the area. The watersheds have been logged extensively, yet turbidity is low, indicating generally little long-term impacts and a lack of silt in the soils and/or little erosion from logging practices. The existing Haul Roads at the in and around the Beaver Dam Mine Site have been used to haul timber as well; however, measured TSS levels were low, which may be attributable to limited use, existing road conditions and allowable speeds.

Along the Haul Road, similar to as described for the Beaver Dam Mine Site Area, most nutrients were below or slightly above detectable concentrations, but below available water quality guidelines, indicating little to no influence from agricultural operations in the area. The watersheds have been logged extensively, yet turbidity is low, indicating generally little long-term impacts and a

lack of silt in the soils and/or little erosion from logging practices. Metal concentrations were typically below detectable levels and/or available water quality guidelines.

Based on a review of the 2017 baseline surface water quality results (Stantec 2018a), surface water at the monitoring stations upstream and downstream of the Touquoy Mine Site had elevated baseline concentrations of arsenic, aluminum, cadmium, copper, iron, lead, manganese, and zinc that exceeded NSE Tier 1 EQS. In addition, cobalt, manganese, silver and mercury exceeded the Canadian Council of Ministers of the Environment (CCME 2018) guideline for the protection of freshwater aquatic life. These exceedances are considered to be naturally occurring, or the result of historical anthropogenic (i.e., non-Project related) activities, varying seasonally and representing baseline conditions at the Touquoy Mine Site.

Surface Water Quantity

FMS Mine Site

The average monthly temperature at the site ranges from a low of -6.2°C in January to a high of 18.5°C in July. The lowest average total monthly precipitation occurs in June (94.8 mm), while the highest occurs in November (137.1 mm). Snowfall was converted to snowmelt using the degree-day method. The rainfall plus snowmelt values were taken from this analysis for use in the water balance and predictive water quality assessments. Rainfall plus snowmelt depths peaked in March due to the rising temperature depleting the snow pack, creating a greater volume of available water for discharge. The lowest rainfall plus snowmelt occurred in June to August.

The total contributing drainage area to the Killag River downstream of the site, which includes the Project Site and Mud Lake and Crusher Lake, is approximately 3,933.5 ha.

Touquoy Mine Site

Scraggy Lake is part of the Moose River drainage system. It has an area of 6.4 km^2 (Stantec 2018c) and forms two major basins which are separated by islands and peninsulas. Scraggy Lake is the freshwater make-up supply for the active Touquoy mill process. Water flows into Scraggy Lake from approximately twenty-two inlets consisting of mapped watercourses or adjacent waterbodies. Water flows out of Scraggy Lake over the Fish River Dam and into the Fish River. The Fish River drains Square Lake located north of the existing Touquoy waste rock area to Scraggy Lake. Both lakes are part of the Fish River Watershed which flows west and then south into Lake Charlotte, eventually emptying into the Atlantic Ocean at Ship Harbour.

As per the Reclamation Plan for Touquoy (Stantec 2017b), Moose River is proposed as a second point of final discharge under closure of the exhausted Touquoy open pit. At SW-2, Moose River is a 3rd order watercourse with an approximately 12.5 m bankfull width as measured in the 2017 hydrometric program. The substrate was noted in the 2017 hydrometric monitoring report (Atlantis 2017) as characteristically muddy consisting predominantly of cobbles and small boulders, silt/sand with gravel.

Baseline flow in Moose River and Scraggy Lake at the end of Touquoy operations will be similar to the existing conditions prior to the development of the Touquoy Gold Project. The flow conditions in Moose River are represented by a stage-discharge curve derived based on an annual hydrometric monitoring program at stations SW-2, HM-1, and SW-11. Baseline flow statistics on Moose River were generated based on a regional analysis of thirteen representative ECCC (ECCC 2018) hydrometric stations, prorated to the Moose River catchment area at TQ-SW-2. The record of daily average flow for each station was fitted to the Log Pearson Type III distribution and prorated to the site based on catchment area. The log relationship of catchment area and flow was graphically plotted to establish a relationship between the catchment area and the average spring flow (April), summer flow (June/July/August), and low flow (July).

Surface water in Moose River is based a statistical analysis of regional flow records. As presented on Figure 6.7-6, strong linear trends exist between the average monthly flow rates of the selected monitoring stations and drainage area for April, August, and June to August with a correlation coefficient (R^2) of 0.98, 0.93, and 0.96, respectively. From these regional relationships, the average April and August flows for SW-2 in Moose River (catchment area of 39.03 km^2) are estimated to be 2.42 m^3/s and 0.45 m^3/s, respectively. Results of the analysis indicated that generally the peak and low flow events occur in April and August, respectively.

8.5.4.2 Analysis of Effects

8.5.4.2.1 Residual Effects of Proposed Project

Beaver Dam Mine Site Water Quantity Summary

A water balance analysis was conducted to assess the hydrologic impact of mine development on the surrounding water features. The water balance was calculated for five assessment points where the site will discharge or impact flows in the natural environment, including the Killag River, Mud Lake (outlet to WC-27), Crusher Lake (outlet to WC-5), Tent Brook and Cope Brook systems.

Mine site development will increase the Killag River catchment area, and decrease the Mud Lake, Tent Brook and Cope Brook catchments due to the placement of mine features in their baseline drainage areas. Surface runoff from mine features will be directed to settling ponds for treatment prior to being released into the Killag River and Tent Brook systems. The north settling pond will receive and treat runoff from the waste rock, low-grade ore and topsoil stockpiles, the crusher pad, administrative building area and site roads. Surface water and groundwater collected in the pit sump will also be dewatered to the north settling pond. The east settling pond will receive runoff from the till stockpiles, part of the organic stockpile and site roads. The north and east settling ponds discharge to the Killag River. The south settling pond will receive runoff from another other part of the organic stockpile and a topsoil stockpile. The south settling pond discharges to WC-19 of the Tent Brook system.

As part of the site reclamation plan, the pit will be filled with water from groundwater inflows, direct precipitation, and site contact water. Water will no longer be pumped from the pit to the north settling pond, and the north settling pond discharge will be re-directed into the pit. Once the pit is filled, the north settling pond will be decommissioned and site runoff will be diverted directly into the pit (Figure 6.7-14). Overflow from the pit will be directed to the Killag River through an engineered outfall in the east pit wall and existing outlet channel (WC-13). The capacity of the pit is approximately 16,000,000 m^3. During PC conditions an additional 8.6 ha will be routed to Mud Lake, reducing the impact to the Mud Lake drainage area to from a 18.3% decrease between baseline and EOM conditions to a 13.7% decrease between baseline and PC conditions. The impact to the drainage area of the Tent Brook and Cope Brook assessment points remain the same as in EOM conditions.

Beaver Dam Mine Site Water Quality Summary

During EOM conditions site water from the waste rock, low grade ore stockpiles and the pit will be routed through the North Settling Pond prior to discharge into the Killag River. Additionally, clean water from the site will be diverted and discharged directly to Mud Lake. There will also be clean discharge from the eastern till stockpiles to the Killag River. During PC conditions, site water from the waste rock stockpiles will be routed through the pit prior to discharge into the Killag River.

In summary, under the EOM scenarios, predicted mass balance near-field mixing zone and far-field mixing zone chemical concentrations in the base case are consistently below selected water quality benchmarks. The initial analysis assumed no treatment of mine contact water in the north settling pond and only analyzed the results from a mass balance (dilution) calculation

at the extent of the predicted mixing zone. The results indicated that, while concentrations for some parameters are anticipated to increase above baseline levels, at the near-field mixing zone there are no exceedances of either CCME, NSE Tier 1 criteria. As water quality criteria are defined by national and international entities as protective of the receiving environment and all water users, there are no anticipated effects to surface waters are a result of discharges from the Project to the Killag River.

However, in the EOM upper case scenario, nitrite is predicted to exceed CCME regulatory guidelines in three months of the year. Note, modelling for the Project is conservative, and based on the principles of mass balance. That is, while mass and water balance models (including GoldSim) provide capabilities for simulating mass and water balances, these processes do not represent complete reaction paths and water quality predictions are expected to be further governed by in situ processes. This included equilibrium reactions, sorption reactions and solubility limits which, together, would generally service to reduce concentrations of many quality parameters predicted by the mass balance. In particular, nitrite is known to be unstable in oxygenated environments (such as the Killag River), oxidizing to Nitrate and/or bio-assimilated. Thus, it is likely that nitrite concentrations have been overestimated for the Killag River, in both base case and upper-case scenarios. However, in response to IR2, potential nitrite removal technologies have been identified and evaluated for the Project (Appendix F.2 [Water Treatment Assessment Operation] of Appendix P.4 Mine Water Management Plan).

During PC conditions the pit lake discharges into the Killag River directly. Predictions were generated for the PC at near-field mixing zone assessment point and PC far-field mixing zone assessment point. The initial analysis assumed no treatment of mine contact water in the pit lake and only analyzed the results from a mass balance (dilution) calculation at the extent of the predicted mixing zone. There is contingency for an interception trench during PC if there are potential impacts from the PAG pile on groundwater. Water from the interception trench will be directed to the pit and/or treated

At the near-field and far field mixing zones the results from the analysis concluded that during base case scenario, while concentrations for some parameters are anticipated to increase above baseline levels, there are no exceedances of either CCME, NSE Tier 1 criteria. As water quality criteria are defined by national and international entities as protective of the receiving environment and all water users, there are no anticipated effects to surface waters are a result of discharges from the Project to the Killag River. However, results from the upper-case scenario suggest there is potential for a slight exceedance of the CCME guideline for cobalt and zinc in July and August, which is within range of natural variability. If monitoring data deviates from impact predictions, then water treatment will be undertaken.

Under the PC scenarios, there is little difference between predicted chemical concentrations at near-field mixing zone (pit lake discharge) and far-field mixing zone locations for each assessment each case. The results for the mass balance assessment during the base case PC scenarios the chemical concentrations are consistently below selected water quality benchmarks. In upper case PC scenarios, cobalt and zinc concentrations are predicted to exceed selected water quality benchmarks at both locations without during the months of July and August. An aquatic ecological risk assessment is provided in (Appendix G.2). If monitoring data deviates from impact predictions, then water treatment will be undertaken. Results for cobalt and zinc, are further discussed below.

- **Cobalt**, the predicted PC cobalt concentration at the near-field location marginally exceeds the Federal Environmental Quality Guideline (FEQG; 0.78 µg/L) in the upper case (0.8 and 0.85 µg/L in July and August; Table 6.7-35). The concentrations are up to 1.1 times the FEQG. A similar situation occurs with the PC far field location, wherein cobalt concentrations are predicted to range between 0.8 to 0.84 µg/L in July and August (upper case; Table 6.7-39). Additional water quality modelling was conducted to confirm hardness levels in the receiving environment, following effluent release. his modelling indicates that hardness in the near field receiving environment is predicted to increase to 11.4 mg/L $CaCO_3$ in the PC upper case. These hardness levels are also predicted for the far field location. The FEQG considers hardness as a modifying factor, and was derived for water hardness values ranging between 52 to 396 mg/L. The FEQG of 0.78 µg/L

represents the guideline value using a water hardness of 52 mg/L. Given that the water hardness in the near field receiving environment is predicted to be below this range, there is some uncertainty associated with the use of this guideline value. However, the SSD model developed by Environment Canada in this guideline setting approach is very conservative, and the data used in the assessment do not fit the selected model of the SSD in the lower quartile of the dataset well (see Figure 1; ECCC, 2017). This results in the estimated HC5 value being considerably lower than it should be, relative to the toxicity dataset. This indicates that the selected guideline is over predicting toxicity of cobalt, and hence, the marginal exceedances predicted are unlikely to pose a risk in the receiving environment. In addition, Dissolved Organic Carbon (DOC) is an additional modifying factor for cobalt toxicity (Stubblefield et al., 2020). This factor was not considered in the development of the FEQG, and would assist in mitigating potential for toxicity, based values that cobalt is largely non-detect in the baseline data, at a detection limit of 0.4 µg/L (Table 6.7-12). The predicted concentrations have been added to a mean value which may be biased high due to the non-detect samples. For additional context, it is interesting to note that Stubblefield et al. (2020) published two water quality guidelines for cobalt recently as follows:

  - European-based approach and EC_{10} values and a species sensitivity distribution (SSD), yielding a median hazardous concentration for 5% of the organisms (HC5, 50%) of 1.8 µg/L; and
  - A US EPA-style approach, using EC_{20} values in a SSD to derive a final chronic value (FCV) of 7.13 µg/L (note: this approach is more relaxed than typical Canadian approaches for deriving water quality standards, and hence, it is not recommended to use this value).

Neither of these approaches used hardness, or other water quality factors as modifiers. Based on the marginal degree of exceedance, the presence of elevated DOC concentrations, and increased hardness levels associated with the release of effluent, cobalt is considered unlikely to pose a risk to aquatic life.

- **Zinc**: The predicted concentrations do not exceed the new CCME guideline for zinc (7 µg/L) in the EOM scenarios for near field or far field. Additionally, predicted concentrations do not exceed the CCME guideline for zinc in the PC scenarios for near or far field in the base case, but do in the upper case. In the near field PC scenario, upper case predicted exceedances from the pit are 7.09 and 7.39 µg/L in July and August, respectively (Table 6.7-35). In the far field PC scenario, upper case predicted exceedances are 7.05 and 7.35 µg/L in July and August, respectively (Table 6.7-39). The Lowest observed effect concentration (LOEC) listed in the CCME (2018) fact sheet is 9.89 µg/L (11-week study; development; Chironomid sp.; normalized to 50 mg/L $CaCO_3$ and Dissolved Organic Carbon (DOC) of 0.5 mg/L). The predicted concentrations are within the range of background (<5 to 7.8 µg/L; based on sample size N=15). The waters of the Killag River are soft (<10 mg/L $CaCO_3$), but the DOC is reasonably high (ranging from 7 to 20 mg/L; mean of 12.2 mg/L, based on 2019 and 2020 data), and would be expected to provide adequate protection, for several of the months where predictions indicate elevated levels. Additional water quality modelling was conducted to confirm hardness levels in the receiving environment, following effluent release. This modelling indicates in the PC base case, hardness in the near field receiving environment is predicted to increase to 11.4 mg/L $CaCO_3$ in the PC upper case. These hardness levels are also predicted for the far field location. Based on these hardness levels, and accounting for site specific pH and DOC, the zinc guideline changes to 33 µg/L (based on an assumed mean hardness: 11.4 mg/L; mean pH: 5.43; mean DOC: 12.2 mg/L). None of the predicted concentrations exceed this guideline value, and hence, predicted zinc concentrations are considered to have a low potential for toxicity.

The site will be monitored during construction and operations. The outcomes from the modelling will inform updates to water quality model to refine PC predictions. The principals of adaptive management will be applied if the outcomes from modelling differ from those predicted.

In response to IR2 issued by Canadian Environmental Assessment Agency and Nova Scotia Environment, and as a result of ongoing water quality, water quantity and geochemical studies for the Project, water treatment for both EOM and PC is planned

for the Project. Details for water management and evaluation of water treatment alternatives are presented (F.1 [Water Treatment Assessment Post-closure of Appendix P.4 Mine Water Management Plan, Appendix]). Note, the treatment system will be designed to ensure that all site effluent water meets MDMER and will reflect assimilation capacity of the receiving environment, such that any potential effects to the Surface Water Quality VC, and downstream water users, will be fully mitigated.

Touquoy Surface Water Quality

Based on the water balance model results (Appendix A of Appendix P.4 [Mne Water Management Plan]), no water will be discharged from the exhausted Touquoy open pit until the pit reaches the spillway elevation in Year 12. This allows for many years of water treatment in the pit as a batch reactor with the objective of adjusting the pH to precipitate metals, potentially improving discharge criteria toward MDMER discharge criteria. As an additional benefit of the slow filling of the pit over time, the residence time and exposure to the atmosphere will increase, thus enhancing the natural UV degradation of cyanide and improving water quality in the pit lake.

The water quality in the Touquoy open pit will be monitored during the pit filling and as the pit level approaches the spillway elevation. The water quality will be compared to the MDMER discharge limits and will be treated as required to meet these limits. The MDMER discharge limits will decrease from the existing limits to those presented in Table 6.7-15 effective June 2, 2021. The discharge from the Touquoy Mine Site is anticipated to occur after this period, and therefore the lower MDMER limits will apply.

The water quality model of Moose River predicts the effluent concentrations under normal discharge from the Touquoy open pit combined with the groundwater seepage contributions in Moose River under the same climate conditions. Moose River will primarily be driven by climatic conditions, and April flows were selected in the modelling to represent a worst-case dilution ratio between the effluent discharge from the Touquoy open pit and Moose River. This results in conservatively higher estimates of mass loadings to the receiving environment from the Project.

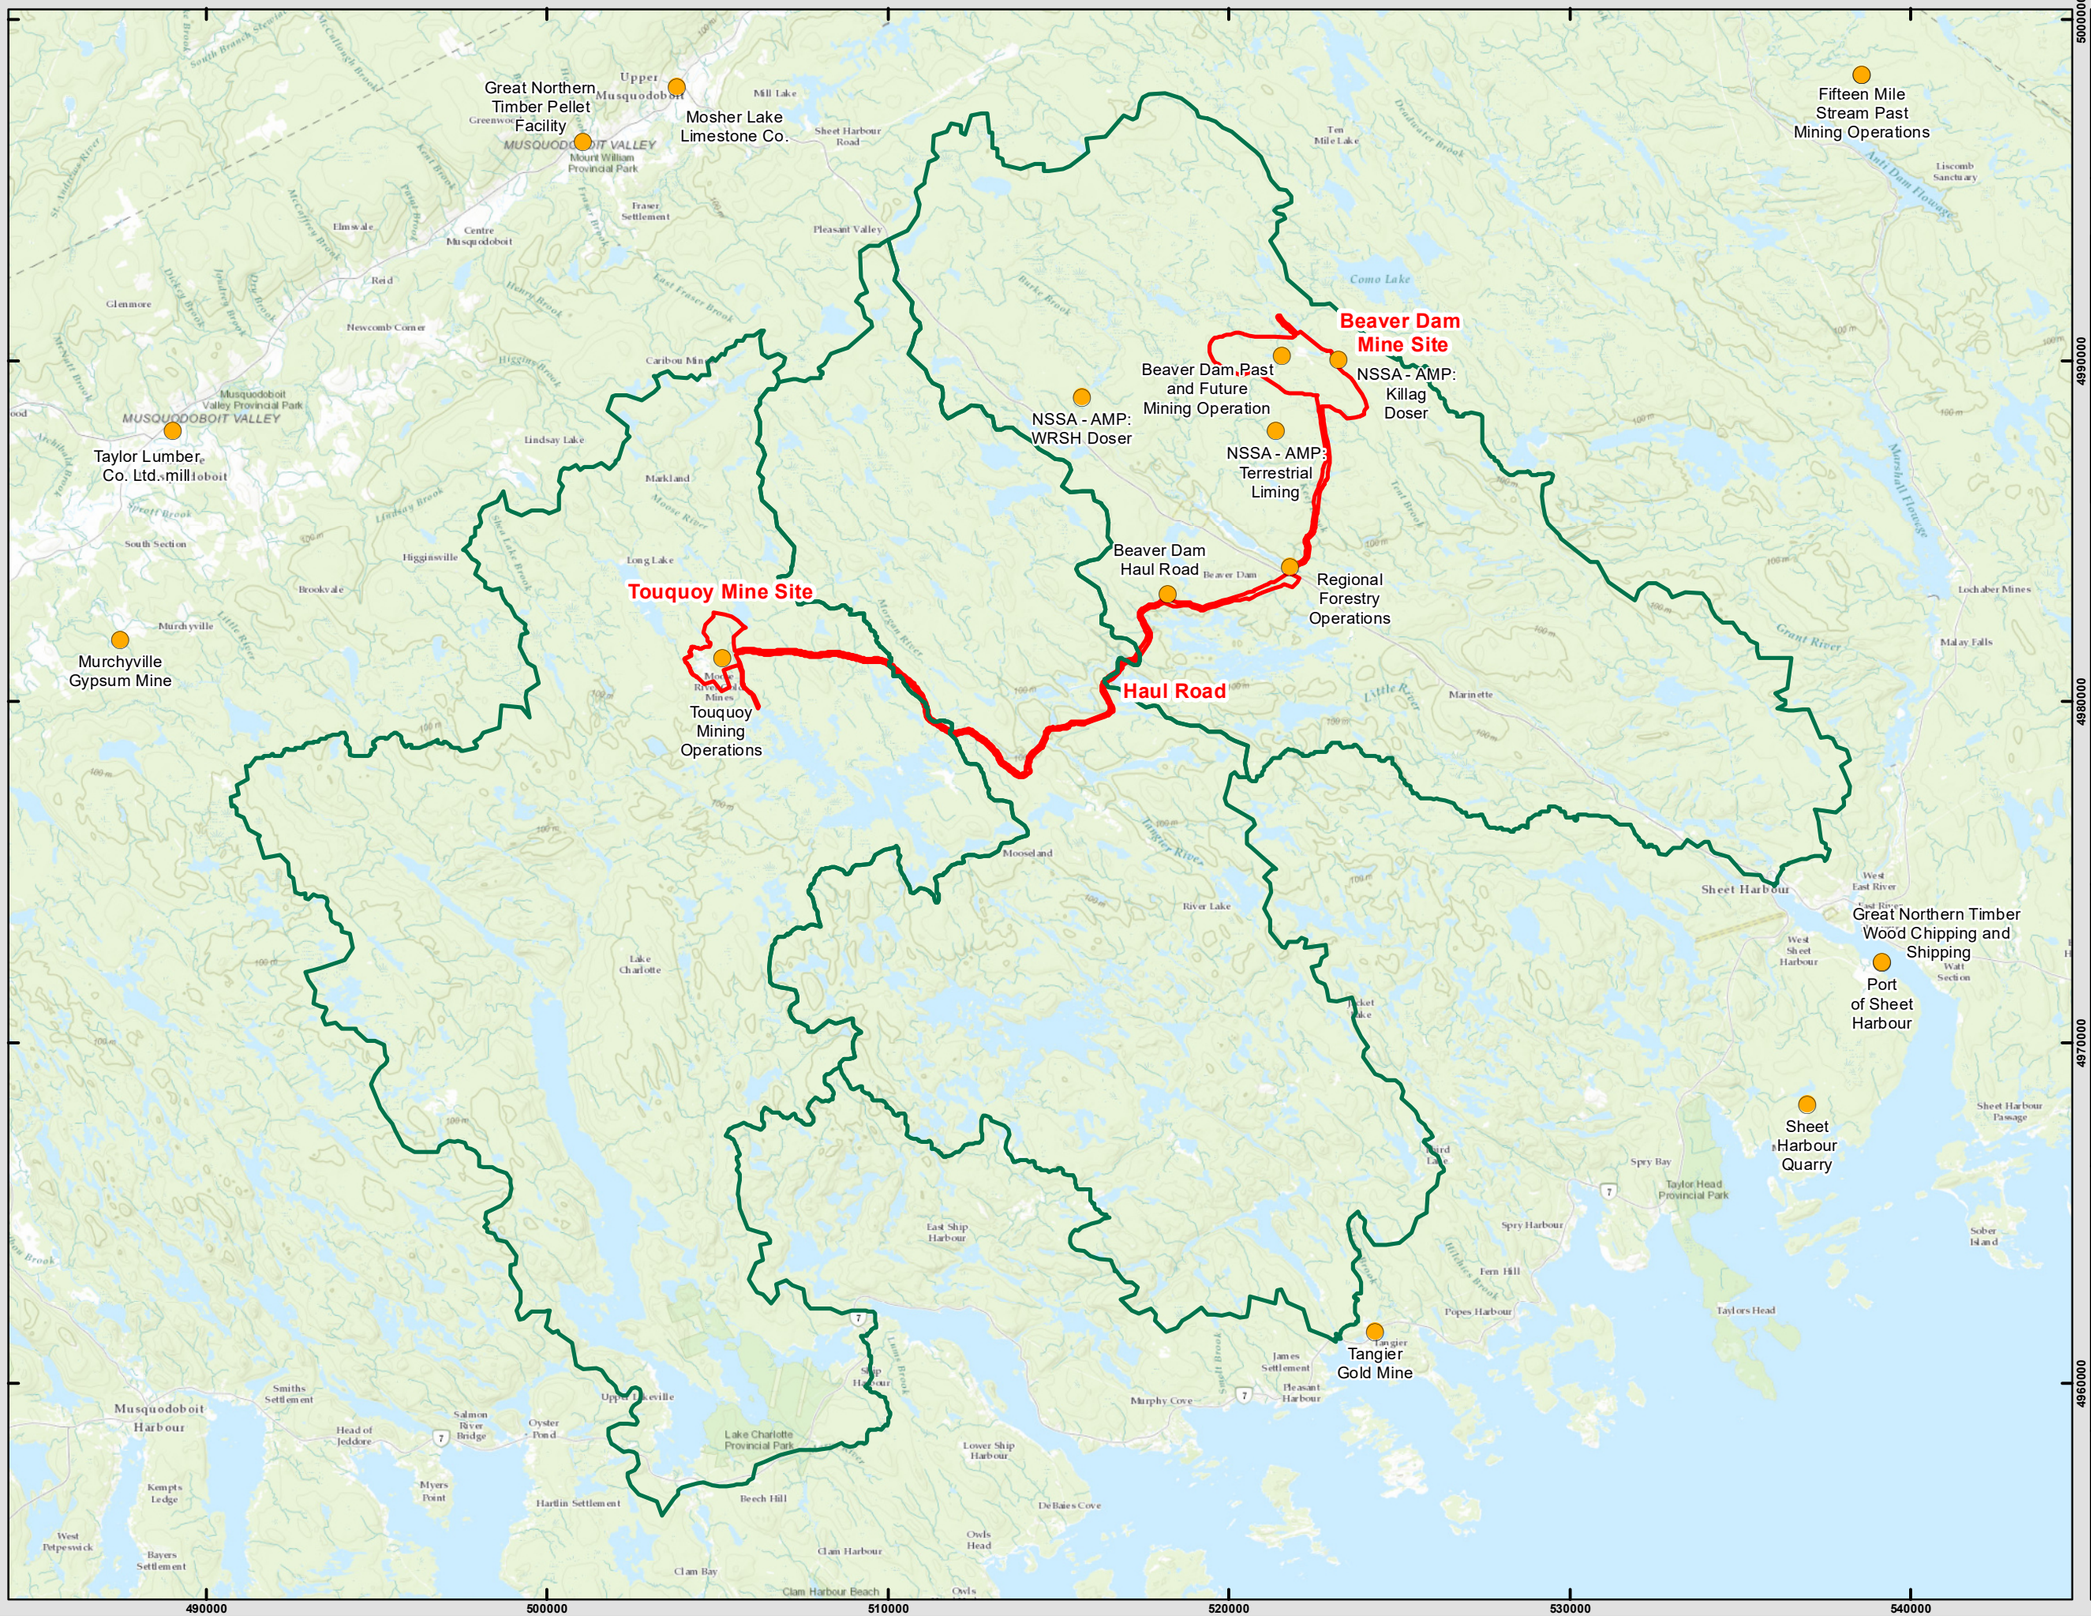
It is important to note that the NS Tier 1 guideline of 5 µg/L (which is based on the CCME guideline), is for free cyanide. This guideline is not a relevant guideline to compare Total cyanide, SAD or even WAD forms of cyanide to, as it is based on the free ion, as opposed to bound forms of cyanide, which have far lower toxic potential. Based on the receiving environment predictions, WAD cyanide is approximately half of the Total Cyanide predicted concentration (0.0032 mg/L WAD, compared to 0.0074 mg/L Total). This implies that the half of the Total Cyanide prediction would be SAD, and hence, less likely to dissociate in the receiving environment (mean pH in receiving environment is 6.05). Predicted WAD concentrations in the receiving environment are below the NS Tier 1 guideline, indicating acceptable levels of risk to aquatic life. Based on this, risk to aquatic life are predicted to be low.

Predicted cobalt levels in the receiving environment (0.0011 mg/L) marginally exceed the new FEQG for cobalt (0.00078 mg/L), but are less than the NS Tier 1 cobalt value of 0.01 mg/L. The FEQG considers hardness as a modifying factor, but the SSD model developed by Environment Canada in this guideline setting approach is very conservative, and the data used in the assessment do not fit the selected model of the SSD in the lower quartile of the dataset well (Figure 1; ECCC, 2017). This results in the estimated HC5 value being considerably lower than it should be, relative to the toxicity dataset. This indicates that the selected guideline is over predicting toxicity of cobalt, and hence, the marginal exceedance is not considered to represent a concern, with respect to toxicity to aquatic species. Cobalt concentrations are predicted to decrease to 0.0010 mg/L by 120 m from the effluent discharge point (Appendix F.8, Table 10 [Project Assimilative Capacity Study of Moose River - Touquoy Open Pit Discharge]), which is 0.1 ppb above the guideline. Risks to aquatic life at this concentration are anticipated to be low (Appendix G.2).

Touquoy Surface Water Quantity

The use of the exhausted Touquoy facility for tailings storage will result in the accelerated filling of the pit from that of the Touquoy reclamation plan.

Based on a three-dimensional model of the Touquoy ore body presented in the water and tailings management plan (Appendix F.7 [Touquoy Integrated Water and Tailings Management Plan]), the total storage capacity of the exhausted open pit at the maximum surface water elevation of 108 m CGVD2013 is estimated at 8.962 Mm^3. The water balance model predicted the amount of water and tailings stored in the pit until the pit was filled to 108 m CGVD2013. Based on results of the water balance model and the derived elevation storage relationship, tailings will be deposited in the open pit for a total of 41 months reaching an elevation in the pit of 93.2 m CGVD2013. This amounts to approximately 14.8 m of water cover above the tailings, assuming the spillway invert elevation of 108 m CGVD2013. The water balance model simulated that it would take an additional 100 months or a total of 141 months from commencement of operation to fill the pit to the spillway invert elevation.



Initially, process water will be reclaimed at a rate of 8,960 m^3/d from the existing Touquoy TMF until surplus water storage in the pond is depleted. Based on results of the water balance model under climate normal conditions, three to five months of process water surplus will be available depending on the month of start-up. Subsequently, process water will be reclaimed from the exhausted Touquoy open pit at the same rate, recirculated as a closed loop through the mill facility during the remaining period of processing Beaver Dam ore at the Touquoy facility. As the current practice at Touquoy, this water management strategy reduces the quantity of mine contact water or the at the site and a lower demand on freshwater supplies.

8.5.4.2.2 Effects of Other Projects in the Area

The RAA for surface water quality and quantity, and projects which fall within this RAA are shown on Figure 8.5-4. There is direct spatial overlap between the Project and historic mining operations in the Beaver Dam Haul Road, Touquoy Mine Site, regional forestry operations and the NSSA AMP. Any potential cumulative effects from these projects related to surface water would be based on potential impacts to water quality from mobilization of historic tailings. The potential impact of this interaction will be mitigated by implementation of the Historical Tailings Management Plan (Appendix E.9). As such, these historic operations are not carried through the CEA process.

Regional forestry operations

The local forestry industry has the potential to have cumulative effects on surface water. As the forestry industry is ongoing in the region and has been for many decades, its effects on surface water quantity and quality are already accounted for in the local baseline conditions. Furthermore, in Nova Scotia forestry operations are regulated under the *Wildlife Habitat and Watercourse Protection* regulations, which imposes various restrictions on timber harvesting with the purpose of limiting impact of forestry on aquatic habitats. Presuming forestry operators adhere to these regulations, the likelihood of a cumulative effect on surface water from timber harvesting and the Project is limited.

NSSA Acid Mitigation Project

The NSSA AMP operates three main components. Two lime dosing stations are located on the West River Sheet Harbour and on the Killag River, downstream of Cameron Flowage. Neither of these components have direct spatial overlap with the Proposed Project, although the dosing station on the Killag River is approximately 650 m southeast of the proposed pit. Despite its close proximity to the proposed Project; the spatial extent of direct and indirect impacts to fish and fish habitat does not extend to this portion of the Killag River, as specified in Section 6.9.7.1.6.

Terrestrial liming has occurred within the Paul Brook, Keef Brook and Tent Lake watersheds. According to Rotteveel (2018), terrestrial liming occurred in MacGregor Brook and Colwell Brook during the fall of 2016, with some expected 'blowout' from helicopter liming affecting Cope Brook as well. The upper portion of the Killag River (above the lime dosing station) and Brandon lake Brook were used as control sites for this study. On September 25, 2019, MEL and AMNS met with the NSSA and ASF to discuss the second round of information requests related to the Project. During that meeting, it was stated that the NSSA would be commencing terrestrial lime application in the Tent Lake watershed; but indicated that terrestrial liming would not occur in proximity to the proposed organics stockpile until 2020. Of the three watersheds where terrestrial liming is known, or expected to have occurred, the Project only has a spatial overlap with the Tent Lake watershed (1EM-2-F) and the Keef Brook watershed (1EM-2-G). According to Rotteveel (2018), acidification of Nova Scotia's freshwater ecosystems has resulted in decreased habitat quality for Southern Uplands Atlantic Salmon, due in part to the mobilization of aluminum which has been mobilized due to low pH.

The residual effect of the NSSA AMP on surface water quality, is a positive due to reduction of the effect of historic acidification on water quality within the treated catchment areas of the West River Sheet Harbour watershed. This Project is defined as having direct spatial and temporal overlap with the Beaver Dam Project specifically within the Tent Brook watershed (Project effects related to low magnitude flow reductions), and to a lesser extent, the Keef Brook watershed (Project effects related to Haul Road construction).

Touquoy Gold Project

The effects of the Touquoy Gold Project on surface water include (based on CRA 2007a and GHD 2017b):

- Reduced water quality from sedimentation/siltation, deposition of fines during construction, operation and decommissioning;
- Introduction of contaminants (e.g., nitrate) from blasting operations and pit dewatering;
- Effluent released into Scraggy Lake from the tailings and polishing ponds;
- Water withdrawal from Scraggy Lake; and
- Potential impact to surface water quality from spills of hazardous materials stored on site during mine construction and operation.

Given the implementation of mitigation measures to control erosion and sedimentation, significant adverse effects from operation of the Touquoy Gold Project are not anticipated on surface water resources. The Touquoy Gold Project currently holds an Industrial Approval for water withdrawal, permitting withdrawal of up to 720 m^3 per day, to a maximum of 262,800 m^3 annually from Scraggy Lake (Approval #2017-103502-01). Treated effluent is released form the polishing pond into Scraggy Lake, with monitoring completed under the EEMP to ensure compliance with MDMER.

The discharge of treated mine effluent is controlled by MDMER regulations. The effluent must meet the limits put in place to protect the aquatic environment and the effects monitoring program will ensure that operational discharges are compliant. Therefore, no significant adverse effects on surface water resources from tailings effluent on Scraggy Lake are expected. Water monitoring

completed under the EEMP for release of water to Scraggy Lake, and authorization for water withdrawal, it Is not expected that the Touquoy Gold Project results in a significant adverse effect to aquatic resources in Scraggy Lake.

Touquoy Gold Project and Beaver Dam Mine Project- deposition of tailings in Touquoy exhausted pit

The Proponent proposes the operation and closure of a tailings management facility in the exhausted Touquoy pit developed for the Touquoy Project. Tailings from the processing of ore or ore concentrates from four deposits at the Touquoy mill are proposed to be disposed of in the Touquoy pit. These include the processing of lower grades of ore stockpiled for the Touquoy Project, processing of ore transported from the Beaver Dam Mine Project (the Project), and processing of ore concentrates from the Fifteen Mile Stream Gold Project and Cochrane Hill Gold Project.

The total capacity of the expanded Touquoy pit at the proposed spillway elevation of 108.0 m is 11.83 million cubic metres (Mm^3). This is sufficient to store tailings using subaqueous deposition. Considering subaqueous deposition, the exhausted Touquoy pit can accommodate the estimated total deposited volume of 7.91 Mm^3 based on an average tailings density of 1.3 tonnes per cubic metre (t/m^3) from the four projects (Appendix F.10).

Modelling conducted for the Beaver Dam Mine Project simulates the filling of the Touquoy pit with tailings, which are assumed to have a hydraulic conductivity of 1×10^{-6} m/s (Appendix F.6). The volumes of tailings disposed of in the Touquoy pit are the only important difference between the groundwater models prepared for the Beaver Dam, Fifteen Mile Stream, and Cochrane Hill projects.

In addition to the deposition of tailings from the Beaver Dam, Fifteen Mile Stream, and Cochrane Hill projects, an expansion of the Touquoy open pit is proposed to extract additional high-grade ore. Groundwater modelling was conducted to assess the dewatering of the expanded open pit (Appendix F.6). This model forms the basis of the modelling for the cumulative effects, following the scenarios generally described in Appendix F.6.

The cumulative effects of the various projects on groundwater are simulated through the deposition of tailings in the expanded Touquoy open pit. The processed tailings were assumed to share the same source terms for the prediction of downstream groundwater quality effects. These source terms are based on the geochemical testing conducted on the Touquoy tailings (Appendix E.3).

Cumulative Conclusions (Water Quality) (provided in Appendix E.3):

- The water quality modelling considered the pore water quality in the tailings and the pit floor/ walls, the dilution from surface runoff, direct precipitation in the pit and the water quality of the mixture based on the geochemistry of the individual water quality parameters using source terms presented by Lorax (as described in Appendix E.3). The geochemical source term predictions of pore water quality of pit walls/floor had elevated metal (e.g., arsenic, cobalt, copper), ammonia, nitrate and cyanide concentrations thus reducing pit lake water quality at the time of discharge.
- The updated water quality modelling presented in Section 3 of Appendix E.3 shows that the pit lake is simulated to reach the spillway elevation in March of Year 9 of the operation of the expanded Touquoy pit for tailings disposal. The corresponding water quality model predicted elevated concentrations of arsenic, cobalt, copper, nitrate, nitrite as summarized in Table 4.1 not considering planned water treatment.
- Water quality that is predicted to exceed the MDMER discharge limits will be treated prior to discharge. The pit lake will be treated to meet MDMER discharge limits for an existing mine prior to discharge to Moose River. As the pit lake is simulated to take about 10 years to fill from commencement of tailings deposition in the exhausted Touquoy pit, the final water treatment design will be fully developed during operation and pit filling.
- As presented in the assimilative capacity study of Moose River by Stantec (Appendix F.8), the effluent concentrations under normal discharge from the filled exhausted Touquoy pit, combined with the groundwater seepage contributions in Moose

River under the same climate conditions are predicted. Moose River will primarily be driven by climatic conditions, with April flows representing a worst-case dilution ratio between the effluent discharge from the exhausted Touquoy pit and Moose River. Based on results of the assimilative capacity model (Appendix F.8), once mixed with the background water quality in Moose River, the concentration 100 m downstream of SW-2 is predicted to be 0.0238 mg/L for arsenic and 0.184 for aluminum. Although the simulated arsenic concentration is above the NSE Tier 1 and CCME guidelines of 0.005 mg/L, the background levels at SW-2 also exceed the guidelines at 0.018 mg/L. The aluminum concentration is predicted below the 75th percentile receiver quality in Moose River.

- An assessment of the potential environmental effects of elevated arsenic in the downstream environment in Moose River are presented in Appendix G.2 and the cumulative effects of operating the four projects are not likely to result in adverse arsenic concentrations for the existing aquatic environment.
- Groundwater seepage discharging to Moose River will be consistent between scenarios and therefore groundwater quality predictions are also consistent with the Beaver Dam project.

Cumulative Conclusions (Water Quantity) (provided in Appendix F.10):

- The potential effect of the addition of tailings from Touquoy, FMS, Beaver Dam and Cochrane Hill Projects to the Touquoy Pit has been outlined in Appendix F.10. Tailings will be deposited in the exhausted Touquoy pit for a total of 47 months reaching an elevation in the pit of 94.0 m CGVD2013. As presented in the Touquoy Gold Mine Project Reclamation Plan (Stantec 2017), the inflow of groundwater, surface runoff and precipitation into the pit will naturally create a lake upon closure of the site. The water balance model simulated that it would take an additional 48 months or a total of 95 months from commencement of tailings deposition in the exhausted Touquoy pit to fill the pit to the spillway invert elevation.
- The proposed Touquoy pit extension and subsequent tailings deposition from all four deposits has been evaluated (Appendix F.10). Based on results of the water balance model, process water can be reclaimed from the TMF for approximately three to seven months depending on the climatic conditions and with no water discharged to the effluent treatment plant during this time to maintain the reservoir supply. When the TMF pond volume is no longer adequate for process water supply, process water will be reclaimed from the Touquoy pit as a closed loop, with the exception of freshwater make-up from Scraggy Lake.
- Water supply in the Touquoy pit is adequate for operation of the Project under normal and wet climate conditions, considering the 5.8% fresh water make-up from Scraggy Lake. Should operation commence under dry climate conditions, there will be little water available in the TMF for reclaim and insufficient time to store water in the Touquoy pit prior to start-up. The water balance simulated a water deficit under dry climate conditions that would require takings exceeding the permitted water volume from Scraggy Lake for Touquoy operation. Therefore, under dry climate conditions or based on the operational requirements of pumping infrastructure, start-up water in the Touquoy pit may be supplied from Scraggy lake (subject to provincial permitting) and/or effluent from the effluent treatment plant.
- As mill production rates are simulated to remain consistent throughout the processing of ores from all projects, the existing Touquoy reclaim water lines and tailings slurry lines are anticipated to be adequate both in capacity and length for continued ore processing. Additional lift booster pumps may be required to reclaim water from the Touquoy pit. Methods for tailings deposition in the Touquoy pit will differ during cold and mild climatic conditions and the tailings deposition progress should be monitored and updated as more information becomes available.

8.5.4.2.3 Cumulative Effects on the Surface Water Quality and Quantity

The use of the Touquoy processing plant and waste disposal systems by the Beaver Dam Mine Project (2023 to 2027), the Project (2023 to 2029), and the Cochrane Hill Gold Project (2025-2030) extends the period in which effects to the surrounding surface

water (both Scraggy Lake and the Moose River) may occur by up to 8+ years. Water withdrawal from Scraggy Lake may be required to be extended for the life of the Beaver Dam, FMS and Cochrane Hill Projects. An extension to the existing approval will be requested by the Proponent. Incremental effects to surface water quantity at Scraggy Lake is not expected, due to the extended withdrawal period and small daily operational water withdrawal needs in comparison to the large size of the lake. Water will also be recycled from the exhausted Touquoy pit when sufficient supply is available. However, with the application of the mitigation measures proposed for the operation of the site for both projects, the residual effects of both projects are predicted to be not significant.

The cumulative effect of the combined projects could mean a reduction in the streamflow from Scraggy Lake to the Fish River system; however, assuming that the rate of withdrawal is consistent with current needs of the project, then it has been shown that the withdrawal from Scraggy Lake is sustainable given the current level of inputs to the watershed. The cumulative effects of the three projects using the Touquoy processing facilities and the Touquoy Gold Project itself are therefore also expected to be not significant. There is some uncertainty as to the effects assessments for these projects. These would be addressed through the monitoring and follow-up programs established for the Project (Section 6.6.9).

No surface water will be discharged from the exhausted Touquoy pit to Moose River until the pit reaches the spillway elevation in Year 10 of the Project. Water withdrawal from Scraggy Lake will require to be extended to process ore associated with the Project. As the pre-development and post-development catchment areas draining to the ultimate discharge location at Moose River are similar, Moose River is capable of handling the resultant flow. No cumulative effects to surface water quantity in the Moose River are predicted. Modelling for the cumulative scenario (all four projects tailings deposition into the exhausted pit) predict water levels in the pit will reach the spillway elevated in 10 years.

The use of the Touquoy processing plant and waste disposal systems by the proposed extension of the Touquoy pit and deposition of these tailings into the exhausted pit, the Beaver Dam Mine Project, the Fifteen Mile Stream Project, and the Cochrane Hill Gold Project have been modelled (Appendix F.10) and predict the same conclusions relating to surface water quality in the receiving environments (Moose River) as that described in Section 6.7 for the Project. The potential effects of these projects to surface water quality in the receiving environment will be mitigated by a commitment to treat effluent to MDMER discharge limits and water quality objectives prior to release and a commitment to acceptable water quality in the receiving environment that is protective of aquatic health.

8.5.4.3 Mitigation

The effects of each project with the potential to result in a cumulative effect to surface water all require a suite of mitigation to ensure compliance with MDMER, and water quality objectives. Through monitoring and aquatic effects assessment, there is no expectation that these projects will result in a cumulative adverse effect to fish and aquatic species. As the potential effects are limited to the area surrounding the Project's LAA, no mitigation measures beyond those already presented to mitigate Project effects (Section 6.6.7) are warranted.

8.5.4.4 Residual Cumulative Effects and Significance Assessment

The thresholds for the determination of significant effects to surface water quality and quantity are thoroughly defined in Section 6.7, but it includes an effect to water quantity or quality that is high magnitude, regional geographic extent and medium to long term duration, and be partially reversible or irreversible. Overall, the residual cumulative effects are considered to be not significant (Table 8.5-5).

Table 8.5-5: Residual Cumulative Environmental Effects for Surface Water

Residual Adverse Cumulative Effects (After Mitigation)	Significance Levels						Overall Significance of Residual Adverse Effects (and Rationale)
	Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility	
Potential for residual cumulative effects to all surface water systems within each RAA (Touquoy Mine Site and Beaver Dam Mine Site).	L With mitigation strategies, predicted receiver concentrations are predicted to be greater than guidelines and increase by greater than 10% over baseline levels, but remains well within the observed range of natural variation (25th to 75th percentile baseline water quality).	LAA Cumulative effects are confined to the LAA.	A Cumulative effect would be more significant during low flow conditions and/or sensitive spawning windows.	LT Effects may extend beyond 7 years.	R Effects will occur at regular intervals throughout operations.	PR Mitigation cannot guarantee a return to baseline conditions.	Minor Adverse Effect (Not Significant) Given implementation of proposed mitigation methods, no significant adverse cumulative effect is expected.

Legend (refer to Section 5.11, Table 5.11-1 for definitions)

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	PR	Partially reversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	IR	Irreversible
H	High					P	Permanent	C	Continuous		

8.5.4.5 Follow-up and Monitoring Programs

No additional follow-up or monitoring beyond that presented in Section 6.6.9 is warranted.

8.5.5 Fish and Fish Habitat Cumulative Effects Assessment

In response to NSE-IR-123, the Proponent has determined that an ecosystem-based approach to the spatial boundary determination is the most appropriate to identify cumulative effects to fish and fish habitat. The spatial boundary determination is based on the VC geographic range and the zone of influence (ZOI) for that VC. The ZOI sets a spatial limit beyond which the residual effects of the Project on a VC are not detectable. For all aquatic VCs, the secondary watershed boundary (West River Sheet Harbour, 1-EM-2) has been selected as the appropriate spatial boundary (ZOI, or regional assessment area) for the Beaver Dam Mine Site (plus the Tangier River and Fish River-Lake Charlotte secondary watersheds for the Haul Road and Touquoy Mine Site). Based on the pathways of effects to fish and fish habitat, the spatial boundary for the CEA followed the ecosystem-based approach. This approach is supported by the CEA methodology guidance document (CEAA 2016).

While the Southern Upland (SU) Atlantic Salmon range encompasses the entire southern coast of Nova Scotia, from Canso through to Cape Split in the Bay of Fundy, Gibson et al. (2009a,b) state that they have very "precise homing to natal streams [which] restricts gene flow among fish at different spawning locations". They continue to state that "this can lead to local adaptation and dissimilarities in life-history characteristics among fish inhabiting geographically distinct or environmentally distinct rivers". Given that salmon return to natal rivers, the probability of a Project in one watershed or natal stream affecting a population in another natal stream is very low. Fish from each natal stream would experience the same effects in the marine environment, but effects to salmon from inland projects do not have a pathway of effect from one watershed to the next.

The determination of the secondary watersheds as the appropriate scale for the CEA (rather than the entire SU Atlantic Salmon range) is supported by the CEA methodology in another manner. The CEA methodology states that "adopting a large spatial area may lead to misinterpreting the incremental cumulative effects of the project as being insignificant relative to everything else that is affecting the VC in that region, i.e., negligible. If the Regional Assessment Area (RAA) were to be expanded to incorporate the entire range of the SU Atlantic salmon, it would necessitate inclusion of all marine effects, which present substantial threats to the recovery of the Atlantic salmon, negating the incremental effects of land-based Projects.

The salmon's return to natal streams and the incremental cumulative effect of the project being insignificant relative to everything else when adopting a large spatial area (i.e., negligible effect) justifies the determination of the secondary watershed as the appropriate spatial boundary for the CEA of fish and fish habitat. Therefore, the CEA focuses on identifying cumulative effects of projects within the defined RAA.

8.5.5.1 Baseline conditions

8.5.5.1.1 Fish Habitat

Beaver Dam Mine Site

Watercourses, waterbodies and wetlands within the PA are known to support various life stages of 12 species of fish. Within the Beaver Dam Mine Site, the quality of the habitat is generally limited by low pH in small, first order streams. The majority of habitat proposed for direct alteration is limited to an anthropogenic, shallow open water wetland complex (3.7 ha of open water), created in the 1980's to support mining activities. Indirect effects to fish habitat are anticipated; primarily related to flow reduction. The Beaver Dam Mine Site is located adjacent to Cameron Flowage/Killag River, a tributary to the West River Sheet Harbour. Both the West River and the Killag River are known to support Southern Uplands Atlantic Salmon. Historic effects of acid rain have reduced

habitat quality for Atlantic Salmon; as a result, the Nova Scotia Salmon Association has implemented a three-pronged Acid Mitigation project, which includes two lime dosing stations and a terrestrial liming program. Preferred Atlantic Salmon habitat within and in proximity to the Beaver Dam Mine Site is confined to the main bodies of the Killag River/Cameron Flowage.

Development of the Beaver Dam Pit and associated mine infrastructure will result in direct loss of fish habitat within the proposed pit and associated site infrastructure. Smaller impacts are expected within watercourses intersected by the Haul Road, to facilitate upgrades to the existing road and associated culverts. A Fish Habitat Offset Plan and Habitat Bank: Preliminary Design (Offset Plan; Appendix: J.3) has been developed to compensate for loss of fish habitat. Site infrastructure has been micro-sited for fish habitat avoidance wherever practicable. A *Fisheries Act* Authorization will be required for the Project.

Touquoy Mine Site

Moose River, which runs along the western extent of the Touquoy Mine Site, was determined to provide habitat for Atlantic salmon and brook trout during surveys conducted in 2005 as part of the Environmental Assessment (CRA, 2007a). Atlantic salmon (juveniles) were observed and suitable rearing and potential spawning habitat is available for the species. It was presumed that the Atlantic salmon observed were landlocked due to their proximity to a known landlocked population within Scraggy Lake. American Eel, White Sucker, and various forage fish species were also observed in Moose River. Although not observed, surveys determined that there is good adult and juvenile Brook Trout feeding habitat, fair rearing habitat, and potential spawning habitat available within Moose River (CRA, 2007a).

8.5.5.1.2 Fish Species

Beaver Dam Mine Site

A desktop review was conducted for fish species within major watercourses and waterbodies within the SA. The West River Sheet Harbour, contiguous with the Killag River, is known to support Atlantic salmon, brook trout, American eel, brown bullhead, yellow perch, lake chub, creek chub, banded killifish, ninespine stickleback, golden shiner, and white sucker (Halfyard, 2007; NSFA, 2016). The Morgan River located near the south end of the Haul Road within the Tangier River secondary watershed, is known to support white sucker, brook trout, white perch, yellow perch, banded killifish, rainbow trout, American eel, golden shiner, sticklebacks, alewife, northern redbelly dace, and brown bullhead (Alexander, Kerekes, & Sabean, 1986).

A portion of the Haul Road lies within the Tangier River secondary watershed. Fish species known to occur within this watershed include white sucker, brook trout, white perch, yellow perch, banded killifish, rainbow trout, golden shiner, stickleback sp., alewife, northern redbelly dace, and brown bullhead (Alexander et al, 1986). Nova Scotia Fisheries & Aquaculture (2019) have also recorded common shiner and smallmouth bass in this watershed. Atlantic salmon are considered extirpated from the Tangier River (DFO, 2009).

Fish surveys were completed throughout the PA within the Beaver Dam Mine Site and Haul Road through 2015-2020. Methods employed include electrofishing, minnow traps, eel pots, fyke nets and eDNA (using a non-species-specific primer called eFish). During 2015-2017, 145 individuals representing 10 species were identified within the Beaver Dam Mine Site and Haul Road – 84 individuals across nine species were captured within the Beaver Da Mine Site, while 61 individuals representing seven species were identified in watercourse along the Haul Road. In 2019-2020, the level of fishing effort was increased within the Beaver Dam Mine site, and a total of 1732 individuals representing 11 species were identified. Species identified during all surveys include Atlantic Salmon, American Eel, Banded Killifish, Brook Trout, Brown Bullhead, Creek Chub, Golden Shiner, Lake Chub, Ninespine Stickleback, Northern redbelly Dace, White Sucker and Yellow Perch. Atlantic Salmon was identified only within the Killag River, downstream of the NSSA lime dosing station.

Touquoy Mine Site

Fish observed from 2006 electrofishing surveys of Moose River as part of the EARD include; American Eel, White Sucker, and various forage fish (CRA 2007a). Further aquatic baseline studies completed by Stantec Consulting Ltd. In 2017 and 2018 confirmed presence of alewife, American eel, Atlantic salmon, banded killifish, brown bullhead, brook trout, golden shiner, lake chub, lake trout, white perch, white sucker and yellow perch.

8.5.5.2 Analysis of Effects

8.5.5.2.1 Residual Effects of Proposed Project

The development of the proposed open pit within the Beaver Dam Mine Site will require direct impact to open water wetland habitat within wetlands 59 and 56, along with several small tributaries to support construction of associated mine infrastructure. Direct impacts to fish bearing habitats are expected along the Haul Road to allow for widening of the existing Haul Road and construction of an ATV Bypass Road. For the most part, this involves upgrades to an existing road and culverts (many of which are improperly installed based on current watercourse crossing standards), though one section of the Haul Road will require new construction. The Project is expected to result in indirect effects to fish habitat, primarily through reduction in flows from groundwater interaction and collection of surface water to allow for treatment prior to release. Indirect impacts to fish habitat is described in detail in Section 6.9.7.1.2.

The impacted area includes open water wetland habitat within the proposed open pit. This habitat was anthropogenically formed by construction of a berm during the 1980's to support historic mine activity. Other habitats propose for direct impact within the Mine Site includes small, first order streams, which are typically limited in habitat quality by low pH and/or high summer temperatures. The pit development and associated fish habitat loss is considered an unavoidable impact of the Project development. The development of site infrastructure, primarily the pit is anticipated to result in a total direct impact area of 4.18 ha of fish habitat. Extensive work has been completed to revise the site infrastructure layout to avoid direct impacts to fish habitat. Direct impact to fish habitat is described in Section 6.9.7.1.1. Further to the efforts to avoid impacts to fish habitat, mitigation measures are described in Section 6.9.8.1. Mortality is anticipated to be low, given the implementation of appropriate mitigation measures, such as a fish rescue prior to the completion of construction. The fish rescue plan is outlined in Section 6.9.8.2.2. Finally, an offset plan has been developed to compensate for both direct and indirect impacts to fish habitat, as required under the *Fisheries Act* (described in Section 6.9.8.3, attached in Appendix J.3).

Indirect effects to fish habitat have been evaluated through a series of pathways, including water quality effects, groundwater interactions, blasting and surface water interactions. Through this evaluation, it was determined that effects to fish habitat are of low magnitude; and not anticipated to require authorization under the *Fisheries Act*, with the exception of reduction in surface flow in four watercourses. The detailed evaluation of indirect impacts to fish is outlined in Section 6.9.7.1.2.

Based on reduced flow comparisons to DFO framework for ecological flow, it was determined that reductions in four watercourses would have a moderate probability of detectable impacts to ecosystems that support fisheries. Flow reduction is anticipated due to drainage area and/or baseflow reductions in Crusher Lake Outflow (WC-5), South Tributary (WC-23), West Tributary (WC-26), and Mud Lake Outflow (WC-27). Although the actual area of reduced wetted channel due to the flow reductions is quantified at 322.41 m^2 we have quantified a much larger area as potentially altered. Through discussion with DFO the entire area below 30% MAD (approximately 7,728.88 m^2) is considered potentially altered due to uncertainty associated with extreme low flow and physicochemical habitat parameters. The amount of this habitat considered harmfully altered with be determined with DFO during the fisheries authorization process and is expected to be reduced or require less offsetting given that the habitats are expected to maintain the ability to support the existing fish communities.

Direct and potential indirect impacts to fish habitat are expected to require authorization under the *Fisheries Act*, and both are incorporated into the draft Fish Habitat Offset Plan (Appendix J.3).

The maximum expected spatial extent of direct and indirect effects to fish and fish habitat is shown on Figure 6.9-5. This includes direct impacts to fish habitat within the Beaver Dam Mine Site and Haul Road, and indirect impacts to watercourses 5, 23, 26 and 27 related to flow reduction. Water quality modelling shows compliance with all applicable guidelines at the North Settling Pond effluent release point within the 100 m mixing zone.

8.5.5.2.2 Effects of Other Projects in the Area

The RAA for fish and fish habitat, and projects which fall within this RAA are shown on Figure 8.5-4. There is direct spatial overlap between the Project and historic mining operations in the Beaver Dam Mine Site and the Touquoy Mine Site. Any potential cumulative effects from these projects related to surface water would be based on potential impacts to water quality from mobilization of historic tailings. The potential impact of this interaction will be mitigated by implementation of a Historical Tailings Management Plan (Appendix E.9). As such, these historic operations are not carried through the CEA process. Additional overlapping projects include regional timber harvesting, Haul Road usage, and the NSSA Acid Mitigation Project (specifically the terrestrial liming component of their project). Timber harvesting is not expected to result in adverse cumulative effects to fish and fish habitat, provided timber harvesters adhere to the Watercourse and Wildlife Habitat Protection Regulations.

Regional Forestry Operations

Forestry operations have been ongoing through the region for many decades. As such, the effects of these operations are included in the baseline conditions. Forestry operators are obliged to follow provincial *Wildlife Habitat and Watercourse Protection* regulations, which provide restrictions to timber harvesting with the purpose of protecting wildlife habitat and water quality. Presuming forestry operators adhere to these regulations, the potential for cumulative impacts occurring where the Project and forestry operations overlap is minimal.

Touquoy Gold Project and Beaver Dam Mine Project- deposition of tailings in Touquoy exhausted pit

The deposition of tailings from the Project, the proposed use of the exhausted pit for Touquoy tailings deposition, the FMS Project and the Cochrane Hill Gold Project at the Touquoy Mine Site has potential to affect water quality in the receiving environment (Moose River), and ultimately the fish and other aquatic organisms which inhabit it. The effect of tailings deposition on surface water quality in the receiving environment is described in Section 6.7, and the potential cumulative effect thereof is discussed in Section 8.5.4. Overall, the residual effect of tailings deposition in the Touquoy Pit, and the potential cumulative effect is expected to be minimal, considering that treatment to meet MDMER and water quality objectives will be implemented where necessary.

NSSA Acid Mitigation Project

The NSSA AMP operates three main components. Two lime dosing stations are located on the West River Sheet Harbour and on the Killag River, downstream of Cameron Flowage. Neither of these components have direct spatial overlap with the Proposed Project, although the dosing station on the Killag River is approximately 650 m southeast of the proposed pit. Despite its close proximity to the proposed Project; the spatial extent of direct and indirect impacts to fish and fish habitat does not extend to this portion of the Killag River, as specified in Section 6.9.7.1.6.

Terrestrial liming has occurred within the Paul Brook, Keef Brook and Tent Lake watersheds. According to Rotteveel (2018), terrestrial liming occurred in MacGregor Brook and Colwell Brook during the fall of 2016, with some expected 'blowout' from

helicopter liming affecting Cope Brook as well. The upper portion of the Killag River (above the lime dosing station) and Brandon lake Brook were used as control sites for this study. On September 25, 2019, MEL and AMNS met with the NSSA and ASF to discuss the second round of information requests related to the Project. During that meeting, it was stated that the NSSA would be commencing terrestrial lime application in the Tent Lake watershed; but indicated that terrestrial liming would not occur in proximity to the proposed organics stockpile until 2020. Of the three watersheds where terrestrial liming is known, or expected to have occurred, the Project only has a spatial overlap with the Tent Lake watershed (1EM-2-F) and the Keef Brook watershed (1EM-2-G). According to Rotteveel (2018), acidification of Nova Scotia's freshwater ecosystems has resulted in decreased habitat quality for Southern Uplands Atlantic Salmon, due in part to the mobilization of aluminum which has been mobilized due to low pH.

The residual effect of the NSSA AMP on fish and fish habitat, particularly Atlantic salmon, is a positive due to reduction of the effect of historic acidification on water quality within the treated catchment areas of the West River Sheet Harbour watershed. This Project is defined as having direct spatial and temporal overlap with the Beaver Dam Project specifically within the Tent Brook watershed (Project effects related to low magnitude flow reductions), and to a lesser extent, the Keef Brook watershed (Project effects related to Haul Road construction).

8.5.5.2.3 Cumulative Effects on the Fish and Fish Habitat

Residual effects on fish and fish habitat within the Beaver Dam Study Area are primarily related to loss of fish habitat from the development of the pit and other infrastructure. The key mitigation measures associated with this loss of fish habitat involve the fish rescue and offsetting for loss of fish habitat.

Spatial and temporal overlap of other projects within the RAA for fish and fish habitat is limited to the NSSA AMP; specifically terrestrial liming within Tent Brook and Keef Brook Watersheds. Given the proximity of the Project to the Killag Dosing station, a summary of water quality effects is provided herein. The downstream extent of impact to Cameron Flowage/Killag River is defined as the 100 m mixing zone of the effluent release location from the North Settling Pond, upstream of the Killag River Dosing Station (no spatial or temporal overlap of effects). The results of the predictive water quality assessment demonstrate the need for treatment of the mine effluent water prior to discharge to the Killag River. Nitrite (EOM) and cobalt and zinc (PC) have the potential to exceed CCME, background or site-specific guidelines within the Killag River at the near-field mixing zone locations and far-field mixing zone location. Treatment will occur, as required, prior to discharge into the receiving environment to ensure discharge meets MDMER regulations and concentrations in the Killag River do not exceed CCME or site-specific guidelines.

The Killag lime dosing station was installed to mitigate the effects of historic acidification within the Killag River, and to improve the quality of fish habitat within the Killag River, particularly for Atlantic salmon. As part of the predictive water quality modelling, the effect of the Project on pH in the receiving environment was evaluated. pH cannot be predicted with certainty by mass-balance models as used in the predictive water quality evaluation. That is, while modelling for the Project is conservative, mass balances modelling processes/predictions do not represent complete reaction paths and thus for non-conservative parameters (such as pH) water quality predictions are expected to be further governed by in situ processes. Note, discharges from the project will be subject to the MDMER such that effluent concentrations must be within pH range of 6.0 to 9.5, which is protective of aquatic life. Therefore, there are no effects to Surface Water Quality as a result of Project effluent discharges; and no expected negative cumulative impact of the Project on pH in the Killag River.

The Project is expected to have a direct spatial overlap within the Keef Brook Watershed, and the Tent Brook watershed. The spatial scale of terrestrial liming within each of these watersheds is unknown; therefore, it was assumed that the entire catchment areas are treated with lime in an effort to be conservatively inclusive. Impacts of the Project to fish habitat within the Keef Brook watershed are limited to upgrading the existing Haul Road and associated watercourse crossings. Upgrading the Haul Road is

expected to result in direct impacts to fish habitat (420.2 m^2, in WC J and WL76) to allow for culvert installation, which has been incorporated in the draft Fish Habitat Offset Plan (Appendix J.3). Of the watercourse crossings located within the Keef Brook watershed, five are currently acting as barriers to fish passage, so upgrading Haul Road infrastructure is expected to result in improvements to fish passage in watercourses E, F, G, J and K. Provided mitigation measures for watercourse crossings are adhered to (as will be required under provincial watercourse permits), no indirect effects are expected to fish habitat within this tertiary watershed. Furthermore, it is unknown whether terrestrial liming within this system is ongoing, based on results published by Rotteveel (2018) and communication from DFO (2019). Terrestrial liming was selected as a treatment within several catchment areas in this watershed due to the long-lasting effects of helicopter-based liming; which essentially acts as a 'slow-release' of lime through the soil into the watercourses. While the benefits of liming may continue to occur through the temporal scale of the Project; activities within this watershed are not expected to have any type of cumulative interaction with terrestrial liming which has already occurred.

Within the Tent Brook tertiary watershed, Project interactions include construction of an organics stockpile, ATV bypass road, crusher pad, and topsoil stockpile. The ATV bypass road will remain in place through post-construction, while the crusher pad, topsoil stockpile and organics stockpile will be reclaimed in the active reclamation stage of the Post Closure phase of the Project. Upgrading Haul Road infrastructure is expected to result in direct impacts to 535 m^2 of fish habitat in Wetlands 64 and 66, and will result in fish passage improvements in watercourses A and B. Direct impacts to fish habitat have been incorporated into the Offsetting Plan (Appendix J.3). Provided mitigation measures for watercourse crossings are adhered to, no indirect impacts in watercourses within the Tent Brook watershed are expected based on upgrades to the Haul Road.

To identify potential indirect effects to fish and fish habitat within Tent Brook watershed, an updated Water Balance Assessment is provided. Based on the results of the water balance, collection of contact water is expected to result in a 1.1% reduction in flow at EOM, and a 1.2% reduction at PC. As a result, a low magnitude of effect is expected to fish habitat within the Tent Brook watershed, as this change has been determined to fall within natural variation. Furthermore, water quality effects are not expected within the Tent Brook watershed; as all site contact water will be collected in the South Settling Pond prior to release. The primary purpose of the south settling pond is to reduce the TSS levels to acceptable limits, and control stormwater runoff. Effects to the downstream environment are not expected.

Data related to the NSSA terrestrial liming program inputs, objectives, and results were not available with sufficient detail to allow interpretation of interacting effects between terrestrial liming and direct and indirect effects within the Tent Brook or Keef Brook watersheds. AMNS requested further detail from the NSSA; however, NSSA did not provide a response (Appendix A.4b). Therefore, the evaluation of cumulative effects within the Tent Brook and Keef Brook watersheds are qualitative in nature. Direct impacts to fish habitat within each of these watersheds is limited to construction of the Haul Road and associated watercourse crossings. These impacts range from negligible to high, based on the area of impact within each individual crossing. Given implementation of mitigation measures including Offsetting, these effects are determined to be not significant, especially considering the improvements to fish passage which will be provided. The indirect effects of the Project on fish habitat within the Tent Brook watersheds are limited to low magnitude effects to flow reduction in the Tent Brook watershed, and no indirect effects are expected within the Keef Brook watershed. The Project related effects to fish habitat within these two watersheds are adverse and not significant; given that the residual effects of the terrestrial liming are positive (magnitude and significance are unknown); it is likely that any cumulative effect to fish habitat would be classified as a compensatory interaction, with a non-significant residual cumulative effect.

The deposition of tailings from the proposed Fifteen Mile Stream Project and the existing Touquoy Gold Project in the Touquoy Pit overlap the current Project both spatially and temporally. As discussed, with appropriate mitigation to ensure compliance with

MDMER criteria and water quality objectives, the potential for residual cumulative effect on fish and fish habitat is expected to be minimal.

There is some uncertainty as to the Project effects on fish and fish habitat. This uncertainty is addressed through the monitoring and follow-up programs established for the Project (Section 6.9.10). No significant cumulative effects on fish habitat beyond the effects assessed for the Project are anticipated.

8.5.5.3 Mitigation

No mitigation measures beyond those proposed in Section 6.9.8 are warranted.

8.5.5.4 Residual Cumulative Effects and Significance Assessment

A significant adverse effect from the Project on fish and fish habitat is defined as an effect that results in an unmitigated or uncompensated net loss of fish habitat as defined under the *Fisheries Act*, and its associated no-net loss policy. The screening of project effects, mitigation measures, and the subsequent fish and fish habitat results are assessed in aggregate to determine whether the residual impacts are “Not Significant” or “Significant” according to the following definitions:

Significant Residual Effect: residual effects have high magnitude, be of potential regional geographic extent and of medium to long term duration, occur at any frequency and only be partially reversible to irreversible.

Not Significant Residual Effect: is defined as: negligible to moderate magnitude, are restricted to the PA or near-field receiving environment, are of sporadic or short-term duration, occur at any frequency or are reversible to partially reversible.

A residual cumulative effect would be determined using the same determination provided in section 6.9; however, the evaluation of a significant residual cumulative effect would be based on the RAA spatial boundary, considering the interacting and overlapping project interactions within the RAA.

Within the RAA for fish and fish habitat, the Project effects overlap spatially and temporally with other Projects only within the Tent Brook and Keef Brook Watersheds. Within these watersheds, direct impacts are proposed to allow for construction of the Haul Road, and indirect effects are predicted for a minor level of flow reduction to the Tent Brook watershed (<2%). The predicted residual cumulative effects on fish and fish habitat are assessed to be adverse, but not significant (Table 8.5-6).

8.5.5.5 Follow-up and Monitoring Programs

No additional follow-up or monitoring beyond that presented in Section 6.9.10 is warranted.

Table 8.5-6: Residual Cumulative Environmental Effects for Fish and Fish Habitat

Residual Adverse Cumulative Effects (After Mitigation)	Significance Levels						Overall Significance of Residual Adverse Effects (and Rationale)
	Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility	
Cumulative disturbance to fish and fish habitat within the RAA.	L Differing from the existing environment/ baseline conditions, within natural variation	LAA Potential adverse cumulative effect to fish habitat outside of the PA.	A Cumulative effect would be more significant during sensitive spawning windows.	P Effect is expected to be permanent.	C Effects will occur on a continuous basis throughout operations and closure.	IR Effects of flow reduction and direct impacts from Haul road crossings are expected to be irreversible.	Low Adverse Effect (Not Significant) Fish habitat offsetting is anticipated to compensate for lost fish habitat from the Project itself. No other pathway for residual effects from surrounding projects has been identified.

Legend (refer to Section 5.11, Table 5.11-1 for definitions)

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	PR	Partially reversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	IR	Irreversible
H	High					P	Permanent	C	Continuous		

8.5.6 Species of Conservation Interest and Species at Risk Cumulative Effects Assessment

8.5.6.1 Baseline conditions

8.5.6.1.1 Priority Fish Species

A desktop evaluation for priority fish species revealed that four priority species have been identified within 5 km of the SA. These include Atlantic salmon (*Salmo salar*), American eel (*Anguilla rostrata*), alewife *(Alosa pseudoharengus*) and brook trout (S*alvelinus fontinalis*) (ACCDC 2021). Priority fish species identified as having an elevated potential to be located within the PA, based on habitat preferences, and broad geographic range, include American eel, Atlantic salmon, brook trout, brook stickleback (*Culaea inconstans*), and landlocked rainbow smelt *(Osmerus mordax*).

Within and in proximity to the Beaver Dam Mine Site and Haul Road, three priority species (Atlantic Salmon, American Eel and Brook Trout) were identified during electrofishing and fish collection. Atlantic Salmon were only identified within the Killag River in the 2020 fish sampling program, downstream of the NSSA lime doser, which is considered to provide suitable spawning and rearing habitat for Atlantic Salmon.

From 2015-2017, adult American Eel were confirmed in watercourses along the Haul Road including WC-N, WC-V, and WC-AH. Juvenile Eel were also observed in WC-N and WC-AH. During the 2019-2020 field program, adult American Eel were confirmed in Mud Lake/WC27, Cameron Flowage, WC13, and the Killag River. Juvenile Eel were also observed in WC13. Based on the wide distribution of American Eel within the province, their generalist habitat preference, and capacity to migrate over barriers, all hydrologically connected watercourses within the PA are believed to be potentially accessible to the American Eel, even if habitat provision in those watercourses is determined to be low.

From 2015-2017, juvenile Brook Trout were captured in WC5 (north of Crusher Lake), WC12, and WC13 within the Beaver Dam Mine Site. Along the Haul Road, juvenile Brook Trout were confirmed in WC-N and WC-V. One individual adult Brook Trout was captured in WC-AH. During the 2019-2020 field program, adult Brook Trout were captured within Crusher Lake, WC5 Reach B, Mud Lake/WC27, Cameron Flowage, WC13, and WC23. Juvenile Brook Trout (young of the year and parr) were also documented in WC13, WL59, Crusher Lake, WC5, and the Killag River. Potential brook trout spawning habitat was identified within four watercourses within the Beaver Dam Mine Site (Watercourses 5, 12, 13, and 14), and 11 watercourses along the Haul Road (Watercourses E, K, L, N, S, T, V, Z, AE, AF, and AH). Suitable rearing areas were also identified within these watercourses, along with WC23 in the Beaver Dam Mine Site, and Watercourses I, H, P, Q, and AG within the Haul Road.

According to the Nova Scotia Salmon Association (pers. comm. 2016), rainbow smelt and brook stickleback are not known to be present within the West River Sheet Harbour or Tangier River systems. Therefore, the likelihood of these species being present within the PA is very low. Alewife has been historically documented within the Tangier River secondary watershed, and may use watercourses within the Haul Road as migration corridors to upstream spawning areas. The likelihood of alewife being present within the Beaver Dam Mine Site and Haul Road watercourses within the West River Sheet Harbour watershed is considered low.

Moose River, within the Touquoy Mine Site, provides habitat for Atlantic Salmon and Brook Trout. Good juvenile and rearing habitat and potential spawning habitat is available for Atlantic Salmon. Several juvenile Atlantic Salmon were observed, however, these species were believed to be from the landlocked population known to Scraggy Lake. Good adult and juvenile Brook Trout feeding habitat, fair rearing habitat, and potential spawning habitat is available within Moose River (CRA 2007a).

The Nova Scotia Department of Agriculture and Fisheries conducted a fisheries resource study in Scraggy Lake in July of 1975. Fish captured included; brook trout and American eel. Atlantic Salmon smolts were recorded during creel census in 1979. Fingerling landlocked Atlantic Salmon and Brook Trout were stocked in Scraggy Lake between 1998-2000 and 1994-1996, respectively (CRA 2007a). Additional fish community and fish habitat assessments were completed under the EEM to support MDMER regulations under the *Fisheries Act*. These baseline aquatic environment surveys were completed by Stantec Consulting Ltd. in 2017 and 2018. According to the 2017 report, fish surveys completed in Scraggy Lake identified a total of 1,091 individual fish, representing 12 species of fish. Priority species observed include American Eel, Atlantic salmon, Brook Trout, and Lake Trout.

8.5.6.1.2 Priority Vascular Flora and Lichens

Priority Vascular Flora Species

A comprehensive list of species identified is provided in Appendix K.1 and discussed in Section 6.10.4.3. No SAR vascular plant species were observed. A total of six plants are priority species (SOCI), based on provincial status ranks (S3 and S3S4), including weigand's sedge, lesser rattlesnake plantain, southern twayblade, Appalachian polypody, highbush blueberry and Nova Scotia agalinis. Micro-siting of infrastructure has been completed to avoid priority flora species, wherever practicable, and has reduced the direct impact of the Project on flora and lichens. One occurrence of a southern twayblade, within Wetland 161, is expected to be impacted by the proposed Haul Road alignment. No priority vascular flora are anticipated to be directly impacted within the Beaver Dam Mine Site.

Southern twayblade (*Listera australis*, syn. *Neottia bifolia*) is a small inconspicuous member of the orchid family (Orchidaceae), which has been found in eight locations (wetlands 80, 115, 129, 137, 135, 147, and 161, and in upland habitat north of Wetland 136) within the PA. This species belongs to the Atlantic Coastal Plain Flora community and its primary habitat is shaded sphagnum mosses in bogs or coniferous treed swamps. Within the PA, it was typically found in clusters of 5-10 individual plants at the base of small sphagnum hummocks in treed swamps. Its distribution is scattered throughout Nova Scotia and it is considered vulnerable by the ACCDC (S3).

Surveys of the Touquoy site did not detect any plant species of special status within surveyed area (CRA 2007a). During follow up evaluation for wetland alteration permitting in 2015, a single black ash (NSESA Threatened) was identified in Wetland 2, within the (at the time) proposed TMF. Through consultation with NSE and the Mi'kmaq of Nova Scotia, this tree was harvested prior to construction of the TMF. No other Priority species of vascular flora were identified in the Touquoy Study Area.

Priority Lichen Species

Eleven priority lichen species were observed within the broader LSA as described in Section 6.10.4.4. Of the eleven species, three SAR and eight SOCI species were observed, as provided in Table 6.13-7. Of the three SAR identified, two are located within the PA. Blue felt lichen was observed in the Beaver Dam Mine Site and Haul Road and in the broader Lichen Study Area, while frosted glass whiskers was identified within the Beaver Dam Mine Site. Boreal felt lichen was identified in the LSA originally by the Project Team, but not within the PA. However, upon return in 2016 and 2017, the three observed locations of the boreal felt lichen were no longer present.

While micro-sitting infrastructure has avoided occurrences of priority lichen wherever practicable, the Project is expected to result in direct impacts to two blue felt lichen (*Pectenia plumbea*) occurrences and 10 SOCI lichen occurrences: six salted shell lichen *(Coccocarpia palmicola*), three slender monk's hood lichen (*Hypogymnia vittata*) and one eastern candlewax lichen (*Ahtiana aurescens*) within the Beaver Dam Mine Site. No priority lichens are anticipated to be directly impacted along the Haul Road. Locations of all priority lichen species documented within the LSA and the proposed Haul Road are provided in Figure 6.13-2.

Lichen surveys conducted in the Touquoy Mine Site in 2004 and 2005 as part of the EARD process found the presence of blue felt lichen (*Pectenia plumbea* syn. *Degelia plumbea*). An additional lichen survey in 2007 found seven additional SOCI including; salted shell lichen (*Coccocarpia palmicola*), corrugated shingles lichen (*Fuscopannaria ahlneri*), powdered fringe lichen (*Heterodermia speciosa*), blistered jellyskin lichen (*Leptogium corticola*), blue-gray moss shingle lichen (*Moelleropsis nebulosa*), naked kidney lichen (*Nephroma bellum*), and peppered moon lichen (*Sticta fuliginosa*) (CRA 2007a). These lichens were observed in the northern, southern and south eastern portions of the Project Area. Both locations of blue felt lichen have not been directly impacted by infrastructure from the Touquoy Project, however, direct impacts to corrugated shingles lichen and blue-gray moss shingle lichen have occurred.

8.5.6.1.3 Priority Terrestrial Fauna

Priority Mammal Species

Through all targeted surveys and incidental observations, evidence of a single mammalian priority species was observed. Within the PA, mainland moose tracks were observed within the Beaver Dam Mine Site in disturbed, roadside habitat north of Wetland 56 on May 24th, 2015 during a targeted PGI survey. Moose tracks were observed incidentally-in two locations on September 9th, 2014. One set of tracks was observed in Wetland 210 and a second set of tracks was observed adjacent to Wetland 206, just beyond the Beaver Dam Mine Site. No signs of mainland moose were observed during any survey within Haul Road. Mainland moose are not particularly affected by habitat fragmentation based on habitat preference; however, increased access into a site (construction of new roads) may increase poaching levels. As such, low-level habitat fragmentation can indirectly affect mainland moose.

Eighteen AMOs within the Beaver Dam Mine Site were evaluated for their potential to provide bat hibernacula on September 18, 2014. Of the eighteen AMOs evaluated at the site, all were either in-filled, contained a concrete cap blocking access, or were flooded, with the exception of one (BED-1-003), which was identified during the desktop evaluation as a potential bat hibernaculum. The BED-1-003 AMO was determined to be inaccessible to bats, as described further in Section 6.13.3.4. No bat hibernacula were identified within the Haul Road. According to the ACCDC reports, no known bat hibernaculum are present within 5 km of the Haul Road or Beaver Dam Mine Site. No bats, or evidence thereof, were observed incidentally during biophysical surveys, particularly bird surveys which are conducted when bats are more active.

Mainland moose tracks were observed within the Touquoy Mine Site in a bog during field surveys to support the Touquoy Gold Project EARD in 2006. Moose are known to the Tangier Grand Lake Wilderness Area (CRA, 2007a). In addition to the information above, a Post-Construction Moose Monitoring Program for Mainland Moose has been underway in lands surrounding the Touquoy Mine Site during each winter and spring since 2017. Surveys are ongoing throughout 2021 and include a combination of winter tracking surveys and spring pellet group inventory surveys. Surveys are completed on foot along transects surrounding the Touquoy Mine Site throughout a diversity of habitat types. During surveys, moose observations are recorded including a description of moose sign observed, a GPS location and a microhabitat assessment. To date, three observations of Mainland Moose Sign (scat and tracks) were documented during 2017, and two sightings of moose were encountered during 2018 surveys. No signs of the animal were observed during surveys in 2019, however, an incidental observation of a moose on a road near the mine was reported by an Atlantic Gold staff member. No moose were observed in 2020; 2021 surveys are ongoing. Annual reports have been provided to NSL&F as per the Touquoy Gold Project Environmental Assessment Approval conditions.

No suitable bat hibernacula were found within the Touquoy Mine Site during environmental screening to support the Touquoy Gold Project EA (CRA, 2007a).

Priority Herpetofauna Species

One female snapping turtle (SARA/COSEWIC, Special Concern; NSESA, Vulnerable; S3) and nest was observed by DFO within the Beaver Dam Mine Site on June 27, 2019. The observation was on a rocky, man-made berm east of Wetland 59 (historic settling pond; Figure 6.13-1. Previously, there were only incidental observations, outside field surveys, of this species; one on June 26, 2016 where the Mooseland Road section of the Haul Road crosses Fish River, during bird surveys (near PC45), and two adjacent to the Touquoy Mine Site in the scope of the EIS (Figure 6.13-1).

Potential suitable habitat for snapping turtles has been observed in Wetlands 8, 10, 14, 17, 29, 44, 56, 59, 61, 64, 66, 68, 69, 159, 168, 171, and 207 within the Beaver Dam Mine Site and the Haul Road. These wetlands are identified as potentially providing hibernacula for snapping turtles where open water is present (i.e., standing water to a depth exceeding 0.5 m).

Targeted turtle surveys within the Beaver Dam Mine Site did not reveal any sightings of wood turtles, painted turtle or suitable nesting habitat. No opportunistic observations of wood turtles, painted turtle or suitable nesting habitat were documented during any wetland or watercourse surveys throughout the PA.

No wood turtle or suitable habitat were observed within the Touquoy Mine Site during Wood Turtle habitat surveys conducted in 2004 (CRA 2007a). No snapping turtles were recorded within the Touquoy Mine Site during the EARD process. A WMMP was implemented upon commencement of operations of the Touquoy Mine Site. Under this Plan, wildlife sightings, particularly turtles, were reported to the site Environmental Technicians. Between 19 June 2017 and 2 July 2020, sixteen observations of snapping turtles were recorded by Atlantic Gold staff and contractors at various locations throughout the Touquoy Project Area, typically in close proximity to the Moose River (AMNS, Pers. Comm., 2021).

Priority Invertebrates

A review of data provided by the Maritime Butterfly Atlas confirmed that one monarch butterfly was observed in squares 20NQ17, 20NQ18, 20NQ19, 20NQ28, and 20NQ29. This 10 km x 10 km survey grid covers Mud Lake and Crusher Lake, extending north to Beaver Lake, and east to Smith Lake and Rocky Lake. As the monarch has been recorded in this survey square, it is possible that it uses the Beaver Dam Mine Site, at least periodically, such as during migration. Monarch butterflies rely on milkweed as a host plant for their larvae; as such, it is a key indicator for presence of the monarch. Surveys for vascular plants were conducted throughout the PA, and staff were instructed to identify any suitable habitat for monarchs based on presence of milkweed. No milkweed was documented during surveys for vascular flora, or opportunistically during any other surveys.

No other targeted surveys were completed for invertebrates; however, no opportunistic observations of priority invertebrate species were recorded. No other priority invertebrate species were identified during the desktop review.

Aquatic benthic invertebrates were surveyed during the aquatic surveys. No priority invertebrate (terrestrial and aquatic) species were observed within the Touquoy Mine Site during environmental screening to support the Touquoy Environmental Assessment (CRA, 2007).

8.5.6.1.4 Priority Avifauna

Across all survey seasons completed within the PA, a total of 32 priority species were observed either during dedicated survey periods or incidentally, including 23 SOCI and nine SAR. All avifauna SAR observed were as expected based on habitat and geographic range. The presence of wetlands, forested uplands, watercourses, clearings and fragmented habitats (resulting in edge habitats) provided suitable habitat for many of the priority bird species in Nova Scotia.

During all breeding bird surveys, evidence of breeding behavior was recorded for all species, with particular attention towards SAR and SOCI. Breeding evidence was recorded in accordance with guidance provided by Bird Studies Canada (2016), which defines behavior in terms of possible, probable, and confirmed breeders. Any species observed during breeding season singing in suitable habitat is identified as a possible breeder. Signs of probable breeding observed are agitation and established territories. Evidence of confirmed breeders observed includes distraction displays, feeding young or carrying food, nests with young, or recently fledged young. Canada warbler is identified as a probable breeder, while olive-sided flycatcher and common nighthawk are identified as possible breeders. Breeding evidence for other SAR was not observed. Nine SOCI are identified as possible breeders, while five show evidence of probable breeding. One SOCI species (Swainson's thrush) was recorded as a confirmed breeder.

The 2005 breeding bird surveys of the Touquoy Mine Site found ten priority species. They are as follows; pine grosbeak, willow flycatcher, yellow-bellied flycatcher, barn swallow, boreal chickadee, ruby-crowned kinglet, rusty blackbird, bay-breasted warbler, Swainson's thrush, and pine siskin.

8.5.6.2 Analysis of Effects

8.5.6.2.1 Residual Effects of Proposed Project

Priority Fish Species

The geographic extent, timing, duration, frequency, reversibility, and magnitude of direct and indirect impacts to priority fish species remains the same as is with non-priority specific fish and fish habitat, however, the level of scrutiny and analysis undertaken to determine the magnitude of each effect was substantially higher for priority species, particularly Atlantic salmon. Direct impacts are proposed in several habitats known to support brook trout and American eel. The residual effects to these species is reflected in Section 6.9.9.

The Project is expected to result in direct impact to fish habitat within the Beaver Dam Mine Site and Haul Road to facilitate infrastructure development. Specific habitats proposed for direct impact have been identified as providing suitable habitat for American eel and brook trout; however no direct impacts are proposed in habitats known or expected to support Atlantic salmon. Indirect effects to fish and fish habitat are predicted occur in watercourses 5, 23, 26 and 27 due to flow reduction, incorporating both daily and monthly flow estimates. Extensive work has been completed to predict indirect effects to fish and fish habitat in Cameron Flowage/Killag River due to the presence of Atlantic salmon downstream within the Killag River. This modelling is presented in Section 6.9.7.1.6. Through this evaluation, it was determined that no harmful alteration disruption or destruction to fish or fish habitat is expected within Cameron Flowage/Killag River.

Along the Haul Road, it is expected that direct impact to fish habitat can be minimized through proper planning, micro-sighting of the upgraded road footprint, and installation of culverts in accordance with the Nova Scotia Watercourse Alteration Standard (2015). All direct impacts to fish habitat proposed for construction of the Beaver Dam Mine Site and Haul Road are quantified and accounted for in the draft Fish Offset Plan (Appendix J.3).

The mitigation sequence was used to avoid, mitigate, and offset impacts to fish and fish habitat, with an emphasis on mitigating impacts to priority fish species. Project infrastructure was redesigned to avoid direct impacts to fish habitat relative to the 2019 EIS, however direct impacts to fish habitat within the proposed pit was determined an unavoidable impact of the Project. Indirect impacts to fish habitat were reduced through re-evaluating the site water balance Mitigation measures include collection and treatment of surface water, and development of a plan to supplement baseflow in Cameron Flowage if required. The details of this plan are outlined in the Mine Water Management Plan (Appendix P.4), and described in Section 6.9.7.

Project activities are not expected to result in significant adverse effect to fish and fish habitat in general, or specifically to priority fish species, with appropriate mitigation measures in place (including obtaining a *Fisheries Act* authorization and implementing the Offset Plan).

The Touquoy Mine Site is currently operational. Potential impacts to surface water quality and quantity as a result of the storage of Beaver Dam tailings in the exhausted Touquoy open pit mine were examined in Section 6.7.8. There are no direct or indirect effects to priority fish or fish habitat anticipated to be caused by the processing of ore and the management of tailings (exhausted pit) from the Beaver Dam Mine Project.

Priority Vascular Flora and Lichens

Clearing and grubbing will occur during the construction phase of the Project and is limited to the Beaver Dam Mine Site and Haul Road where infrastructure is proposed. No additional clearing and grubbing are required at Touquoy Mine Site to support the Project. Clearing and grubbing requires full vegetative removal which will directly affect vascular and non-vascular individuals, and to flora communities at the full or partial forest stand level. One priority vascular species, an occurrence of southern twayblade, is expected to be directly impacted by the proposed Haul Road alignment. No priority vascular flora are anticipated to be directly impacted within the Beaver Dam Mine Site. No SAR vascular flora were observed within the PA.

Translocation of SAR lichen species is proposed for occurrences directly and indirectly impacted by the Project, as described below. Blue felt lichen populations expected to be directly and indirectly (within 60 m of Project infrastructure) impacted by the Project are proposed to be translocated, as described in the Lichen SAR Translocation and Monitoring Plan (Appendix Q). Furthermore, this plan includes a monitoring component to monitor all SAR lichen transplants and occurrences proposed to be indirectly impacted by the Project. Monitoring is proposed to occur for the duration of operations and to be continued post-closure (timeline to be determined).

Heavy machinery operation and vehicle activity will occur within the Beaver Dam Mine Site and Haul Road during the construction phase and throughout the PA during the operation and closure phases. Both heavy machinery operation and vehicle activity can cause impacts to vascular and non-vascular flora from edge effects, dust, erosion, invasive species transportation and accidents (e.g. spills). Due to their non-vascular physiology, lichens are especially sensitive to changing environmental conditions, particularly air quality and edge effects (Boudreault et al. 2008; COSEWIC 2002). The impact of edge effects (depth of influence) on lichen has been well studied (Moen & Jonsson, 2002). The dept of influence on lichen species can range from 60-240 m (Esseen & Renhorn, 1997; Gauslaa et al., 2018; Haughian & Harpre, 2020) and is highly species and context dependant.

Studies, such as Neitlich et al. (2017), Naeth and Wilkinson (2008), Loppi and Frati (2005) and Farmer (1993), present the primary drivers of atmospheric contamination to lichen from mine operations: sulfur dioxide and nitrous oxide emissions, metal mobilization and dust generation. The Project is predicted to result in localized particulate and metal mobilization through dust generation during construction and operations (i.e., mining and hauling ore; Appendix C.1). Deposition of dust on flora can temporarily reduce evapotranspiration, photosynthesis and can bioaccumulate within tissue, which may reduce overall growth rates, especially for non-vascular flora such as lichen (Degtjarenko, 2016; Naeth and Wilkinson 2008; Farmer, 1993). The Haul Road is expected to the be largest source of particulate emissions within the PA. While dust deposition-related impacts to lichens were assessed for Project only truck traffic, the modelled deposition rates have been reviewed under the cumulative truck traffic scenario and did not result in changes to predicted effects.

Potential indirect impacts to vascular plants and lichens surrounding Project infrastructure will be reduced through best management strategies and mitigation measures. No SAR vascular flora will be directly impacted by the Project. Mitigations for the two blue felt lichen occurrences that are expected to be directly impacted and for additional Lichen SAR where indirect impacts

are anticipated is proposed in the draft Lichen Mitigation and Monitoring Plan (Appendix P.6) and Section 6.10.8. As a result, no lichen SAR will be directly impacted by the Project. Through the implementation of mitigations, the magnitude for residual environmental effects to flora is assessed as moderate, primarily as a result of direct loss of habitat area.

Priority Terrestrial Fauna

Clearing and grubbing is limited to the Beaver Dam Mine Site and Haul Road during the construction phase. Clearing and grubbing are not required at the Touquoy Mine Site. Clearing and grubbing will result in habitat loss for priority fauna. Best management practices will be used to limit unnecessary loss of habitat, and infrastructure layout has been planned to limit unnecessary clearing and grubbing. Grubbed material will be stockpiled and used for remedial efforts during the closure phase of the Project. Clearing and grubbing is expected to have a low magnitude of impact on priority fauna. This is based on the lack of direct impact to fauna SAR and the recognition that the loss of habitat within the PA is expected to be temporary in nature (considering reclamation of habitat following operations). Clearing and grubbing can reduce cover for priority turtle species (e.g. snapping turtle), indirectly affect water quality, and can isolate populations (ECCC 2016c). Regarding Mainland Moose, it is documented that habitat loss and fragmentation caused by clearing and grubbing interferes with the long-term population viability and is a serious threat to the species (NSDNR 2007).

Fragmentation of a particular species' habitat implies a loss of habitat, reduced patch size, and/or increasing distance between patches. While Project activities are expected to result in increased habitat fragmentation and a decrease in habitat quality (e.g., sensory disturbance), the level of new fragmentation associated with the Beaver Dam Mine Site is anticipated to be low, given the current level of disturbance within the PA. The Beaver Dam Mine Site infrastructure footprint is situated primarily on an area of high existing disturbance and is expected to only have fringe effects on the interior forest availability. There will be minimal isolation of habitat that is currently contiguous. Undisturbed, unfragmented habitat is present in the LAA and RAA, and the larger tracts are maintained around the PA, particularly to the north. The RAA is generally remote, with a moderate network of roads and forestry activity, though large tracts of forest landscape undisturbed by roads still exist in this region (NSDNR 2015b). A total of 72,663 ha of predicted interior forest has been identified within the RAA. The maximum Project edge effect as discussed in Section 6.10.7.1.1, will affect 237 ha of interior forest habitat, which accounts for 0.3% of predicted interior forest in the RAA.

Sensory disturbance to terrestrial fauna would result from rock blasting (weekly during operation), clearing and grubbing, infrastructure construction during the construction phase and, overall increased traffic, mining activities and trucking during operations within the PA. Changes to ambient noise and light levels and the presence of periodic vibrations have the potential to adversely affect fauna by influencing circadian patterns, seasonal patterns, movement and distribution, and community interactions and composition (Pauwels, 2018). The Environment Code of Practice for Metal Mines (Environment Canada, 2012) has established parameters for ambient noise levels for wildlife. These parameters indicate that ambient noise observed above 55 dBA during the day and 45 dBA at night can affect wildlife. Noise may simply act as a sensory disturbance resulting in avoidance (Ware et al. 2015), however, noise can also affect fauna behavioral patterns (Patthey et al. 2008), stress levels (Knight and Swaddle, 2011), affect communication and hunting success (Barber et al. 2009). Combined, these effects can negatively impact the overall population health of a particular species (Ware et al. 2015). Studies, some specific to ungulates, have found that sound levels of 46-68 dBA can elicited responses and have observed impacts on mammals (Maier et al. 1998; and Flydal et al, 2001; Drolet et al., 2016; Shannon et al. 2016). Elevated noise above background concentrations around the PA may cause avoidance by terrestrial fauna within 400 m (S, W, E) to 1,000 m (N) of the Beaver Dam Mine Site, <500 m on either side of the Haul Road and within 850 m the Touquoy Mine Site property boundaries, based on the most conservative guideline (45 dBA) identified for potential broad wildlife effects (Appendix B.1; Environment Canada, 2012).

Light effects on terrestrial fauna include changes to circadian patterns, seasonal patterns, movement and distribution, and community interactions and composition (Pauwels, 2018). Artificial light can also disrupt habitat connectivity and indirectly create habitat fragmentation (Bliss-Ketchum et al. 2016). However, there is limited data is available for larger mammalian species. While effects of light on wildlife are documented, it is still an emerging area of research and artificial lighting thresholds (e.g., duration, intensity, spectrum, etc.) for fauna are not well defined. Light levels from the Project have been modeled in the Light Impact Assessment (Appendix D.1). While the calculated light levels at the sensitive receptors are below the guidelines recommended by the Institution of Lighting Professionals (ILP) guidelines, nighttime light propagation from the Project may still cause sensory disturbance to fauna. Project-related changes in ambient light levels are likely to result in localized avoidance of the Beaver Dam Mine Site and Haul Road and directly surrounding areas by some species. The impact distance will also be dependent on the type of lighting used. These distances have been considered in the delineation of the RAA. Light impacts from trucks on the Haul Road are expected to be insignificant compared to baseline daylight illuminance and will be blocked by the surrounding natural buffers and topography. The impacts of Haul Road lighting on fauna is expected to be less than that of noise. No permanent lighting will be installed on the Haul Road. There are no new or additional effects from light anticipated at the Touquoy Mine Site, with the exception of temporal increase of the life span as a result of the Project.

Mainland moose are likely to be less significantly affected by sensory disturbance due to their ability to easily travel to avoid this disturbance. Hibernating snapping turtles, on the other hand, are unable to easily escape sensory disturbance easily during hibernation. As such, practices should be implemented to reduce blasting near wetlands with suitable snapping turtle hibernacula during hibernation. Hibernation generally occurs from October through March, depending on seasonal temperatures (i.e., hibernation can start later in a warm fall and end sooner in an early spring, and vice versa).

Construction of the Haul Road will involve a combination of new road construction (4.0 km) and upgrades to the existing logging road. The majority of the proposed Haul Road (30 km) follows an existing road corridor, used by local residences and lumber trucks. Vehicle traffic volumes will increase throughout the PA during the construction, operation, and closure phases. Vehicle and haul truck activity can cause impacts to priority fauna from wildlife vehicle collisions, dust, noise, and accidents (e.g. spills). Mitigation measures such as spill preparedness, emergency response measures, and best management practices (e.g. noise/dust control, speed limits) will minimize the likelihood of a negative impact.

Direct mortality of priority fauna species could result from Project activities, particularly due to the increase in traffic during construction and operation of the facility. Increased traffic poses a risk to wildlife such as the mainland moose and snapping turtle along the entire length of the Haul Road between the Beaver Dam Mine Site and the Touquoy Mine Site. Indirect mortality to these species could also occur from exposure to contaminants or spills from unplanned incidents.

Through the implementation of mitigations, overall, the magnitude of the Project's effect on priority fauna species is determined to be low. A low magnitude of effect on priority species is defined as an effect which results in no direct loss of SAR individuals, and loss of habitat for those species is mitigated in the long term through reclamation planning. Table 6.11-7 presents a habitat loss by observed fauna species (or species group) based on the habitat analysis described in Section 6.10.3.5. Based on the definitions of magnitude of impact, it is anticipated that all impacts to habitat types used by observed SAR terrestrial fauna (i.e., mainland moose and snapping turtle) will be low, in comparison to habitat availability within the LAA.

Priority Avifauna

The geographic extent, timing, duration, frequency, and reversibility of the effects of clearing and grubbing to priority birds remains the same as is with non-priority specific birds. Clearing and grubbing is limited to the Beaver Dam Mine Site and portions of the Haul Road during the construction phase. No clearing and grubbing is required at the Touquoy Mine Site. Clearing and grubbing will result in habitat loss for avifauna.

Avian usage of the PA during construction and operation of the Beaver Dam Mine will largely be driven by changes to habitat, resulting in localized avoidance of the PA by some species. Habitat connectivity is critical for maintaining biodiversity and healthy species populations and interior forests are often an important feature that supports this movement (NSDNR, 2015b). While Project activities are expected to result in increased habitat fragmentation and a decrease in habitat quality (e.g., sensory disturbance), the level of new fragmentation associated with the Beaver Dam Mine Site is anticipated to be low, given the current level of disturbance within the PA. The Beaver Dam Mine Site infrastructure footprint is situated primarily on an area of high existing disturbance and is expected to only have fringe effects on the interior forest availability. There will be minimal isolation of habitat that is currently contiguous, limited to the patch of potential interior forest west of the NAG waste rock stick pile (Figure 6.10-6). Undisturbed, unfragmented habitat is present in the LAA and RAA, and the larger tracts are maintained around the PA, particularly to the north. The LAA is covered with a network of roads, historical mining and forestry activities, and forestry trails creating a largely disturbed forest landscape. Section 6.10, Figure 6.10-5 shows the extent of the simulated existing disturbance and edge effect largely covering the majority of the LAA. As presented in Section 6.10, the Project will affect 237 ha of interior forest habitat, which accounts for 9% of the predicted interior forest area within the respective LAA (Section 6.10, Figure 6.10-5).

The effect of the Project on avifauna can largely be attributed to sensory disturbance, specialty noise and light. Sensory disturbance would result from rock blasting, clearing and grubbing, infrastructure construction, lighting and operations, internal mine traffic and traffic along the Haul Road during operations. Artificial noise and light, especially at night, have been shown to influence avian migration and behavior pattens, which could affect individual fitness and reproductive success (Da Silva et al. 2014). The Environment Code of Practice for Metal Mines (Environment Canada, 2012) has established parameters for ambient noise levels for wildlife. These parameters indicate that ambient noise observed above 55 dBA during the day and 45 dBA at night can affect wildlife. A literature review conducted by Shannon et al. (2016) found that avifauna have the potential to exhibit changes in song characteristics, reproduction, abundance, stress levels, and species richness at levels greater than 45 dBA, on average. Impacts can also differ between acute and chronic noise sources. Elevated noise above background concentrations around the PA may cause avifauna avoidance within 400 m (S, W, E) to 1,000 m (N) of the Beaver Dam Mine Site, <500 m on either side of the Haul Road and within 850 m the Touquoy Mine Site property boundaries, based on the most conservative guideline (45 dBA) identified for potential broad wildlife effects (Appendix B.1 and B.2; Environment Canada, 2012). These ranges of noise distribution are due to changes in local topography. Avifauna within these approximate ranges of noise distribution surrounding the PA have the potential to be affected by noise during the day and overnight. However, it should be noted that noise effects are rarely isolated from other disturbances and impacts likely coincide with habitat suitability changes that accompany increased noise levels (Shannon et al, 2016).

Light can impact avifauna by potentially causing disorientation or by causing attraction or avoidance (Langcore and Rich, 2004). Avifauna may be attracted to or disoriented by open pit lighting at night, particularly during migration periods, leading to mortality (Jones and Francis 2003). While effects of light on wildlife are documented, it is still an emerging area of research and artificial lighting thresholds (e.g., duration, intensity, spectrum, etc.) for wildlife are not well defined. Light levels from the Project have been modeled in the Light Impact Assessment (Appendix D.1). While the calculated light levels at the sensitive receptors are below the guidelines recommended by the Institute of Lighting Engineers (ILE) guidelines, nighttime light propagation from the Project may still cause sensory disturbance to avifauna. Project-related changes in ambient light levels are likely to result in localized avoidance of the Beaver Dam Mine Site and Haul Road and directly surrounding areas by some species. The impact distance will also be dependent on the type of lighting used. These distances have been considered in the delineation of the RAA. Light impacts from trucks on the Haul Road are expected to be insignificant compared to baseline daylight illuminance and will be blocked by the surrounding natural buffers and topography. The impacts of Haul Road lighting on fauna is expected to be less than that of noise. No permanent lighting will be installed on the Haul Road. There are no new or additional effects from light anticipated at the Touquoy Mine Site, with the exception of temporal increase of the life span as a result of the Project.

Some priority species may avoid the PA in favor of undisturbed habitat in the surrounding landscape. Other priority species are anticipated to be attracted to the mine infrastructure and newly created habitat. The common nighthawk, for instance, is a crepuscular insectivore which nests on exposed gravel and disturbed areas. Lighting of buildings at dawn and dusk can create a foraging opportunity where insects are attracted to the lights. Barn swallows commonly nest in the eaves of built structures and bank swallows can nest in vertical slopes in sandy or silty soil, even in areas with high activity levels. These species of swallows have similar feeding habits as the common nighthawk. As such, Project activities may increase habitat suitability for both these species.

Direct mortality of avifauna species could result from Project activities, particularly due to the increase in traffic during construction and operation of the facility. Increased traffic poses a risk to avifauna along the length of the Haul Road between the Beaver Dam Mine Site and the Touquoy Mine Site. Vehicle and haul truck activity can cause impacts to priority avifauna from wildlife vehicle collisions, dust, noise, and accidents (e.g. spills). Wildlife vehicle collisions can directly affect priority fauna and noise can indirectly affect priority fauna by encouraging avoidance behaviour. Mitigation measures such as spill preparedness, emergency response measures, and best management practices (e.g. noise/dust control, speed limits) will minimize the likelihood of a negative impact.

Overall, the magnitude of the Project's effect on priority fauna species is determined to be low. A low magnitude of effect on priority species is defined as an effect which results in no direct loss of SAR individuals, and loss of habitat for those species is mitigated in the long term through reclamation planning. With appropriate mitigations, best management practices and operational monitoring (Appendix A of Appendix P.7 draft Wildlife Mitigation and Monitoring Plan), no direct mortality of priority bird species is anticipated, with the exception of the low potential for a bird strike with a haul truck. Best management practices include the avoidance of clearing and grubbing during the breeding season for migratory birds where practical. Table 6.12-11 presents a habitat loss by observed avifauna functional groups based on the habitat analysis described in Section 6.10.3.5. Based on the definitions of magnitude of impact, it is anticipated that all impacts to habitat types used by observed SAR avifauna will be low, in comparison to habitat availability within the LAA.

8.5.6.2.2 Effects of Other Projects in the Area

For SAR and SOCI, the RAAs align with taxa specific RAAs defined previously. There is direct spatial overlap between the Project and historic mining operations in the Beaver Dam and Touquoy Mine Sites (Figure 8.5-5). Any potential cumulative effects from these projects related to SAR and SOCI would be based on potential impacts to water quality from mobilization of historic tailings. The remediation of historic tailings is expected to result in a positive effect of the Project. The potential impact of this interaction will be mitigated by implementation of the dHistorical Tailings Management Plan (Appendix E.9). As such, these historic operations are not carried through the CEA process.

Current Regional Forestry Operations

Habitat throughout the region exhibits fragmented conditions related to current and historic timber harvesting activity. This has led to habitat fragmentation and an increase in young regenerating stands to the detriment of older undisturbed forest, and the species which rely on these forests.

The existing roads that service the regional forestry industry contribute to the disturbance and risk of collision to species such as Moose. Timber harvesting is expected to have direct and indirect impacts to priority avifauna. According to Freedman, Woodley & Loo (1994), the effects of timber harvesting on birds is reflective of the physical and botanical changes in the structure of the forest in a given landscape. Habitat preferences for avifauna vary quite widely, so the effects of timber harvesting can result in creation of habitat for some species, while negatively affecting habitat for others. As described previously, this can be particularly important for species relying on old forest conditions, which is not supported in a landscape with abundant timber harvesting activity.

Generally speaking, the removal of trees for timber harvesting is anticipated to have a negative effect on priority avifauna species. The extent of the impact of timber harvesting on priority avifauna within the LAA is not well documented in literature. The likelihood that timber harvesting would have an adverse residual effect on priority fish species is moderate, presuming forestry operators adhere to provincial Wildlife Habitat and Watercourse Protection regulations. These regulations also provide stipulations to reduce the effect of habitat fragmentation on terrestrial and avifauna, by requiring stream buffers (to act as corridors) and patches of live trees, protection of Moose shelter patches, allowing for passage of wild species across clear-cut landscapes. As such, while habitat loss and fragmentation do occur as a result of timber harvesting, some level of habitat connectivity is provided by these regulations and provincial oversight and integrated resource management processes.

Touquoy Gold Project

Some loss of Mainland Moose habitat, although limited to the Touquoy Project footprint, has occurred through the construction of the Touquoy Mine Site. Snapping Turtles have been observed in the riparian zone of the Moose River, and the Moose River is known to support priority fish species such as Atlantic Salmon and Brook Trout. The construction of this facility has resulted in some loss of habitat for avifauna, including priority species. The Touquoy Project has resulted in the loss of a single Black Ash to allow construction of the TMF. While the Touquoy Gold Project is discussed in terms of a cumulative effects assessment, the extension of the operation of this facility is also tied directly to the FMS Project. As such, the effects assessment of the temporal extension of the Touquoy Gold Project is presented herein. The effects of the Touquoy Gold Project are similar in nature to the effects of the addition of the FMS Project to the Touquoy facility, with the primary difference related to the temporal extension of effects.

Potential impacts to priority species include direct mortality (vehicles), alteration or loss of habitat, disturbance of reproductive or feeding activities (generally due to noise or site activity), increased predation (natural predators, vehicle collision or hunting/trapping) due to improved access and traffic or disruption of migration patterns and habitat fragmentation. Accidental events could result in similar impacts. Vehicle use on-site could result in accidental mortality of Mainland Moose and Snapping Turtles. As few moose are in the area, it is unlikely that encounters will occur; however, the importance of individual moose within this area is recognized. As collisions can be avoided by ensuring on-site vehicle speeds are under 50 km/hr, speed limits below this level will be enforced year-round.

A WMMP has been implemented at the Touquoy Mine Site, requiring reporting of wildlife, particularly turtles and Mainland Moose observations to the site Environmental Technicians. No additional clearing or grubbing is required at the Touquoy Mine Site to facilitate deposition of FMS tailings, so additional habitat loss is not an important factor in assessing cumulative effects to SAR/SOCI at the Touquoy Mine Site. Aside from trucking of gold concentrate and deposition of tailings, the effects of the FMS Project and the Touquoy facility do not overlap spatially or temporally, reducing potential cumulative effects to SAR and SOCI.

Fifteen Mile Stream Mine Project

Some loss of interior forest is expected to occur to support development of the Fifteen Mile Stream (FMS) Project. Project activities are expected to result in increased habitat fragmentation and a decrease in habitat quality for those species, including mainland moose and several bird species, which rely especially on interior forest conditions. The decrease in habitat quality for species relying on interior forest condition is based on increased activity and sensory disturbance, along with increased physical fragmentation and direct habitat loss. The loss of interior forest has been determined to represent approximately 0.49% of predicted interior forest within the RAA (AMNS, 2020).

Twenty-two (six of which are SAR) priority avifauna species were observed within the Beaver Dam Mine Site and proposed Project infrastructure and a direct loss of their habitat is expected. The six SAR avifauna species are common nighthawk, Canada warbler,

rusty blackbird, olive-sided flycatcher, evening grosbeak, and eastern wood-peewee. A cumulative effects modelling exercise was completed within the FMS EIS, to understand the effects of cumulative wetland loss on several Species at Risk. This exercise is described in Section 6.7.5.2 of the FMS EIS (AMNS, 2021c). Through the cumulative effects modelling completed regarding wetland loss and species at risk, it was determined that the FMS Project will result in a 5.2% loss of wetland area in the LAA, and a 1.2% loss of wetland area in the RAA. Specific to Species at Risk, habitat suitability across the entire RAA was not modelled for specific species. The FMS Project is predicted to result in a 2.5% loss of modelled wetland habitat for mainland moose, along with a 5.5% loss of suitable modelled wetland habitat for olive-sided flycatcher, and a 0.3% loss of suitable modelled wetland habitat for the rusty blackbird, within the Projects' LAA. This demonstrated that large amounts of equivalent habitat is available to these mobile species in close proximity to the FMS Project; therefore, there is no predicted significant adverse effect from the Project on wetland habitat for the selected species.

The FMS Project is expected to result in loss of habitat for brook trout to support development of Project components including the diversion and realignment of Seloam Brook. Within the Beaver Dam Mine Site, four locations with a total of 11 thalli of blue felt lichen are expected to be directly impacted by the construction of the TMF (3) and WRSA (1). An additional four individuals representing three lichen SOCI are expected to be impacted, along with four individuals of three species of SOCI vascular flora.

Project interactions for the FMS Mine are detailed in the respective VC chapters. The Projects' effects on SAR and SOCI were determined to be adverse, but not significant. The RAA associated with the proposed Beaver Dam Haul Route overlaps the FMS Project both spatially and temporally due to trucking of gold concentrate to the Touquoy Mine Site, which is described below. As a result, there is some potential additive cumulative effect to priority species due to habitat fragmentation and sensory disturbance, especially given the concurrent timelines of the Beaver Dam Mine Project and the Project.

Beaver Dam Haul Road Use by the FMS Project and Cochrane Hill Gold Project

As stated above, during the operation phase of Project and the Cochrane Hill Gold Project, gold concentrate from each surface mine will be transported to the Touquoy Mine Site for final processing into gold doré bar. The proposed haul route for each project is proposed to overlap with the Beaver Dam Haul Road west of the Highway 224, which will be constructed to transport ore from Beaver Dam Mine Site to the Touquoy Mine Site. It is expected that the FMS Mine Site and the Cochrane Hill Mine Site will each transport 11 round-trip truckloads of gold concentrate to Touquoy Mine Site per day for final processing. This accounts for a total of 44 single trip trucks per day from both projects, in addition to the 95 single-trip trucks (190 two-way trips) using the road to transport Beaver Dam ore, and average of 14 single-trips per day anticipated from timber harvesting operations. The total number of trucks for cumulative effects assessment is 288 trucks round trip (Appendix C1).

The trucking operations associated with the Project and Cochrane Hill Gold Project along the Beaver Dam Haul Road west of Highway 224 has the potential to increase the potential impact SAR and SOCI from wildlife vehicle collisions, dust, noise, and accidents (e.g. spills) due to cumulative truck traffic from these projects. The pathway for effects of this activity to SAR and SOCI involves disturbance through increased air, noise and light, potential physical interaction with trucks, and habitat disturbance from construction of the haul road. The incremental effects related to disturbance are expected to be similar with respect to impact to SAR and SOCI. Adherence to provincial and federal guidance, along with mitigation measures presented in the Beaver Dam Mine Project EIS will limit the effects to priority species from trucking on the Beaver Dam Haul Road.

NSSA Acid Mitigation Project

One or more component of the Acid Mitigation Project overlap the RAA for priority fish species (Terrestrial liming component in the Tent Lake and Keef Brook watersheds), priority flora fauna and avifauna. The NSSA AMP operates three main components. Two lime dosing stations are located on the West River Sheet Harbour and on the Killag River, downstream of Cameron Flowage.

Neither of these components have direct spatial overlap with the Proposed Project, although the dosing station on the Killag River is approximately 650 m southeast of the proposed pit. Despite its close proximity to the proposed Project; the spatial extent of direct and indirect impacts to fish and fish habitat does not extend to this portion of the Killag River, as specified in Section 6.9.7.1.6.

Terrestrial liming has occurred within the Paul Brook, Keef Brook and Tent Lake watersheds. According to Rotteveel (2018), terrestrial liming occurred in MacGregor Brook and Colwell Brook during the fall of 2016, with some expected 'blowout' from helicopter liming affecting Cope Brook as well. The upper portion of the Killag River (above the lime dosing station) and Brandon lake Brook were used as control sites for this study. On September 25, 2019, MEL and AMNS met with the NSSA and ASF to discuss the second round of information requests related to the Project. During that meeting, it was stated that the NSSA would be commencing terrestrial lime application in the Tent Lake watershed; but indicated that terrestrial liming would not occur in proximity to the proposed organics stockpile until 2020. Of the three watersheds where terrestrial liming is known, or expected to have occurred, the Project only has a spatial overlap with the Tent Lake watershed (1EM-2-F) and the Keef Brook watershed (1EM-2-G). According to Rotteveel (2018), acidification of Nova Scotia's freshwater ecosystems has resulted in decreased habitat quality for Southern Uplands Atlantic Salmon, due in part to the mobilization of aluminum which has been mobilized due to low pH.

The residual effect of the NSSA AMP on fish and fish habitat, particularly Atlantic salmon, is a positive due to reduction of the effect of historic acidification on water quality within the treated catchment areas of the West River Sheet Harbour watershed. This Project is defined as having direct spatial and temporal overlap with the Beaver Dam Project specifically within the Tent Brook watershed (Project effects related to low magnitude flow reductions), and to a lesser extent, the Keef Brook watershed (Project effects related to Haul Road construction). The residual effects of the NSSA AMP on other taxa of rare species are unknown.

<u>Dufferin Gold Mine</u>

The Environmental Assessment Registration Document for this project is not currently publicly available. As such, a thorough cumulative effects assessment for the Dufferin Gold Mine is limited to the Project's description on the companies' website and a review of satellite images in Google Earth, along with MEL biologists' experience with SAR and SOCI in that region of the Province.

According to the proponents' website, "The Dufferin Mine is a high-grade underground gold mine and fully permitted mill in Nova Scotia, Canada, with historic and recent production, a planned near-term restart, and potential for extensive expansion. The mine has a 300 tpd gravity and flotation mill and, with certain upgrades and refurbishment, all necessary infrastructure in place to conduct full-scale gold mining operations" (Resource Capital Gold Corp, 2019).

"The Company has completed refurbishment of the major mill components and is performing test milling. As part of the test milling process, the Company produced its first gold on the project in early March 2017. RCG is preparing to begin trial mining of an initial approximately 15,000 tonnes in order to confirm mineralization grade and prepare for a full restart of the mine and mill. The project comprises 1,684 ha, accessible by gravel road 25 km from Sheet Harbour in southeastern Nova Scotia, about 135 km northeast of Halifax " (Resource Capital Gold Corp, 2019).

The Dufferin deposit consists of mineralized gold in quartz veins, mined by underground shafts, rather than an open pit. Milling operations continued through 2017, and according to a press release dated January 29th, 2018, the bulk sampling program was completed with favorable results. A press release dated January 29th, 2019 indicated, however, that the company has filed a Notice of Interest to make a proposal under the Bankruptcy and Insolvency Act. According to the press release, "The initial NOI period will allow RCG to evaluate, with its partners, all available legal recourses and financial alternatives that may allow the Company to resume its operational production efforts as soon as possible and continue as a going concern" (Resource Capital Gold Corp, 2019).

Given this most recent press release, the future development of the Dufferin Project is uncertain. In its current state, the shaft, plant site and access road has resulted in some habitat fragmentation which could impact habitat quality for SAR and SOCI at a localized level. Given the uncertainty moving forward, it is unknown whether the Dufferin Project will overlap temporally with the FMS Project. The Dufferin Project Area is located more than 26km southeast of the Beaver Dam Mine Site, though there is potential for an additive cumulative effect between the projects, based on habitat fragmentation if the Project were to proceed.

8.5.6.2.3 Cumulative Effects on the Species of Conservation Interest and Species at Risk

Cumulative effects to SAR and SOCI are specific to each species, meaning that cumulative effects are only considered for species on which the Project has adverse residual effects and for which adverse effects from other identified projects in the area are expected.

Priority Fish

Residual effects on priority fish and fish habitat within the Beaver Dam Study Area are primarily related to loss of fish habitat from the development of the pit and other infrastructure. The key mitigation measures associated with this loss of fish habitat involve the fish rescue and offsetting for loss of fish habitat.

Spatial and temporal overlap of other projects within the RAA for fish and fish habitat is presented in Section 8.5.5.2.3.

The Killag lime dosing station was installed to mitigate the effects of historic acidification within the Killag River, and to improve the quality of fish habitat within the Killag River, particularly for Atlantic salmon. As part of the predictive water quality modelling, the effect of the Project on pH in the receiving environment was evaluated. pH cannot be predicted with certainty by mass-balance models as used in the predictive water quality evaluation. That is, while modelling for the Project is conservative, mass balances modelling processes/predictions do not represent complete reaction paths and thus for non-conservative parameters (such as pH) water quality predictions are expected to be further governed by in situ processes. Note, discharges from the project will be subject to the MDMER such that effluent concentrations must be within pH range of 6.0 to 9.5, which is protective of aquatic life. Therefore, there are no effects to Surface Water Quality as a result of Project effluent discharges; and no expected negative cumulative impact of the Project on pH in the Killag River.

The Project is expected to have a direct spatial overlap within the Keef Brook Watershed, and the Tent Brook watershed. The spatial scale of terrestrial liming within each of these watersheds is unknown; therefore, it was assumed that the entire catchment areas are treated with lime in an effort to be conservatively inclusive. Impacts of the Project to fish habitat within the Keef Brook watershed are limited to upgrading the existing Haul Road and associated watercourse crossings. Upgrading the Haul Road is expected to result in direct impacts to fish habitat (420.2 m^2, in WC J and WL76) to allow for culvert installation, which has been incorporated in the Offsetting Plan (Appendix J.3). Of the watercourse crossings located within the Keef Brook watershed, five are currently acting as barriers to fish passage, so upgrading Haul Road infrastructure is expected to result in improvements to fish passage in watercourses E, F, G, J and K. Provided mitigation measures for watercourse crossings are adhered to (as will be required under provincial watercourse permits), no indirect effects are expected to fish habitat within this tertiary watershed. Furthermore, it is unknown whether terrestrial liming within this system is ongoing, based on results published by Rotteveel (2018) and communication from DFO (2019). Terrestrial liming was selected as a treatment within several catchment areas in this watershed due to the long-lasting effects of helicopter-based liming; which essentially acts as a 'slow-release' of lime through the soil into the watercourses. While the benefits of liming may continue to occur through the temporal scale of the Project; activities within this watershed are not expected to have any type of cumulative interaction with terrestrial liming which has already occurred.

Within the Tent Brook tertiary watershed, Project interactions include construction of an organics stockpile, ATV bypass road, crusher pad, and topsoil stockpile. The ATV bypass road will remain in place through post-construction, while the crusher pad, topsoil stockpile and organics stockpile will be reclaimed in the active reclamation stage of the Post Closure phase of the Project. Upgrading Haul Road infrastructure is expected to result in direct impacts to 535 m^2 of fish habitat in Wetlands 64 and 66, and will result in fish passage improvements in watercourses A and B. Direct impacts to fish habitat have been incorporated into the Offsetting Plan (Appendix J.3). Provided mitigation measures for watercourse crossings are adhered to, no indirect impacts in watercourses within the Tent Brook watershed are expected based on upgrades to the Haul Road.

To identify potential indirect effects to fish and fish habitat within Tent Brook watershed, an updated Water Balance Assessment is provided (within the Mine Water Management Plan, Appendix Q1). Based on the results of the water balance, collection of contact water is expected to result in a 1.1% reduction in flow at EOM, and a 1.2% reduction at PC. As a result, a low magnitude of effect is expected to fish habitat within the Tent Brook watershed, as this change has been determined to fall within natural variation. Furthermore, water quality effects are not expected within the Tent Brook watershed; as all site contact water will be collected in the South Settling Pond prior to release. The primary purpose of the south settling pond is to reduce the TSS levels to acceptable limits, and control stormwater runoff. Effects to the downstream environment are not expected.

Data related to the NSSA terrestrial liming program inputs, objectives, and results were not available with sufficient detail to allow interpretation of interacting effects between terrestrial liming and direct and indirect effects within the Tent Brook or Keef Brook watersheds. AMNS requested further detail from the NSSA; however, NSSA did not provide a response. Therefore, the evaluation of cumulative effects within the Tent Brook and Keef Brook watersheds are qualitative in nature. Direct impacts to fish habitat within each of these watersheds is limited to construction of the Haul Road and associated watercourse crossings. These impacts range from negligible to high, based on the area of impact within each individual crossing. Given implementation of mitigation measures including Offsetting, these effects are determined to be not significant, especially considering the improvements to fish passage which will be provided. The indirect effects of the Project on fish habitat within the Keef Brook and Tent Brook watersheds are limited to low magnitude effects to flow reduction in the Tent Brook watershed. The Project related effects to fish habitat within these two watersheds are adverse and not significant; given that the residual effects of the terrestrial liming are positive (magnitude and significance are unknown); it is likely that any cumulative effect to fish habitat would be classified as a compensatory interaction, with a non-significant residual cumulative effect.

The deposition of tailings from the proposed Fifteen Mile Stream Project and the existing Touquoy Gold Project in the Touquoy Pit overlap the current Project both spatially and temporally. As discussed, with appropriate mitigation to ensure compliance with MDMER criteria and water quality objectives, the potential for residual cumulative effect on fish and fish habitat is expected to be minimal.

There is limited uncertainty as to the Project effects on priority fish species. Follow-up monitoring programs established for the Project (i.e. monitoring the effectiveness of fish habitat offsetting measures) will be used to address any uncertainty (Section 6.9.10). Surface water quality and quantity monitoring completed within he AEMP will identify any potential indirect cumulative effects to fish and fish habitat.

Priority Vascular Flora and Lichens

Projects which overlap the RAA for priority vascular flora and lichens include historic mining operations at both FMS and Touquoy Mine Sites, current operations of the Touquoy Mine Site, the FMS Project, cumulative use of the Haul Road west of the Highway 224 by the FMS Mine Project and the Cochrane Hill Mine Project, regional forestry operations, the Dufferin Gold Mine, and the NSSA Acid Mitigation Projects. No significant adverse effects to priority vascular flora and lichens are anticipated as a result of the Touquoy Gold Project or FMS Project.

Residual effects to priority vascular flora and lichens as a result of the timber harvesting, historic mining operations, the Dufferin Gold Project and the NSSA Acid Mitigation Projects are largely unknown, and little information is available, with the exception of the general understanding that habitat loss or change from these projects results in potential loss of priority flora and lichen species. The general habitat disturbances from historic and ongoing forestry activities, and these projects listed above, are likely to have had some effect on species that prefer undisturbed habitat and especially those sensitive to edge effects, such as priority lichens.

The NSSA Acid Mitigation Projects, specifically the terrestrial liming component in the Tent Lake and Keef Brook watersheds, may have an adverse effect on priority lichen. As one of the main factors affecting epiphytic lichen occurrences is the pH of the host tree on which it is growing (Marmor & Randlane, 2007), aerial lime dosing may cause a shift in lichen community and result in alteration in cell tissue pH which can impact lichen health and richness (Naeth and Wilkinson 2008; Farmer, 1991). The level and spatial extent of impact will depend on the specifics of the project, such as weather conditions at time of dosing, elevation of lime release, concentration, etc. Aerial liming impacts will be considered during the implementation of the Lichen SAR translocation and Monitoring Plan, specifically when selecting transplant recipient sites.

The Air Emission Assessment Technical Report (Appendix C.1) presents Project only and cumulative dust deposition rates along the Haul Road. While the cumulative use of the Haul Road west of the Highway 224 by the FMS Mine Project and the Cochrane Hill Mine Project does increase deposition rates, these rates have been reviewed with respect to lichen impacts and it was found that they did not result in changes to predicted effects. As a result, no additional monitoring or mitigations are recommended.

There is a significant level of uncertainty as to the cumulative effects, especially as to the effects from past disturbances and other projects in the region. However, given the small footprint of the Project on the regional scale there is some confidence that the Project's effects on priority flora contributes only a small portion to the total cumulative effects, and that any additive cumulative effects would be negligible.

Priority Terrestrial Fauna

Projects which overlap within the RAA for priority terrestrial fauna include historic mining operations at both FMS and Touquoy Mine Sites, current operations of the Touquoy Mine Site, the FMS Project, cumulative use of the Haul Road west of the Highway 224 by the FMS Mine Project and the Cochrane Hill Mine Project, regional forestry operations, the Dufferin Gold Mine, and the NSSA Acid Mitigation Projects. No significant adverse effects to priority terrestrial fauna are anticipated as a result of the Touquoy Gold Project or FMS Project.

The Beaver Dam Mine Project will result in the loss of 10 ha of mainland moose wetland habitat. The additional wetland impacts from the FMS Mine Project will result in a loss of 26 ha of this habitat, resulting in a cumulative loss of 36 ha of mainland moose wetland habitat within the terrestrial fauna RAA, as a result of these Projects. This habitat loss represents 0.03% of the total RAA area. Large amounts of equivalent mainland moose habitat are still available within the RAA and abundant intact area exists between these projects to maintain unimpeded movement.

Residual effects to priority terrestrial fauna as a result of the timber harvesting, historic mining operations, the Dufferin Gold Project and the NSSA Acid Mitigation Projects are largely unknown, and little information is available, with the exception of the general understanding that these projects can result in habitat loss or change for priority fauna species. Given the distance between the Dufferin Gold Project and all components of the PA, a spatial overlap in effects is unlikely. Given the current state of the Dufferin Gold Project (detailed in Section 85.6.2.2.6), it is unlikely that there will be a temporal overlap with the current proposal.

The general habitat disturbances and fragmentation from historic and ongoing forestry activities are likely to have had some effect on priority species that prefer undisturbed habitat and interior forest. Specifically, timber harvesting, the Project, the FMS Project

and the Touquoy Gold Project are expected to have an adverse effect on the mainland moose. A Mainland Moose Management Plan will be developed as part of the Project's Wildlife Management Plan (Appendix Q) to help mitigate these effects. The effects are the result of loss of habitat and from the risk of collision with vehicles. Habitat loss and disturbance, and traffic from other activities in the region contribute to the resulting cumulative effects.

Similar cumulative effects are expected for the snapping turtle, which have been observed at the Beaver Dam Mine Site and along roadsides near the Touquoy Mine Site during nesting season. Increasing traffic levels will increase risk of collisions to snapping turtles. A Wildlife Management Plan has been implemented at the Touquoy Mine Site and has been developed for the Beaver Dam Mine Site (Appendix P.7) to reduce potential impact to wildlife, specifically turtles. No other specific project causing loss of habitat for this species has been identified.

There is a significant level of uncertainty as to the cumulative effects on priority terrestrial fauna. Given the small footprint of the Project on the regional scale there is some confidence that the Project's effects on priority terrestrial fauna contributes only a small portion to the total cumulative effects, and that there is low potential for significant additive cumulative effects.

Priority Avifauna

Projects which overlap within the RAA for priority avifauna include historic mining operations at both FMS and Touquoy Mine Sites, current operations of the Touquoy Mine Site, the FMS Project, cumulative use of the Haul Road west of the Highway 224 by the FMS Mine Project and the Cochrane Hill Mine Project, regional forestry operations, the Dufferin Gold Mine, and the NSSA Acid Mitigation Projects. No significant adverse effects to priority terrestrial fauna are anticipated as a result of the Touquoy Gold Project or FMS Project.

The Beaver Dam Mine Project will result in the loss of a total of 35 ha of SAR avifauna wetland habitat for Canada warbler, olive-sided flycatcher and rusty blackbird. The additional wetland impacts from the FMS Mine Project will result in a loss of 72 ha of this habitat, resulting in a cumulative loss of 107 ha of Canada warbler, olive-sided flycatcher and rusty blackbird wetland habitat within the avifauna RAA, as a result of these Projects. This habitat loss represents 0.07% of the total RAA area. Large amounts of equivalent habitat is still available within the RAA and abundant intact area exists between these projects to maintain unimpeded movement.

Residual effects to priority terrestrial fauna as a result of the timber harvesting, historic mining operations, the Dufferin Gold Project and the NSSA Acid Mitigation Projects are largely unknown, and little information is available, with the exception of the general understanding that these projects can result in habitat loss or change for priority avifauna species. Given the distance between the Dufferin Gold Project and all components of the PA, a spatial overlap in effects is unlikely. Given the current state of the Dufferin Gold Project (detailed in Section 8.4.3.1.13), it is unlikely that there will be a temporal overlap with the current proposal.

The general habitat disturbances and fragmentation from historic and ongoing forestry activities are likely to have had some effect on priority species that prefer undisturbed habitat and interior forest. The cumulative effects to priority birds are therefore driven by habitat loss and disturbance and are essentially the same as those noted for birds in general. Overall, the generalized disturbance of the landscape by proposed and active gold projects, and forestry activities (past, present and future) are the main source of cumulative effects to priority birds throughout the area. A Landbird Mitigation and Monitoring Plan has been developed for the Project (Appendix P.6) to help mitigate effects to avifauna SAR during operations. The largest adverse effects expected would be to species preferring undisturbed and unfragmented habitats, although the impact to interior forest from the Beaver Dam Mine Project and FMS Project have been determined to be low.

There is a moderate level of uncertainty as to the cumulative effects on priority avifauna. The main assumption behind this assessment is that the overall patterns of land use in the region will remain unchanged in the foreseeable future and that the Project will be approved and carried out during the anticipated timelines. Considering the temporal scale and small footprint of the Project on the regional scale, there is some confidence that the Project's effects on priority avifauna contributes only a small portion to the total cumulative effects, and that there is low potential for significant additive cumulative effects.

8.5.6.3 Mitigation

No specific mitigations are recommended to reduce cumulative effect, other than those presented in Sections 6.8 to 6.13 (Fish and Wetlands, Fish Habitat, Habitat and Flora, Terrestrial Fauna, Avifauna and SAR/SOCI, respectively). The Touquoy Gold Project and FMS Gold Projects will adhere to their own mitigation measures as outlined in their Approval and EIS, respectively. The mitigation of the effects originating from regional forestry and land management practices falls outside the scope of the Proponent's authority and responsibility.

8.5.6.4 Residual Cumulative Effects and Significance Assessment

A significant adverse effect from the Project on SAR and SOCI is defined as an effect that is likely to cause a permanent, unmitigated alteration to habitat that supports a species' distribution, or alteration of critical habitat. Sedentary species such as vascular and non-vascular flora do not have the opportunity to move to avoid direct or indirect impact. For these species, the loss of an individual or individuals of a SAR species that is important in the context of the province, or that species' overall abundance or distribution, may be considered significant, if appropriate mitigation measures are not implemented.

Within the Project, the FMS Gold Project, the Touquoy Gold Project and the use of the Beaver Dam Haul Road by all three projects, there is no expectation of significant cumulative effects to SAR or SOCI. The NSSA AMP has a partial spatial and temporal overlap with the Project where terrestrial liming is ongoing within the Tent Brook and Keef Brook watersheds. The effects of this project on fish and fish habitat is anticipated to be positive, and there is no predicted adverse cumulative effect on fish and fish habitat when combined with residual effects of the Project. Based on lour limited understanding of the details of the NSSA AMP, particularly related to the potential effects to priority species, we anticipate the potential cumulative effects as not significant; however available information was limited for this assessment, and therefore, there is some uncertainty in this conclusion.

The alteration of the disturbance of habitats throughout the region from historic and current land use is likely to have affected the local distribution and abundance of various species, especially those associated with undisturbed mature habitats. However, the overall footprint of mining activities in the area, including the Beaver Dam and Touquoy Mine Sites, is quite small in relation to the VCs respective RAAs. As such, no significant residual cumulative effects are anticipated (Table 8.5-7).

8.5.6.5 Follow-up and Monitoring Programs

No additional monitoring beyond that indicated for the Project in Section 6.12.10 is proposed.

Table 8.5-7: Residual Cumulative Environmental Effects for SOCI and SAR

Residual Adverse Cumulative Effects (After Mitigation)	Significance Levels						Overall Significance of Residual Adverse Effects (and Rationale)
	Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility	
Cumulative loss, alteration and the disturbance of habitats throughout the RAA relating to SOCI and SAR.	L The maximum cumulative Project edge effect will affect 512 ha of interior forest habitat in consideration of the Beaver Dam and FMS Projects, which accounts for 0.7% of predicted interior forest in the RAA. There is limited additional development pressures from other projects in the RAA, as demonstrated by the few projects identified within this evaluation.	RAA Loss of habitat used by priority species has occurred on a regional scale.	A Cumulative effect would be more significant during sensitive period for each priority species.	LT Effects may extend beyond 7 years.	S The loss of habitat associated with the Beaver Dam Mine Site will occur once. However, the potential future loss of habitat associated with the Beaver Dam Project and other regional projects in the future could occur throughout the lifetime of the Project.	PR Reclamation cannot guarantee a return to baseline conditions.	Low Adverse Effect (Not Significant) The small proportion of regional habitat that supports priority species that would be lost as a result of this Project will be restored during the reclamation stage of Closure Phase. There is limited additional development pressure from projects in the RAA.

Legend (refer to Section 5.11, Table 5.11-1 for definitions)

8.5.7 Mi'kmaq of Nova Scotia Cumulative Effects Assessment

8.5.7.1 Baseline conditions

There are 13 Mi'kmaq communities in Nova Scotia, with two First Nation (Mi'kmaq) reserves in the vicinity of the Project: Beaver Lake IR 17 (49.4 ha) is located approximately 5 km southwest from the Beaver Dam Mine Site, and Sheet Harbour IR 36 (32.7 ha) is located 20 km south of the Project. Both these reserves belong to the Millbrook First Nation which is located in Truro, Nova Scotia, 54 km northwest of the Beaver Dam Mine Site. The 2017 Census reports 21 and 25 Mi'kmaw residents at Beaver Lake and Sheet Harbour, respectively (Statistics Canada 2017, 2017a).

Beaver Lake: established in 1867 and approximately 49.4 ha in size is situated along Hwy 224. The estimated population on reserve is 21 with a total of five homes and four small cottages/camps.

Sheet Harbour: set aside under Millbrook administration in 1960 and approximately 32.7 ha along Hwy 7, the estimated population on reserve is 25 with a total of nine homes, two trailers, a community hall and a convenience/gas bar.

The Sipekne'katik First Nation, located in Indian Brook, Nova Scotia, is located approximately 61 km west of the Project. The Pictou Landing First Nation (PLFN), located north of the town of New Glasgow, is located 66 km north of the Project.

Mi'kmaq rights are communal rights and therefore shared amongst all members of the Mi'kmaq Nation in Nova Scotia. Community profiles of the 13 Mi'kmaw First Nations in Nova Scotia have been included in Table 6.14-1 (Stantec 2018c, CBU 2020).

8.5.7.1.1 Historic Mi'kmaq Land and Resource Use

Mi'kmaq traditional use of the land in Nova Scotia involved semi-permanent and permanent settlements. Summer villages of the Mi'kmaq were usually located on the banks of streams or rivers. The most important factor in the choice of a site was the proximity of the site to a navigable body of water. Sites around the mouths of rivers with heavy spawning runs were highly favourable for use, as well as smaller rivers running back into a system of lakes (Appendix M.1).

Beaver Dam lies within Eskikewa'kik or the "skin dressing territory". This particular district spans from Halifax County across to Guysborough County. Various authors and historians have differed in their description of how far this territory expands, but all have agreed that Beaver Dam lies within this district (Appendix M.1).

Although little historical information has been written about Mi'kmaq inhabiting these areas in large numbers, there is some documentation that suggests that they mainly inhabited Halifax and Port Mulgrave. Bernard Hoffman has noted that there were seven main sites within Eskikewa'kik; including sites at Ship Harbour, Spry Bay Harbour and Liscomb Harbour near the study area (Appendix M.1).

Mi'kmaq cultures hunted land and marine mammals and fish for sustenance and some trading until the late sixteenth century, when traditional activities began to change in response to contact with the Europeans. Settlements, although not permanent, were located near major waterways and harbours, providing accessibility to trade with the Europeans. The Mi'kmaq traveled inland through minor streams and rivers, either by canoe or on foot (Appendix M.1).

More details outlining historic land and resource use by the Mi'kmaq of Nova Scotia are presented in Section 6.14.

8.5.7.1.2 Current Mi'kmaq Land and Resource Use

Drawing from information provided through the MEKS, the TLRUS (MFC 2019), direct information gathered from engagement activities between AMNS and the Millbrook First Nation and Sipekne'katik First Nation, and the KMKNO, and the Project team's knowledge of the Beaver Dam Mine Site and the Haul Road, the following summary of current Mi'kmaq land and resource use has been prepared as a basis from which to understand and evaluate Project interactions and potential effects of the Project on the Mi'kmaq of Nova Scotia. The description and analysis in this section has been tailored to Millbrook First Nation, unless specific mention of information relating to a different Mi'kmaq community is noted. Information was requested from all Mi'kmaq communities in Nova Scotia through the MEKS and direct engagement with KMKNO and Sipekne'katik First Nation; however, the TLRUS (MFC 2019) prepared for Millbrook First Nation and information received directly from the Millbrook First Nation community informs AMNS's specific understanding of traditional and current use. Some generalized information, especially relating to traditional use, was available through the MEKS and is presented herein. The baseline information provided in the MEKS is generally consistent with that baseline data collected by the Millbrook First Nation through the TLRUS (MFC 2019).

The following key aspects were considered and requested from the Mi'kmaw communities during collection of baseline data (either through direct engagement or the completion of the MEKS and TLRUS):

- General information about Mi'kmaq of Nova Scotia populations;
- General description of baseline conditions within the Beaver Dam Mine Site and Haul Road and surrounding landscape to support an understanding of the current experience of the traditional practice for the Mi'kmaq of Nova Scotia;
- Sites or areas that are used by the Mi'kmaq of Nova Scotia either for permanent residences or on a seasonal/temporary basis and the number of people that use each site/area identified;
- Drinking water sources (permanent, seasonal, periodic, or occasional);
- Consumption of country foods (also known as traditional foods) including food that is trapped, fished, hunted, harvested, or grown for subsistence or medicinal purposes, outside of the commercial food chain;
- Which country foods are consumed by which groups, how frequently, and where these country foods are harvested;
- How are different subpopulations of the Mi'kmaq communities using the land;
- How often is the right practiced or exercised and timing/seasonality of the practice; the context in which the right is practiced;
- Commercial activities (e.g. fishing, trapping, hunting, forestry, outfitting) and the frequency, duration and timing of these activities including maps and data sets; and
- Recreational uses and the frequency, duration and timing of these activities.

Baseline information that was shared and available for the Project is described in this section. This summary of current use is specific to the Millbrook First Nation, through the completion of the TLRUS (MFC 2019), supported by conclusion of the MEKS. This report describes Millbrook traditional land and resource use in the regional and local study areas through careful documentation of harvesting and occupancy locations, as well as the presentation of qualitative information relating to participants' relationships with these locations (MFC 2019).

It is important to note that some limitations relating to baseline information are present and thus, evaluation of Project interactions and potential effects to the Millbrook First Nation and more broadly the Mi'kmaq of Nova Scotia, are provided with some limitations on specific analysis:

- **Drinking Water Sources:** No surface drinking water sources were identified through the MEKS or TLRUS, and direct engagement activities with the communities. As a result, no analysis of specific surface water drinking water sources is completed. However, a discussion of impact to drinking water at the Cameron Flowage/Killag River (the discharge location from the Project) is included as it is considered the reasonable worst case predicted water quality conditions stemming from the Project.
- **Residences (Permanent or Seasonal):** No specific detail relating to location of seasonal or temporary camps/cottages/residences were provided to AMNS. The MEKS did not provide any information relating to seasonal or permanent residences, with the exception of the Beaver Lake IR. The TLRUS identified several Millbrook camp locations, but no specific locations were provided. Thus, no analysis of specific Millbrook residential receptors has been included in this Project EIS. Conclusions relating to Project impacts at the Beaver Dam Mine Site and Haul Road property boundaries have been provided for each VC in Table 6.14-4 and these conclusions can support analysis of camps/cottages that have been identified in a more generalized way surrounding, and in close proximity to, the Beaver Dam Mine Site and Haul Road.
- **Ceremonial/Spiritual Activities and Sites:** General or specific information about sacred sites was not provided in the MEKS or TLRUS.

Additional information relating to strengthening AMNS understanding of current Millbrook and more broadly, Mi'kmaq, land use was requested as documented in detail in Section 4.0 and summarized herein. AMNS will continue to work with the Millbrook First Nation and the Mi'kmaq of Nova Scotia to identify any outstanding traditional and current use information related to the Project.

The Mi'kmaq of Nova Scotia have established Aboriginal and Treaty rights. This includes traditional rights to hunt, gather and fish, as well as treaty-protected rights to hunt and gather, and to fish for a "moderate livelihood", which may take place throughout the year. According to the TLRUS (MFC 2019), the LAA is used by the Millbrook First Nation for the following purposes:

- Hunting deer, bear, rabbit and grouse for sustenance;
- Trapping rabbits, bobcat, beaver, coyotes, musrat, mink, otter, weasel and other small fur bearing animals for pelts and food;
- Gathering/harvesting various plants for medicinal and sustenance purposes;
- Gathering/harvesting fallen wood and birchbark for handicrafts and cultural items;
- Fishing for trout and other freshwater species; and
- Modern-day camps for recreational purposes.

The TLRUS (MFC 2019) states that local residents of the Beaver Dam, Sheet Harbour and Millbrook IRs frequently use the area (range of use from weekly to yearly, depending on availability of species) for hunting (deer, bear, rabbit, grouse, porcupine) and rely on the wild harvest as an important food and dietary source. Equally, community members harvest berries when in season, and a number of plants that are also used for sustenance, as well as traditional medicines. The seasonal and recreational use of animals and plants important to the Millbrook community members supports the continuity of traditional practices and is very important to the maintenance of their culture and the practice of their rights. Millbrook harvesting activities and practices are culturally important as they ensure the sharing and maintenance of cultural values and their practice. Millbrook First Nation community members use plants and animals harvested in the area for traditional sustenance purposes, health-related medicinal purposes, and spiritual and cultural purposes.

Additionally, the MEKS (CCM 2016) provided the following information related to current Mi'kmaq land and resource use sites, species of significance to Mi'kmaq, and Mi'kmaw communities, with the current Mi'kmaq land and resource uses categorized and identified as:

- Kill/hunting: trout, eel, bear, rabbit, deer, porcupine, partridge, coyote, mink, muskrat, weasels, raccoon, fox, otter and beaver;
- Burial/birth: potential burial sites recorded within the MEKS study area on the western side of the Beaver Dam Mine Road but not within the PA;
- Ceremonial: none identified;
- Gathering: wild fruit, berries, water, food plant, specialty wood, logs, feathers, quills; and
- Habitation: anchored boat, travel route, overnight site.

Species of significance to the Mi'kmaq are associated with three categories; these are listed below with the number of occurrences in the study area based on field work completed by CMM in summer 2016:

- Medicinal: 49 species present;
- Food/beverage: 27 species present; and
- Craft/art: 11 species present.

An overview of the Millbrook First Nation local fisheries activity within the identified LAA was provided in the TLRUS (MFC 2019). Additional information relating to the local Mi'kmaq fisheries was also reported in the MEKS and through direct engagement with the Mi'kmaq of Nova Scotia which supports the conclusions presented in the TLRUS (MFC 2019).

Fishing is generally for sustenance/subsistence, as well as for recreational purposes. Trout is the key fish species described in the TLRUS (MFC 2019) with additional species including brook and rainbow trout, sea trout, American eel, Atlantic salmon, herring, mackerel, gaspereau, various groundfish species, smelt, striped bass and sucker. Shellfish harvesting within the LAA include clams, lobster, mussels, snowcrab, and scallop (MFC 2019). Fishing is practiced across the LAA in most major rivers and lakes, as documented in the TLRUS and MEKS. Within the Beaver Dam Mine Site, there is documentation of trout fishing within Cameron Flowage/Killag River and possibly Mud Lake and Crusher Lake (MFC 2019). Within the 4km footprint of new construction for the Haul Road, there are no documented rivers or lakes that support the Mi'kmaq fisheries. However, adjacent to this new construction corridor and along the road footprint proposed for upgrades to construct the Haul Road, fishing locations are common, and Millbrook First Nation use of these lakes (and rivers) is well documented from the Beaver Dam Mine Site to the Mooseland Road (MFC 2019). AMNS acknowledges documented fish harvesting by Millbrook First Nation within the area directly surrounding the Project and the broader LAA.

There are a number of activities associated with the harvest and use of plants, animals and fish within the PA and in the LAA that relate to historical traditions and customs of the Mi'kmaq that are still practiced today. As described, the TLRUS (MFC 2019), the MEKS and residents of the Beaver Lake IR identify trapping and hunting activities, plant and berry gathering, and fishing in, near and surrounding the PA for purposes of sustenance, spiritual and cultural practice. The TLRUS (MFC 2019) described the frequency of use within the LAA which can be summarized as regular: weekly to annually across all seasons. This means the area was, and still is, an important resource area for the Millbrook First Nation community members and by extension, all Mi'kmaq of Nova Scotia, and any Project activities may have potential impacts on the ability of the Mi'kmaq of Nova Scotia to access certain areas to practice their rights where species with important cultural relevance may be found. Wild meat was traditionally a staple of the Millbrook First Nation diet, and a few of the harvesters interviewed for the TLRUS (MFC 2019) indicated they rely mainly on this food source and they share their food with other community members, rather than purchase their meat at a local supermarket.

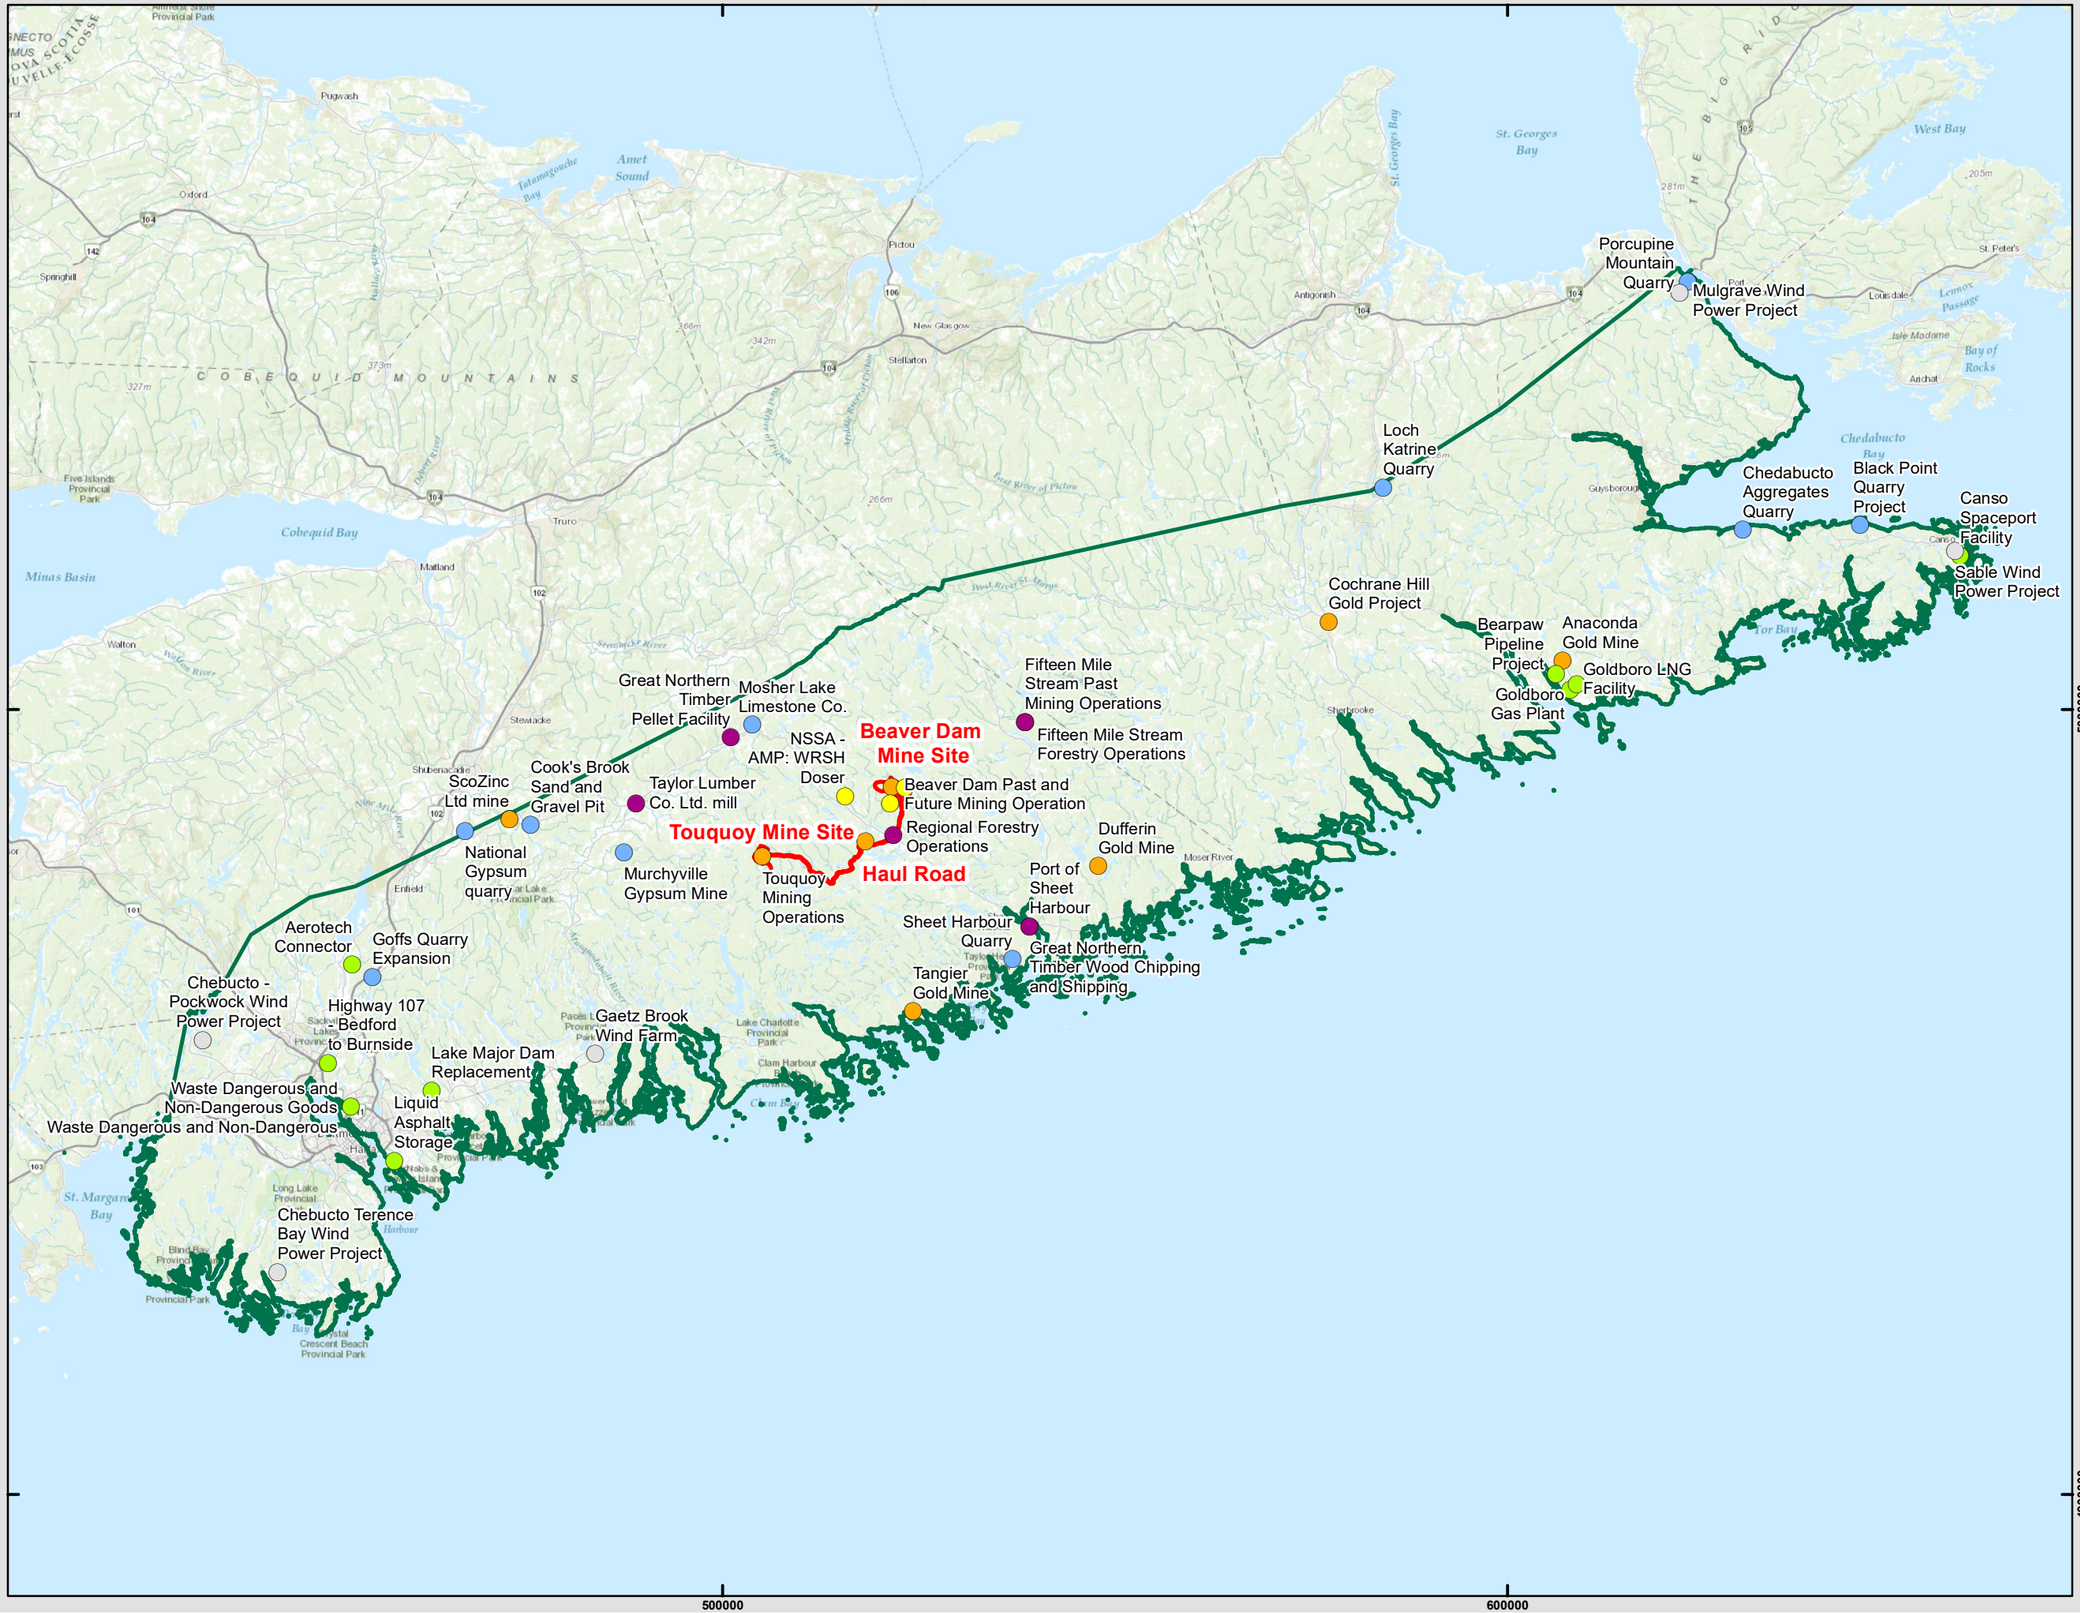
Some Mi'kmaq community members have camps on Crown land where they go to enjoy peaceful recreational and traditional activities with family and community members. There are five camps documented within 1 km of the Haul Road and multiple other camp locations throughout the LAA (MFC 2019). The Millbrook community is concerned that noise and activity from the Beaver Dam Mine Site and the Haul Road will negatively impact their ability to enjoy the remoteness and quiet of the area, as well as impact wildlife patterns and their hunting practices.

The evidence presented above shows Mi'kmaw occupancy and land/resource use in the PA, LAA and wider region of Eskikewa'kik – are changing, and more limited but uninterrupted use from pre-contact times to today.

In summary, both those aspects, the economic and cultural motivations for traditional land and resource uses, feed into a third impetus: the need to express, affirm and exercise their Aboriginal rights to live their cultural heritage within Mi'kma'ki, and their Treaty rights to continue harvesting the resources of their traditional territory.

8.5.7.2 Analysis of Effects

8.5.7.2.1 Residual Effects of Proposed Project



The predicted residual environmental effects of the Project on the Mi'kmaq of Nova Scotia are assessed to be adverse, but not significant following implementation of applicable mitigation measures (Table 6.14-8). Potential residual effects to the Mi'kmaq of Nova Scotia's physical health from Project-related changes to the environment (e.g., changes to country foods, water, and soils) are anticipated to be not significant. Potential pathways of effects on human health associated with consumption of or contact with country foods, water and soils will be minimized by implementing mitigation measures such as dust control, water management infrastructure and processes and water treatment (if required). Mitigation measures to reduce atmospheric emissions will be implemented to minimize potential related effects on human health, and the residual risk to human health from inhalation of Project-related dust and airborne contaminants is considered low.

Mitigation measures and conclusions relating to impacts to traditional practices and socio-economic, mental and social well-being will continue to be evaluated directly with Millbrook First Nation and the Mi'kmaq of Nova Scotia throughout the environmental assessment process, and throughout the lifecycle of the Project. AMNS has reviewed with Millbrook First Nation and the Mi'kmaq of Nova Scotia the proposed mitigation measure of a multi-use bypass road to access to lands surrounding the Haul Road and north of the Beaver Dam Mine Site, as well as the availability and proposed suitability of nearby Crown land as partial mitigation for loss of access during the eight years that the mine will be limiting access to the Beaver Dam Mine Site and Haul Road. Feedback on the summary of impacts and proposed mitigation measures is expected once Millbrook First Nation community meetings can be safely and effectively completed, given COVID restrictions. Mitigations and monitoring can be adjusted at the permitting stage as necessary.

8.5.7.2.2 Effects of Other Projects in the Area

The Project is located in a rural area, with a rural community of residents, and the presence of regional forestry activities. The RAA for the Mi'kmaq of Nova Scotia is spatially large, based on historical migration patterns and movements of the Mi'kmaq and territorial boundaries of the *Eskikewa'kik (Skin Dressing Territory).* This RAA allows for impacts that may be felt locally from the Project to be contextualized within the geographical setting of *Eskikewa'kik* land and resource use.

There are 37 identified projects within the RAA for the Mi'kmaq of Nova Scotia (Figure 8.5-6). Cumulative effects on the Mi'kmaq of Nova Scotia are indirect and will be caused by effects to other VCs from the Project and other projects that have been shown to act cumulatively with overlapping effects within the RAA.

The 37 projects can be categorized in five categories by activity:

- **Mining** including Fifteen Mile Stream Gold Project, Touquoy Gold Project, Cochrane Hill Gold Project, Beaver Dam Gold Project, Beaver Dam Haul Road use, Anaconda Gold Mine, Scozinc Mine, Tangier and Dufferin Gold Mines, and the Goldboro Gold Mine.
- **Pits and Quarries** including Cooks Sand and Gravel, National Gypsum, Murchyville Gypsum, Porcupine Mountain, Chedabucto Quarry, Black Point Quarry, Sheet Harbour Quarry, Goff's Quarry, Mosher Lake Limestone, and Loch Katrine Quarry.
- **Forestry and Associated** including forestry activities, Taylor Lumber Mill, Great Northern Timber Wood Chipping and Shipping, and Great Northern Timber Pellet Facility.
- **Wind Power Projects (WPP)** including Gaetz, Mulgrave, Chebucto/Pockwock, Sable, Terence Bay WPPs.
- **Infrastructure and other** including the Lake Major Dam Replacement, Port of Sheet Harbour, Highway 107 Bedford to Burnside Connector, Liquid Asphalt Storage, Waste Dangerous and Non Dangerous Goods Storage, Canso Spaceport Facility Goldbro LNG Facility, Goldboro Gas Plant, Bearpaw Pipeline, and the Highway 102 Aerotech connector.

8.5.7.2.3 Cumulative Effects on the Mi'kmaq of Nova Scotia

Cumulative effects on the Mi'kmaq of Nova Scotia are indirect and will be caused by effects to other VCs from the Project and other projects that have been shown to act cumulatively with overlapping effects within the RAA.

Assessment of the potential for cumulative effects to the Mi'kmaq of Nova Scotia is included in consideration of its socio-economic, socio-cultural, and/or traditional importance; in recognition of potential or established Aboriginal and Treaty rights; and due to the nature of potential Project-VC interactions, and cumulative-VC interactions of other projects in the RAA. Additionally, subparagraph 5(1)(c) of CEAA 2012 and the EIS Guidelines require assessment of potential effects to Indigenous Peoples including consideration of:

- Health and socio-economic conditions;
- Physical and cultural heritage, including any structure, site or thing that is of historical, archaeological, paleontological or architectural significance; and
- Current use of lands and resources for traditional purposes.

In order to evaluate the potential cumulative effect to the Mi'kmaq from the Project and other projects within the RAA, a summary of VC cumulative conclusions identified within Section 8 has been prepared and is presented in Table 8.5-8. These conclusions are then considered in the context of the broader categories of projects within the RAA provided in Section 8.5.7.2.2, and then finally reviewed to evaluate the potential effect to the health and socio-economic condition, physical and cultural heritage and current use of the lands for traditional purposes of the Mi'kmaq of Nova Scotia.

Table 8.5-8: Analysis of Cumulative Effect on the Mi'kmaq of Nova Scotia

Valued Component	Cumulative Effects Residual Effect Summary	Projects (by Category) within RAA and interaction with VC cumulative effects conclusions	Impact to the Mi'kmaq of Nova Scotia			Residual Effect
			Health/Socio	Physical/ Cultural	Traditional Use	
Noise	Additive periods of potential effects from the Project and forestry operations are likely to be limited in frequency. Additive cumulative effects may occur when forestry operations occasionally coincide with Project activities, and hauling ore from Beaver Dam, and FMS and Cochrane Hill concentrate to Touquoy for processing. Cumulative effects to baseline noise levels from the use of the Beaver Dam Haul Road by Beaver Dam, FMS and Cochrane Hill Gold Projects will occur regularly throughout the operational phase of the Project.	Within the noise RAA, forestry operations were considered in the cumulative effects assessment, and cumulative noise impacts along the BD Haul Road from truck traffic from the Project, Cochrane Hill Gold Project, the Beaver Dam Mine Project, and forestry activity. The NSSA AMP lies within the Noise RAA, but is not expected to produce noise on any consistent or substantial basis aside from occasional (annual) helicopter activity. There is no further cumulative impact from noise to the Mi'kmaq within the broader RAA. Individual projects as described in Section 8.5.7.2.2. contribute spatially isolated noise impacts within the RAA, but do not overlap with the Project.	Limited to cumulative effects described within Noise sub-section of Section 8. Specific to BD Haul Road and potential for additive (sporadic) Project + Forestry activities within the Beaer Dam Mine Site	No impact from noise to physical and cultural including any structure, site or thing that is of historical, archaeological, paleontological or architectural significance	Limited to cumulative effects described within Noise sub-section of Section 8. Noise impacts from other projects would be felt in isolation of the Project and its cumulative effects	No additional residual effect beyond that defined in the subsection of Section 8 dedicated to the Noise VC.
Air	Additive periods of potential effects from the Project and forestry operations are likely to be limited in frequency. Elevated dust levels are possible when forestry operations coincide with hauling ore from the Beaver Dam Mine Site to the Touquoy Processing Facility along with concentrate from Fifteen Mile Stream and Cochrane Hill Projects. Cumulative effects to ambient dust levels from the use of the Beaver Dam Haul Road by the Project and Fifteen Mile Stream and Cochrane Hill Gold Project will occur regularly throughout the operational phase of the Project. These cumulative effects are not considered significant, and the Proponent has committed to 80% dust suppression along the Beaver Dam Haul Road to reduce dust levels.	Within the air RAA, fifteen projects were considered in the cumulative effects assessment. These projects were determined to have spatial and temporal overlap with the Project interactions, and were carried through the evaluation of cumulative effects. There is no further cumulative impact from air to the Mi'kmaq within the broader RAA. Individual projects as described in Section 8.5.7.2.2. contribute spatially isolated air impacts within the RAA, but do not overlap with the Project.	Limited to cumulative effects described within Air sub-section of Section 8. Specific to BD Haul Road and potential for additive (sporadic) Project + Forestry activities within the Beaver Dam Mine Site	No impact from air to physical and cultural including any structure, site or thing that is of historical, archaeological, paleontological or architectural significance	Limited to cumulative effects described within Air sub-section of Section 8. Air impacts from other projects would be felt in isolation of the Project and its cumulative effects	No additional residual effect beyond that defined in the subsection of Section 8 dedicated to the Air VC.
Light	Additive periods of potential effects from the Project and forestry operations are likely to be limited in frequency. However, cumulative effects to ambient light levels from the use of the Beaver Dam Haul Road Use by Fifteen Mile Stream, Cochrane Hill Gold Projects and forestry activities will occur regularly throughout the operational phase of the Project, although maximum light levels are limited by two trucks passing by at a single occurrence in space and time.	Within the light RAA, only forestry operations were considered in the cumulative effects assessment, and cumulative light impacts along the BD Haul Road from truck traffic from the Project, Cochrane Hill Gold Project, the Beaver Dam Mine Project, and forestry activity. The NSSA AMP lies within the Light RAA, however light production is not involved in the acid mitigation project, so it was not carried through the evaluation of cumulative effects to light. There is no further cumulative impact from light to the Mi'kmaq within the broader RAA. Individual projects as described in Section 8.5.7.2.2. contribute spatially isolated light impacts within the RAA, but do not overlap with the Project.	Limited to cumulative effects described within Light sub-section of Section 8. Specific to BD Haul Road and potential for additive (sporadic) Project + Forestry activities within the Beaver Dam Mine Site	No impact from light to physical and cultural including any structure, site or thing that is of historical, archaeological, paleontological or architectural significance	Limited to cumulative effects described within Light sub-section of Section 8. Light impacts from other projects would be felt in isolation of the Project and its cumulative effects	No additional residual effect beyond that defined in the subsection of Section 8 dedicated to the Light VC.
Surface Water	Additive periods of potential effects from the Project and forestry operations are likely to be limited in frequency and limited in scale, assuming forestry activities are well managed. The Beaver Dam Mine Project and the Fifteen Mile Stream Gold Project and Cochrane Hill Gold Project interaction cumulatively at the Touquoy Mine Site with the deposition of tailings into the exhausted pit and the resulting effect to the Moose River. With water treatment, this residual effect is considered low magnitude. The presence of historical tailings at Beaver Dam Mine Site has an additive effect with the Project, resulting in a positive residual effect through improvement of water quality with property management and disposal of historical tailings during Project development.	Within the surface water RAA, forestry operations and the NSSA AMP were considered in the cumulative effects assessment; along with the Touquoy Mine Project. There is no further cumulative impact of surface water to the Mi'kmaq within the broader RAA. Individual projects as described in Section 8.5.7.2.2. contribute spatially isolated surface water impacts within the RAA, but do not overlap with the Project.	Limited to cumulative effects described within Surface Water sub-section of Section 8. Recreational swimming within Cameron Flowage has been evaluated from Project water quality. Adverse health effects from recreational water use (swimming) are not anticipated. Swimming in Moose River has been discounted due to low water levels.	No impact from surface water to physical and cultural including any structure, site or thing that is of historical, archaeological, paleontological or architectural significance	Limited to cumulative effects described within Surface Water sub-section of Section 8.	No additional residual effect beyond that defined in the subsection of Section 8 dedicated to the Surface Water VC.

Valued Component	Cumulative Effects Residual Effect Summary	Projects (by Category) within RAA and interaction with VC cumulative effects conclusions	Impact to the Mi'kmaq of Nova Scotia			Residual Effect
			Health/Socio	Physical/ Cultural	Traditional Use	
Fish and Fish Habitat	Additive periods of potential effects from the Project and forestry operations are likely to be limited in frequency and limited in scale, assuming forestry activities are well managed. The NSSA AMP is expected to provide a positive residual impact to fish and fish habitat. Water quality will meet CCME Freshwater Aquatic Guidelines with necessary water treatment and thus will not impact fish and fish habitat in the receiving environment (Anti-Dam Flowage) The Fifteen Mile Stream Project and the Project interaction cumulatively at the Touquoy Mine Site with the deposition of tailings into the exhausted pit and the resulting effect to the Moose River. With water treatment, this residual effect is considered low magnitude and the effect to Mi'kmaq consumption of country foods (fish) has been concluded to be low.	Within the fish RAA, forestry operations and the NSSA AMP were considered in the cumulative effects assessment; along with the Touquoy Mine Project. There is no further cumulative impact of surface water to the Mi'kmaq within the broader RAA. Individual projects as described in Section 8.5.7.2.2. contribute spatially isolated surface water impacts within the RAA, but do not overlap with the Project.	Limited to cumulative effects described within Surface Water sub-section of Section 8. It is unlikely that effluent releases will result in levels of metals in country foods (fish) that would be harmful to human health.	No impact from fish to physical and cultural including any structure, site or thing that is of historical, archaeological, paleontological or architectural significance	Limited to cumulative effects described within Fish sub-section of Section 8. Fishing activities to support Mi'kmaq traditional uses and commercial fisheries are not expected to be affected by the Project or its cumulative impact with identified projects as described in the Fish sub-section of Section 8.	No additional residual effect beyond that defined in the subsection of Section 8 dedicated to the Fish VC.

The cumulative effect of all projects within the RAA combined result in a loss of potential access to lands for traditional or spiritual purposes. The total area of the identified projects in the RAA was calculated in order to quantify the area of land (for the purposes of this exercise, limited to crown land only) which may be lost for traditional purposes. The total estimated project footprint was calculated for each individual project, using publicly available study area boundaries where available, property boundaries, and aerial photo interpretation of project infrastructure if a study area boundary was not publicly available. As the calculations were based on each project's study area or property boundary rather than actual infrastructure, this method is considered an overestimate of land lost to traditional purposes. Furthermore, all projects were considered, regardless of the temporal nature of a project's implementation (past, present or future). As such, this exercise presents a worst-case scenario, assuming all projects overlap temporally to limit access for the Mi'kmaq for their traditional practices.

Two projects have been excluded from this spatial land use exercise. The Nova Scotia Salmon Association's Acid Mitigation Project in the West River Sheet Harbour was not considered as removing land available for traditional or spiritual purposes. These habitats are still available, but work has been completed to mitigate the effects of acid rain on the watercourses. Secondly, timber harvesting was not considered as a loss of access to land for traditional purposes. Reliable, accurate data quantifying the area of timber harvesting which occurs on private land and crown land is not available. Timber harvesting changes the habitat type for some time, but it does not result in permanent change in the capacity of the forest to support habitats and species (i.e. natural succession will, in time, allow forest habitat to regenerate), and it does not result in loss of access to the land on any time frame, with the exception of during active cutting periods. As such, these two projects were not quantified for this cumulative effects assessment.

The total area of projects within the RAA, and the proportion of crown land is presented in Table 8.5-9 and 8.5-10. All projects quantified within the RAA account for 6,282 ha of total area, 3,148 ha of which is crown land. The loss of access to a maximum area of 3,148 ha from all identified projects in the RAA accounts for 0.32% of all land within the RAA, and 0.88% of available crown land within the RAA. The maximum project footprints used for this calculation are presented on Figure 8.5-6. Figure 8.5-7 shows the proportion of industrial development in the RAA, which accounts for less than 1% of the region (0.6%). The proposed Beaver Dam Mine Project, as well as all other AMNS projects, account for only 0.4% of the RAA (Figure 8.5-7).

8.5.7.3 Mitigation

In part to mitigate the adverse effects on the use of surface waters and the fish that inhabit them for traditional purposes, the Proponent has committed to water treatment during operations and during post closure as required, at the Beaver Dam Mine Site. In order to mitigate the adverse effects of dust dispersion onto plants and berries for traditional purposes that inhabit the forests surrounding the Beaver Dam Mine Site and Haul Road, the Proponent has committed to the use of chemical dust suppressants as required to reduce dust by 80% on the Haul Road.

The Beaver Dam Mine Site and Haul Road will limit access to Millbrook First Nation and other Mi'kmaq of Nova Scotia for a period of eight years. The proposed property extents of the Beaver Dam Mine Site and Haul Road encompasses a 727-ha area, of which 123 ha is Crown land.

The Proponent has committed to the development of a multi-use bypass road parallel to the Haul Road. This bypass road will allow continued access for the Mi'kmaq of Nova Scotia and specifically, Millbrook First Nation community members, to lands and lakes used for traditional purposes to the south and north of the Beaver Dam Haul Road between Highway 224 and the Mooseland Road, to the east and west of the Beaver Dam Haul Road between Highway 224 and the Beaver Dam Mine Site, as well as access to the lands north of the Beaver Dam Mine Site.

Tracts of crown land are present in close proximity to the Project (Figure 6.14-7). These tracts of land are adjacent to the Project Area and, in most cases, overlap with areas with documented traditional use (MFC 2019). These areas of land are publicly owned, not limited by provincial or federal parks and protected areas, are all accessible and available with consideration of the mitigation measures described in CEAA 2-48. These areas are presented as potential suitable alternative areas for traditional practices to continue, during the eight-year temporal scale of the Project.

The Proponent is committed to engaging in fisheries offsetting plans, and wetland compensation activities for the fish habitat and wetland loss associated with the Project as required by the Fisheries Act Authorization Process and provincial wetland alteration process for the Project.

The mitigation of the effects on land use and resources for traditional purposes originating from regional forestry and land management practices falls outside the scope of the project Proponent's authority and responsibility.

8.5.7.4 Residual Cumulative Effects and Significance Assessment

A significant cumulative adverse residual effect on the Mi'kmaq of Nova Scotia is defined as an environmental effect that results in one or more of the following outcomes:

Long-term (greater than 20 years) or permanent loss of the availability of, or access to, land and resources currently relied on for traditional use practices; or if long-term or permanent loss is expected, no allowance for agreed-upon compensation with the affected Mi'kmaq community(s). A twenty-year temporal scale was chosen to represent a generational loss of access to an area.

Human health risk assessments are inherently conservative, and hence, development of a threshold of significance for human health is complicated, since risk estimates tend to be biased high, based on the degree of conservatism included in any given risk assessment. The threshold for a significant residual effect has been defined as a potential adverse effect to health, identified through the conclusions presented in the HHRA.

An unmitigated loss of a physical or cultural structure, site or thing that is of historical, archaeological, paleontological or architectural significance to the Mi'kmaq.

Short-term (less than 20 years) loss of availability of land and resources caused by displacement due to Project activities are not considered to be significant.

The significance of potential effects on potential or established Aboriginal or treaty rights is a matter of consideration by the Crown and Mi'kmaq representatives (Assembly of Nova Scotia Chiefs and the Governments of Canada and Nova Scotia).

Assuming that the proposed mitigation and compensation measures are applied for the Project, and that they achieve their objectives, the predicted residual cumulative effects on the Mi'kmaq of Nova Scotia are assessed to be adverse, but not significant (Table 8.5-11).

Historical and current land use with the region has affected the local habitats in ways that have affected the local distribution and abundance of several species of flora and fauna. However, the total area of crown land that has been limited by all projects identified within the RAA is only 0.88% of available crown land present within the RAA.

Table 8.5-11: Residual Cumulative Environmental Effects on the Mi'kmaq of Nova Scotia

Residual Adverse Cumulative Effects (After Mitigation and Compensation if required)	Significance Levels						Overall Significance of Residual Adverse Effects (and Rationale)
	Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility	
Effects to Mi'kmaq of Nova Scotia and their traditional land use as a result from impacts to air quality, noise, light, surface water, fish habitat, and human health, and cumulative limitations to land use for traditional purposes from multiple projects within the RAA.	L Mitigation and best management strategies reduce magnitude of impact. The loss of access to a maximum area of 6,282 ha from all identified projects in the RAA accounts for 0.64% of all land within the RAA, and 0.88% of available crown land within the RAA.	LAA Direct cumulative effects within PA, indirect cumulative effects within LAA. BD Haul Road cumulative effects within LAA for BD Haul Road.	A Seasonal windows applicable. Air dispersion affected by season and wind direction, noise and light effects will be limited by foliage when present on trees, effects to fish and fish habitat are more sensitive during spawning windows (spring and fall).	LT Effects will extend beyond 8+ years – will extend to eight years of limited access to the Beaver Dam Mine Site, less than the defined 20 years in the context of the Mi'kmaq of Nova Scotia VC significant threshold.	R VC interaction will occur regularly.	R VC interaction will recover to baseline after Project activities are completed.	Moderate Adverse Effect (Not Significant) Assuming that the proposed compensation measures are applied for the Project and that they achieve their objectives, the predicted residual cumulative effects on the Mi'kmaq of Nova Scotia with regards to impacts to air quality, noise, light, surface water, fish habitat, and human health, are assessed to be adverse, but not significant. Loss of access is limited to 0.88% of available crown land within the RAA.

Legend (refer to Section 5.11, Table 5.11-1 for definitions)

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	IR	Irreversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular		
H	High					P	Permanent	C	Continuous		

8.5.7.5 Follow-up and Monitoring Programs

No additional monitoring is recommended, beyond that provided in each VC section and associated cumulative effects section. The monitoring and follow-up of the residual cumulative effects, primarily caused by past and ongoing forestry practices, falls outside the scope of the project Proponent's authority and responsibility.

Follow-up and monitoring of the site reclamation for the Beaver Dam Mine Site will be required. In addition, it is expected that the development of benefit agreement(s) and implementation of the overall Mi'kmaq engagement strategy with regards to the Project will include regular review of compliance and effects monitoring programs associated with other VCs, as well as monitoring of Project benefits to the Mi'kmaq of Nova Scotia.

8.6 Cumulative Effects Summary

A Cumulative Effects Assessment was carried out in order to meet the general requirements of the CEAA 2012, as well as the specific requirements laid out in the *Guidelines for the Preparation of an* Environmental *Impact Statement pursuant to the Canadian Environmental Assessment Act, 2012* and *Nova Scotia Registration Document pursuant to the Nova Scotia Environment Act – Beaver Dam Mine Project – Atlantic Gold Corporation*.

The VCs included in the Cumulative Effects Assessment into consideration were the following:

- Physical Environment:
  - Noise;
  - Air;
  - Light; and
  - Surface Water Quality and Quantity.
- Biophysical Environment:
  - Fish and Fish Habitat; and
  - Species of Conservation Interest and Species at Risk.
- Socio-Economic Environment:
  - Mi'kmaq of Nova Scotia.

Major industrial projects that have or are taking place within each VC's respective RAA were identified. Figure 8.5-6 identifies the complete suite of Projects which were considered in the Cumulative Effects Assessment.

The main conclusions of the Cumulative Effects Assessments are as follows:

- The cumulative effects to Noise, Air and Light are considered to be adverse but not significant. The primary pathway for cumulative effects for these VCs is through increased traffic along the Beaver Dam Haul Road. Logging trucks, and traffic from both the FMS and Cochrane Hill Projects will account for approximately 11.6% of the total proposed traffic rates. This is not expected to result in a significant cumulative effect to any of these three VCs, as described in Sections 8.5.1 to 8.5.3.
- The primary pathway for cumulative effects regarding surface water quantity and quality is through the addition of the Project, the proposed expansion of the Touquoy pit and subsequent disposal of Touquoy tailings in the exhausted pit, the Fifteen

Mile Stream Gold Project and Cochrane Hill Gold Project to the processing and waste disposal facilities at the Touquoy Mine Site. The cumulative effects of these combined projects on the receiving environments are adverse, but not significant, provided all mitigation measures are implemented.

- Cumulative effects to fish and fish habitat can occur directly (through direct loss of fish habitat, for instance), or indirectly through effects of projects on water quantity and quality. No significant cumulative effects to surface water quantity and quality is expected. Timber harvesting is a predominant land use within the fish and fish habitat RAA. It is expected that timber harvesting be carried out under the Wildlife and Watercourse Protection Regulations, reducing the potential cumulative effect on fish and fish habitat. Therefore, the primary pathway for cumulative effects to fish and fish habitat is through direct fish habitat loss. The Beaver Dam Project will result in approximately 4.18 ha of direct loss of fish habitat to allow for construction of the Open Pit and associated infrastructure. The Project is expected to result in an additional 322 m^2 of indirect impact to fish habitat based on flow reduction in local catchment areas. There is spatial and temporal overlap between the Project and terrestrial liming work being completed by the NSSA, however the NSSA AMP work is expected to result in a positive residual effect to fish and fish habitat, and will not lead to an adverse residual effect to fish and fish habitat when combined with the proposed Beaver Dam Project.
- Overall, the generalized disturbance of the landscape by forestry activities, past, present and future are the main source of cumulative effects of habitats, flora, terrestrial fauna and birds throughout the area. These cumulative effects also lead to effects on current use of land and resources for traditional purposes by the Mi'kmaq of Nova Scotia and to effects to priority species (SOCI and SAR). The maximum Project edge effect will affect 237 ha of interior forest habitat, which accounts for 0.3% of predicted interior forest in the RAA. There is limited additional development pressures from other projects in the RAA, as demonstrated by the few projects identified within this evaluation with small footprints of disturbance.
- The main pathways for cumulative effects to the Mi'kmaq of Nova Scotia are described as any adverse effect to the health and socioeconomic conditions, physical and cultural heritage, and current use of lands and resources for traditional purposes, as described in detail in Section 8.5.7. Cumulative effects of the Project on the Mi'kmaq of Nova Scotia, considering these three primary pathways, has been assessed as adverse, but not significant. The loss of access to a maximum area of 6,282 ha from all identified projects in the RAA accounts for 0.64% of all land within the RAA, and 0.88% of available crown land within the RAA. The largest regional impact to the landscape appears to be from regional forestry activities based only on aerial photography review. This impact could not be quantified herein due to a lack of publicly available data to support quantitative analysis.

Once the mitigation measures are taken into account, there are no significant residual cumulative effects anticipated for the VCs evaluated herein. The predicted residual cumulative effects on the Mi'kmaq of Nova Scotia with regards to indirect effects from impacts to water quality, wetland habitats, and road safety, are assessed to be adverse, but not significant.

Historical and current land use within the region has undeniably affected the local habitats in ways that have affected the local distribution and abundance of several species of flora terrestrial fauna and birds, including SOCI and SAR. However, the mitigation of the effects originating from regional forestry and land management practices falls outside the scope of the Project Proponent's authority and responsibility.

9 SUMMARY OF ENVIRONMENTAL EFFECTS ASSESSMENT MITIGATIONS AND ENVIRONMENTAL RESIDUAL EFFECTS

This section provides tables summarizing the following key information:

- Proposed mitigation measures to address the effects identified above as described in Section 6 of this EIS. AMNS acknowledges that responsibility for implementation of all mitigation measures proposed within this EIS during the Project phases (i.e., construction, operation, active closure, and post-closure) ultimately rests with AMNS; and
- Potential residual effects and the significance of the residual environmental effects for each Valued Components (VCs (Section 6) and the cumulative effects assessment (Section 8).

9.1 Summary of the Environmental Impact Statement

As described throughout the EIS, Project-environment interactions are expected to occur throughout the life of the Project during the construction, operations, active closure (i.e., decommissioning and reclamation), and post-closure phases. These interactions are expected and are typical of environmental impacts associated with mineral extraction projects in the region.

Given the considerations identified above and based on baseline studies completed for each of the identified VCs, the Project is not predicted to result in any significant adverse environmental effects after mitigation measures have been applied. Monitoring programs will proceed to gather pre-construction data for select VCs. This data will be used to refine mitigation measures and monitoring programs for the construction, operation, reclamation and decommissioning, and post-closure phases. Monitoring programs will continue throughout the life of the Project to verify baseline conditions and to determine the effects of the Project on the surrounding environment.

Key mitigation measures that will specifically mitigate the potential adverse residual effects are summarized in Table 9.1-1. Proposed mitigation measures are described in greater detail in the effects assessment for each individual VC in Section 6. A summary of the potential adverse residual effects associated with the Project, and their associated significance, and the Project's cumulative effects is summarized in Table 9.1-2 and Table 9.1-4.

AMNS acknowledges that responsibility for all mitigation commitments ultimately rest with AMNS.

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
Noise		
C, O	Operations, infrastructure, and property boundaries for the Beaver Dam Mine have been updated to mitigate predicted noise levels at the property line. The following noise mitigation measures are incorporated into the current design of the Beaver Dam Mine: • The pit entrance/exit has been relocated to the west side of the pit, farther from the northeast property boundary. • No more than four drills will operate concurrently during any day, evening or nighttime hour. • Increase the height of the safety berm along the north boundary of the pit.	6.1.7.3.2
C, O	Restrict blasting to a specific and regular daytime schedule during weekdays. Specifically, lasting will not be undertaken on Sundays, statutory holidays, or any day between the hours of 1800 hours and 0800 hours (NSEL 1999).	6.1.8
C	Haul road construction will be restricted to the day and evening periods	6.1.8
O	If necessary, construct a large safety berm along the north boundary of the pit, dependent on how raw materials are processed at the Beaver Dam Mine Site	6.1.8
O	Operating hours for processing plants and trucking on the Haul Road will be limited to reduce nighttime noise levels	6.1.8
O	Maximum 4 drills will operate at the Beaver Dam Mine Site pit at any time during the Operation Phase of the Project.	6.1.8
C, O, CL	Implement preventative maintenance plans for all mobile and stationary equipment.	6.1.8
C	Noise-reduction as criteria in equipment selection.	6.1.8
C, O	Communicate general blasting schedule to the local community.	6.1.8
C	Consider the use of natural landforms when available as noise barriers when designing final site details and when placing fixed equipment.	6.1.8
O	Operating hours for processing plants and trucking on the Haul Road will be limited to reduce nighttime noise levels.	6.1.8
O	Regular check by site manager for excessive noise on site and in relation to sensitive receptors so that resolution can be timely.	6.1.8
C, O, CL	Implement preventative maintenance plans for all mobile and stationary equipment.	6.1.8
C	Noise-reduction as criteria in equipment selection.	6.1.8
C, O	Speed reduction.	6.1.8
C, O	Use equipment that meets appropriate noise emission standards for off-road diesel equipment.	6.1.8
C, O	Subcontractor agreements will include an obligation to comply with environmental protection including noise reduction.	6.1.8
C, O	Site design to reduce need for reversing and vehicle reversing alarms.	6.1.8
C, O	A procedure, including a response plan, will be available for public to be able to register complaints regarding noise concerns.	6.1.8

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
Air		
C, O	Use wet suppression controls on unpaved surfaces.	6.2.8
C, O	Utilize paved surfaces where available.	6.2.8
C, O	Speed reduction.	6.2.8
O	Apply stabilized covers on inactive stockpiles.	6.2.8
O	Use mechanical sweeper on paved surfaces to prevent dust from remobilizing.	6.2.8
O	Apply dust suppressants, when and where practicable, to target 80 to 90% percent effectiveness.	6.2.8
O	Size haul vehicles appropriately to minimize trip frequency.	6.2.8
O	Implement appropriate dust suppression measures for crusher trains and associated activities/stockpiles.	6.2.8
O	Cover haul trucks to minimize dust during transportation between the mine site and the Touquoy facility.	6.2.8
O	Implement Dust Suppression Plan as part of the Fugitive Dust Control Plan (Appendix C.3).	6.2.8
O	A procedure, including a response plan, will be available for public to be able to register complaints regarding dust concerns.	6.2.8
CL	Stabilize slopes on inactive stockpiles to a safe and long-term angle of repose.	6.2.8
CL	Use soil and organics stockpiles for final capping and stabilization. Hydroseed as required.	6.2.8
Light		
C	Temporary lighting will be directly focused on work areas and shielded where practicable to avoid light trespass	6.3.8
C, O, CL	Use of only downward-facing lights on site infrastructure and Mine Site roads	6.3.8
	Install motion-sensing lights, where practicable	6.3.8
	Only use direct and focused light when needed for worker safety	6.3.8
	All floodlights will employ full horizontal cutoff, as appropriate	6.3.8
	Lighting not in use will be turned off, whenever practicable	6.3.8
	Site perimeter lighting will be directed to minimize light offsite light trespass	6.3.8
	Utilize efficient sources of light to reduce overall magnitude of light, wherever practicable	6.3.8
	A procedure, including a response plan, will be available for public to be able to register complaints regarding light concerns	6.3.8

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
Greenhouse Gases		
C, O, CL	Limit engine idling where practicable.	6.4.8
C, O, CL	Implement fuel efficiencies where practicable.	6.4.8
C, O, CL	Implement preventative maintenance plans for all mobile and stationary equipment.	6.4.8
C, O, CL	Use renewable energy where reasonable (e.g., solar-powered lights).	6.4.8
Geology, Soils and Sediment		
C, O, CL	Use of the following routine controls, as needed: • Silt fences • Silt curtains • Riprap • Check dams • Settling ponds	6.5.8
C, O, CL	Segregate and manage waste rock with the potential for acid generation	6.5.8
C, O	Implement Erosion and Sediment Control Plan	6.5.8, Appendix C of Appendix P.4 (Mine Water Management Plan)
C, O	Secure overburden stockpiles using a combination of mulching, hydroseeding, and slope stabilization	6.5.8
C, O, CL	Limit exposed soil	6.5.8
CL	Use soil and organics stockpiles for final capping and stabilization. Hydroseed as required	6.5.8
Groundwater		
C	Conduct pre-construction well survey at Beaver Lake IR.	6.6.8
C, O	Use above ground fuel storage tanks that meet applicable regulatory standards.	6.6.8
C, O	Select appropriate type of explosive that will minimize nitrogen release to surface water and groundwater.	6.6.8
C, O, CL	Sub-aqueous deposition of mine tailings to reduce/prevent oxides and leaching.	6.6.8
CL	In the event of acid rock drainage and metal leaching, implement mitigative measures that will manage the source material and drainage effectively utilizing methods such as segregation and encapsulation.	6.6.8

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C	Based on evaluation of predicted aquatic risk, pump and treatment of groundwater (if required based on monitoring results) from installed groundwater wells at Beaver Dam Mine Site including those at Crusher Lake, Mud Lake, outlet from Mud Lake to the Killag, and Cameron Flowage, and existing groundwater wells at Touquoy between the open pit and the Moose River. The purpose of this groundwater treatment is to intersect groundwater seepage impacted with Constituents of Concern (COCs) above Tier II pathway specific guidelines or groundwater baseline/background prior to seepage discharging into surface water bodies.	6.6.8
C,O	Use blasting and pit construction techniques that minimize the potential for negatively interacting with the adjacent groundwater table and nearby surface water.	6.6.8
C,O	Implement water conservation program for onsite facilities.	6.6.8
C,O	Recycle site water for reuse wherever practical to reduce water withdrawal from lakes or streams.	6.6.8
C,O	Recycled water must meet acceptable water quality criteria for its intended use.	6.6.8
Surface Water		
C, O, CL	Use of the following structures, as needed: • Silt fences • Silt curtains • Riprap • Check dams	6.7.9, Appendix P.4 (Mine Water Management Plan)
C, O, CL	Limit exposed soil	6.7.9
C, O	Implement Erosion and Sediment Control Plan	6.7.9
O, CL	Segregate and manage waste rock with the potential for acid generation	6.7.9
O	Use adequately sized settling and containment ponds as required	6.7.9
O	Use flocculants and coagulants as required	6.7.9
C, O	Install perimeter ditches around site infrastructure	6.7.9
O	Provide appropriate settling time for suspended solids prior to discharge	6.7.9
O	Ensure pit water meets applicable regulatory quality criteria for discharge – otherwise treat water prior to discharge	6.7.9
O	Direct drainage ditches to designated settling ponds or other locations	6.7.9
C, O	Use above ground fuel storage tanks that meet applicable regulatory standards	6.7.9
C, O	Select appropriate type of explosive that will minimize nitrogen release to surface water and groundwater	6.7.9
C, O	Implement Surface Water Management Plan	6.7.9, Appendix P.4 (Mine Water Management Plan)

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O	Develop and implement an Emergency Response Spill Contingency Plan	6.7.9
C, O	Use clean, non-ore-bearing, non-watercourse derived and non-toxic materials for erosion control methods	6.7.9
C, O, CL	Sub-aqueous deposition of mine tailings to reduce/prevent oxides and leaching	6.7.9
CL	In the event of the potential for acid rock drainage and metal leaching, implement additional studies required to assess to actual risk and, as warranted, implement mitigative measures that will manage the source material and drainage effectively utilizing methods such as segregation and encapsulation	6.7.9
C, O, CL, PC	Minimize snow deposition into watercourses during snow removal activities	6.7.9
C	Construct drainage ditches and ponds to maintain natural flow directions when practical	6.7.9
O	Control release of settling ponds to mimic natural hydrograph, where practicable	6.7.9
O	Recycle site water for reuse wherever practical to reduce water withdrawal from lakes or streams	6.7.9
O	Recycled water must meet acceptable water quality criteria for its intended use	6.7.9
C	Mine infrastructure will be designed to minimize erosion during construction and operations, so as to preserve the stability of the ground surface surrounding mine infrastructure, SWM ditches, settling ponds and conveyance pathways, dykes, berms and any other Mine installations. The potential for scouring downstream of structures and the potential impacts of sudden changes in flow volume will also be considered. Short courses on erosion and sediment control design and inspection will be given to all managers and supervisors prior to mining or construction activities that may cause erosion or sediment movement and deposition. Environmental monitors will participate in a short course or seminar on inspection activities associated with erosion and sediment control. An 'Erosion Awareness and Identification' module will be a component of Mine specific training provided to all workers associated with earthwork mining activities. Principles for the ESCP for the Site include: 1. Fit the activity to the existing topography, soils, waterways, and natural vegetation of the site 2. Expose the smallest practical area of land for the shortest possible time 3. Apply erosion control practices as the primary method to prevent on-site damage 4. Apply sediment control practices as perimeter protection to prevent off-site damage 5. Implement a thorough maintenance plan during construction and operations	Appendix C draft Erosion and Sediment Control Plan of Appendix P.4 (Mine Water Management Plan)
C	To prevent discharge of sediment laden water from the Site during construction the first piece of site infrastructure to be constructed is to be the north settling pond. All site water will be directed towards the north settling pond (via an expanding network of surface water ditches or via pumping) prior to discharge until the east settling pond and south settling pond have been constructed. The north settling pond is to be constructed prior to any clearing or grubbing for other components of the Mine Site.	Appendix C draft Erosion and Sediment Control Plan of Appendix P.4 (Mine Water Management Plan)

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C	Following the development of the north settling pond, other aspects of the mine will be developed including the open pit, administrative areas, and haul road. Prior to the development of other aspects of the mine the associated mine water infrastructure components are to be developed as well. For example, prior to clearing, grubbing and development of the till and organics stockpile areas the east and south settling ponds must be developed first. The contact water ditch network is to be developed in conjunction with the stockpile and haul road development, starting at the downstream end and working upstream.	Appendix C draft Erosion and Sediment Control Plan of Appendix P.4 (Mine Water Management Plan)
O	Climate change impacts were accounted for in the design of mine water management infrastructure using Nova Scotia Environment climate change projections for the province.	Section 2.2 Mine Water Management Plan (Appendix P.4)
O	All site contact water will be collected into the north settling pond during construction and operations. The north pond will be connected to a robust water treatment system to ensure discharge water quality meets regulatory guidelines. An emergency spillway has been designed to direct excess runoff water into the open pit should an event larger than a 1:100 year storm event occur, to mitigate against the potential release of non-treated contact water from an extreme flood event.	Mine Water Management Plan (Appendix P.4, Appendix B Hydrologic Modelling Section 4)
O	All settling ponds include a filter berm to further improve the removal of TSS prior to discharge into the natural environment	Section 3.3 Mine Water Management Plan (Appendix P.4)
O	The settling ponds have been designed to control discharge for all storm events up to and including the 100-year design storm event over a minimum of duration of 24 hours. All ponds also include an emergency overflow spillway that has been designed to control the largest hurricane on record, Hurricane Beth	Section 3.3 Mine Water Management Plan (Appendix P.4)
O	Contact water ditches are proposed to be lined with impermeable membranes to mitigate against infiltration into the groundwater system	Section 6.1 Mine Water Management Plan (Appendix P.4)
O	Water treatment system used during dewatering of historical tailings (construction period) will remain on-site and connected to the north pond system to be used if it is identified, through on-going monitoring, that discharge water exceeds regulatory discharge requirements	Section 7.2 Mine Water Management Plan (Appendix P.4)
O	The proposed mine development is anticipated to increase streamflow volumes in the Killag River. AMNS will ensure post-development peak discharge does not exceed baseline peak discharge in the Killag River by providing peak flow attenuation through the settling ponds	Mine Water Management Plan Appendix A Water Balance Analysis Section 6 (Appendix P.4)
O	To further mitigate impacts to fish and fish habitat downstream of the settling ponds during more frequent events, all pond outlet structures (including the aeration lagoon) will be equipped with emergency shut-off valves that will be closed if any water quality parameter exceedances are triggered. The east, south and west settling ponds can contain the 10-year 24-hour rain event with no outflow, while the north settling pond can contain up to the 5-year 24-hour event with no outflow.	Mine Water Management Plan Appendix B Hydrologic Modelling Section 3 (Appendix P.4)

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
O	If the nitrite or metal concentration objectives are exceeded in the east or south settling ponds, the impacted water will be pumped, or collected in a vacuum truck, and transported to the north settling pond for further treatment.	Mine Water Management Plan Appendix B Hydrologic Modelling Section 3 (Appendix P.4)
O	Each settling pond will maintain a permanent pool to the level of the first low flow orifice and will control the three design storms with a minimum detention time of 24 hours. There will be a minimum of 0.3 m of freeboard between the 100-year design event and the emergency spillway invert. Above the 100-year event, the emergency spillway is designed to pass Hurricane Beth	Mine Water Management Plan Appendix B Hydrologic Modelling Section 4 (Appendix P.4)
CL	The WBM predicts a decrease in streamflow at the Killag River DS assessment point while the pit is being filled with water in PC conditions. AMNS will implement a circular pumping system that uses water collected in the open pit, (including groundwater that is drawn from the Killag River), to mitigate against baseflow reduction in the Killag River caused by the open pit during low flow periods as described in the Baseflow Mitigation Assessment	Mine Water Management Plan Appendix H Baseflow Mitigation Assessment (Appendix P.4)
CL	The north settling pond will remain active during post closure and pit lake filling. The purpose will be to allow for the diversion of flow directly to the Killag River during low flow periods to augment flow volume to maintain environmental flows	Section 3.3 Mine Water Management Plan (Appendix P.4)
CL	The PAG waste rock pile will be capped with an impermeable liner and vegetated to reduce infiltration and seepage of contact water.	Section 3.3 Mine Water Management Plan (Appendix P.4)
CL	As part of the reclamation plan, the LGO stockpile will be removed and surface runoff from this area will be directed back toward Mud Lake to reduce the environmental impact to the lake	Section 3.3 Mine Water Management Plan (Appendix P.4)
CL	Based on the results from the Baseflow Mitigation Study, the discharge point of the Pit Lake has been set to re-establish ~99% of baseflow through this section of Cameron Flowage	Mine Water Management Plan Appendix H Baseflow Mitigation Assessment (Appendix P.4)
Wetlands		
C, O, CL	Complete pre-construction site meetings for all relevant staff/contractors related to working around wetlands and watercourses to minimize unauthorized disturbance, such as the introduction of invasive species	6.8.8.2
C, O, CL	Implement Erosion and Sediment Control Plan and measures to ensure site runoff is not directed towards wetlands to ensure habitat integrity and existing drainage patterns are maintained.	6.8.8.2, Appendix C draft Erosion and Sediment Control Plan of Appendix P.4 (Mine Water Management Plan)

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O, CL	Maintain pre-construction hydrological flows through wetland habitats and partially altered wetlands, wherever practicable	6.8.8.2
C, O, CL	Topsoil will be salvaged and stored for use in site restoration where practicable.	6.8.8.2
C, O, CL	Re-vegetate slopes adjacent to wetlands, using native seed mixes, to limit erosion and sediment release	6.8.8.2
C, O, CL	Implement the Preliminary Wetland Monitoring Plan, as refined through the permitting process.	6.8.8.2, Preliminary Wetland Compensation Plan (Appendix H.3)
C	Ensure all wetlands are visually delineated (e.g. flagged)	6.8.8.2
C	Complete detailed design of Haul Road and micro-siting of Beaver Dam Mine Site infrastructure to avoid or minimize impacts to wetlands	6.8.8.2
C	Implement construction methods that reduce the potential to drain or flood surrounding wetlands	6.8.8.2
C	Acquire and adhere to wetland alteration permits	6.8.8.2
C	Detailed culvert design of upgraded/replaced culverts to maintain current hydrology and necessary fish passage.	6.8.8.2, 6.9.8.2.3
C	Translocation of blue felt lichen and monitoring of lichen SAR where direct and indirect impacts are expected to occur as per the Lichen Mitigation and Monitoring Plan.	6.8.8.2, 6.10.8, 6.13.8.2, draft Lichen Mitigation and Monitoring Plan (Appendix P.6)
C	Complete work within Wetland 64 outside of the breeding season in consideration of greater yellowlegs observations and probable breeding habitat.	6.8.8.2, 6.13.8
C, O	Direct runoff through natural vegetation, wherever practicable	6.8.8.2
C, O	Minimize erosion of wetland soils by limiting flow velocities by means of hydraulic dissipation techniques	6.8.8.2
C, O	Minimize the rutting of wetland habitat by limiting the use of machinery within wetland habitat and use of swamp mats/corduroy bridges as required	6.8.8.2
C, O	Conduct vegetation management (cutting and clearing) in or near wetlands and watercourses in accordance with applicable guidelines	6.8.8.2
C, O	Employ measures to reduce the spread of invasive species (particularly by vehicles) into wetlands and retain habitat integrity Inspect vehicles regularly, particularly vehicles arriving from outside the PA. If necessary, cleaning will be undertaken at a designated cleaning station, away from wetlands and watercourses.	6.8.8.2

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
CL	Compensate for permanent loss of wetland function through implementation of the Preliminary Wetland Compensation Plan, subject to NSE approval. The preliminary plan includes: On-the-ground restoration opportunities to meet a minimum 2:1 ratio and to be completed in a watershed near the Project area to the extent practicable; Wetland restoration opportunities within the Beaver Dam Mine Site will be considered where practicable; Other secondary forms of compensation that ECCC and NSE consider valuable to support the wetland conservation program in Nova Scotia; Collaboration with local community groups and the Mi'kmaq of Nova Scotia to the extent possible; and Inclusion of a conservation allowance in the Preliminary Wetland Compensation Plan to address restoration of equivalent habitat for wildlife SAR.	6.8.8.2, Preliminary Wetland Compensation Plan (Appendix H.3), draft Lichen Mitigation and Monitoring Plan (Appendix P.6)
CL	Review and consider alternatives to traditional hydroseeding methods to advance vegetation re-establishment and reclamation methods	6.8.8.2
Post-Closure	Follow monitoring requirements in wetland alteration permits and final Wetland Monitoring Plan (to be completed at permitting stage).	6.8.8.2, Preliminary Wetland Compensation Plan (Appendix H.3)
Fish and Fish Habitat		
C, O, CL	Complete site meetings with relevant staff/contractors to educate and confirm policies related to working around fish bearing surface water systems including schedule of construction activities to minimize unauthorized disturbance and limit vegetation clearing	6.9.8.2.3
C, O, CL	Implement a groundwater interceptor trench on the west side of the PAG stockpile, if necessary.	6.9.8.2.3
C, O, CL	Collect and treat all contact water, as required.	6.9.8.2.3
C, O, CL	Implement Erosion and Sediment Control Plan	6.9.8.2.3, Appendix C draft Erosion and Sediment Control Plan of Appendix P.4 (Mine Water Management Plan)
C, O, CL	Maintain pre-construction hydrological flows into and out of down-stream surface water habitats, to the extent practicable, to limit indirect impacts to fish habitat	6.9.8.2.3
C, O, CL	Complete offsetting for HADD including for permanent loss of fish habitat through fish habitat restoration activities, subject to DFO approval, as required under the *Fisheries Act*	6.9.8.2.3, 6.13.8
C, O, CL	Develop and implement the Aquatic Effects Monitoring Program (to be completed prior to the permitting stage) to identify and further mitigate any additional adverse impacts to fish and fish habitat	6.9.8.2.3
C, O, CL	Provide signage on fish habitat streams	6.9.8.2.3
C, O, CL	Complete micro siting of mine infrastructure to avoid or minimize fish habitat impact as necessary	6.9.8.2.3

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O, CL	Complete fish rescue within all fish bearing streams to be impacted by the Project, prior to commencement of mine development, with DFO approval if required	6.9.8.2.3
C, O, CL	Implement construction methods that reduce potential interaction with fish habitat and limit vegetation clearing around watercourses	6.9.8.2.3
C, O, CL	Complete culvert installations and upgrades in accordance with the NSE Watercourse Standard (2015) or as updated at time of construction. Limit vegetation clearing	6.9.8.2.3, 6.8.9.2
C, O, CL	Minimize the removal of vegetation upgradient of watercourses and stabilize shorelines or banks disturbed by any activity associated with Project activities	6.9.8.2.3
C, O, CL	Minimize the temporal extent of in-stream works as much as practicable	6.9.8.2.3
C, O, CL	Monitoring of standard mitigations will be supported by the Mine Water Management Plan and Aquatic Effects Monitoring Program (to be submitted as part of the Industrial Approval), both of which will be in place prior to construction activities to minimize possible disturbances of fish and fish habitat.	6.9.8.2.3, Appendix P.4 (Mine Water Management Plan)
C, O	Maintain 30 m riparian wetland and watercourse buffers, where practicable.	6.9.8.2.3
C, O	Use vegetated buffers and aquatic vegetation wherever practicable to provide shade to on-site ponds.	6.9.8.2.3
C, O	Install groundwater pumps to supplement baseflow in Cameron Flowage, if necessary	6.9.8.2.3
C, O	Follow DFO-advised Measures to avoid causing harm to fish and fish habitat pertaining to blasting (DFO 2019)	6.9.8.2.3
C, O	A detailed explosive management plan will be developed as part of the permitting process.	6.9.8.2.3
C, O	Use an emulsion-type explosive that will minimize nitrogen release to surface water and groundwater	6.9.8.2.3
C, O	Use clean, non-ore-bearing, non-watercourse derived and non-toxic materials for erosion control methods	6.9.8.2.3
C, O	Incorporate drainage structures, where necessary, to dissipate hydraulic energy and maintain flow velocities sufficiently low to prevent erosion of native soil material	6.9.8.2.3
C, O	Limit clearing within confirmed fish habitat outside of approved alteration areas to within approved areas.	6.9.8.2.3
C, O	Acquire and follow watercourse alteration permits	6.9.8.2.3, 6.7.9
C, O	Adhere to applicable timing windows, as directed by DFO, for construction where infilling has been approved in wetlands and watercourses where fish habitat is present	6.9.8.2.3
C, O	Locate fueling areas are a minimum of 30 m from waterbodies	6.9.8.2.3
C, O	Use and maintain properly sized screens on any water intakes or outlet pipes to prevent entrainment or impingement of fish (DFO, 2020)	6.9.8.2.3
C, O	Ensure that machinery arrives on site in a clean condition and is maintained and free of fluid leaks	6.9.8.2.3, 6.18

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O	Develop and implement Mine Water Management Plan	6.9.8.2.3, Appendix P.4 (Mine Water Management Plan)
Habitat and Flora		
C, O	Intact forest stands and wetlands will be avoided wherever practicable during detailed Project planning and design in favor of previously disturbed areas (e.g., stands disturbed by timber harvesting, roads, or other development).	6.10.8
C, O	Where natural, intact habitat cannot be avoided, maintain existing vegetation cover whenever practicable and minimize overall areas of disturbance.	6.10.8
C, O	A wetland alteration application will be submitted during Project planning and design to request an authorization to alter wetland habitat and to address loss of wetland function.	6.10.8
C, O	Compensation for permanent loss of wetland function will be completed through wetland restoration activities to support no net loss of wetland function, subject to NSE approval.	6.10.8, Preliminary Wetland Compensation Plan (Appendix H.3)
C, O	Topsoil will be salvaged and stored for use in site restoration where possible. Upland and wetland soils should be stockpiled separately.	6.10.8
C, O	Conduct vegetation management by cutting (e.g., no use of herbicides)	6.10.8
C, O	Implement Erosion and Sediment Control Plan and measures to ensure site runoff is not directed towards unaltered habitat where possible to ensure existing drainage patterns are maintained.	6.10.8, Appendix C of Appendix P.4 (Mine Water Management Plan)
C, O	Avoid frequent or unnecessary travel over erosion prone areas through communication with personnel and project planning	6.10.8
C, O	Monitor dust conditions and implement dust suppression mitigation (refer to air mitigation) when normal precipitation levels are not enough to suppress fugitive dust. In addition to water suppression, provincially approvable chemical dust suppressants will be used along the Haul Road. Implement Dust Control Plan.	6.10.8, Appendix C.3 (draft Fugitive Dust Control Plan)
C, O	Haul trucks will be equipped with spill kits and instructed on their use and spill prevention and appropriate site personnel will be trained in spill isolation, containment, and recovery.	6.10.8
C, O	Winter road maintenance will include conventional snow clearing and deposition of sand for traction control where necessary.	6.10.8
C, O	Employ measures to reduce the spread of invasive species (particularly by vehicles) and retain habitat integrity. Inspect vehicles regularly, particularly vehicles arriving from outside the PA. If necessary, cleaning will be undertaken at a designated cleaning station, away from wetlands and watercourses.	6.10.8
C, O	Confirm Potential Old Growth areas with NSLF and asses possible avoidance through the alternative Haul Road route, dependant on NSLF findings.	6.10.8

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O	Consider on-site opportunities for progressive reclamation during construction and operations to avoid viability issues with long-term stockpiling of organic material.	6.10.8
C, O	Translocation of blue felt lichen and monitoring of lichen SAR where direct and indirect impacts are expected to occur as per the draft Lichen Mitigation and Monitoring Plan.	6.8.8.2, 6.10.8, 6.13.8.2, draft Lichen Mitigation Monitoring Plan (Appendix P.6)
CL	Hydroseed areas that have erosion potential to return the area to pre-disturbance conditions in a timely fashion upon final reclamation	6.10.8
CL	Alternatives to traditional hydroseeding methods will be reviewed to advance vegetation re-establishment and reclamation methods. Consideration will be given to native species with Indigenous significance.	6.10.8
CL	Implement reclamation program within the Beaver Dam Mine Site to re-establish native vegetation communities	6.10.8
CL	Consider on-site opportunities for progressive reclamation during construction and operations to avoid viability issues with long-term stockpiling of organic material.	6.10.8
Terrestrial Fauna		
C, O	Provide wildlife awareness training to site personnel to reduce interactions between site personnel and wildlife.	6.11.8
C, O	Intact forest stands and wetlands will be avoided wherever practicable during detailed Project planning and design in favor of previously disturbed areas (e.g., stands disturbed by timber harvesting, roads, or other development). Micro-site Haul Road and mine infrastructure to avoid major fauna habitat.	6.11.8
C, O	Where natural, intact habitat cannot be avoided, maintain existing vegetation cover whenever practicable and minimize overall areas of disturbance.	6.11.8
C, O	Minimization of impact to old forest.	6.11.8, 6.10.8
C, O	For those species reliant on wetland habitat, a wetland alteration application will be submitted during Project planning and design to request an authorization to alter wetland habitat and to address loss of wetland function.	6.11.8, Preliminary Wetland Compensation Plan (Appendix H.3)
C, O	Compensation for permanent loss of wetland function will be completed through wetland restoration activities to support no net loss of wetland function, subject to NSE approval.	6.11.8, Preliminary Wetland Compensation Plan (Appendix H.3)
C, O	Habitat fragmentation will be reduced by limiting the area of new roads, favoring upgrading of existing roads where possible instead.	6.11.8
C, O	Site infrastructure will be fenced in, where practical, to reduce interactions between Project infrastructure and wildlife.	6.11.8
C, O	A speed limit of 40 km/hr within the Beaver Dam Mine Site and 70 km/hr along the Haul Road (or not exceeding posted speed limits) will be implemented to reduce likelihood of collisions with fauna.	6.11.8
C, O	Install signage where specific wildlife concerns have been identified. Vehicles will yield to wildlife on roads.	6.11.8

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O	Monitor and manage road conditions through dust suppression and traction control (sand on icy roads) to reduce potential for collisions with wildlife. Implement Dust Control Plan.	6.11.8, Appendix C.3 (draft Fugitive Dust Control Plan)
C, O	An un-vegetated buffer of 10 m along roadsides will be maintained, where possible, to improve visibility along roadsides and reduce the potential for collisions with wildlife.	6.11.8
C, O	Clearing and construction will be limited within wetlands that could support snapping turtles during winter hibernation period	6.11.8
C, O	Erosion and sediment control planning will be completed to ensure site runoff is not directed towards unaltered habitat. Implement Erosion and Sediment Control Plan.	6.11.8, Appendix C of Appendix P.4 (Mine Water Management Plan)
C, O	Culverts installed within wetlands and watercourses will provide an alternative crossing location to amphibians and reptiles, thereby reducing direct mortality of species attempting to cross a road. Upgrade culverts along the new and upgraded Haul Road sections to improve habitat connectivity.	6.11.8, 6.8.9.2
C, O	Implement Emergency Response and Spill Contingency Plans to protect fauna and their habitat from accidental spills	6.11.8, 6.18
C, O	Store hazardous and non-hazardous waste in designated locations, in appropriate containers to reduce potential for spills, and to prevent attracting wildlife (e.g., food waste in bear proof containers).	6.11.8, 6.18
C, O	Follow the Pit and Quarry Guidelines to reduce impact of noise and vibration on wildlife	6.11.8
C, O	Limit use of lights to the amount necessary to ensure safe operation within the PA, with the recognition that excessive lighting can be disruptive to wildlife. Install lights facing downward and wherever practicable using motion-sensing lights.	6.11.8, 6.3.8
C, O	Consider limiting use of lights that emit more blue shortwave light (e.g., LEDs, metal halides) which have greater impacts to wildlife at night, where practicable and considering operational safety.	6.11.8, 6.3.8
C, O	Restrict blasting to a specific and regular daytime schedule during weekdays to allow time for wildlife to recover from potential noise disturbance.	6.11.8
C, O	Implement draft Wildlife Management Plan	6.11.8, draft Wildlife Management Plan (Appendix P.7)
C, O	Site-specific measures to protect wildlife will be addressed in the EPP.	6.11.8

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O	The following actions will be implemented to reduce the potential for indirect impacts to adjacent undisturbed habitat: For species which rely on wetland habitat, maintain pre-construction hydrological flows into and out of downstream wetland habitats, to the extent possible (post alteration wetland monitoring may be required as a result of the provincial permitting process); In order to protect adjacent habitats from accidental spills, ensure that spill control and contingency planning is in effect, and its procedures fully communicated to staff; Vegetation management will be conducted by cutting (i.e., no use of herbicides); Ensure all development related activity (construction areas, access roads, etc.) are located within areas where biophysical field evaluations have been completed and approvals/written authorizations are in place as required; Erosion control materials shall be clean, non-ore-bearing, non-watercourse derived and non-toxic materials; Machinery and personnel will be instructed not to enter the habitats outside of approved Project footprint; and Slopes will be re-vegetated to stabilize them and limit erosion and sedimentation into adjacent habitats.	6.11.8
CL	Implement remediation plans to restore natural habitat and food source re-establishment to support fauna	6.11.8
CL	Install signage where specific wildlife concerns have been identified. Vehicles will yield to wildlife on roads.	6.11.8
Post-Closure	A deterrent system will be considered at the Touquoy Mine Site when the pit fills as tailing deposition will be present. This will deter wildlife from using the pit during and after filling which may have deleterious effects resulting from long-term exposure.	6.11.8
Avifauna		
C, O, CL	Conduct routine inspections as directed by regulators. Inspections are anticipated to be conducted daily by operators, and as required by qualified avian experts during construction, operation and active closure activities to identify and remove any trapped or injured avifauna	6.12.9, 6.13.8.4, SAR Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7)
C	Avoid construction on native vegetation during the regional breeding season for migratory avifauna where practicable (beginning of April to end of August for migratory avifauna; ECCC 2015). Where this is not practicable, an avifauna nest mitigation plan will be developed	6.12.9
C	If a raptor nest is found within the forested areas to be cleared, a buffer zone appropriate to the species (as determined in consultation with NSL&F) would be placed around the nest	6.12.9
C	In instances where mature and interior forest cannot be avoided the following mitigation measures are proposed to identify and reduce indirect impacts to migratory avifauna that rely on this habitat throughout the PA: Grubbing and clearing activities will be avoided during nesting season if possible; The Project will limit further disruptions to interior forests by utilizing existing roads and disturbed sites where possible; Where possible, to avoid this habitat, adjustments will be made to infrastructure locations during detailed design phase; and Monitoring of the effectiveness of mitigation is recommended.	6.12.9
C, O	Limit the amount of exposed soil during nesting season	6.12.9

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O	Discourage ground-nesting or burrow-nesting species (such as common nighthawk and bank swallows), by limiting large piles or patches of bare soil during the breeding season, wherever practicable	6.12.9, 6.13.8.4, SAR Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7)
C, O	Should any ground- or burrow-nesting species initiate breeding activities on stockpiles or exposed areas, AMNS will work with ECCC and NSE to develop buffer zones that incorporate adaptive management	6.12.9
C, O	Maintain speed limits on mine roads (max. 40 km/hr. within Beaver Dam Mine Site, 70 km/hr. along Haul Road) to minimize collisions with avifauna	6.12.9
C, O	Implement Dust Control Plan	6.12.9, Appendix C.3 (draft Fugitive Dust Control Plan)
C, O	Install downward-facing lights on site infrastructure and mine site haul roads. Wherever practicable, install motion-sensing lights to ensure lights are not turned on when they are not necessary	6.12.9, 6.3.8
C, O	Consider limiting use of lights that emit more blue shortwave light (e.g., LEDs, metal halides) which have greater impacts to wildlife at night, where practicable and considering operational safety.	6.12.9, 6.3.8
C, O	Conduct mobile refueling at least 30 m from any identified breeding locations	6.12.9
C, O	Monitor known nests around stockpiles and exposed areas from a distance with a spotting scope or binoculars to verify the effectiveness of an identified buffer until the nests are inactive	6.12.9
C, O	Conduct routine inspections of the open pit area to remove any trapped or injured avifauna. If identified, determine a plan for removal in consultation with an avian expert	6.12.9
C, O	Notify ECCC within 24 hours in the event of the mortality or injury of ten or more migratory avifauna in a single event or in the event of the mortality or injury of a migratory avifauna SAR	6.12.9, 6.13.8.4, SAR Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7)
C, O	Mitigation measures will be applied to reduce the potential environmental impacts of the Project on migratory avifauna at the Touquoy Mine Site as per existing operational approvals. Audio and visual deterrents are currently being utilized at Touquoy Mine Site to dissuade avifauna from landing in the TMF.	6.12.9
CL	Continued monitoring, as described in the above section.	6.12.9

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
Species of Conservation Interest and Species at Risk		
C, O, CL	Blue Felt Lichen • Complete further detailed design of Haul Road and micro siting of mine infrastructure to avoid priority lichen species. • Reduce disturbance through buffering of habitat - maintain 100m buffer, wherever practicable • Implement air quality monitoring and dust suppression plans • Flag host trees and setback areas • Implement dust suppression plan • Provide map of all priority vascular and non-vascular flora, and their setbacks, to site personnel during site orientation • Implement the SAR Lichen Mitigation and Monitoring Plan, developed in consultation with lichen specialists and regulators, for observations within and in close proximity to the PA • Wherever avoidance of SAR lichen species is not possible, the Project Team will implement the SAR Lichen Mitigation and Monitoring Plan, developed in consultation with lichen specialists and regulators. The two directly impacted blue felt lichen occurrences are proposed for translocation. • Where avoidance and translocation are not possible, the Project Team will collect specimens for submission to Frances Anderson or equivalent contact at time of construction (Lichen Specialist, Research Associate, and Nova Scotia Museum)	6.8.8.2, 6.10.8, 6.13.8.2 Lichen Mitigation and Monitoring Plan (Appendix P.6)
C, O, CL	Frosted Glass-whiskers • Complete further detailed design of Haul Road and micro siting of mine infrastructure to avoid priority lichen species • Complete further detailed design of Haul Road and micro siting of mine infrastructure to avoid priority lichen species. • Reduce disturbance through buffering of habitat - maintain 100m buffer, wherever practicable • Implement air quality monitoring and dust suppression plans • Flag host trees and setback areas • Implement dust suppression plan • Provide map of all priority vascular and non-vascular flora, and their setbacks, to site personnel during site orientation • Implement the SAR Lichen Mitigation and Monitoring Plan, developed in consultation with lichen specialists and regulators, for observations within and in close proximity to the PA • Wherever avoidance of SAR lichen species is not possible, the Project Team will implement the SAR Lichen Mitigation and Monitoring Plan, developed in consultation with lichen specialists and regulators. Where avoidance and transplantation are not possible, the Project Team will collect specimens for submission to Frances Anderson or equivalent contact at time of construction (Lichen Specialist, Research Associate, and Nova Scotia Museum)	6.8.8.2, 6.10.8, 6.13.8.2 Lichen Mitigation and Monitoring Plan (Appendix P.6)

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O, CL	Boreal Felt Lichen • Micro-siting of Project infrastructure has been completed to avoid observations and Boreal Felt Lichen Critical Habitat Areas • Continued detailed Project design to ensure no development occurs within the Boreal Felt Lichen Critical Habitat Areas • Implement air quality monitoring and dust suppression plans • Flag host tree and setback areas • Implement dust suppression plan • Provide map of all priority vascular and non-vascular flora, and their setbacks, to site personnel during site orientation • Implement the SAR Lichen Mitigation and Monitoring Plan, developed in consultation with lichen specialists and regulators.	6.8.9.2, 6.10.9, 6.13.9.2, Lichen Mitigation and Monitoring Plan (Appendix P.6)
C, O, CL	Atlantic Salmon • Complete further detailed surveys for wetland and watercourse alteration permitting • Complete further design phase micro siting of infrastructure and Haul Road to avoid or minimize impacts to fish and fish habitat • Complete fish rescue and relocation as anticipated for Wetland 59 prior to pit development • Adhere to approved timing windows for construction to minimize impact to eggs, larvae, and juvenile fish, wherever practicable • Limit direct alteration within the Beaver Dam Mine Site to first order streams that have limited potential to support spawning, wherever practicable • Limit access to the PA and prohibit staff fishing within the PA to avoid increased fishing pressures • Blasting activities will adhere to setback recommendations and other mitigation strategies advised by DFO for measures to avoid causing harm to fish and fish habitat • Implement accidental spill and contingency plans – e.g. use of spill kits and booms • Implement wetland and surface water quality monitoring programs • Implement downstream water quality and quantity monitoring program • Replace crushed, hung, or improperly installed culverts along the Haul Road that are impeding fish passage	6.13.8.1, 6.9.8.2.3

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O, CL	American Eel • Further detailed surveys for wetland and watercourse alteration permitting • Further design phase micro siting of infrastructure and Haul Road to avoid or minimize impacts to fish and fish habitat • Fish rescue and relocation is anticipated for Wetland 59 prior to pit development • Adherence to approved timing windows for construction to minimize impact to juvenile and adult eels. • Limit access to the PA and prohibit staff fishing within the PA to avoid increased fishing pressures • Blasting activities will adhere to setback recommendations and other mitigation strategies advised by DFO for measures to avoid causing harm to fish and fish habitat including aquatic species at risk. • Implementation of accidental spill and contingency plans – e.g. use of spill kits and booms • Implementation of wetland and surface water quality monitoring programs • Implementation of downstream water quality and quantity monitoring program • Replacement of crushed, hung, or improperly installed culverts along the Haul Road that are impeding fish passage	6.13.8.1, 6.9.8.2.3

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O, CL	<u>Snapping Turtle</u> • Include in the development and implementation of the draft Wildlife Management Plan • Implement wildlife observation reporting to appropriate site personnel during construction, operation, and decommissioning of Project • Safety and Environment orientation and training will include information on turtles and nesting season awareness training, particularly along the Haul Road. • If snapping turtle activity is occurring within and/or adjacent to the Beaver Dam Mine Site or Haul Road, additional turtle awareness and management program will be implemented to ensure all staff are well informed regarding the increased turtle activity, especially during breeding season • Complete further detailed design of Haul Road and micro siting of Beaver Dam Mine Site infrastructure to avoid aquatic habitat • Upgrade existing roads, wherever practicable, instead of building new roads • Replace crushed, hung, or improperly installed culverts, wherever practicable, to improve habitat connectivity (while maintaining existing hydrological conditions) • Reduce disturbance through buffering of habitat - a 30m buffer on aquatic habitat deemed suitable for snapping turtles, wherever practicable • Where avoidance of potential turtle hibernation habitat is not possible, construction in these habitats will be limited to the growing season when hibernating turtles are not likely to be impacted (Overwintering period - October through April), wherever practicable • Implement surface water quality monitoring program • Install turtle crossing signs near major watercourse crossings, or in areas where snapping turtles have been observed, in an effort to increase awareness and reduce vehicular collisions - preferably only seasonally when turtles are active • Vehicles will yield to wildlife on roads • Dust suppression to improve visibility during nesting and hatchling emergence • Vehicles will adhere to safe speed limits, particularly around blind corners • An un-vegetated buffer along roadsides will be maintained, where possible, to improve visibility along roadsides and reduce the potential for collisions with wildlife • If a turtle is found, report immediately to site Environmental Technician; if found on road, move away provided not actively nesting using proper moving technique • Use predator excluders on identified nests • Install fencing, where practicable, to prevent wildlife from accessing areas with increased risk of injuries to wild species - appropriate dimensions to address and eliminate accidental falls of species of varying size including turtles into the open pit	6.11.8, 6.13.8.3, draft Wildlife Monitoring and Management Plan (Appendix P.7), Appendix C.3 (draft Fugitive Dust Control Plan)

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O, CL	Mainland Moose • Include in the development and implementation of the Wildlife Management Plan. Implement Moose Management and Monitoring Program - including activities such as repeated winter track surveys and pellet group inventories, and collaboration with the Mi'kmaq of Nova Scotia to study Mainland Moose in a broader context • Implement wildlife observation reporting to appropriate site personnel during construction, operation, and decommissioning of Project • Vehicles will yield to wildlife on roads • Vehicles will adhere to safe speed limits, particularly around blind corners. • An un-vegetated buffer along roadsides will be maintained, where possible, to improve visibility along roadsides and reduce the potential for collisions with wildlife • Install fencing, where practicable, to prevent wildlife from accessing areas with increased risk of injuries to wild species - appropriate dimensions to address and eliminate accidental falls of species of varying size including deer and moose into the open pit • AMNS encourages the public to report mainland moose sightings to the province at https://novascotia.ca/natr/wildlife/sustainable/msform.asp.	6.11.8, 6.13.8.3, draft Wildlife Monitoring and Management Plan (Appendix P.7)
C, O, CL	Common nighthawk • Avoid clearing/grubbing activities during nesting season • If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation • Discourage ground- or burrow-nesting species by limiting the amount of exposed soil • Limit light use to direct and focused light when needed for worker safety • Implement noise management including use of mufflers on equipment and regular maintenance • Implement dust suppression plan • Implement the Landbird SAR Mitigation and Monitoring Plan and Wildlife Management Plan • All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	6.3.8, 6.10.8, 6.12.9, 6.13.8.4, SAR Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7), draft Wildlife Monitoring and Management Plan (Appendix P.7), Appendix C.3 (draft Fugitive Dust Control Plan)

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O, CL	Canada Warbler • Avoid clearing/grubbing activities during nesting season • If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation • Limit light use to direct and focused light when needed for worker safety • Implement noise management including use of mufflers on equipment and regular maintenance • Implement dust suppression plan • Implement the Landbird SAR Mitigation and Monitoring Plan and Wildlife Management Plan • All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	6.3.8, 6.12.9, 6.13.8.4, SAR Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7), draft Wildlife Monitoring and Management Plan (Appendix P.7), Appendix C.3 (draft Fugitive Dust Control Plan)
C, O, CL	Olive-sided Flycatcher • Avoid clearing/grubbing activities during nesting season • If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation • Limit light use to direct and focused light when needed for worker safety • Implement noise management including use of mufflers on equipment and regular maintenance • Implement dust suppression plan • Implement surface water quality monitoring program • Implement the Landbird SAR Mitigation and Monitoring Plan and Wildlife Management Plan • All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	6.3.8, 6.12.9, 6.13.8.4, SAR Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7), draft Wildlife Monitoring and Management Plan (Appendix P.7), Appendix C.3 (draft Fugitive Dust Control Plan)

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O, CL	Eastern Wood-Pewee • Avoid clearing/grubbing activities during nesting season • If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation • Limit light use to direct and focused light when needed for worker safety • Implement noise management including use of mufflers on equipment and regular maintenance • Implement dust suppression plan • Implement the Landbird SAR Mitigation and Monitoring Plan and Wildlife Management Plan • All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	6.3.8, 6.12.9, 6.13.8.4, SAR Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7), draft Wildlife Monitoring and Management Plan (Appendix P.7), Appendix C.3 (draft Fugitive Dust Control Plan)
C, O, CL	Chimney Swift • Avoid clearing/grubbing activities during nesting season • If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation • Limit light use to direct and focused light when needed for worker safety • Implement dust suppression plan • Implement noise management including use of mufflers on equipment and regular maintenance • Implement the Landbird SAR Mitigation and Monitoring Plan and Wildlife Management Plan • All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	6.3.8, 6.12.9, 6.13.8.4, SAR Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7), draft Wildlife Monitoring and Management Plan (Appendix P.7), Appendix C.3 (draft Fugitive Dust Control Plan)

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O, CL	Rusty Blackbird • Avoid clearing/grubbing activities during nesting season • Complete further detailed design of Haul Road and micro siting of mine infrastructure to avoid major wetlands. Where wetlands cannot be avoided, total Project footprint within the wetland will be minimized to the extent practicable. • Implement wetland monitoring programs • If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation • Limit light use to direct and focused light when needed for worker safety • Implement dust suppression plans • Implement noise management including use of mufflers on equipment and regular maintenance • Implement the Landbird SAR Mitigation and Monitoring Plan and Wildlife Management Plan • All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	6.3.8, 6.8.8, 6.12.9, 6.13.8.4, SAR Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7), draft Wildlife Monitoring and Management Plan (Appendix P.7), Appendix C.3 (draft Fugitive Dust Control Plan)
C, O, CL	Barn Swallow • Avoid clearing/grubbing activities during nesting season • If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation • Check abandoned structures on site for nests prior to any demolition • Limit light use to direct and focused light when needed for worker safety • Implement dust suppression plans • Implement noise management including use of mufflers on equipment and regular maintenance • Implement the Landbird SAR Mitigation and Monitoring Plan and Wildlife Management Plan • All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	6.3.8, 6.12.9, 6.13.8.4, SAR Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7), draft Wildlife Monitoring and Management Plan (Appendix P.7), Appendix C.3 (draft Fugitive Dust Control Plan)

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O, CL	Evening Grosbeak • Avoid clearing/grubbing activities during nesting season • If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation • Limit light use to direct and focused light when needed for worker safety • Implement dust suppression plans • Implement noise management including use of mufflers on equipment and regular maintenance • Implement the Landbird SAR Mitigation and Monitoring Plan and Wildlife Management Plan • All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	6.3.8, 6.12.9, 6.13.8.4, SAR Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7), draft Wildlife Monitoring and Management Plan (Appendix P.7), Appendix C.3 (draft Fugitive Dust Control Plan)
C, O, CL	Peregrine Falcon • Avoid clearing/grubbing activities during nesting season • If construction is required during the active nesting season, an avian specialist will monitor for nesting activity. If evidence of nesting is observed, the Proponent will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation • Limit light use to direct and focused light when needed for worker safety • Implement dust suppression plan • Implement noise management including use of mufflers on equipment and regular maintenance • Implement the Landbird SAR Mitigation and Monitoring Plan and Wildlife Management Plan • All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	6.3.8, 6.12.9, 6.13.8.4, SAR Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7), draft Wildlife Monitoring and Management Plan (Appendix P.7), Appendix C.3 (draft Fugitive Dust Control Plan)

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C, O, CL	Greater Yellowlegs • Avoid clearing/grubbing activities during nesting season • Complete construction and upgrades of Haul Road within Wetland 64 outside of the active nesting season for Greater Yellowlegs, if practicable • If construction is required during the active nesting season, an avian specialist will monitor for nesting activity within Wetland 64 and adjacent undisturbed habitat. If evidence of nesting is observed, AMNS will consult with appropriate regulatory agencies to determine an appropriate spatial and temporal buffer, based on site and seasonal specific parameters at the time of the observation. • If new breeding evidence or nests are observed within 300 m of Project activities, a site mitigation plan will be developed in consultation with regulators. Nests will be monitored from a distance using binoculars or a spotting scope to avoid further human disturbance from monitoring. An acceptable setback (to be established in consultation with regulatory authorities) will be established. • New bypass roads have been micro-sited to avoid Wetland 64 and, as a result of PA and infrastructure modifications, a waterline has been rerouted and will no longer discharge into Wetland 64, avoiding resultant changes in hydrology • To avoid nesting activity, bird deterrents will be implemented within Wetland 64, as this is the only location where probably breading was observed, following best-management-practices used in the mining industry. • Implement dust suppression plans • Limit light use to direct and focused light when needed for worker safety • Implement noise management including use of mufflers on equipment and regular maintenance • Implement the Landbird SAR Mitigation and Monitoring Plan and Wildlife Management Plan • All site workers shall comply with regulations outlined in the Migratory Bird Convention Act, which prohibits the disturbance of migratory birds, their nests and eggs. If any nest is identified, the Proponent Environmental Technician must be notified immediately, so steps can be taken to identify the species and determine appropriate mitigation or avoidance if required. Species identified of particular risk and several species of birds known to nest around active construction sites will be included in the Wildlife Sighting Report Card similar to those required at the Touquoy Mine Site	6.3.8, 6.8.8, 6.12.9, 6.13.8.4, SAR Landbird Mitigation and Monitoring Plan (Appendix A of Appendix P.7), draft Wildlife Monitoring and Management Plan (Appendix P.7), Appendix C.3 (draft Fugitive Dust Control Plan)
Mi'kmaq of Nova Scotia		
EIS Review	Support Mi'kmaq third party review of AMNS's EIS, including mitigation and monitoring programs.	6.14.8, 6.14.10
EIS Review	Continuing to provide the opportunity for Mi'kmaq to delineate the specificity of Mi'kmaq traditional use, and meet with the Mi'kmaq to receive feedback on EIS conclusions and impacts.	6.14.8
Pre-Construction	Provide Mi'kmaq land users the opportunity to walk the Beaver Dam Mine Site and Haul Road with Proponent representatives to identify and document sensitive sites prior to construction	6.14.8
Pre-Construction	Provide a tour of the Beaver Dam Mine Site and Haul Road and information on Project operations to interested Mi'kmaq peoples.	6.14.8
Pre-Construction	Develop a Mi'kmaq Communication Plan with the Mi'kmaq of Nova Scotia that outlines an ongoing two-way communication process throughout the lifecycle of the Project.	6.14.8

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
Pre-Construction	As part of the existing communications process, AMNS will build upon and strengthen a Complaints Management and Action Program for Mi'kmaq input in advance of Project commencement, as an opportunity for having grievances heard and addressed, and development of an emergency communication protocol.	6.14.8
Pre-Construction	Possible establishment of an environmental protection committee to review proposed and develop additional environmental mitigation protocols, oversee monitoring procedures and review/evaluate results. This committee should have representation from Proponent environmental experts, as well as Mi'kmaw representatives from Millbrook First Nation, Unama'ki Institute of Natural Resources, the Mi'kmaq Conservation Group, and NSE.	6.14.8
Construction	Design and construct bypass roads allow for travel routes to by-pass the Beaver Dam Mine Site and Haul Road and allow access to areas surrounding the Project.	6.14.8
Construction	In the event that Mi'kmaw archaeological features are encountered during construction or operation of the Project, all work in the area will be halted and immediate notification made to the Special Places Coordinator, Nova Scotia Museum, the KMKNO and the communities of Sipekne'katik and Millbrook As part of the EMS, AMNS will ensure mitigation measures are undertaken to prevent irreversible damage to Mi'kmaq archaeological resources and known burial site(s), including ensuring all Project activities are within the defined Project property boundaries only.	6.14.8, 6.15.8
On-going	AMNS will provide various opportunities for Mi'kmaq participation in the Project, including opportunities to participate in environmental monitoring and implementation of Mi'kmaq projects such as fish habitat offsetting, wetland compensation, and others. AMNS will continue to engage with the Mi'kmaq on various Project benefits.	6.14.8, 6.14.10, Appendix N.1 to N.7
On-going	Engage in open dialogue with affected communities relating to issues of limited Mi'kmaq access to the Beaver Dam Mine Site and Haul Road for the eight year project window and continue to review and discuss mitigation options including suitable alternative crown land access in close proximity to the Beaver Dam Mine Site and Haul Road.	6.14.8
On-going	Continue to engage with the Mi'kmaq of Nova Scotia to determine how they would like to participate and integrate traditional knowledge into the Reclamation and Closure Plan for the Project. AMNS will also provide the opportunity for the Mi'kmaq to provide input on species end land uses, revegetation, reclamation techniques, and for Mi'kmaq members to join the reclamation team to execute this Project phase.	6.14.8
On-going	Commitment to developing and conducting a Mi'kmaq Cultural Awareness Program for staff and contractors. Scope to be determined based on further discussions.	6.14.8
Physical and Cultural Heritage		
C	A program of archaeological shovel testing was conducted in fall 2020, in advance of any disturbance to Site 6, Areas 2 and 3. CRM Group cleared these areas of any requirement for further archaeological investigation	6.15.8, Appendix N.1 to N.7
C	If any development is to occur within 100 metres of Crusher Lake, intensified reconnaissance (i.e., shovel testing) should be conducted to identify any additional features.	6.15.8, Appendix N.1 to N.7
C	If any development is to occur specifically around the historic features identified during the 2014, 2015, 2016, 2018 and 2019 reconnaissance, intensified historical research and archaeological shovel testing should be conducted in advance of disturbance.	6.15.8, Appendix N.1 to N.7

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
C	Any further changes in the layout of the mine and associated facilities be evaluated as to potential impacts to archaeological resources.	6.15.8, Appendix N.1 to N.7
O	In the event that archaeological resources or human remains are encountered during ground disturbance activities, it is required that all activity stop, and the Coordinator of Special Places, Nova Scotia Communities, Culture, & Heritage Department be contacted.	6.15.8, Appendix N.1 to N.7
Socio-economic Conditions		
C	Restriction of recreational activities within the spatial boundaries of the Project. Notification will be provided by signage. Communication Plan to communication access information to key stakeholders (Sections 3 and 4 [Public Engagement and Indigenous Peoples Engagement, respectively]). Liaison with any local recreation groups, such as ATV associations through an Ad Hoc group. Equipment maintenance. Reduction of mobile equipment accident risk through discussions with NSTIR, appropriate signage, and operator training.	6.16.11
O	Restriction of recreational activities within the spatial boundaries of the Project. Notification will be provided by signage. Liaison with local recreation groups, such as ATV associations. Equipment maintenance. Limiting haul truck operational hours to approximately 16 hours per day. Reduction of mobile equipment accident risk through discussions with NSTIR, appropriate signage, and operator training. Ongoing engagement with community associations, CLC and residents to assess and adaptively manage the site. Potential housing and employment studies to monitor impacts on population growth and housing market.	6.16.11
CL	Ongoing engagement with community associations, CLC and residents to assess and adaptively manage the site.	6.16.11
Accidents and Malfunctions		
Open Pit Mine Slope Failure	The pit slope design, construction and monitoring follow applicable regulations and recommendations provided by a qualified geotechnical professional.	6.18.6.1, Appendix A.2a and Golder (2021 In Progress)
Stockpile Slope Failure	The stockpile design, construction and monitoring follow applicable regulations and recommendations provided by a qualified geotechnical professional.	16.8.6.2
Settling Pond Failure	The water management ponds are designed by a qualified professional and lined with suitable materials, such as clay or a geosynthetic liner.	6.18.6.3
Infrastructure Failure	The infrastructure is designed following applicable regulations and recommendations provided by a qualified professional.	6.18.6.4

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
Fuel and/or other spills	Fuel delivery suppliers and their personnel will have certification and training in fuel transport and delivery in compliance with applicable regulatory requirements. Onsite storage and dispensing of fuel products will be conducted in accordance with applicable regulatory requirements and adhere to the Petroleum Operation Procedure and related site-specific procedures. Staff will be trained in spill response measures. Spill response kits will be accessible and dedicated in areas of fuel storage and transfer.	6.18.7.1, Appendix A draft Spill Contingency Plan of Appendix P.1 draft Emergency Response Plan
Mobile Equipment Accident	The Beaver Dam Mine Site will have restricted traffic patterns, speed limits, right-of-way signage and training that will minimize the risk of mobile equipment accidents. Highway haul trucks will be remotely tracked and monitored. Communications will be maintained between vehicles using radios to minimize adverse interactions and ensure prompt response to any incident.	6.18.7.3
Tailings and Reclaim Water Pipelines Spills	Tailings and reclaim pipelines between the plant site, TMF and open pit will be designed and constructed to minimize the potential for release. Measures may include double walled tailings pipes, lined service trenches and adequately sized, lined, collection pond capable of containing the volume of the pipeline. The catchment pond would be lined with suitable materials, such as clay or a geosynthetic liner.	6.18.7.5
Cyanide Release (Touquoy Mine Site)	Cyanide is transported stored and handled in accordance with applicable regulatory requirements and the International Cyanide Management Code. Cyanide is stored and handled inside the plant footprint within a restricted containment area	6.18.7.6
Forest and/or Site Fires	Fire protection for the plant site will be via a "wet system" with hydrants located around the plant site area. The water contained within the lower portion of the raw water tank will be reserved for fire protection. Fire detection systems will be installed in buildings and key areas of the Beaver Dam Mine Site.	6.18.8
Effects of the Environment on the Project		
C	Project design to consider extreme weather events, temperature extremes, wind speed ranges, flood or drought conditions, lightning strikes. Project design will follow industry standards, including the National Building Code of Canada. An Emergency Response Plan will be implemented during the construction phase. An Occupational Health and Safety Plan will be implemented to protect worker health and safety	7.3
C	Stockpile design will consider collected geological data and will be designed with slopes at the angle determined by geotechnical analysis and acceptable safety factors. An Emergency Action Plan will be implemented during the construction phase	7.3
O	An Emergency Action Plan will be implemented during the operations phase. An Occupational Health and Safety Plan will be implemented to protect worker health and safety	7.3

Table 9.1-1: Summary of Key Mitigation Measures by Valued Component (continued)

Project Phase	Mitigation Measures	Corresponding EIS Section Number and/or Appendix
O	Stockpile design will be re-assessed following material placement to ensure slopes are geotechnical stable and within acceptable safety factors An Emergency Action Plan will be implemented during the operation phase	7.3
CL	Stockpile design will consider collected geological data and will be designed with slopes at the angle determined by geotechnical analysis and acceptable safety factors.	7.3

Table 9.1-2: Summary of Residual Effects by Valued Component

Project - VC Interactions	Summary of Mitigation	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
NOISE									
Construction – Beaver Dam Mine Site and Haul Road Noise from haul trucks, Haul Road widening and construction, and blasting and drilling of in-situ rocks	Equipment maintenance, best management practices, minimize blasting events.	N-L	Beaver Dam Mine Site and Haul Road LAA: Noise generated will likely extend beyond the PA	A	ST Effects can occur up to 1 year	R Effects occur regularly in the construction phase of the Project	R VC will recover to baseline conditions	Increased ambient noise	Not significant
Operations - Beaver Dam Mine Site and Haul Road Noise from haul trucks, blasting and drilling of in-situ rocks and the crushing of ore heavy machinery operation, and site vehicles	Equipment maintenance, dust suppression, hardened surface where practical, vehicle speed reduction, use of large haul vehicles to minimize trips, stabilization of stockpile slopes, covering of haul trucks, minimize blasts. Equipment maintenance, haul truck operations < 24 hours per day to minimize noise disturbance, limited engine idling, shutting off vehicle when parked unless this is precluded for safety or maintenance reasons.	N-L	At Points of Reception for Beaver Dam Mine Site, Haul Road, Touquoy Mine Sire) At Property Lines for Beaver Dam Mine Site, Haul Road LAA: effect extend beyond the PA into the LAA	A	LT Effects may extend beyond 3 years	R Effects occur regularly in the operational phase of the Project	R VC will recover to baseline conditions	Increased ambient noise	Not significant
Operations – Touquoy Mine Site Noise from blasting, crushing of ore, heavy machinery operation and site vehicles	Equipment maintenance, haul truck operations < 24 hours per day to minimize noise disturbance, limited engine idling, shutting off vehicle when parked unless this is precluded for safety or maintenance reasons.	N	At Property Lines LAA Noise generated is predicted to extend beyond the PA	A	LT Effects may extend beyond 3 years	R Effects occur regularly in the operational phase of the Project	R VC will recover to baseline conditions	Increased ambient noise	Not significant
AIR									
Construction – Beaver Dam Mine Site and Haul Road (Dust from haul trucks, Haul Road widening and construction)	Equipment maintenance, best management practices, minimize blasting events.	N Does not exceed guidelines or threshold	LAA Dust generated will likely extend beyond the PA	N/A VC is not expected to be affected by timing	MT Effects can occur beyond 12 months	R Effects occur regularly in the construction	R VC will recover to baseline conditions	Increased ambient dust	Not significant
Operations- Mine Site and Touquoy Mine Site at Property Lines and Points of Reception (Dust from onsite activities, vehicle travel, material handling and the crushing of ore)	Equipment maintenance, dust suppression, hardened surface where practical, vehicles to minimize trips, stabilization of stockpile slopes, cover of haul trucks, minimize blasts	N Does not exceed guidelines or threshold	LAA Dust generated will likely extend beyond the PA	N/A VC is not expected to be affected by timing	LT Effects may extend beyond 3 years	R Effects occur regularly during Operations	R VC will recover to baseline conditions	Increased ambient dust	Not significant
Operations- Haul Road at Property Lines (Dust from haul trucks)	Haul truck operations to minimize road surface disturbance during nighttime hours, implementation of Road Dust Best Management Practices Plan (with 80-90% or greater targeted dust suppression efficiency).	L Exceeds guidelines or threshold values by more than 20%	LAA Dust generated will likely extend beyond the PA	N/A VC is not expected to be affected by timing	LT Effects may extend beyond 3 years	S Exceedances are maximum values, sporadic to regular occurrence at Property Lines.	R VC will recover to baseline conditions	Increased ambient dust	Not Significant
Operations - Haul Road at Points of Reception (Dust from haul trucks)	Haul truck operations to minimize road surface disturbance during nighttime hours, implementation of Road Dust Best Management Practices Plan (with 80-90% or greater targeted dust suppression efficiency).	L Marginally exceeds guidelines or threshold values	LAA Dust generated will likely extend beyond the PA	N/A VC is not expected to be affected by timing	LT Effects may extend beyond 3 years	R Effects occur regularly in the operational phase of the Project	R VC will recover to baseline conditions	Increased ambient dust	Not Significant
LIGHT									
Construction and Active Closure – Beaver Dam Mine Site and Haul Road (Lights from haul trucks, site lighting)	Equipment maintenance, limited vegetation clearing.	L (qualitative assessment only – predicted to be less light propagation than operations phase described below)	RAA Lighting impacts may extend beyond the PA	A Seasonal aspects may affect VC (i.e., daylight hours)	MT Effects can occur beyond 12 months and up to 3 years	S Effects occur at regular intervals throughout the Project	R VC will return to baseline conditions	Increased ambient light	Not significant

Table 9.1-2: Summary of Residual Effects by Valued Component (continued)

Project - VC Interactions	Summary of Mitigation	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Operational – Beaver Dam Mine Site, Haul Road, Touquoy Mine Site (Lights from haul trucks, site lighting)	Equipment maintenance, haul truck operation <24 hours per day, minimize lighting (downward facing lighting, motion sensor lights, light positioning away from property boundaries were practical).	L Less than or equal to appropriate guidelines or threshold values	RAA Lighting impacts may extend beyond the PA	A Seasonal aspects may affect VC (i.e., daylight hours)	LT Effects may extend beyond 3 years	R Effects occur at regular intervals throughout the Project	R VC will return to baseline conditions	Increased ambient light	Not significant
GREENHOUSE GASES									
Construction – Beaver Dam Mine Site and Haul Road (Haul Road widening and construction, use of heavy machinery, haul trucks and site vehicle emissions)	Equipment maintenance, implementing fuel efficiencies, limited engine idling, use of more fuel efficient vehicles.	L	RAA	N/A	ST	C	R	Increased greenhouse gas emissions during operations	Not Significant
Operation – Beaver Dam Mine Site, Haul Road and Touquoy Mine Site (Emissions from haul trucks, site vehicles, heavy machinery, blasting and drilling of in-situ rocks)	Equipment maintenance, implementing fuel efficiencies, minimizing blasts, limited engine idling, use of more fuel efficient vehicles.	L	RAA	N/A	MT	C	R	Increased greenhouse gas emissions	Not Significant
Active Closure – Beaver Dam Mine Site (Emissions from haul trucks, site vehicles, heavy machinery)	Equipment maintenance, implementing fuel efficiencies, limited engine idling, use of more fuel efficient vehicles.	N-L	RAA	N/A	MT	I	R	Increased greenhouse gas emissions	Not Significant
GEOLOGY, SOIL, AND SEDIMENT QUALITY									
Construction and Operation – Beaver Dam Mine Site (exposure of acid generating material, impacted soil/sediment through migration of contaminants via dust deposition and runoff events.)	Select removal of impacted materials, wet dust suppression controls, hardened surfaces where practical, covering of haul trucks to reduce dust during transportation, vehicle speed reduction to minimize dust, spill preparedness. reclaiming/spreading stockpiles, soil/sediment quality,	L Minor changes from baseline conditions	LAA Potential adverse effects to soil/sediment quality and quantity outside the PA	A Seasonal aspects may affect VC (i.e., wind)	LT Effects may extend beyond 3 years	S Effects occur at irregular intervals throughout the Project	IR VC will not recover to baseline conditions	Soil and sediment quality, increased dust impact (i.e., flora and fauna/habitat, human health, etc.)	Not significant
Construction and Operational – Haul Road (Haul Road widening and construction, trucking activity, and sediment quality impacts through migration of contaminants via dust deposition and runoff events.	Slope stabilization, sediment and erosion control, best management practices, spill preparedness. reclaiming/spreading stockpiles, soil/sediment quality	L Minor changes from baseline conditions	PA Potential adverse effects confined to the PA	N/A VC is not expected to be affected by timing	MT Effects can occur beyond 12 months and up to 3 years	O Potential effects to occur once during the construction phase	R Sediment Quality will recover to baseline conditions after cessation of activities/ closure of the mine IR Soil under the footprint of the road will be lost.	Erosion, soil and sediment quality	Not significant
Operational – Touquoy Mine Site (soil/sediment quality)	Covering of haul trucks to reduce dust during transportation onsite, vehicle speed reduction to minimize dust onsite. reclaiming/spreading stockpiles, soil/sediment quality	L Minor changes from baseline conditions	LAA Potential adverse effects to soil/sediment quality and quantity outside the PA	A Seasonal aspects may affect VC (i.e., wind)	LT Effects may extend beyond 3 years	S Effects occur at irregular intervals throughout the Project	R Soil Sediment Quality will recover to existing conditions after cessation of activities/ closure of the mine	Soil and sediment quality, increased dust impact (i.e., flora and fauna/habitat, human health, etc.)	Not significant

Table 9.1-2: Summary of Residual Effects by Valued Component (continued)

Project - VC Interactions	Summary of Mitigation	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
GROUNDWATER QUALITY AND QUANTITY									
Construction – Beaver Dam Mine Site and Haul Road (Surface Water Alteration resulting in reduction of recharge to groundwater, blasting effects on GW, elevated nitrogen in GW from blasting residue)	Sediment and erosion control, pre-blast surveys within 800 m of potable wells, watercourse alteration permitting, inclusion of use of pit dewatering water and collected surface water instead of groundwater for dust control in the project design	M Mitigation strategies and best management practices reduce the magnitude of impact	PA VC confined to the Mine Site	A VC interaction is by timing considerations/during low flows	LT VC interaction effects extend into PCs	R VC interaction will occur regularly during construction phase	PR Mitigation not necessarily return to baseline conditions	Reduction in Water Quantity	Not Significant
Post-Closure – Beaver Dam Mine Site (Groundwater seepage from stockpiles discharge to surface water [Mud Lake, outlet watercourse from Mud Lake, Crusher Lake])	Installation of groundwater wells at the shores of these locations; periodic sampling to evaluate this prediction; modelling updates to include updated source term data/water quality inputs; if necessary groundwater will be intercepted (i.e., interception trench) upstream of wells and treatment will be considered to meet regulatory requirements prior to discharge into receiving environment. Monitoring will determine if additional adaptive management measures will be applied.	L Mitigation strategies and best management practices reduce the magnitude of impact	PA VC confined to the Mine Site	A VC interaction during low flow conditions is assessed	LT VC interaction effects extend into PCs	R Effects will occur at regular intervals during post closure phase of project	PR Mitigation not necessarily return to baseline conditions	Reduction in Water Quality	Not Significant
SURFACE WATER QUANTITY AND QUALITY									
Surface Water Quantity									
Construction – Beaver Dam Mine Site and Haul Road	Project Design to evaluate hydrology patterns. Erosion and Sediment Control Measures	Low Minor changes from baseline conditions	Discrete Effects are confined to the PA (Beaver Dam Mine Site and Haul Road)	N/A	Short-Term	S VC interaction will occur at irregular intervals throughout construction phase	Reversible to Partially Reversible	Change in Water Quantity (baseflow, stream flow in Mud Lake and WC23, WC26 due to project development/construction of water management diversions etc.)	Not Significant
Surface Water Quality									
Construction – Beaver Dam Mine Site and Haul Road (TSS and Dust Deposition)	Project Design to evaluate hydrology patterns. Erosion and Sediment Control Measures	Low Minor changes from baseline conditions	Discrete Effects are confined to the PA (Beaver Dam Mine Site and Haul Road)	N/A	Short-Term Effects can occur beyond 12 months and up to three years	S VC interaction will occur at irregular intervals throughout construction phase	R VC will recover to baseline conditions	Change in Water Quality Disturbance	Not Significant
Surface Water Quantity									
Beaver Dam Mine Site (Crusher Lake, Killag River, Tent Brook)	Surface water from pit dewatering activities will be designed to discharge back into Cameron Flowage/Killag River at rates to mimic seasonal flows, where practicable.	Negligible to Low Minor changes from baseline conditions	Local Effect are confined to the near-field assessment area	N/A	Short-Term to Medium Term	R Effects will occur at regular intervals throughout operations	Reversible VC will recover to baseline conditions once project activities have been completed	Change in hydrology in Cameron Flowage/Killag River	Not Significant
Beaver Dam Mine Site (Reduction in base flow to WC26 and WC23)	Predicted flow reduction. Monitoring to confirm, watercourse alteration permitting, fisheries authorization, if required	Low to High VC interaction Causes reduction in surface flow	Discrete Effects are confined to the Beaver Dam Mine Site	N/A	P VC interaction is permanent	C VC interaction will occur continuously	Irreversible While effect is reduced in PC, it is still measurable/ medium to high magnetite	Disturbance; impacts are due to the placement of stockpiles catchment	Not Significant
Beaver Dam Mine Site (Mud Lake)	Predicted flow reduction. Monitoring to confirm.	Medium to High Resultant change is outside natural variations from baseline conditions	Discrete Effects are confined to the PA (Beaver Dam Mine Site)	N/A	Long Term	C VC interaction will occur continuously	Partially Reversible Effect decreases in PC phases	Disturbance	Not significant

Table 9.1-2: Summary of Residual Effects by Valued Component (continued)

Project - VC Interactions	Summary of Mitigation	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Surface Water Quality									
Operations – Beaver Dam Mine Site (Surface water quality of Killag River from effluent discharge through north settling pond and groundwater seepage)	Water Treatment at discharge (as required)	Low to Negligible Negligible change in water quality	Local Effect are confined to the near-field assessment area	N/A	Short-Term to medium term	R VC interaction will occur regularly	IR VC will not return to baseline condition	Change in water quality in the Killag	Not significant
Operations Beaver Dam Mine Site and Haul Road (Release of non-mine-contact surface water to receiving waters resulting in reduction in water quality)	Erosion and Sediment Control Measures	Low to Negligible Minor change from baseline conditions	Local Effect are confined to the near-field assessment area	N/A	Short-Term to medium term	S VC interaction will occur sporadically	R VC will return to baseline conditions	Disturbance	Not Significant
Closure – Beaver Dam Mine Site (Surface water quality of Killag River from pit from effluent discharge)	Water Treatment at discharge (as required)	Low to Negligible Negligible change in water quality	Local Effect are confined to the near-field assessment area	N/A	Short-Term to medium term	R VC interaction will occur regularly	Partially Reversible Effect decreases in PC phases	Disturbance	Not Significant
Closure – Touquoy Mine Site (Storage of Beaver Dam tailings in the Touquoy open pit mine and surface water quality of Moose River from effluent discharge and groundwater seepage)	Treatment of water quality in pit as tailings are disposed in the open pit Water Treatment at discharge (as required) Continuation of the monitoring program that is currently underway at Touquoy since 2016	Low to Negligible Negligible change in water quality	Local Effect are confined to the near-field assessment area	N/A	Short-Term to medium term	R VC interaction will occur regularly	IR VC remains at the end of the activity	Disturbance	Not significant
WETLANDS									
Construction – Beaver Dam Mine Site and Haul Road (clearing and grubbing, direct wetland alteration, and upgrading and new Haul Road construction))	Sediment and erosion control, best management practices, spill preparedness, and engagement in the wetland permitting process.	M VC interaction causes direct loss of 4% of NSE mapped wetlands in the LAA. Direct impact to WSS.	PA Potential adverse effect to wetlands inside the PA	A Seasonal aspects may affect VC	P VC unlikely to recover to baseline conditions	O Effects occur once during the construction phase	IR VC will not recover to baseline conditions	Habitat Loss and Disturbance	Not Significant
Operational – Beaver Dam Mine Site (groundwater interactions, water quality, changes to flow regimes, accidents/malfunctions)	Sediment and erosion control, best management practices, spill preparedness, wetland monitoring and water management.	L VC interaction predicted to result in indirect loss of <1% of NSE mapped wetlands in the LAA	LAA Potential adverse effect to wetlands outside of the PA	A Seasonal aspects may affect VC	LT Effects may extend beyond 5 years	R Effects occur at regular intervals throughout the project	PR Mitigation cannot guarantee a return to baseline conditions	Disturbance	Not Significant
Operational – Haul Road (water quality, changes to flow regimes, accidents/malfunctions)	Sediment and erosion control, best management practices, spill preparedness, and wetland monitoring.	L Small change from baseline conditions	LAA Potential adverse effect to wetlands outside of the PA	A Seasonal aspects may affect VC	LT Effects may extend beyond 5 years	S Effects occur at irregular intervals throughout the Project	R VC will recover to baseline condition	Disturbance	Not Significant
Post Closure – Touquoy Mine Site (potential changes to hydrology in Moose River and associated riparian wetlands)	Sediment and erosion control, best management practices, and spill preparedness, wetland monitoring and water management. Discharge to mimic seasonal flows wherever practicable	N Negligible increase in water quantity, no expected impact to downstream wetlands	LAA VC interaction may extend beyond PA	A Seasonal aspects may affect VC	LT Effects may extend beyond 5 years	R Effects are expected to occur over a regular interval	PR VC will partially recover to baseline conditions	Disturbance	Not Significant
Closure (Active) – Beaver Dam Mine Site (wetland restoration and compensation)	Sediment and erosion control, best management practices, spill preparedness, wetland compensation	L VC interaction restores and compensates lost wetland habitat	PA Potential adverse effect confined to the PA	A Seasonal aspects may affect VC	LT Effects may extend beyond 5 years	O Effects occur once during the reclamation phase	PR Mitigation cannot guarantee a return to baseline conditions	Habitat Reclamation	Not Significant

Table 9.1-2: Summary of Residual Effects by Valued Component (continued)

Project - VC Interactions	Summary of Mitigation	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
FISH AND FISH HABITAT									
Direct									
Construction – Beaver Dam Mine Site & Haul Road Direct watercourse and wetland alteration	Sediment and erosion control, best management practices, spill preparedness, and completion of watercourse and fish habitat alteration permitting. Offset Plan. Fish Rescue	H VC interaction causes direct loss of fish habitat.	PA Potential adverse effect to fish habitat is limited to the PA	A Watercourse alteration will occur outside of sensitive periods for fish; however, other interactions may seasonally affect VC	P Effect is expected to be permanent	O Effects occur once during the construction phase	IR VC will not recover to baseline conditions	Habitat Alteration Disruption or Destruction	Not significant
Indirect									
Construction – Beaver Dam Mine Site Altered hydrology and altered surface water quality. Removal of historical tailings	Sediment and erosion control, best management practices, spill preparedness, and completion of watercourse and fish habitat alteration permitting. Offset Plan.	M (WC5) H (WC23, WC26, WC27)L moderate to high changes to baseline conditions on downstream habitats	LAA Potential adverse effect to fish habitat outside of the PA	A Seasonal habitat provisions may affect VC	P Effect is expected to be permanent	R Effects occur at regular intervals as construction progresses	IR VC will not recover to baseline conditions	Habitat Alteration	Not significant
Direct									
Construction – Haul Road Watercourse crossings	Sediment and erosion control, best management practices, spill preparedness, and completion of watercourse and fish habitat alteration permitting. Offset Plan.	L to H VC interaction causes direct loss of fish habitat. L < 20 m2, M 20 m2 - 100 m2, H > 100 m2 per crossing	PA Potential adverse effect to fish habitat is limited to the PA	A Seasonal habitat provisions may affect the VC	P Effect is expected to be permanent	O Effects occur once during the construction phase	IR VC will not return to baseline conditions	Habitat Alteration Disruption or Destruction	Not significant
Construction – Haul Road Watercourse crossings – improve fish passage	N/A	N/A	LAA Potential adverse effect to fish habitat outside of the PA	A Seasonal habitat provisions may affect the VC	P Increased habitat connectivity is permanent	O Effects occur once during the construction phase	IR VC will not return to baseline conditions	Increased habitat connectivity	Not significant
Indirect									
Operations –Beaver Dam Mine Site Indirect impacts including groundwater drawdown, groundwater seepage, altered surface water quality Cameron Flowage/Killag River Tent Lake Cope Brook	Interceptor trench west of PAG stockpile Water treatment (as required) Discharge point location at northern end of Cameron Flowage Surface water from pit dewatering activities will be designed to discharge back into Cameron Flowage/Killag River at rates to mimic seasonal flows, where practical Vegetative buffers to provide shade to on-site ponds Install groundwater pumps to supplement baseflow in Cameron Flowage Explosives Management Best Management Practices	L Interaction likely to cause indirect impacts to fish habitat	LAA Potential adverse effect to fish habitat outside of the PA	A Seasonal habitat provisions may affect VC	P Effect is expected to be permanent	R Effects occur at regular intervals throughout the Project	PR Groundwater drawdown effects will cease once the pit lake has filled. Surface water interactions are partially reversible	Habitat alteration	Not significant
Operations – Haul Road Indirect impacts to surface water quality	Sediment and erosion control, best management practices, and spill preparedness.	N Negligible change to fish and fish habitat	LAA Potential adverse effect to fish habitat outside of the PA	A Seasonal habitat provisions may affect VC	P Effect is expected to be permanent	R Effects occur at regular intervals throughout the Project	PR VC will partially return to baseline conditions (reduction in traffic once haul trucks cease)	Habitat alteration	Not significant

Table 9.1-2: Summary of Residual Effects by Valued Component (continued)

Project - VC Interactions	Summary of Mitigation	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Post Closure – Beaver Dam Mine Site and Touquoy Mine site Surface water quality Cameron Flowage/Killag River Moose River	Water treatment (as required)	N VC interaction will remain below appropriate guidelines	LAA VC interaction will extend beyond PA	A Seasonal aspects will affect VC	P Effect is expected to be permanent	R Effects are expected to occur over a regular interval	PR VC will partially recover to baseline conditions	Change in water quality	Not significant
HABITAT AND FLORA									
Construction – Beaver Dam Mine Site and Haul Road (clearing and grubbing, and Haul Road widening and construction)	Limit habitat disturbance and minimize Project Area during detailed design, sediment and erosion control, best-management practices, spill preparedness, dust control, re-establish habitat and associated vegetation communities during closure.	M Direct loss to habitat and flora. Partial mitigation through restoration.	PA Effects confined to the PA.	N/A VC is not expected to be affected by timing.	MT (Beaver Dam Mine Site) Effects occur beyond 5 years when closure activities commence at Beaver Dam Mine Site. P (Haul Road) Closure of the Haul Road not expected.	O Effects occur once during the construction phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Disturbance, Habitat Loss	Not Significant
Operation – Beaver Dam Mine Site, Haul Road and Touquoy Mine Site (dust from haul trucks, heavy machinery and mine operations)	Dust control, sediment and erosion control, best management practices, and spill preparedness.	M	LAA Potential effects below guideline levels beyond the PA.	N/A VC is not expected to be affected by timing.	MT Effects may occur up to 5 years.	R Effects will occur at regular intervals.	R VC will return to baseline conditions.	Disturbance	Not Significant
Closure (Active) – Beaver Dam Mine Site (re-vegetate using stockpile materials)	N/A	L Minor change from baseline conditions.	LAA Potential effects beyond the PA.	N/A VC is not expected to be affected by timing.	LT Effects extend beyond active closure phase.	O Effects occur once during the closure phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Reclamation	Not Significant
TERRESTRIAL FAUNA									
Construction – Beaver Dam Mine Site and Haul Road (habitat loss and fragmentation from clearing and grubbing)	Limit habitat disturbance and minimize Project footprint during detailed design, implement speed limits, install fences where necessary, and minimize lighting.	L < 5% direct loss of habitat types used by observed species within the LAA Partial mitigation through restoration.	RAA Potential adverse effect to fauna outside of the LAA (fragmentation)	A VC interaction may affect seasonal aspects of fauna.	MT (Beaver Dam Mine Site) Effects occur beyond 5 years when closure activities commence at Beaver Dam Mine Site. P (Haul Road) Closure of the Haul Road not expected.	O Effects occur once during the construction phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Loss	
Construction – Beaver Dam Mine Site and Haul Road (sensory disturbance (noise, light, dust deposition) and wildlife vehicle collisions from construction activities)	Implement speed limits, install fences where necessary, and minimize lighting.	M	LAA Potential adverse effect to fauna outside of the PA	A VC interaction may affect seasonal aspects of fauna.	ST Effects are limited to occur from as little as 1 day to 12 months	R Effects occur at regular intervals during the construction phase	R VC will recover to baseline conditions	Disturbance	
Operational – Beaver Dam Mine Site, Haul Road and Touquoy Mine Site (disturbance (noise, light, dust deposition and wildlife vehicle collisions) from haul trucks, heavy machinery and mine operations)	Implement speed limits, install fences where necessary, and minimize lighting.	M Moderate changes relative to baseline conditions in remaining and surrounding habitat.	LAA Potential adverse effect to fauna beyond the PA.	A VC interaction may affect seasonal aspects of fauna.	MT Effects may occur up to 5 years.	R Effects occur at regular intervals.	R VC will recover to baseline conditions	Disturbance	
Closure (Active) – Beaver Dam Mine Site (re-establishment of habitat for fauna)	N/A	L Minor change from baseline conditions.	LAA Potential effect to fauna outside of the PA	A VC interaction may affect seasonal aspects of fauna.	LT Effects extend beyond active closure phase.	O Effects occur once during the closure phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Reclamation	

Table 9.1-2: Summary of Residual Effects by Valued Component (continued)

Project - VC Interactions	Summary of Mitigation	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
AVIFAUNA									
Construction – Beaver Dam Mine Site and Haul Road (habitat loss from clearing and grubbing)	Limit habitat disturbance and minimize Project Area during detailed design, implement speed limits and minimize lighting.	L < 5% direct loss of habitat types used by observed species within the LAA Partial mitigation through restoration.	LAA Potential adverse effect to avifauna outside of the PA	A Although clearing and grubbing will occur outside of the sensitive period for avifauna, other activities will not.	MT (Beaver Dam Mine Site) Effects occur beyond 5 years when closure activities commence at Beaver Dam Mine Site. P (Haul Road) Closure of the Haul Road not expected.	O Effects occur once during the construction phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Loss	Not Significant
Construction – Beaver Dam Mine Site and Haul Road (sensory disturbance (noise, light, dust deposition) and wildlife vehicle collisions from construction activities)	Implement speed limits and minimize lighting.	M	LAA Potential adverse effect to avifauna outside of the PA	A VC interaction may affect seasonal aspects of avifauna.	ST Effects are limited to occur from as little as 1 day to 12 months	R Effects occur at regular intervals during the construction phase	R VC will recover to baseline conditions	Disturbance	Not Significant
Operational – Beaver Dam Mine Site, Haul Road and Touquoy Mine Site (disturbance (noise, light, dust deposition and wildlife vehicle collisions) from haul trucks, heavy machinery and mine operations)	Implement speed limits, install fences where necessary, and minimize lighting.	M Moderate changes relative to baseline conditions in remaining and surrounding habitat.	LAA Potential adverse effect to avifauna outside of the PA	A VC interaction may affect seasonal aspects of fauna.	MT Effects may occur up to 5 years.	R Effects occur at regular intervals.	R VC will recover to baseline conditions	Disturbance	Not Significant
Operations – Touquoy Mine Site Tailings deposition	Best management practices, Bird Deterrent Program implementation	L Change in habitat for avifauna	PA VC interaction is confined to the PA.	A VC interaction may occur during sensitive period for avifauna.	LT Effects may extend beyond 5 years	R VC interaction will occur at regular intervals	PR Mitigation cannot guarantee a return to baseline conditions	Creation of potential open water habitat; decreased water quality	Not Significant
SPECIES OF CONSERVATION INTEREST AND SPECIES AT RISK									
Priority Fish									
Operations –Beaver Dam Mine Site Indirect impacts including groundwater drawdown, groundwater seepage, altered surface water quality Cameron Flowage/Killag River Tent Lake Cope Brook	Indirect	Interceptor trench west of PAG stockpile Water treatment (as required) Discharge point location at northern end of Cameron Flowage Vegetative buffers to provide shade to on-site ponds Install groundwater pumps to supplement baseflow in Cameron Flowage Explosives Management Best Management Practices	L Interaction likely to cause indirect impacts to fish habitat	LAA Potential adverse effect to fish habitat outside of the PA	A Seasonal habitat provisions may affect VC	P Effect is expected to be permanent	R Effects occur at regular intervals throughout the Project	PR Groundwater drawdown effects will cease once the pit lake has filled. Surface water interactions are partially reversible	Habitat alteration
Post Closure – Beaver Dam Mine Site and Touquoy Mine site Surface water quality Cameron Flowage/Killag River Moose River	Indirect	Water treatment (as required)	N VC interaction will remain below appropriate guidelines	LAA VC interaction will extend beyond PA	A Seasonal aspects will affect VC	P Effect is expected to be permanent	R Effects are expected to occur over a regular interval	PR VC will partially recover to baseline conditions	Change in water quality

Table 9.1-2: Summary of Residual Effects by Valued Component (continued)

Project - VC Interactions	Summary of Mitigation	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Priority Terrestrial Fauna									
Construction – Beaver Dam Mine Site and Haul Road (habitat loss and fragmentation from clearing and grubbing)	Limit habitat disturbance and minimize Project footprint during detailed design, implement speed limits, install fences where necessary, and minimize lighting.	L < 5% direct loss of habitat types used by observed SAR and SOCI within the LAA Partial mitigation through restoration.	RAA Potential adverse effect to fauna outside of the LAA (fragmentation)	A VC interaction may affect seasonal aspects of fauna.	MT (Beaver Dam Mine Site) Effects occur beyond 5 years when closure activities commence at Beaver Dam Mine Site. P (Haul Road) Closure of the Haul Road not expected.	O Effects occur once during the construction phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Loss	Not Significant
Construction – Beaver Dam Mine Site and Haul Road (sensory disturbance (noise, light, dust deposition) and wildlife vehicle collisions from construction activities)	Implement speed limits, install fences where necessary, and minimize lighting.	M	LAA Potential adverse effect to fauna outside of the PA	A VC interaction may affect seasonal aspects of fauna.	ST Effects are limited to occur from as little as 1 day to 12 months	R Effects occur at regular intervals during the construction phase	R VC will recover to baseline conditions	Disturbance	Not Significant
Operational – Beaver Dam Mine Site, Haul Road and Touquoy Mine Site (disturbance (noise, light, dust deposition and wildlife vehicle collisions) from haul trucks, heavy machinery and mine operations)	Implement speed limits, install fences where necessary, and minimize lighting.	M Moderate changes relative to baseline conditions in remaining and surrounding habitat.	LAA Potential adverse effect to fauna beyond the PA.	A VC interaction may affect seasonal aspects of fauna.	MT Effects may occur up to 5 years.	R Effects occur at regular intervals.	R VC will recover to baseline conditions	Disturbance	Not Significant
Closure (Active) – Beaver Dam Mine Site (re-establishment of habitat for fauna)	N/A	L Minor change from baseline conditions.	LAA Potential effect to fauna outside of the PA	A VC interaction may affect seasonal aspects of fauna.	LT Effects extend beyond active closure phase.	O Effects occur once during the closure phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Reclamation	Not Significant
Priority Avifauna									
Construction – Beaver Dam Mine Site and Haul Road (habitat loss from clearing and grubbing)	Limit habitat disturbance and minimize Project footprint during detailed design, implement speed limits and minimize lighting.	L < 5% direct loss of habitat types used by observed species within the LAA Partial mitigation through restoration.	LAA Potential adverse effect to avifauna outside of the PA	A Although clearing and grubbing will occur outside of the sensitive period for avifauna, other activities will not.	MT (Beaver Dam Mine Site) Effects occur beyond 5 years when closure activities commence at Beaver Dam Mine Site. P (Haul Road) Closure of the Haul Road not expected.	O Effects occur once during the construction phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Loss	Not Significant
Construction – Beaver Dam Mine Site and Haul Road (sensory disturbance (noise, light, dust deposition) and wildlife vehicle collisions from construction activities)	Implement speed limits and minimize lighting.	M	LAA Potential adverse effect to avifauna outside of the PA	A VC interaction may affect seasonal aspects of avifauna.	ST Effects are limited to occur from as little as 1 day to 12 months	R Effects occur at regular intervals during the construction phase	R VC will recover to baseline conditions	Disturbance	Not Significant
Operational – Beaver Dam Mine Site, Haul Road and Touquoy Mine Site (disturbance (noise, light, dust deposition and wildlife vehicle collisions) from haul trucks, heavy machinery and mine operations)	Implement speed limits, install fences where necessary, and minimize lighting.	M Moderate changes relative to baseline conditions in remaining and surrounding habitat.	LAA Potential adverse effect to avifauna outside of the PA	A VC interaction may affect seasonal aspects of fauna.	MT Effects may occur up to 5 years.	R Effects occur at regular intervals.	R VC will recover to baseline conditions	Disturbance	Not Significant
Operations – Touquoy Mine Site Tailings deposition	Best management practices, Bird Deterrent Program implementation	L Change in habitat for avifauna	PA VC interaction is confined to the PA.	A VC interaction may occur during sensitive period for avifauna.	LT Effects may extend beyond 5 years	R VC interaction will occur at regular intervals	PR Mitigation cannot guarantee a return to baseline conditions	Creation of potential open water habitat; decreased water quality	Not Significant

Table 9.1-2: Summary of Residual Effects by Valued Component (continued)

Project - VC Interactions	Summary of Mitigation	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Closure (Active) – Beaver Dam Mine Site (re-establishment of habitat for fauna)	N/A	L Minor change from baseline conditions.	LAA Potential effect to avifauna outside of the PA	A VC interaction may affect seasonal aspects of fauna.	LT Effects extend beyond active closure phase.	O Effects occur once during the closure phase.	PR Mitigation and reclamation cannot guarantee a return to baseline conditions.	Habitat Reclamation	Not Significant
MI'KMAQ OF NOVA SCOTIA									
Construction – Beaver Dam Mine Site and Haul Road Direct effect on archaeological resources and burial site	Ensure no Project activities occur outside of PA, education and procedures in place as part of the EPP to halt work and notify the Mi'kmaq if archaeological deposits are encountered.	N No interactions with known archaeological Mi'kmaq resources and burial sites are expected. Identified resources will be avoided	PA VC confined to the mine site	N/A This project interaction is not expected to be affected by timing	ST VC interaction will occur during construction phase	O VC interaction will occur once	IR VC remains at the end of the activity	None	Not Significant
Construction – Beaver Dam Mine Site and Haul Road Direct habitat loss, including wetlands, and loss of plants of significance to the Mi'kmaq	Minimize footprint as per Project design, implementation of mitigation and monitoring as per other VCs to minimize indirect effects, engagement and involvement of the Mi'kmaq throughout Project (including monitoring and compensation)	L Mitigation strategies and best management practices reduce the magnitude of impact	PA VC confined to the mine site	A timing is applicable and clearing and grubbing will be completed outside of the growing season wherever practicable	ST VC interaction will occur during construction phase	O VC interaction will occur once	PR VC remains at the end of the activity	Loss of plant specimens, habitat loss. Reclamation will restore some native plant species but not expected to return to baseline	Not Significant
Construction and Operations – Beaver Dam Mine Site and Haul Road Direct and indirect impacts to fish and fish habitat	Minimize footprint as per Project Design, erosion and sediment control to minimize impact, and water quality treatment, if required. Fisheries Act Authorization and Fish Habitat Offset Plan	L Mitigation strategies and best management practices reduce the magnitude of impact	PA/LAA Direct effect within PA, indirect effect within LAA	A Seasonality (spawning) windows applicable	MT VC interaction will occur during construction, operations and active reclamation	O/S Effects will be once from direct impacts, effects will be sporadic from indirect impacts	IR VC interactions are permanent	Habitat loss, change in water quality/quantity. Positive change in water quality due to historical tailings management	Not Significant
Construction and Operations – Beaver Dam Mine Site and Haul Road Indirect impacts to fauna- loss of habitat; noise and fragmentation	Minimize footprint as per Project Design, utilize existing roads wherever practicable, provision of bypass roads to maintain access.	L Mitigation and best management strategies reduce magnitude of impact	PA/LAA Direct effect within PA, indirect effect within LAA	A Seasonality (breeding windows) applicable	MT VC interaction will occur during construction, operations and active reclamation	R effects will be regular from indirect impacts	PR Traffic will reduce on roads once operations cease	Habitat loss, potential changes in species movement patterns	Not Significant
Construction and Operations – Beaver Dam Mine Site and Haul Road Predicted noise and air potential interaction with traditional practices surrounding the Project	Utilize berms and other mitigation where required to reduce noise levels to minimize indirect impact to Mi'kmaq; share noise study results and involve Mi'kmaq in data collection. Use of chemical dust suppressants on Haul Road to ensure 80% dust control.	L noise and dust levels predicted to be elevated above background but in compliance at the property boundaries,	LAA Noise will potentially affect wildlife patterns in close proximity to the Mine (LAA)	N/A This project interaction is not expected to be affected by timing	MT VC interaction will occur during construction, operations and active reclamation (2-3 yrs) phases of the Project	R VC interaction will occur at regular intervals throughout the Project	R VC interaction will recover to baseline after Project activities are completed	Sensory Disturbance	Not Significant
Construction and Operations – Beaver Dam Mine Site and Haul Road Predicted Light levels and potential interaction with traditional practices surrounding the Project	Maintenance of forested canopy wherever practicable within the Project property boundaries. Limit unnecessary lighting at Beaver Dam Mine Site; utilization of potential green energy options	L Light levels are predicted to meet guidelines at residences. Elevated light levels above background will be present up to 2 km from the Mine	LAA light from the Beaver Dam Mine Site is predicted to extend into the LAA	A Timing is applicable as visual effect is adjusted based on foliage on trees	MT VC interaction will occur during construction, operations and active reclamation (2-3 yrs) phases of the Project	R VC interaction will occur at regular intervals throughout the Project	R VC interaction will recover to baseline after Project activities are completed	Sensory Disturbance	Not Significant
Construction, Operations and Closure, Beaver Dam Mine Site and Haul Road Potential impact to human health from the Project	Implement mitigation and monitoring measures identified for each VC for the life of the Project as required	L Adverse health effects from dust exposure, the consumption of country foods harvested from the vicinity of the Mine Site, and recreational water use are not anticipated.	LAA This project interactions resulting in potential health effects extend into the LAA	N/A This project interaction is not expected to be affected by timing	MT VC interaction will occur during construction, operations and active reclamation (2-3 yrs) phases of the Project	R VC interaction will occur at regular intervals throughout the Project	R VC interaction will recover to baseline after Project activities are completed	Human Health	Not Significant

Table 9.1-2: Summary of Residual Effects by Valued Component (continued)

Project - VC Interactions	Summary of Mitigation	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction, Operations and Closure, Beaver Dam Mine Site and Haul Road Potential impact to the economic, social and mental well being of the Mi'kmaq of Nova Scotia from the Project	Continue discussions with the Mi'kmaq to determine appropriate mitigation and compensation requirements, where appropriate. Proposed multi-use bypass road. Potentially suitable alternative tracts of Crown land are available surrounding the Beaver Dam Mine Site and Haul Road. Mi'kmaq participation in monitoring programs and development of Reclamation and Closure Plan for the Project.	L	LAA	A	MT VC interaction will occur during construction, operations and active reclamation (2-3 yrs) phases of the Project	C	PR	Change in economic, social and mental well being of the Mi'kmaq of Nova Scotia	Not Significant
Construction, Operations and Closure – Beaver Dam Mine Site and Haul Road Restriction and loss of access for traditional practice during construction, operations and active reclamation of the Mine	Continue discussions with the Mi'kmaq to determine appropriate mitigation and compensation requirements, where appropriate. Proposed multi-use bypass road. Potentially suitable alternative tracts of crown land are available surrounding the Beaver Dam Mine Site and Haul Road	L Mitigation strategies and best management practices reduce the magnitude of impact	LAA Access restriction is confined to PA; hunting effects may be felt within LAA due to sensory disturbance and/or firearm restrictions	N/A This project interaction is not expected to be affected by timing	MT VC interaction will occur during construction, operations and active reclamation (2-3 yrs) phases of the Project	R VC interaction will occur regularly	R VC returns to baseline conditions at the end of the activity	Loss of Access	Not Significant
Construction, Operations and Closure – Beaver Dam Mine Site and Haul Road Development of Project	Continue confidential discussions with the Mi'kmaq of Nova Scotia (parallel to the federal environmental assessment) to identify employment, community and economic benefits.	L Considerable and tangible opportunities for Mi'kmaq communities	RAA Opportunities can be considered across the RAA	N/A This project interaction is not expected to be affected by timing	MT to LT Opportunities will extend past operational period into reclamation and post closure.	C There are continuous opportunities throughout all project phases.	R VC returns to baseline conditions at the end of the activity	Benefits to the Mi'kmaq of Nova Scotia	Not Significant
PHYSICAL AND CULTURAL HERITAGE									
Construction – Beaver Dam Mine Site and Haul Road (Identification and/or damage to physical and cultural heritage resources – Site 6 and Areas 2 and 3)	Evaluate changes to layout for potential impacts to archaeological resources. Complete intensified historical research, additional shovel pit testing, where required, and detailed documentation at archeological features prior to disturbance cause by Project activities, in conjunction with Mi'kmaq agencies as required. Contact Coordinator of Special Places, Nova Scotia Communities, Culture, & Heritage Department if human remains or archaeological deposits are identified.	L Site 6 will be lost due to Project activities. This site contains the remains of a twentieth century structure. Impacts to Areas 2 and 3 will be minimized where practicable. These areas underwent additional shovel tests in fall 2020 and were cleared of further investigation.	PA Effects confined to the PA.	N/A VC is not expected to be affected by timing.	P Effects are permanent.	O Effects will occur once within the life of the Project.	IR VC will not return to baseline conditions.	Loss of resource	Not significant

Notes: See each Valued Components Thresholds for Determination subsections for specific for magnitude criteria definitions (Section 6) and Section 5.11, Table 5.11-1 for general definitions of the below characteristics.

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	IR	Irreversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	PR	Partially Reversible
H	High					P	Permanent	C	Continuous		

Table 9.1-3: Summary of Residual Effects for Socio-economic Conditions

Theme Areas	Topics within Theme Area	Linkages to other Plans and Guiding Documents	Pathway	Mitigation	Direction	Magnitude	Duration	Geographical Extent	Reversibility	Frequency	Residual Effect
Workforce Development	Training Opportunities	One NS Goal, Atlantic Growth Strategy	Apprenticeship training program and internal training opportunities provide opportunities for certifications and training.	N/A	Positive	L	Short Term	RAA	N/A	C	Insignificant
	Opportunities for Advancement within career	One NS Goal	Internal hiring and opportunities for graduates provided by AMNS employment opportunities, support career advancement.	N/A	Positive	L	Short Term	RAA	N/A	C	Insignificant
	New employment - direct and indirect	One NS Goal, Atlantic Growth Strategy	Beaver Dam will provide new employment opportunities, both through direct and indirect sources.	N/A	Positive	H	Short Term	LAA	N/A	C	Significant
	Labour Force attachment	One NS Goal	New high quality employment opportunities provide opportunities for working age people to attached to the labour force.	N/A	Positive	L	Short Term	RAA	N/A	C	Insignificant
	Impact on Educational Attainment	One NS Goal, Atlantic Growth Strategy; SDG	Apprenticeship training program supports educational attainment and providing opportunity for graduates of both NSCC and university programs.	N/A	Positive	N	Short Term	RAA	N/A	C	Insignificant
	Youth Employment Rate	One NS Goal; Halifax Partnership	Employment opportunities for young people (under 30) through both direct and indirect sources.	N/A	Positive	N	Short Term	RAA	N/A	C	Insignificant
	Suppliers	Halifax Partnership, One NS Goal	There will be need for suppliers from the local areas to provide supports, which may impact the suppliers labour needs.	N/A	Positive	M	Short Term	RAA	N/A	C	Significant
	Labour Force Attachment - Indigenous	One NS Goal; Halifax Partnership; KMKNO Pillars	MOU and IBA provide support to Mi'kmaq lead employment programs.	N/A	Positive	N	Short Term	RAA	N/A	C	Insignificant
Demographics	In-Migration	Halifax Partnership, One NS Goal, Atlantic Growth Strategy	New employment opportunities may attract new residents to the province.	N/A	Positive	N	Short Term	LAA	N/A	C	Insignificant
	Rural Re-Population	Halifax Partnership, One NS Goal	New employment opportunities may attract new residents to the LOA supporting communities that are seeing population declines.	Monitoring of population growth related to mine operations	Positive	N	Short Term	LAA	N/A	C	Insignificant
Healthy Communities	Hospitals	SDG	With new populations and industry, local hospital usage may increase.	N/A	Negative	N	Short Term	LAA	R	C	Insignificant
	Family Doctor Availability	SDG	New resident may impact family doctor availability.	N/A	Negative	N	Short Term	LAA	R	C	Insignificant
	Seniors Supports	SDG	Through Community investment AMNS has made and plans to continue to make investments to seniors related initiatives.	N/A	Positive	N	Short Term	LAA	R	I	Insignificant
	Schools	SDG	If rural re-population occurs, there may be an increase in school populations.	N/A	Positive	N	Short Term	LAA	R	C	Insignificant
	Recreational Facilities		Potential increase of recreational facilities or support for new recreation facilities planned for the area.	N/A	Positive	N	Short Term	LAA	R	I	Insignificant
	Housing	SDG	Impact on housing availability requires further study and is market dependent	Monitoring of population increase on housing market		U	Short Term	LAA	R		
	Climate Change and Energy	SDG					Short Term				
	Local Taxation	Once Nova Scotia	Direct and indirect benefits to the local, provincial and federal governments.	N/A	Positive	L	Short Term	LAA	R	C	Insignificant

Theme Areas	Topics within Theme Area	Linkages to other Plans and Guiding Documents	Pathway	Mitigation	Direction	Magnitude	Duration	Geographical Extent	Reversibility	Frequency	Residual Effect
Land Use, Recreational	Snowmobiling and ATV Use	Halifax Partnership	Support and upgrades to existing and proposes off-road trail systems and potential partnership opportunities.	Construction of bypass roads.	Positive	N	Long Term	LAA	R	C	Significant
	Active Transportation	HRM Policies	Increased traffic on public roads in limited locations may create concerns about walking and biking safety.	Construction of bypass roads	Negative	N	Long Term	LAA	R	C	Significant
	Access to Camps		With the construction of a haul road, access to camps will be maintained or possibly improved.	Construction of bypass roads	Positive	N	Long Term	LAA	R	C	Significant
	Haul Road Safety		The existing haul road will have increase operational safety parameters which will improve the safety on the road by separating heavy traffic from recreational users, small vehicles and non motorized usage.	Construction of bypass roads	Positive	N	Short Term	LAA	R	C	Significant
	Noise		See section on noise.	See Chapter ???					R		
	Hunting and Fishing	Halifax Partnership	The haul road and mine site may impact hunting by altering migration patterns and by reducing hunting opportunities near the mine site and haul road, as required by the relevant act. Access to fishing areas will be improved, potentially leading to increased recreational fishing.	Construction of bypass roads	Negative	L	Short Term	LAA	R	C	Significant
Parks and Open Space, Tourism	Protected Areas and Wilderness Areas	Halifax Partnership	No impact.	N/A	Neutral	N	Short term	LAA	N/A	N/A	Insignificant
	Local Community Sites	SDG	No impact.	Protection of Date Rock	Neutral	N	Short Term	LAA	R	C	Insignificant
	Tourism Opportunities	Halifax Partnership, One NS Goal	Potential for increased attraction to the area to view mining related activities.	N/A	Positive	N	Short Term	LAA	N/A	N/A	Insignificant
	Regional Visitation	Halifax Partnership, One NS Goal	No anticipated impact.	N/A	Neutral	N	Short Term	LAA	N/A	N/A	Insignificant
Roads and Traffic	Traffic Impact		Increased traffic on public roads in limited locations may create concerns about walking and biking safety.	Access and Safety Plan	Negative	M	Short Term	LAA	R	C	Insignificant
	Road Infrastructure		Potential for improvements to public roads to address increased usage by proponent. Increased usage may result in negative impacts or degradation of public road infrastructure.	Insert language about paying for paving.	Negative and Positive	M	Long Term	LAA	R	C	Insignificant
	Private Road Infrastructure		Private road will be improved to a high standard, which will be left in place after mine operations cease.	N/A	Positive	N	Long Term	LAA	R	C	Insignificant
	Public Road Crossings		Improvements to road crossings at the haul road and highway 224.	Install crossings to allow access to other lands	Positive	N	Permanent	LAA	R	C	Insignificant
	Pedestrian Safety		Increased traffic on public roads in limited locations may create concerns about walking and biking safety.	Access and Safety Plan	Negative	N	Short Term	LAA	R	C	Insignificant
Impact on Government Revenues	Provincial Taxation and Benefits	One Nova Scotia	Direct and indirect taxation benefits to the province.	N/A	Positive	L	Short Term	RAA	R	C	Insignificant
	Federal Taxation and Benefits	Atlantic Growth Strategy	Direct and indirect taxation benefits to the province.	N/A	Positive	L	Short Term	RAA	R	C	Insignificant

Notes: Section 6.16.12, Table 6.16-27 for specific Socio-economic Conditions residual effects and significance rating criteria and Section 5.11, Table 5.11-1 for general definitions of the below characteristics.

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	LAA	Local Assessment Area	N/A	Not Applicable	ST	Short-Term – within life	O	Once	R	Reversible
L	Low	RAA	Regional Assessment Area	A	Applicable	LT	Long-Term Beyond life	I	Intermittent	IR	Irreversible
M	Moderate					P	Permanent	R	Regular		
H	High							C	Continuous		

Table 9.1-4: Summary of Residual Cumulative Effects by Valued Component

Residual Adverse Cumulative Effects (After Mitigation and Compensation if required)	Significance Levels						Overall Significance of Residual Adverse Effects and Rationale
	Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility	
NOISE							
Cumulative increased noise levels (Noise from construction, operation, reclamation, and operation of mining, haul trucks, forestry activities and haul road usage)	L Noise levels are expected to be less than or equal to appropriate guidelines or threshold values at the Beaver Dam Mine Site and Haul Road property boundary. Additive cumulative effects may occur when forestry operations occasionally coincide with Project activities and hauling ore from FMS and Cochrane Hill to Touquoy Mine Site for processing	LAA The cumulative effects causing increased background noise levels will not extend beyond the LAA.	A VC is expected to be affected by timing, with sporadic nature of timber harvesting.	LT Effects may extend beyond 8 years.	R Additive periods of potential effects from the Project and forestry operations are likely to be limited in frequency. However, cumulative effects to baseline noise levels from the use of the Beaver Dam Haul Road by Beaver Dam, Fifteen Mile Stream and Cochrane Hill Gold Projects will occur regularly throughout the operational phase of the Project.	R VC will recover to baseline conditions once operations have stopped.	Low Adverse Effect (Not Significant) Effects are limited to the LAA based on Project interactions and usage of the Beaver Dam Haul Road by various activities. Furthermore, the VC is anticipated to recover to baseline conditions once the operation of the mine has stopped. Effects would be confirmed through monitoring.
AIR							
Increased cumulative dust during operation of the Project (Dust from mining and haul trucks)	M Possible exceedance of guidelines or threshold values when forestry operations occasionally coincide with hauling from the Project to the Touquoy Processing Facility along with ore or concentrate from Fifteen Mile Stream and Cochrane Hill Projects.	LAA The cumulative effects causing increased background air concentrations will not extend beyond the LAA.	A VC will be affected by timing – drier periods will increase fugitive dust emissions relative to wetter times of the year.	LT Effects may extend beyond 7 years.	R Additive periods of potential effects from the Project and forestry operations are likely to be limited in frequency. However, cumulative effects to ambient dust levels from the use of the Beaver Dam Haul Road by the Project, the Fifteen Mile and Cochrane Hill Gold Projects will occur regularly throughout the operational phase of the Project.	R VC will recover to baseline conditions once operations have stopped.	Moderate Adverse Effect (Not Significant) Effects are limited to the LAA where there are limited sensitive receptors, and the use of the Beaver Dam Haul Road. Furthermore, the VC is anticipated to recover to baseline conditions once the operation Project has been completed. Effects would be confirmed through monitoring.
LIGHT							
Increased light levels during operation of the Project (operational light levels and light from transportation of gold concentrate and use of the Beaver Dam Haul Road by other projects)	L Less than or equal to appropriate guidelines or threshold values.	LAA The cumulative effects causing increased background light concentrations will not extend beyond the LAA. Exception to this is the cumulative light along the Beaver Dam Haul Road which is outside of the Project LAA but described herein.	N/A VC is not expected to be affected by timing.	LT Effects may extend beyond 8 years.	R Additive periods of potential effects from the Project and forestry operations are likely to be limited in frequency. However, cumulative effects to ambient light levels from the use of the Beaver Dam Haul Road Use by Fifteen Mile Stream and Cochrane Hill Gold Projects will occur regularly throughout the operational phase of the Project.	R VC will recover to baseline conditions once operations have stopped.	Low Adverse Effect (Not Significant) Effects are limited to the LAA where there are limited sensitive receptors, and the use of the Beaver Dam Haul Road. Furthermore, the VC is anticipated to recover to baseline conditions once the operation of the Beaver Dam Mine SIte has been completed.
SURFACE WATER							
Potential for residual cumulative effects to all surface water systems within each RAA (Touquoy Mine Site and Beaver Dam Mine Site).	L With mitigation strategies, predicted receiver concentrations are predicted to be greater than guidelines and increase by greater than 10% over baseline levels, but remains well within the observed range of natural variation (25th to 75th percentile baseline water quality).	LAA Cumulative effects are confined to the LAA.	A Cumulative effect would be more significant during low flow conditions and/or sensitive spawning windows.	LT Effects may extend beyond 7 years.	R Effects will occur at regular intervals throughout operations.	PR Mitigation cannot guarantee a return to baseline conditions.	Minor Adverse Effect (Not Significant) Given implementation of proposed mitigation methods, no significant adverse cumulative effect is expected.
FISH AND FISH HABITAT							
Cumulative disturbance to fish and fish habitat within the RAA.	L Differing from the existing environment/ baseline conditions, within natural variation	LAA Potential adverse cumulative effect to fish habitat outside of the PA.	A Cumulative effect would be more significant during sensitive spawning windows.	P Effect is expected to be permanent.	C Effects will occur on a continuous basis throughout operations and closure.	IR Effects of flow reduction and direct impacts from Haul road crossings are expected to be irreversible.	Low Adverse Effect (Not Significant) Fish habitat offsetting is anticipated to compensate for lost fish habitat from the Project itself. No other pathway for residual effects from surrounding projects has been identified.

Table 9.1-4: Summary of Residual Cumulative Effects by Valued Component (continued)

Residual Adverse Cumulative Effects (After Mitigation and Compensation if required)	Significance Levels						Overall Significance of Residual Adverse Effects and Rationale
	Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility	
SPECIES OF CONSERVATION INTEREST AND SPECIES AT RISK							
Cumulative loss, alteration and the disturbance of habitats throughout the RAA relating to SOCI and SAR.	L The maximum cumulative Project edge effect will affect 512 ha of interior forest habitat in consideration of the Beaver Dam and FMS Projects, which accounts for 0.7% of predicted interior forest in the RAA. There is limited additional development pressures from other projects in the RAA, as demonstrated by the few projects identified within this evaluation.	RAA Loss of habitat used by priority species has occurred on a regional scale.	A Cumulative effect would be more significant during sensitive period for each priority species.	LT Effects may extend beyond 7 years.	S The loss of habitat associated with the Beaver Dam Mine Site will occur once. However, the potential future loss of habitat associated with the Beaver Dam Project and other regional projects in the future could occur throughout the lifetime of the Project.	PR Reclamation cannot guarantee a return to baseline conditions.	Low Adverse Effect (Not Significant) The small proportion of regional habitat that supports priority species that would be lost as a result of this Project will be restored during the reclamation stage of Closure Phase. There is limited additional development pressure from projects in the RAA.
MI'KMAQ OF NOVA SCOTIA							
Effects to Mi'kmaq of Nova Scotia and their traditional land use as a result from impacts to air quality, noise, light, surface water, fish habitat, and human health, and cumulative limitations to land use for traditional purposes from multiple projects within the RAA.	L Mitigation and best management strategies reduce magnitude of impact. The loss of access to a maximum area of 6,282 ha from all identified projects in the RAA accounts for 0.64% of all land within the RAA, and 0.88% of available crown land within the RAA.	LAA Direct cumulative effects within PA, indirect cumulative effects within LAA. BD Haul Road cumulative effects within LAA for BD Haul Road.	A Seasonal windows applicable. Air dispersion affected by season and wind direction, noise and light effects will be limited by foliage when present on trees, effects to fish and fish habitat are more sensitive during spawning windows (spring and fall).	LT Effects will extend beyond 8+ years – will extend to eight years of limited access to the Beaver Dam Mine Site, less than the defined 20 years in the context of the Mi'kmaq of Nova Scotia VC significant threshold.	R VC interaction will occur regularly.	R VC interaction will recover to baseline after Project activities are completed.	Moderate Adverse Effect (Not Significant) Assuming that the proposed compensation measures are applied for the Project and that they achieve their objectives, the predicted residual cumulative effects on the Mi'kmaq of Nova Scotia with regards to impacts to air quality, noise, light, surface water, fish habitat, and human health, are assessed to be adverse, but not significant. Loss of access is limited to 0.88% of available crown land within the RAA.

Legend (refer to Section 5.11, Table 5.11-1 for definitions)

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible

Table 9.2-1: Summary of Atlantic Mining NS Inc. Beaver Dam Mine Project General Commitments

Project Phase	General Commitments	EIS Section
Pre-construction	The Proponent will voluntarily establish an Independent Tailings Review Board for design, construction and operational phases of project infrastructure including the TMF.	Section 1 Introduction
Pre-construction	The Proponent intends to maintain adequate insurance and bonding to ensure its commitments are met. This includes maintaining financial bonding to ensure that adequate reclamation security is in place at all times during the construction, development and operational phases of the mining projects, as well as appropriate environmental impairment liability insurance.	Section 1 Introduction
Pre-construction	The Proponent commits to completing its operations in adherence with best available practices (BAPs) and industry standards as per guides developed by Mining Association of Canada, such as the Towards Sustainable Mining initiative, and the Canadian Dam Association.	Section 1 Introduction
On-going	The Proponent is committed to maintaining its CLC for the life of the Project.	Section 3 Public Engagement
On-going	The Proponent is committed to developing a long-term, positive and productive relationship with the Mi'kmaq of Nova Scotia based on principles of mutual respect, transparency, honesty and integrity, and a partnership approach to engagement.	Section 4 Indigenous Peoples Engagement
Construction and Operation to plan for Closure	Commitment to reclamation with Mi'kmaq participation in planning and implementation to restore habitats and allow traditional practices to resume within the Mine Site.	Section 4 Indigenous Peoples Engagement
Construction	The Proponent is committed to removing the historical tailings that may be disturbed as a part of site construction and operation. This tailings removal will be conducted during the construction phase.	Section 6.6 Groundwater Quality and Quantity
Construction (baseline EEM work was initiated in 2020)	Preparation of an Environmental Effects Monitoring Program in conjunction with submission of the Provincial Industrial Approval and the Metal and Diamond Mining Effluent Regulations	Section 6.7 Surface Water Section 6.9 Fish and Fish Habitat
Pre-construction (during permitting)	Development of a Seloam Brook Realignment Construction Plan in conjunction with submission of the Provincial Industrial Approval and Fisheries Act Authorization	Section 6.7 Surface Water
Construction, Operation, Closure	There will be a modular effluent treatment plant present on site during the construction phase and this system can be adapted and utilized throughout the life of mine, as required based on site effluent quality.	Section 6.7 Surface Water
Pre-construction (during permitting)	Development of Detailed Design for Seloam Brook Realignment and associated downstream water control structures and a Fish Rescue Plan to support the Fisheries Act Authorization. This detailed design will be developed through engagement with the Mi'kmaq of Nova Scotia and through consultation with DFO and IAAC.	Section 6.7 Surface Water Section 6.9 Fish and Fish Habitat
Pre-construction	Development of a Bird Nest Mitigation Plan if clearing and grubbing is required within the approved breeding bird timing window	Section 6.12 Avifauna Section 6.13 SAR/SOCI
Pre-construction (on-going)	On-going refinement of a communication protocol which will describe how the Proponent will communicate with the Mi'kmaq of Nova Scotia during ongoing exploration and operational phases of the projects, and in the event of a release or spill of a hazardous substance	Section 6.13 Mi'kmaq of Nova Scotia

Table 9.2-1: Summary of Atlantic Mining NS Inc. Beaver Dam Mine Project General Commitments (continued)

Project Phase	General Commitments	EIS Section
On-going	The Proponent is committed to ongoing Mi'kmaq engagement and participation for the life the Project – prior to, during and post environmental assessment. This includes communication and information sharing, face-to-face meetings, discussion of impacts and mitigations, and any other issues that may arise as the Project develops.	Section 4 Indigenous Peoples Engagement Section 6.14 Mi'kmaq of Nova Scotia
On-going	The Proponent will continue to work with the Mi'kmaq of Nova Scotia to provide specificity in analysis, where possible, to support comprehensive conclusions of Project impacts and to support mitigation and accommodation opportunities.	Section 6.14 Mi'kmaq of Nova Scotia
On-going and Pre-construction	The results of Mi'kmaq engagement have been considered and incorporated in the environmental effects assessment and are reflected in the Proponent's commitments to involve the Mi'kmaq in the development and implementation of mitigation and monitoring measures and proposed compliance and effects monitoring programs.	Section 6.14 Mi'kmaq of Nova Scotia
Pre-construction	Develop potential partnerships with Mi'kmaq environmental groups on specific ecological monitoring and restoration projects.	Section 6.14 Mi'kmaq of Nova Scotia
Construction	Development of a Dam Breach Inundation Study for incorporation into an Emergency Response Plan.	Section 6.18 Accidents and Malfunctions
Construction, Operation	Development of an Operation, Monitoring and Surveillance Manual (OMS) which provides a documented framework for actions, and a basis for measuring performance and demonstrating due diligence during the operational phase of the Project.	Section 6.18 Accidents and Malfunctions
Pre-construction	Development of the Environmental Management System (EMS) and all associated management and monitoring plans.	Section 10.1 Environmental Management System (EMS)

10 FOLLOW-UP AND MONITORING PROGRAMS PROPOSED

10.1 Environmental Follow-Up Program

AMNS understands that monitoring is a mechanism to gauge Project performance and measure against baseline conditions and effects as predicted in the EIS, as well as expectations of regulators, the public, the Mi'kmaq of Nova Scotia and interested parties. Results of programs will be documented and where appropriate, summaries of compliance and effects monitoring programs will be available via stakeholder and Mi'kmaq engagement mechanisms, such as CLC and other ad-hoc groups as defined in the draft Public Engagement Plan (Appendix A.6).

The CLC is one of the primary opportunities for AMNS to include the participation of the local community, including First Nations communities wherever possible, during development and implementation of the Project. Beyond the CLC, AMNS will engage with local community groups and the Mi'kmaq of Nova Scotia, as well as sharing information with the pubic as defined in the draft Engagement Plan (Appendix A.6). AMNS recognizes the inherent value in an open and flexible approach to engagement and monitoring. The Proponent views engagement and monitoring programs as dynamic and not static, such as collection of data, review of data, and refinement of programs, as well as mechanisms to share the results of programs. AMNS's approach to engagement is presented in Sections 3 and 4 of the EIS as well as the draft Public Engagement Plan (Appendix A.6).

Select VCs may be monitored, as defined in the EIS, before the start of construction. These monitoring programs will be undertaken to further design and guide mitigation measures as well as defining sampling program components, locations, frequency, and parameters related to the MDMER program and other related permitting, such as those required for wetland and watercourse alterations.

The results of follow-up monitoring programs will be provided to regulators as per the conditions of the EIS and other approvals and permits. The CLC and other interested stakeholders will be informed of the results of the follow-up programs and will be involved in the planning and implementation of these programs, where deemed appropriate and as defined in the draft Engagement Plan (Appendix A.6).

Monitoring results will be documented and reported in a format specified in approvals and permits.

10.2 Environmental Monitoring Plans

AMNS recognizes that the responsibility for all monitoring programs and mitigation commitments ultimately rest with the company. Many aspects of monitoring and mitigation that will occur during all phases of the Project (i.e., construction, operation, closure.) may be conducted through a sub contract but AMNS ultimately has responsibility for implementing mitigation and monitoring strategies committed to in the Updated 2021 EIS and for items added by regulators.

Proposed monitoring programs for the Project in the environmental follow-up program include noise, air, sediment, groundwater, surface water, wetlands, fish and fish habitat, habitat and flora, birds, and SAR and SOCI. The Proponent is commits to the involvement of the Mi'kmaq and in particular Millbrook First Nations in the development of monitoring programs for the Project.

The follow-up monitoring programs may be implemented up to one year prior to the start of construction; however, details of these programs will be determined following discussions with regulators. Preconstruction monitoring will be completed based on seasonality as required (e.g., breeding seasons, winter track surveys, vegetation surveys, etc.).

AMNS also recognizes that there may be additional requirements identified in approvals, such as the Industrial Approval that would be applied for from the Province of Nova Scotia through Part V – Approvals. Monitoring reports will be completed at a frequency determined by NSE. This is anticipated to be annual based on the existing IA for the Touquoy Gold Project. The regulatory agencies will provide guidelines for preparing monitoring reports, such as the number, content, frequency, and format.

Operational practices and compliance programs will be routinely reviewed based on monitoring results and will be adaptively managed based on discussions with regulators, stakeholders, public and Mi'kmaq and in particular Millbrook First Nations, as necessary.

Table 10.1-1: Beaver Dam Mine Project Monitoring Commitments

Valued Component	General Monitoring Commitments	Detailed Monitoring Commitments (if applicable)	Corresponding EIS Section Number
Noise	At the Touquoy Mine Site and Beaver Dam Mine Project, noise monitoring will be undertaken throughout the operation of the facility if any complaints or concerns are received.	No noise monitoring is required since the nearest residence is approximately 5 km south of the BDM Mine Site. However, some noise monitoring at site may be undertaken to determine appropriate noise mitigation.	Section 6.1.4.2
	Further assessment of baseline monitoring before construction, during construction, and during mining operations will be conducted to ensure impacts are below the Nova Scotia Environment (NSE) guidelines and the Health Canada noise guidance which allows for an incremental increase in the percentage of highly annoyed population in the community to remain below 6.5 percent at sensitive receptors.		Section 6.1.7.4.1
	Additional noise monitoring could be undertaken in the future if required as part of the Industrial Approval process.		Section 6.1.7.4.1
	Noise monitoring would be completed during each blasting event, as required by the Nova Scotia Environment and Labour (NSEL) Pit and Quarry Guidelines (NSEL 1999). Blast monitoring generally involves noise and vibration monitoring during each blasting event and includes monitoring at the nearest residence to the Beaver Dam Mine Site, which in this case would be at Beaver Lake IR 17.		Section 6.1.8
	Noise monitoring will be completed as directed by regulators or as a result of a complaint or engagement.		
Air	Ongoing monitoring of air pollutants will determine compliance with these standards, and any exceedance or complaint by the general public and/or Mi'kmaq o Nova Scotia and in particular Millbrook First Nations, will be discussed with regulators and/or the Citizen Liaison Committee (CLC), and mitigation programs and operational practices will be reviewed to determine the appropriate course of action.	Air Monitoring Program will be established as directed by NSE. AMNS will implement a Fugitive Dust Monitoring Program A draft Engagement Plan (Appendix A.6) has been developed to help guide engagement over the life of the Project	Section 6.2.10 Appendix A.6
Light	No additional monitoring is recommended. Additional ambient light monitoring would occur if directed by regulators or as a result of a complaint.		Sections 6.3.8, 6.3.10
Greenhouse Gases (GHGs)	Facilities with emissions falling below the reporting threshold of 50 kilotonnes (kt) per year can voluntarily report their GHG emissions. Atlantic Mining NS Inc. (AMNS) voluntarily reports GHG at the Touquoy Mine and will continue to do so should Beaver Mine Project be approved.		Section 6.4.4.1
	AMNS will continue to evaluate opportunities at the sites to reduce GHG emissions at their existing and proposed operations.		Section 6.4.5
	GHG emissions will be reviewed on an annual basis throughout the operation of the Touquoy processing facility.		Section 6.4.10
Geology, Soils, and Sediment	Construction techniques, erosion and sediment control measures, and a sediment monitoring program for the receiving environment is described in the draft Erosion and Sediment Control Plan that will be finalized and submitted as part of Industrial Approval Application process. .		Appendix C of Water Management Plan (Appendix P.4)

Table 10.1-1: Beaver Dam Mine Project Monitoring Commitments (continued)

Valued Component	General Monitoring Commitments	Detailed Monitoring Commitments (if applicable)	Corresponding EIS Section Number
	Monitoring will be undertaken to continue to define Historic Tailings Management. A draft Historic Tailings and Waste Rock Management Plan (Appendix has been drafted and will be finalized as part of the Industrial Approval Process.	Delineation and subsequent management of historical tailings and waste rock (soil and sediment) that is located within the footprint of Project infrastructure	Appendix E.9
	A draft Beaver Dam Project - ML/ARD Assessment Report (Appendix E.2) will continue to assess geochemical source terms and determine PAG. The assessment monitoring report will be finalized as part of the Industrial Approval process.	Operational Geochemical Testing Program: confirmatory testing of open pit blast hole drill cuttings to confirm geochemical predictions of mine rock at a frequency to be determined by the Project geochemists, geologists, and with consideration of available NRCAN and comparable guidance documents.	Appendix E.2
		Geochemical source term predictions heavily rely on theoretical constraints, representative geochemical test work, and the availability of site analogue data. To close data gaps that would increase the confidence in the geochemical source term predictions for future model iterations, the following recommendations are made	Appendix E.2
Groundwater	A draft Groundwater Monitoring Program has been developed (Appendix G of Water Management Plan P.4) that described monitoring that will continue during baseline/pre-construction, construction and through the closure phase to validate the predictions presented in the Groundwater Quality and Quantity Effects Assessment (Section 6.6).	The Groundwater Monitoring Program will form part of a broader Aquatic Effects Monitoring Program (AEMP) that will address interactions among VCs (e.g, surface water, fish and fish habitat).	Section 6.6.10 Appendix G of Water Management Plan (Appendix P.4)
	A groundwater monitoring program will be developed in association with requirements of wetland and watercourse alteration permits issued for direct wetland and watercourse alterations associated with the Project.		
Surface Water	A preliminary monitoring plan has been prepared as part of the Mine Water Management Plan (MWMP) Section 8. This monitoring plan outlines the proposed monitoring commitments for water quality and quantity from baseline conditions through construction, operation, and closure. A total of 16 surface water assessment sites during the construction stage have been selected for continued monitoring at the Beaver Dam Mine for either quality, quantity, or both. Their locations and monitored metrics are shown on Figure 8-1 of the MWMP. total of 19 surface water assessment sites during the operation and 17 during PC have been proposed for continued monitoring at Beaver Dam for either quality, quantity or both. Their proposed locations and monitored metrics are shown on Figure 8-2 and Figure 8-3 respectively. Surface Water Monitoring will form part of part of a broader Aquatic Effects Monitoring Program (AEMP) that will address interactions among VCs a		Mine Water Management Plan (Appendix P.4)
Wetlands	A Preliminary Wetland Monitoring Plan has been prepared for the EIS. A detailed Wetland Monitoring Plan will be established to support the Industrial Approval application, through the life cycle of the permitting process and will commit to monitoring during baseline/pre-construction to establish baseline conditions, and through the operational phase, closure and post closure (as determined to be required). Wetland monitoring will be completed for the Project on selected representative wetlands that have been predicted to have direct or indirect effects from Project development.		6.8.10, Preliminary Wetland Monitoring Plan (Appendix H.3)

Table 10.1-1: Beaver Dam Mine Project Monitoring Commitments (continued)

Valued Component	General Monitoring Commitments	Detailed Monitoring Commitments (if applicable)	Corresponding EIS Section Number
Fish and Fish Habitat	Monitoring of standard mitigations described above will be supported by the Mine Water management Plan (MWMP) and Aquatic Effects Monitoring Program (AEMP). The AEMP will monitor all aquatic ecosystems where Project effects are predicted to validate impact predictions as well as to identify adaptive management measures that may be required during construction, operations, and closure. The scope of the AEMP involves monitoring of water quality, water quantity, sediment quality, periphyton, benthic invertebrates, fish habitat and community, and fish health and fish tissue. The AEMP describes the proposed sampling frequency, schedule and intensity, as well as identified significance thresholds, action levels and suggested responses should significant thresholds be exceeded. The AEMP also provides a proposed reporting schedule to federal and provincial regulators. Complete offsetting for HADD including the finalization of an Offsetting Plan, for permanent loss of fish habitat through fish habitat restoration activities, subject to DFO approval, as required under the *Fisheries Act*. Monitoring will clearly be defined in the final Offset Plan, in consultation with DFO.		6.9.8.2, 6.9.8.3, 6.9.10, Appendix J.3 (Fish and Fish Habitat Baseline), AEMP to be provide prior to permitting stage
Habitat and Flora	No specific monitoring recommended. See SAR/SOCI monitoring recommendations.		6.10.10
Fauna	The Wildlife Management Plan (WMP) outlines protocols to minimize interactions between wildlife and Project activities. As part of the WMP, a Mainland Moose Management Plan (MMMP) will be developed and will commit to monitoring mainland moose during baseline/pre-construction to establish baseline conditions, and through the operational phase, closure, and post-closure (as determined to be required). Monitoring associated with the MMMP will be completed for the Project on selected transects within suitable mainland moose habitat and will be consistent with methods presented in the EIS, described in detail in Section 6.11.		6.11.9, 6.11.11, Wildlife Management Plan (Appendix P.7)
Avifauna	Conduct routine inspections for avifauna during construction, operation and active closure activities as directed by regulators. See SAR/SOCI monitoring recommendations.	Avoid construction on native vegetation during the regional breeding season for migratory avifauna where practicable (beginning of April to end of August for migratory avifauna; ECCC 2015). Where this is not practicable, an avifauna nest mitigation plan will be developed.	6.12.10, 6.12.11
Species at Risk and Species of Conservation Interest	Specific plans have been developed for SAR/SOCI, as part of or in addition to those outlined in Fish and Fish Habitat, Fauna, Avifauna and Habitat and Flora. Permitting may be required for Species at Risk, and additional monitoring requirements will be determined during permitting, in consultation with NSL&F.	Preliminary Wetland Compensation Plan includes proposed SAR conservation allowances WMP includes Mainland Moose Management Plan (MMMP) Lichen Monitoring Plan Landbird SAR Mitigation and Monitoring Plan Conceptual Aquatic Effects Monitoring Program includes priority fish species	6.13.9, 6.13.10, Preliminary Wetland Compensation Plan (Appendix H.3), Wildlife Management Plan (Appendix P.7), Lichen Mitigation and Monitoring Plan (Appendix P.6), Landbird SAR Mitigation and Monitoring Plan (Appendix A of Appendix P.7), Aquatic Effects Monitoring Program (to be provided prior to permitting stage)
Physical and Cultural Heritage	No additional monitoring is recommended, unless further changes to the Project layout or if development is to occur specifically around the historic features identified during the 2014, 2015, 2016, 2018 and 2019 reconnaissance.		6.15.8, 6.15.10

Table 10.1-1: Beaver Dam Mine Project Monitoring Commitments (continued)

Valued Component	General Monitoring Commitments	Detailed Monitoring Commitments (if applicable)	Corresponding EIS Section Number
Mi'kmaq of Nova Scotia	AMNS commits to providing the opportunity for Mi'kmaq participation in community-based monitoring programs and development of the Reclamation and Closure Plan. As the Project moves forward, discussions will continue with the Mi'kmaq of Nova Scotia regarding participation opportunity in the development, implementation and evaluation of proposed compliance and effects monitoring programs. These could include monitoring programs such as: • Wetland Monitoring; • Wildlife Monitoring, including Moose; and • Other monitoring programs such for air, surface water, groundwater, and noise. In addition, AMNS will hold periodic meetings with the Mi'kmaq of Nova Scotia, including Millbrook and Sipekne'katik First Nations, to review overall environmental compliance and effects monitoring programs associated with other VCs, and provide data and results of monitoring programs. On-going dialogue will continue with the Mi'kmaq of Nova Scotia regarding participation in, and implementation of, monitoring programs for the Project. The effects monitoring program will verify the effectiveness of mitigation measures associated with minimizing any potential effects to human health from consumption of or contact with country foods, water and soils, and results will be shared with local Indigenous groups.		6.14.10
Accidents and Malfunctions	Undertaken as necessary, geotechnical monitoring will be ongoing		6.18
Effects of the Environment on the Project	Undertaken as necessary		7

12 ABBREVIATIONS, ACRONYMS AND GLOSSARY

12.1 Abbreviations and Acronyms

AAQC	Ambient Air Quality Criteria
ACCDC	Atlantic Canada Conservation Data Centre
AEMP	Aquatic Effects Monitoring Program
AGS	Atlantic Growth Strategy
ALDs	Anoxic limestone drains
AMNS	Atlantic Mining NS Inc.
AMO	Abandoned Mine Openings
ANFO	Ammonium Nitrate, Fuel Oil
ANSMC	Assembly of Nova Scotia Mi'kmaq Chiefs
APEC	Atlantic Provinces Economic Council
AQI	Air Quality Index
ARD	Acid Rock Drainage
ARM	Acid Rain Mitigation Project of the West River (Sheet Harbour)
As	arsenic
ATV	All terrain vehicles
ATVANS	All-Terrain Vehicle Association of Nova Scotia
BAP	Best Available Practices
BCM	bank cubic metres
BFI	baseflow Index
BMP	best management practices
CAAQS	Canadian Ambient Air Quality Standards
CaCO3	Calcium Carbonate
CCME	Canadian Council of Ministers of the Environment
CCME FWAL	Canadian Council of Ministers of the Environment Water quality Guidelines for the Protection of Freshwater Aquatic Life
CDA	Canadian Dam Association
CEAA	Canadian Environmental Assessment Agency
CEPA	Canadian Environmental Protection Act
CERB	Canada Emergency Response Benefit
CFM	Cubic feet per minute
CH4	Methane
CIL	Carbon in Leach
CLC	Citizen Liaison Committee
CMA	Census Metropolitan Area
CMM	Confederacy of Mainland Mi'kmaq

CO	Carbon Monoxide
CO_2	Carbon Dioxide
CO_{2e}	Carbon Dioxide Equivalent Units
COC	contaminant of concern
COO	Chief Operating Officer
COSEWIC	Committee on the Status of Endangered Wildlife in Canada
CRA	Conestoga-Rovers & Associates
CSM	Conceptual Site Model
CSP	corrugated steel pipe
CWS	Canadian Wildlife Service
DFO	Fisheries and Oceans Canada
DO	Dissolved Oxygen
DO	Dissolved Oxygen
DOC	Dissolved Organic Carbon
DSM	Digital Surface Model
DTH	down the hole
DU	designatable units
EA	Environmental Assessment
EARD	Environmental Assessment Registration Document
ECCC	Environment and Climate Change Canada
eDNA	Environmental DNA
EEM	Environmental Effects Monitoring
EGSPA	Environmental Goals and Sustainable Prosperity Act
EIS	Environmental Impact Statement
EMM	Preliminary Environmental Effects Monitoring Plan
EMS	Environmental Management System
EOM	End of Mine
EP	Engagement Plans
EPP	Environmental Protection Plan
EQS	Nova Scotia Environment Quality Standards
ESFWA	Eastern Shore Forest Watch Association
ESIA	Environmental Study Impact Assessment
ESMH	Eastern Shore Memorial Hospital
FEC	Forest Ecosystem Classification
FHAA	Fish Habitat Assessment Area
FOS	Fine ore stockpile
FTE	Full-time equivalents
FWAL	Freshwater Aquatic Life

GCL	Geosynthetic Clay Liner
GDP	Gross Domestic Product
GHG	Greenhouse Gas
GLC	ground level concentrations
Golder	Golder Associates Ltd
GPS	Global Positioning System
HDPE	High-density Polyethylene
HIS	Habitat Suitability Indexing
HMANA	Hawk Monitoring Association of North America
HRM	Halifax Regional Municipality
HU	habitat units
IA	Industrial Approval
IAAC	Impact Assessment Agency of Canada
ICMC	International Cyanide Management Code
IDF	Intensity, Duration and Frequency
ILE	Institute of Light Engineers
ILR	Intensive Leach Reactor
IR	Indian Reserve
IR2	Round 2, Information Requests
ISQG	Interim Sediment Quality Guidelines
KBCM	kilo bank cubic metre
kLCM	kilo loose cubic metre
KMKNO	Kwilmu'kw Maw-klusuaqn Negotiation Office
KPIs	Key Performance Indicators
LAA	Local Assessment Area
LGO	low-grade ore
LOEC	Lowest observed effect concentration
LSA	Lichen Study Area
MACA	Mooseland and Area Community Association
MAD	mean annual discharge
MBBA	Maritime Breeding Bird Atlas
MBCA	Migratory Birds Convention Act
MBR	Migratory Birds Regulations
MCBA	Migratory Birds Convention Act, 1994
MCG	Mi'kmaw Conservation Group
MDMER	Metal and Diamond Mining Effluent Regulations
MEKS	Mi'kmaq Ecological Knowledge Study
MEL	McCallum Environmental Limited

MIA	Mining Infrastructure Area
MLCM	Million loose cubic metres
MMMP	Mainland Moose Management Plan
MMTS	Moose Mountain Technical Services
MOU	Memorandum of Understanding
MPS	Municipal Planning Strategy
MRC	Moose River Consolidated
MTRI	Mersey Tobeatic Research Institute
MVMH	Musquodoboit Valley Memorial Hospital
MWMP	Mine Water Management Plan
N_2O	Nitrous Oxide
NaCN	Sodium Cyanide
NAG	non-acid generating
NaOH	sodium hydroxide
NAPS	National Air Pollution Surveillance Network
NCNS	Native Council of Nova Scotia
NGO	Non-Governmental Organization
NO_X	Oxides of Nitrogen
NPA	Navigation Protection Act, 1985
NPRI	National Pollutant Release Inventory
NRCAN	Natural Resources Canada
NSAQS	Nova Scotia Air Quality Standards
NSCCH	Nova Scotia Department of Communities, Culture, and Heritage
NSDEM	Nova Scotia Department of Energy and Mines
NSDMA	Nova Scotia Department of Municipal Affairs
NSDNR	Nova Scotia Department of Natural Resources
NSE	Nova Scotia Environment
NSECC	Nova Scotia Environment and Climate Change
NSESA	Nova Scotia Endangered Species Act
NSL&F	Nova Scotia Department of Lands and Forestry
NSSA	Nova Scotia Salmon Association
NSSA AMP	Nova Scotia Salmon Association Acid Mitigation Project
NSTAT	Department of Transportation and Active Transit
NSTIR	Nova Scotia Department of Transportation and Infrastructure Renewal
NWPA	Navigable Waters Protection Act, 1985 (repealed)
O_3	Ozone
OAA	Office of Aboriginal Affairs
OMS	organic material stockpile

PA	Project Area
PAG	potential acid generative
PAPR	powdered air purifying respirators
PC	Post Closure
PEL	Probable Effect Level
PLS	Plain Language Summary
PM	Particulate Matter
PM_{10}	Coarse Particulate Matter; 10 micrometers in aerodynamic diameter
$PM_{2.5}$	Fine Particulate Matter; 2.5 micrometers in aerodynamic diameter
PPE	personal protective equipment
ppm	parts per million
qPCR	quantitative polymerase chain reaction
RAA	Regional Assessment Area
RCMP	Royal Canadian Mounted Police
ROM	Run Of Mine
SAR	Species at Risk
SARA	Species at Risk Act, 2002
SEP	Stakeholder Engagement Plan
SMP	Special Management Practices
SO_2	Sulphur Dioxide
SO_4	Sulfate
SOCI	Species of Conservation Interest
SOP	Standard Operating Procedure
SSD	species sensitivity distribution
SSWQO	site-specific water quality objectives
SU	Southern Uplands
TC	Transport Canada
TDS	Total Dissolved Solids
TIR	Department of Transportation and Infrastructure Renewal
TLRUS	Traditional Land and Resource Use Study
TLS	till stockpiles
TMF	Tailings Management Facility
TOR	Terms of Reference
TPM	Total Particulate Matter
TSP	total suspended particulates
TSS	Total Suspended Solids
USEPA	United States Environmental Protection Agency
VC	Valued Component

VECs	Valued Environmental Components
VOC	Volatile Organic Compounds
VT	Vegetation types
WBM	water balance model
WMP	Wildlife Management Plan
WQG	Water quality guidelines
WRSA	Waste Rock Settlement Area
WRSH	West River Sheet Harbour
WSS	Wetlands of special significance
WTS	water treatment system
YOY	Young of the year
ZVI	Zone of Visual Influence

12.2 Units of Measure

%	percent
<	less than
>	greater than
°C	degrees Celsius
µg/m^3	micrograms per cubic metre
µm	micro metres
cm	centimetre
cm/year	centimetres per year
dBA	decibels
E	East
El.	Elevation
g/s	grams per second
g/t	grams per tonne
ha	hectare
Hz	hertz
kg	kilogram
kg/hr	kilogram per hour
kg/t	kilogram per tonne
km	kilometre
km^2	square kilometre
kt	kilotonne
kt	kilo tonnes
kV	kilovolt
kW	kilowatt
L	litre
L/a	litres per annum
L/d	liters per day

m	metre
m^2	square metre
m^3	cubic metre
m^3/d	cubic metre per day
m^3/h	cubic metres per hour
m^3/sec	cubic metre per second
m^3/y	cubic metre per year
masl	metres above sea level
mg/L	milligram per litre
mg/m^3	milligram per cubic metre
ML	million litres
mm	millimetre
Mm^3	million cubic metres
Mm^3/y	million cubic metres per year
Mt	million tonnes
Mt/yr	million tonnes per year
MW	megawatt
N	North
NTU	nephelometric turbidity unit
oz	ounces
pH	concentration of hydrogen ions
ppb	parts per billion
pphm	parts per hundred million
ppm	parts per million
S	South
t	tonne
t/d	tonne per day
t/hr	tonne per hour
t/m	tonne per cubic metre
t/m^3	tonnes per cubic metres
t/y	tonnes per year
TCU	true colour unit
V	volt
W	West
wt%	percent by weight
µg/g	microgram per gram
µg/L	microgram per litre
µS/cm	microSiemens per centimetre

12.3 Glossary

Abiotic	Non-living factors that influence an ecosystem, such as climate, geology and soil characteristics.
Acid rock drainage	Acidic pH rock drainage due to the oxidation of sulphide minerals that includes natural acidic drainage from rock not related to mining activity; an acidic pH is defined as a value less than 6.0.
Active layer	The layer of ground above the permafrost that thaws seasonally during the summer and refreezes in the fall.
Ammonium nitrate fuel oil	A widely used explosive mixture.
Anthropogenic	Relating to, or resulting from the influence of human beings on nature.
Armouring	Protecting a channel from erosion by covering with protective material.
Backfilling	Using material to refill an excavated area.
Biophysical	The biological (e.g., plants, animals) and physical (e.g., air, water, soil) components of the natural environment.
Bioremediation	Use of microorganisms or their enzymes to return soil altered by contaminants back to its original condition.
Biotic	Living components of an ecosystem.
Boulder	A large rounded mass of rock lying on the surface of the ground or embedded in the soil.
Breccia	A fragmental rock whose fragments are angular.
Catchment	An area of land where water from precipitation drains into a body of water.
Commitments	Actions that AMNS formally agrees to undertake
Degrit	A degrit module consists of cyclones that separate the fine kimberlite (less than 0.25 mm) from the grits (greater than 0.25 mm but less than 1.0 mm).
Diabase	A dark coloured, fine to medium-grained igneous intrusive rock.
Diversion channel	an artificial channel built to reduce excess water flow, particularly during flooding, by diverting some of this flow to a lake or the sea or to a purpose-bult waterway.
Dyke	A tabular body of igneous rock that cuts across the bedding or foliation of the rock it intrudes.
Entrainment	The entrapment of one substance by another substance.
Fetch	An area of a waterbody where waves are generated by a wind having a constant direction and speed (also called Generating Area).
Fines	Silt and clay particles.
Flocculant	Chemicals that promote flocculation by causing colloids and other suspended particles in liquids to aggregate, forming a floc.
Freeboard	The distance between the water level and the top of a containing structure such as a dyke crest or channel top of bank.
Freshet	Seasonal surface runoff associated with spring melt.
Game Sanctuaries	Game Sanctuaries were established early in the 20th century to protect wildlife and a "nucleus of breeding stock". Today, wildlife management tools reduce the risk of extinction, but the game sanctuary designation remains as a tool for government to regulate lands, "where unusual concentrations of wildlife are vulnerable to site specific threats." Game Sanctuaries are enabled under the Nova Scotia Wildlife Act.
General fill	Rock not graded as to size or quality
Granular fill	Screened and sized rock material for earthworks/construction.
Grits	Processed kimberlite particles between 0.25 mm and 1.0 mm in size.
Grizzly	A grating, usually constructed of steel rails to separate coarse material from plant feed.
Groundwater	Water within interconnected pore spaces of the subsurface within the saturated zone below the water table.
Habitat	The place or environment where a plant or animal naturally or normally lives or occurs.

Heat-traced pipes	Piping with electric heating elements to prevent freezing.
Humidity cell	A type of kinetic test in which a small sample (about 1 kg) is placed in an enclosed chamber in a laboratory, alternating cycles of moist and dry air is constantly pumped through the chamber, and once a week the sample is rinsed with water; chemical analysis of rinse water yields concentrations of elements and other parameters used to calculate reaction rates.
Hydraulic gradient	The difference in piezometric level or hydraulic head between two points over a change in distance in the direction, which yields the greatest change in hydraulic head.
Hydrocarbons	Oil based products.
Infrastructure	Basic facilities, such as transportation, communications, power supplies and buildings, which enable an organization, project or community to function.
Landfarm	Facility that contains soil during bioremediation.
Littoral	The shallow, shoreline area of a lake.
Make-up water	The process water required to replace that lost by evaporation or leakage in a closed-circuit, recycle operation.
Mature climax	A forest stand of trees aged 80 to 125 years old
Mine rock	Excavated bed rock surrounding the kimberlite deposits. Mine rock consists primarily of granitic rock material.
Mineralization	To transform a metal into an ore; to impregnate or supply with minerals or an inorganic compound; to convert into mineral or inorganic form.
Mitigation	An approach, action or process to reduce or eliminate impacts of a project on the environment, community, stakeholder or society. To take action on a mitigation AMNS would issue a commitment to the mitigation.
Muskeg	Bog: especially a sphagnum bog of northern North America often with tussocks. A usually thick deposit of partially decayed vegetable matter of wet boreal regions.
Nature Reserves	Nature reserves are areas selected to preserve and protect, in perpetuity, representative and special nature ecosystems, plant and animal species, features and natural processes. Scientific research and education are the primary uses of nature reserves and recreation is generally restricted. Nature Reserves are protected under the Nova Scotia Special Places Protection Act.
Old Forest	A stand or collection of stands containing Old Growth and/or mature climax conditions.
Old Growth Forest	A stand with trees 125 years or older
Open-pit mine	A mine where rock or mineral extraction from the earth is done using a pit or borrow open to the surface, rather than using a tunnel into the earth.
Ore body	An accumulation of ore, which is a type of rock that contains minerals with important elements that are typically mined.
Overburden	Materials of any nature, consolidated or unconsolidated, that overlie a deposit of useful materials. In the present situation, overburden refers to the soil and rock strata that overlie kimberlite deposits.
Overwintering	To remain alive over winter.
Permafrost	Permanently frozen subsoil occurring throughout the polar regions.
pH	The degree of acidity (or alkalinity) of soil or solution. The pH scale is generally presented from 1 (most acidic) to 14 (most alkaline). A difference of one pH unit represents a ten-fold change in hydrogen ion concentration.
Plant phenology	The study of periodic plant life cycle events and how these are influenced by seasonal and interannual variations in climate.
Potable water	Water that is suitable for drinking.
Potentially acid generating rock	Rock that when oxidized by surface weathering may form acid which can then leach metals. Leached metal ions can be harmful to fish and other aquatic life.
Propagules	Root fragments, seeds, and other plant materials that can develop into a plant under the right conditions.

Reagent	A substance or compound that is added to a system to bring about a chemical reaction or is added to see if a reaction occurs.
Runoff	The portion of water from rain and snow that flows over land to streams, ponds or other surface waterbodies. It is the portion of water from precipitation that does not infiltrate into the ground, or evaporate.
Run-of-mine	The raw unprocessed or uncrushed material in its natural state obtained after blasting or digging, from the mineralized zone of a lease area.
Sediment	Solid material that is transported by, suspended in, or deposited from water. It originates mostly from disintegrated rocks; it also includes chemical and biochemical precipitates and decomposed organic material, such as humus. The quantity, characteristics and cause of the occurrence of sediment in streams are influenced by environmental factors. Some major factors are degree of slope, length of slope soil characteristics, land usage and quantity and intensity of precipitation.
Seepage	Slow water movement in subsurface. Flow of water from man-made retaining structures. A spot or zone, where water oozes from the ground, often forming the source of a small spring.
settling pond	An earthen or concrete structure using sedimentation to remove settleable matter and turbidity from wastewater. The basins are used to control water pollution.
Sub-watershed	A smaller portion of a watershed containing a drainage area that is connected to the larger portion by a single channel.
Succession	The progressive replacement of one dominant type of species or community by another in an ecosystem until a stable climax community is established.
Sumps	A well or pit in which liquids collect below floor level.
tailings	Finely ground residuals that remain after the mill process has removed the valuable metals from the ore.
Talik	A layer of year-round unfrozen ground that lies in permafrost areas.
Tertiary watershed	Tertiary Watershed are subdivisions of secondary watershed.
Thermistors	An instrument used to measure temperature.
Till	Till is an unsorted glacial sediment. Glacial drift is a general term for the coarsely graded and extremely heterogeneous sediments of glacial origin. Glacial till is that part of glacial drift which was deposited directly by the glacier. It may vary from clays to mixtures of clay, sand, gravel, and boulders.
Total dissolved solids	The total concentration of all dissolved materials found in a water sample.
Total suspended solids	A measurement of the concentration of particulate matter found in water.
Turbidity	The cloudiness or haziness of a fluid caused by individual particles (suspended solids) in water that are generally invisible to the naked eye.
Utilidors	A utility corridor built underground or aboveground to carry utility lines such as electricity, water and sewer.
Valued Components	Components of the natural and human environment that are considered by the proponent, public, Aboriginal groups, scientists and other technical specialists, and government agencies involved in the assessment process to have scientific, ecological, economic, social, cultural, archaeological, historical, or other importance
Waste rock	Bedrock that has been mined and transported out of the pit but does not have metal concentrations of economic interest.
Waterbody	A body of water forming a physiographical feature, for example a sea or a reservoir
Watercourse	A natural or artificial channel through which water flows.
Watershed	Also know as a catchment basin, includes all land that is drained by a watercourse and its tributaries. Water sheds are split into four categories; Primary, Secondary, Tertiary, and Quaternary.
Wetlands	A wetland is a distinct ecosystem that is flooded by water, either permanently or seasonally, where oxygen-free processes prevail. The primary factor that distinguishes wetlands from other land forms or water bodies is the characteristic vegetation of aquatic plants, adapted to the unique hydric soil.

Wilderness Areas	These are provincially significant protected areas which are designated under the Nova Scotia Wilderness Areas Protection Act. Forestry and road development are not permitted. Other activities such as mining, vehicle use, building structures or trails, and managing or removing plants are prohibited except in certain circumstances as outlined in the legislation. Hunting is permitted.
