Suite 2085, 1903 Barrington Street
PO Box 442, Halifax, NS B3J 2P8

Dear Ms. MacCarthy and Ms. Tutty,

Atlantic Mining NS Inc, a wholly owned subsidiary of St Barbara Limited, is pleased submit the Updated 2021 Environmental Impact Statement (EIS) as per the *Canadian Environmental Assessment Act, 2012* and the Environmental Assessment Registration Document (EARD) as per Nova Scotia *Environmental Assessment Regulations.* The Updated 2021 EIS is being issued to support the Responses to the Information Request, Round 2, for the Beaver Dam Mine Project that was submitted on June 4, 2021.

The Beaver Dam Mine Project Updated 2021 EIS Guidance Concordance table is attached.

The undersigned has signing authority and submits the documents as per the federal and provincial environmental assessment processes.

Any correspondence regarding the Environmental Assessment should be directed to the undersigned.

<Original signed by>

Craig Hudson
Head of Permitting and Projects
Atlantic Mining NS Inc

cc: Mike Atkinson, Impact Assessment Agency of Canada

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
1. INTRODUCTION AND OVERVIEW	-	**1. INTRODUCTION**	**1. INTRODUCTION**	
1.1. The proponent	In the EIS, the proponent will: - provide contact information (e.g. name, address, phone, fax, email); - identify itself and the name of the legal entity that would develop, manage and operate the project; - describe corporate and management structures; - specify the mechanism used to ensure that corporate policies will be implemented and respected for the project; and - identify key personnel, contractors, and/or sub-contractors responsible for preparing the EIS.	1.2 Proponent Information	1.2 Proponent Information	1.4 Proponent Information
1.2. Project overview	The EIS will describe the project, key project components and associated activities, scheduling details, the timing of each phase of the project and other key features. If the project is a part of a larger sequence of projects, the EIS will outline the larger context. The overview is to identify the key components of the project, rather than providing a detailed description, which will follow in Section 3 of this document.	1.1 Project Overview	1.1 Project Overview	1.2 Project Overview
1.3. Project location	The EIS will contain a description of the geographical setting in which the project will take place. This description will focus on those aspects of the project and its setting that are important in order to understand the potential environmental effects of the project. The following information will be included: - the UTM coordinates of the main project site; - land use in the area currently; - distance of the project facilities and components to any federal lands; - Crown lands and other provincially-owned lands; - the environmental significance and value of the geographical setting in which the project will take place and the surrounding area; - environmentally sensitive areas, such as national, provincial and regional parks or wilderness areas, ecological reserves, wetlands, estuaries, designated areas (e.g., important bird habitat), mature or interior forest habitat of migratory birds, and habitats of federally or provincially listed species at risk and other sensitive areas (e.g. habitats of species of conservation concern, colonial nesters, areas of concentration of migratory birds) that are within the project's potential zone of influence including accidents and malfunctions ; - local communities; and - traditional Aboriginal territories and/or consultation areas, treaty lands, Indian reserve lands or other Aboriginal communities	2.1 Project Location	2.1 Project Location	1.2.2 Project Location
1.4 Regulatory framework and the role of government	The EIS will identify: - any federal power, duty or function that may be exercised that would permit the carrying out (in whole or in part) of the project or associated activities; - the environmental and other regulatory approvals and legislation that are applicable to the project at the federal, provincial, regional and municipal levels; - government policies, resource management, planning or study initiatives pertinent to the project and/or EA and their implications; - any treaty or self-government agreements with Aboriginal groups that are pertinent to the project and/or EA; - any relevant land use plans, land zoning, or community plans; and - regional, provincial and/or national objectives, standards or guidelines that have been used by the proponent to assist in the evaluation of any predicted environmental effects.	1.3 Regulatory Framework and Role of Government	1.3 Regulatory Framework and Role of Government	1.5 Regulatory Framework and Role of Government
2. PROJECT JUSTIFICATION AND ALTERNATIVES CONSIDERED	-	1.4 Purpose of the Project 2.6 Alternatives Means of Carrying Out of the Project	1.4 Purpose of the Project 2.6 Alternatives Means of Carrying Out of the Project	1.3 Purpose of the Project 2.10 Alternatives Means of Carrying Out of the Project
2.1. Purpose of the project	The EIS will describe the purpose of the project by providing the rationale for the project, explaining the background, the problems or opportunities that the project is intended to satisfy and the stated objectives from the perspective of the proponent. If the objectives of the project are related to broader private or public sector policies, plans or programs, this information will also be included. The EIS will also describe the predicted environmental, economic and social benefits of the project. This information will be considered in assessing the justifiability of any significant adverse residual environmental effects, if such effects are identified.	2.1 Purpose of the Project	2.1 Purpose of the Project	1.3 Purpose of the Project 2.4 Ecological Setting 2.5 Project History 2.6 Geology and Resources

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
2.2. Alternative means of carrying out the project	The EIS will identify and consider the effects of alternative means of carrying out the project that are technically and economically feasible. The proponent will complete the following procedural steps for addressing alternative means: - identify the alternative means to carry out the project; - identify the effects of each technically and economically feasible alternative means; - select the approach for the analysis of alternative means (i.e., identify a preferred means or bring forward alternative means); and - assess the environmental effects of the alternative means. In its alternative means analysis, the proponent will address, at a minimum, the following project components: - mine type (e.g. open pit, underground); - material extraction methods; - processing (process types); - processing location (e.g. Beaver Dam versus Touquoy Mine Site); - transportation of ore (means and routing considered); - energy sources to power the project site (diesel, electricity, renewables); - location of key project components; - water supply and management; and - mine waste disposal (methods and sites considered including dry stack tailings disposal)[1]. For further information regarding the "purpose of" and "alternative means", please consult the Agency's Operational Policy Statement entitled "Addressing "Purpose of" and "Alternative Means" under the Canadian Environmental Assessment Act, 2012". The Agency recognizes that projects may be in the early planning stages when the EIS is being prepared. Where proponents have not made final decisions concerning the placement of project infrastructure, the technologies to be used, or that several options may exist for various project components, they are strongly encouraged to conduct an environmental effects analysis at the same level of detail assessment of the various options available (alternative means) within the EIS.	2.6 Alternative Means of Carrying Out the Project	2.6 Alternative Means of Carrying Out the Project	2.10 Alternative Means of Carrying Out the Project

[1] Should an MMER Schedule 2 amendment be required for the Project, the proponent is strongly encouraged to include MMER requirements for an assessment of alternatives for mine waste disposal in the EIS. The methodology recommended for the conduct of mine waste disposal alternatives is described in Environment Canada's Guidelines for the Assessment of Alternatives for Mine Waste Disposal (2011). A copy of this guide can be found on Environment Canada's website at www.ec.gc.ca. Proponent should also refer to Part 1, section 4.1 of this document.

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
3. PROJECT DESCRIPTION	-	2. Project Description	2. Project Description	2. Project Description
3.1. Project components	The EIS will describe the project, by presenting the project components, associated and ancillary works, and other characteristics that will assist in understanding the environmental effects. This will include: - maps, at an appropriate scale, of the project location, the project components (at the Beaver Dam Mine Touquoy Mine, and roads), boundaries of the proposed site with UTM coordinates, the major existing infrastructure, Crown lands and any other designated lands, adjacent land uses and any important environmental features; - waste rock, overburden, topsoil, low grade ore storage and stock piles (footprint, locations, volumes, development plans and design criteria); - open pit mine (footprint, location, development plans including pit phases); - crusher and processing facilities (footprint, technology, location); - water (pit water, mine effluent) management and treatment infrastructure (e.g. settling ponds, sumps, water diversion structures); - permanent and temporary linear infrastructures (e.g. roads, transmission lines), identifying the route of each of these linear infrastructures, the location and types of structures used for stream crossings (e.g. culverts and bridges); - drinking and industrial water requirements (source, quantity required, need for water treatment); - energy supply (source, quantity); - pit and infrastructure lighting; - administrative buildings, garages, petroleum product storage facility, other ancillary facilities; - construction camp (location, capacity, wastewater treatment); - waste disposal (type of waste, method of disposal, quantity); and - all changes to components, activities, scheduling, and lifespan at the Touquoy Mine resulting from the Beaver Dam Project (e.g. potential increase in processing, waste rock, tailings management, water management).	2.2 Project Components	2.2 Project Components	2.7 Project Components
3.2. Project activities	The EIS will include descriptions of the construction, operation, decommissioning and abandonment associated with the proposed project. This will include descriptions of the activities to be carried out during each phase, the location of each activity, expected outputs and an indication of the activity's magnitude and scale. Although a complete list of project activities should be provided, the emphasis will be on activities with the greatest potential to have environmental effects. Sufficient information will be included to predict environmental effects and address public concerns identified. Highlight activities that involve periods of increased environmental disturbance or the release of materials into the environment. The EIS will include a summary of the changes that have been made to the project since originally proposed, including the benefits of these changes to the environment, Aboriginal peoples, and the public. The EIS will include a schedule including time of year, frequency, and duration for all project activities. The information will include a description of:	2.3 Project Activities	2.3 Project Activities	2.9 Project Activities
3.2.1. Site preparation and construction	Site preparation and construction - site clearing, excavation - drilling and blasting (frequency and methods, type of explosive used), including any transport and/or storage - borrow materials requirements (source and quantity) - water diversion required (location, methods, timing) - contribution to atmospheric emissions, including emissions profile (type, rate and source) - quantification of direct greenhouse gas emissions - equipment requirements (type, quantity) - administrative buildings, garages, construction camp, other ancillary facilities - number of employees and transportation of employees - dewatering of man-made pond in northeast section of project area or any other waterbody - haul road upgrades (e.g. grading, widening, rerouting, upgrading) and maintenance, including construction, replacement, installation and/or modification of bridges and culverts as well as consideration of geochemical and physical properties of rock to be used for road upgrades (e.g. waste rock from Touquoy mine).	2.3.1 Subsections titled “Site Preparation and Construction”	2.3.1 Subsections titled “Site Preparation and Construction”	2.9.1 Subsections titled “Site Preparation and Construction”

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
3.3.2. Operation	- mining plan, ore production, ore stockpiling, concentrate production - equipment requirements - drilling - explosive uses (storage location [should storage be required], transportation, and management) - blasting (frequency and methods) - water management on the project site, including a detailed water budget - ore crushing and treatment - noise and dust management - reagent requirements (volumes, storage, types) - petroleum products (source, volume, storage) - characterization and management of ore, waste rock, low grade ore, overburden and tailings (volumes generated, mineralogical characterization, potential for metal leaching and acid rock drainage) - effluent management and treatment (quantity, treatment requirement, release point) - contribution to atmospheric emissions, including emissions profile (type, rate and source) - quantification of direct greenhouse gas emissions - water recycling - light management - waste management and recycling (other than mine waste such as tailings and waste rock) - number of employees, transportation of employees, work schedule, lodging requirement on site and off site - maintenance activities - transportation of ore to the Touquoy Mine (e.g. maximum number of trucks per day)	2.3.2 Subsections titled “Operation and Maintenance”	2.3.2 Subsections titled “Operation and Maintenance”	2.9.2 Subsections titled “Operation and Maintenance”
3.2.3. Decommissioning and abandonment	- the outline of a decommissioning and reclamation plan for any components associated with the project - the ownership, transfer and control of the different project components - the responsibility for monitoring and maintaining the integrity of the remaining structures - for permanent facilities, a conceptual discussion on how decommissioning could occur	2.3.3 Subsections titled “Decommissioning and Reclamation”	2.3.3 Subsections titled “Decommissioning and Reclamation”	2.9.3 Subsections titled “Active Reclamation”
4. PUBLIC CONSULTATION AND CONCERNS	The EIS will describe the ongoing and proposed consultations and the information sessions that the proponent will hold or that it has already held on the project. It will provide a description of efforts made to distribute project information and provide a description of information and materials that were distributed during the consultation process. The EIS will indicate the methods used, where the consultation was held, the persons and organizations consulted, the concerns voiced and the extent to which this information was incorporated in the design of the project as well as in the EIS. The EIS will provide a summary of key issues raised related to the environmental assessment as well as describe any outstanding issues and ways to address them.	3. Public Consultation and Engagement Program	3. Public Consultation and Engagement Program	3. Public Engagement Program Appendix A.4a Appendix A.6

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section

5. ABORIGINAL ENGAGEMENT AND CONCERNS	For the purposes of developing the EIS, the proponent will engage with Aboriginal groups that may be affected by the project, to obtain their views on:
	- effects of changes to the environment on Aboriginal peoples (health and socio-economic conditions; physical and cultural heritage, including any structure, site or thing that is of historical, archaeological, paleontological or architectural significance; and current use of lands and resources for traditional purposes) pursuant to subparagraph 5(1)(c) of CEAA 2012, and
	- potential adverse impacts of the project on potential or established Aboriginal or Treaty rights, title and related interests, in respect of the Crown's duty to consult, and where appropriate, accommodate Aboriginal peoples.
	
	With respect to effects of changes to the environment on Aboriginal peoples, the assessment requirements are outlined in Part 2, Sections 6.1.9 and 6.3.5, of these Guidelines. With respect to potential adverse impacts of the project on potential or established Aboriginal or treaty rights, title and related interests, the EIS will document for each group identified in section 5.1 of these Guidelines (or in subsequent correspondence from the Agency):
	- Potential or established Aboriginal or treaty rights[2], title and related interests, when this information is provided by a group to the proponent or available through public records including:
	  - geographical extent, nature, frequency, timing of the practice or exercise of the right; and,
	  - maps and data sets (e.g. fish catch numbers);
	- potential adverse impacts of each of the project components and physical activities, in all phases, on potential or established Aboriginal or treaty rights, title and related interests. This assessment is to be based on a comparison of the exercise or state of the identified rights, title and related interests between the predicted future conditions with the project and the predicted future conditions without the project. Include the perspectives of Aboriginal groups where these were provided to the proponent by the groups;
	- measures identified to mitigate or accommodate potential adverse impacts of the project on the potential or established Aboriginal or treaty rights, title and related interests. These measures will be written as specific commitments that clearly describe how the proponent intends to implement them and may go beyond mitigation measures that are developed to address potential adverse environmental effects;
	- potential adverse impacts on potential or established Aboriginal or treaty rights, title and related interests that have not been fully mitigated or accommodated as part of the environmental assessment and associated engagement with Aboriginal groups. The proponent will also take into account the potential adverse impacts that may result from the residual and cumulative environmental effects. Include the perspectives of Aboriginal groups where these were provided to the proponent by the groups.
		4. Indigenous Peoples Consultation and Engagement Program	4. Indigenous Peoples Consultation and Engagement Program	4. Indigenous Peoples Engagement Program

[2] The 2011 Updated Guidelines for Federal Officials to Fulfill the Duty to Consult (the Guidelines) defines Aboriginal rights as: practices, traditions and customs integral to the distinctive culture of the Aboriginal group claiming the right that existing prior to contact with the Europeans (Van de Peet). In the context of Métis groups, Aboriginal rights means practices, traditions, and customs integral to the distinctive culture of the Métis group that existed prior to effective European control, that is, prior to the time when Europeans effectively established political and legal control in the claimed area (Powley). Generally, these rights are fact and site specific. For greater certainty, the Guidelines also define Aboriginal title as an Aboriginal right. Visit the Aboriginal Affairs and Northern Development Canada website at: www.aadnc-aandc.gc.ca/eng/1100100014680/1100100014681"

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
	The information sources, methodology and findings of the assessment of subparagraph 5(1)(c) effects may be used to inform the assessment of potential adverse impacts of the project on potential or established Aboriginal or treaty rights, title and related interests. However, there may be distinctions between the adverse impacts on potential or established Aboriginal or treaty rights, title and related interests and subparagraph 5(1)(c) effects. The proponent will carefully consider the potential distinction between these two aspects and, where there are differences, will include the relevant information in its assessment. In terms of gathering views from Aboriginal groups with respect to both environmental effects of the project and the potential adverse impacts of the project on potential or established Aboriginal or treaty rights, title and related interests, the EIS will document: - VCs suggested by Aboriginal groups for inclusion in the EIS, whether they were included, and the rationale for any exclusions; - specific suggestions raised by each Aboriginal group for mitigating the effects of changes to the environment on Aboriginal peoples or accommodating potential adverse impacts of the project on potential or established Aboriginal or treaty rights, title and related interests; - views expressed by each Aboriginal group on the effectiveness of the mitigation or accommodation measures; - from the proponent's perspective, any potential cultural, social and/or economic impacts or benefits to each Aboriginal group identified that may arise as a result of the project . Include the perspectives of Aboriginal groups where these were provided to the proponent by the groups ; - any other comments, specific issues and concerns raised by Aboriginal groups and how the key concerns were responded to or addressed; - changes made to the project design and implementation directly as a result of discussions with Aboriginal groups; - where and how Aboriginal traditional knowledge was incorporated into the environmental effects assessment (including methodology, baseline conditions and effects analysis for all VCs) and the consideration of potential adverse impacts on potential or established Aboriginal or treaty rights, title and related interests and related mitigation measures; and - any additional issues and concerns raised by Aboriginal groups in relation to the environmental effects assessment and the potential adverse impacts of the project on potential or established Aboriginal or treaty rights, title and related interests. A suggested format for providing some of the information above is the creation of a tracking table of key issues raised by each Aboriginal group, including the concerns raised related to the Project, proposed mitigation options, and where appropriate, a reference to the proponent's analysis in the EIS. Information provided related to potential adverse impacts on potential or established Aboriginal or treaty rights will be considered by the Crown in meeting its common law duty to consult obligations as set out in the Updated Guidelines for Federal Officials to Fulfill the Duty to Consult (2011)[3].			4. Indigenous Peoples Engagement Program Appendix A.5 Mi'kmaq of Nova Scotia Engagement Log
5.1. Aboriginal groups to engage and engagement activities	With respect to engagement activities, the EIS will document: - the engagement activities undertaken with each Aboriginal group prior to the submission of the EIS, including the date and means of engagement (e.g., meeting, mail, telephone); - any future planned engagement activities; and - how engagement activities by the proponent allowed Aboriginal groups to understand the project and evaluate its effects on their communities, activities, potential or established Aboriginal or treaty rights, title and related interests. In preparing the EIS, the proponent will ensure that Aboriginal groups have access to timely and relevant information on the project and how the project may adversely impact them. The proponent will structure its Aboriginal engagement activities to provide adequate time for Aboriginal groups to review and comment on the relevant information. Engagement activities are to be appropriate to the groups' needs, arranged through discussions with the groups and in keeping with established consultation protocols, where available. The EIS will describe all efforts, successful or not, taken to solicit the information required from Aboriginal groups to support the preparation of the EIS. The proponent will ensure that views of Aboriginal groups are recorded and that each Aboriginal group is provided with opportunities to validate the interpretation of their views. The proponent will keep detailed tracking records of its engagement activities, recording all interactions with Aboriginal groups, the issues raised by each Aboriginal group and how the proponent addressed the concerns raised. The proponent will share these records with the Agency.	4. Indigenous Peoples Consultation and Engagement Program	4. Indigenous Peoples Consultation and Engagement Program	4. Indigenous Peoples Engagement Program Appendix A.5 Mi'kmaq of Nova Scotia Engagement Log

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
	For the Aboriginal groups expected to be most affected by the project, the proponent is expected to strive towards developing a productive and constructive relationship based on on-going dialogue with the groups in order to support information gathering and the effects assessment. These groups include: - Acadia First Nation - Annapolis Valley First Nation - Bear River First Nation - Chapel Island First Nation - Eskasoni First Nation - Glooscap First Nation - Membertou First Nation - Millbrook First Nation - Paq'tnkek (Afton) First Nation - Pictou Landing First Nation - Sipekne'katik First Nation - Wagmatcook First Nation - We'koqma'q First Nation - Assembly of Nova Scotia Mi'kmaq Chiefs and the Kwilmu'kw Maw-klusuaqn Negotiation Office (KMKNO) For the above groups, the proponent will strive to use primary data sources and hold face-to-face meetings to discuss concerns. The proponent will facilitate these meetings by making key EA summary documents (baseline studies, EIS, key findings, plain language summaries) accessible. The proponent will ensure there are sufficient opportunities for individuals and groups to provide oral input in the language of their choice. If possible, the proponent should consider translating information for theseAboriginal groups into the appropriate Aboriginal language(s) in order to facilitate engagement activities during the environmental assessment. The groups referenced above may change as more is understood about the environmental effects of the project and/or if the project or its components change during the EA. The Agency reserves the right to alter the list of Aboriginal groups that the proponent will engage as additional information is gathered during the assessment. In addition, for the purposes of good governance, the proponent should also provide information to and discuss potential environmental effects from the Project, as described under section 5 of CEAA 2012, with the Nova Scotia Native Council. Upon receipt of knowledge or information of potential effects to an Aboriginal group not listed above, the proponent shall provide that information to the Agency at the earliest opportunity.			4. Indigenous Peoples Engagement Program Appendix A.5 Mi'kmaq of Nova Scotia Engagement Log 6.14 Mi'kmaq of Nova Scotia
6. EFFECTS ASSESSMENT	-	6. Environmental Effects Assessment	5. Environmental Effects Assessment Methodology 6. Environmental Effects Assessment	5. Environmental Effects Assessment Methodology 6. Environmental Effects Assessment

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
6.1. Project setting and baseline conditions	Based on the scope of project described in section 3 (Part 1), the EIS will present baseline information in sufficient detail to enable the identification of how the project could affect the VCs and an analysis of those effects. Should other VCs be identified during the conduct of the EA, the baseline condition for these components will also be described in the EIS. To determine the appropriate spatial boundaries to describe the baseline information, refer to section 3.3.3 (Part 1). As a minimum, the EIS will include a description of:	6. Subsections for each VC titled "Baseline Conditions"	6.x.x Subsections for each VC titled "Baseline Conditions"	Subsections for each VC titled "Baseline Conditions" 6.1.3 Noise 6.2.4 Air 6.3.4 Light 6.4.4. Greenhouse Gases 6.5.4 Geology, Soil, and Sediment 6.6.4 Groundwater 6.7.4 Water Quantity 6.7.5 Water Quality 6.8.4 Wetlands 6.9.4 Fish and Fish Habitat 6.10.4 Habitat and Flora 6.11.4 Terrestrial Fauna 6.12.5 Avifauna 6.13.4 Species of Conservation Interest and Species at Risk 6.14.4 Mi'kmaq of Nova Scotia 6.15.4 Physical Cultural Heritage 6.16.4 Socio-economic Conditions
6.1.1. Atmospheric environmental	- ambient air quality in the project areas and, for the mine site, the results of a baseline survey of ambient air quality, including but not limited to the following contaminants: total suspended particulates, fine particulates ($PM_{2.5}$), particulate matters up to 10 micrometers in size (PM_{-10}), sulfur oxides (SO_X), volatile organic compounds (VOCs) and nitrogen oxides (NO_X);existing greenhouse gas emissions in the project study areas; - current provincial/federal limits for greenhouse gas emission targets; - current ambient noise levels in the project area and key receptor points (e.g. Aboriginal communities, closest residences, seasonal cottages, cabins), including the results of a baseline ambient noise survey. Information on typical sound sources, geographic extent and temporal variations will be included; - existing ambient night-time light levels at the project site and at any other areas where project activities could have an effect on light levels. The EIS will describe night-time illumination levels during different weather conditions and seasons; and - historical records of relevant meteorological information (e.g. total precipitation: rain and snow); mean, maximum and minimum temperatures; and typical wind speed and direction.	6.1 Atmospheric Environment	6.1 Noise 6.2 Air 6.3 Light 6.4 Greenhouse Gases	6.1 Noise 6.2 Air 6.3 Light 6.4 Greenhouse Gases
6.1.2. Geology and geochemistry	- the surficial geology, bedrock and host rock geology of the deposit, including a table of geologic descriptions, geological maps and cross-sections of appropriate scale; - geomorphology, topography, structural fabric (e.g. fractures, faults, foliation and lineation) and geotechnical characteristics of areas proposed for construction of major project components; - the geochemical characterization of expected mine material such as waste rock, ore, low grade ore, tailings, overburden and potential construction material in order to predict metal leaching and acid rock drainage[4]; and - geological hazards that exist in the areas planned for the project facilities and infrastructure, including: - history of seismic activity in the area; - isostatic rise or subsidence; and - landslides, slope erosion and the potential for ground and rock instability, and subsidence following project activities.	6.2 Geology, Soil and Sediment Quality	6.5 Geology, Soil and Sediment Quality	6.5 Geology, Soil, and Sediment Quality

[4] The manual produced by the Mine Environment Neutral Drainage (MEND) Program, entitled, MEND Report 1.20.1, "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials", Version 0 - December 2009 is a recommended reference for use in acid rock drainage and metal leaching prediction.

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
6.1.3. Topography and soil	- baseline mapping and description of landforms and soils within the local and regional project area; - maps depicting soil depth by horizon and soil order within the mine site area to support soil salvage and reclamation efforts, and to outline potential for soil erosion; and - suitability of topsoil and overburden for use in the rehabilitation of disturbed areas.	6.2 Geology, Soil and Sediment Quality	6.5 Geology, Soil and Sediment Quality	6.5 Geology, Soil, and Sediment Quality
6.1.4. Groundwater and surface water	- the hydrogeology, including: - the hydrogeological context (e.g., hydrostratigraphy with aquifers and aquitards, major faults, extensive fractures, etc.) including the delineation of key stratigraphic and hydrogeologic boundaries; - the physical properties of the hydrogeological units (e.g., hydraulic conductivity, transmissivity, saturated thickness, storativity, porosity, specific yield); - the regional and local groundwater flow patterns and rates; - a discussion of the hydrogeologic, hydrologic, geomorphic, climatic and anthropogenic controls on groundwater flow; - temporal changes in groundwater flow (e.g., seasonal and long term changes in water levels); - baseline groundwater quality; and - a delineation and characterization of groundwater surface water interactions including the locations of groundwater discharge to surface water and surface water recharge to groundwater.	6.3 Groundwater Quality and Quantity 6.4 Surface Water Quality and Quantity	6.6 Groundwater Quality and Quantity 6.7 Surface Water Quality and Quantity	6.6 Groundwater Quality and Quantity 6.7 Surface Water Quantity and Quality
	- hydrogeological maps and cross-sections for the mine area to outline the extent of aquifers and aquitards, including bedrock fracture and fault zones, locations and depths of wells, groundwater types, springs, surface waters, and project facilities. Groundwater levels, potentiometric contours, flow directions, groundwater divides and areas of recharge and discharge should be included; - all groundwater monitoring wells, including their location, in respect to the project area, including geologic, hydrostratigraphic, piezometric and construction data (e.g., depths of surficial and bedrock units, water level, hydraulic conductivity, diameter and screen depth and intercepted aquifer unit); - monitoring protocol for collection of existing groundwater data; - an appropriate hydrogeologic model for the project area including a detailed conceptual model, which discusses the hydrostratigraphy and groundwater flow systems; the rationale for the selected model will be provided; a sensitivity analysis will be performed to test model sensitivity to climatic variations (e.g., recharge) and hydrogeologic parameters (e.g., hydraulic conductivity); - graphs or tables indicating the seasonal variations in groundwater levels, flow regime, and quality; - local and regional potable groundwater supplies and/or surface water, including their current use and potential for future use; - bedrock fracture sizes and orientations in relation to groundwater flow; - the delineation of drainage basins, at appropriate scales (water bodies and watercourses), including intermittent streams, flood risk areas and wetlands, boundaries of the watershed and subwatersheds, overlaid by key project components; - hydrological regimes, including monthly, seasonal and annual water flow (discharge) data; - for each affected water body, the total surface area, bathymetry, maximum and mean depths, water level fluctuations, type of substrate (sediments); - seasonal water quality field and lab analytical results (e.g. water temperature, turbidity, pH, dissolved oxygen profiles) and interpretation at several representative local stream and water body monitoring stations established at the project site; and - sediment quality analysis for key sites likely to receive mine effluents. Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
6.1.5. Wetlands	Wetlands that may be affected by project activities will be characterized according to their location, size, type (wetland class and form), species composition and ecological function (Canadian Wetland Classification System, National Wetlands Working Group [NWWG] 1997). Efforts should focus on describing the wetlands with the greatest potential to be affected, including those within the project footprint. An overview of the key plant communities and animals that rely on wetlands will be presented. - The locations and extent of all wetlands in the project area will be mapped. The EIS will provide an estimate (in hectares) of each type of wetland ecosystem in the project area. This will include all wetlands previously mapped by the province, as well as wetlands identified by the study team through desktop analysis and field survey programs. - The desktop study to identify and determine the extent of wetlands within the Project area will be conducted using the provincial mapping and databases, aerial imagery, and 1:50,000 topographic mapping. - Nova Scotia requires wetland class to be based on the Canadian Wetland Classification System (NWWG 1997) and descriptions in the Nova Scotia Wetland Conservation Policy. Ecological function of all identified wetlands should be assessed and an evaluation of the following included: wildlife habitat potential (including rare and endangered species and overall plant community composition), groundwater recharge potential, the role of the wetland in surface flow regulation (stormwater retention and flood control), the potential role of the wetland in water quality improvement, and any other notable site specific functions that the wetland may provide. - For those potentially affected wetlands where the Federal Policy on Wetland Conservation would be applicable, and avoidance is deemed not possible, a detailed description of potential effects, and of the reasons why avoidance and minimization of impacts were determined to not be possible should be provided. The mitigation measures and monitoring plan, as well as a proposed compensation plan, should be consistent with those proposed for other projects in Atlantic Canada.	6.5 Wetlands	6.8 Wetlands	6.8 Wetlands
6.1.6. Fish and fish habitat	For potentially affected surface waters: - a characterization of fish populations on the basis of species and life stage, including information on the surveys carried out and the source of data available (e.g. location of sampling stations, catch methods, date of catches, species); - a list of any fish or invertebrate species at risk that are known to be present; - a description of the habitat by homogeneous section, including the length of the section, width of the channel from the high water mark (bankful width), water depths, type of substrate (sediments), aquatic and riparian vegetation, and photos; - a description of natural obstacles (e.g. falls, beaver dams) or existing structures (e.g. water crossings) that hinder the free passage of fish and the location of the obstacle or structure in relation to the site of the impact; - maps, at a suitable scale, indicating the surface area of potential or confirmed fish habitat for spawning, nursery, feeding, overwintering, migration routes, etc. This information should be linked to water depths (bathymetry) to identify the extent of a water body's littoral zone; and - the description and location of suitable habitats for fish species at risk that appear on federal and provincial lists and that are found or are likely to be found in the study area. Note that certain intermittent streams or wetlands may constitute fish habitat or contribute indirectly to fish habitat. The absence of fish at the time of the survey does not irrefutably indicate an absence of fish habitat.	6.6 Fish and Fish Habitat	6.9 Fish and Fish Habitat	6.9 Fish and Fish Habitat
6.1.7. Migratory birds and their habitat[5]	- the various ecosystems found in the project area likely to be affected based on existing information; - migratory and non-migratory birds (including landbirds, waterfowl, raptors, shorebirds, and other waterbirds); - year-round migratory bird use of the area (e.g., winter, spring migration, breeding season, fall migration), based on preliminary data from existing sources; and - the results of any baseline surveys and a description of the methodology. In addition to information obtained from previous environmental assessments in the area, naturalists and Aboriginal peoples, other relevant datasets should be consulted. Existing data will be supplemented by surveys where necessary. The EIS will give particular consideration to areas of concentration of birds, such as breeding, staging and/or wintering areas, species of conservation concern, as well as breeding areas of species low in number and high in the food chain.	6.9 Birds	6.12 Birds	6.12 Avifauna

[5] Surveys should be designed with reference to the Canadian Wildlife Service's guidance such as Technical Report No. 508, A Framework for the Scientific Assessment of Potential Project Impacts on Birds (Hanson et al. 2009). Appendix 3 of the Framework provides examples of project types and recommended techniques for assessing impacts on migratory birds.

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
6.1.8. Species at Risk	- a list of all potential or known species at risk that appear on federal and provincial lists that may be affected by the project (fauna and flora), using existing data and literature as well as surveys to provide current field data; - a list of all federal species designated by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) for listing on Schedule 1 of the Species at Risk Act. This will include those species in the risk categories of extirpated, endangered, threatened and special concern[6]. For the purposes of the provincial EA, any species listed by the Nova Scotia Endangered Species Act and listed as S1, S2 or S3 by the Atlantic Canada Conservation Data Centre; - any published studies that describe the regional importance, abundance and distribution of species at risk; and - residences, seasonal movements, movement corridors, habitat requirements, key habitat areas, identified critical habitat and/or recovery habitat (where applicable) and general life history of species at risk that may occur in the project area, or be affected by the project. Consult recovery strategies for information on the critical habitat of endangered and threatened species, and consult management plans for information on habitat use of species of special status.	6.10 Species at Risk	6.13 Species of Conservation Interest and Species at Risk	6.13 Species of Conservation Interest and Species at Risk
6.1.9. Ecosystems	The EIS will describe the various ecosystems (e.g. grassland, temperate forest) found in the project area which are likely to be affected by the project. For the provincial EA, the description of forest ecosystems within the project footprint should be undertaken using the Nova Scotia Forest Ecosystem Classification (http://novascotia.ca/natr/forestry/veg-types/).	6.7 Habitat and Flora 6.8 Terrestrial Fauna	6.10 Habitat and Flora 6.11 Terrestrial Fauna	6.10 Habitat and Flora 6.11 Terrestrial Fauna
6.1.10. Aboriginal peoples	With respect to potential effects on Aboriginal peoples and the related VCs, baseline information will be provided for each Aboriginal group identified in section 5 (and any groups identified after these guidelines are finalized). Baseline information will describe and characterize the elements in paragraph 5(1)(c) of CEAA 2012 based on the spatial and temporal scope selected for the assessment according to the factors outlined in Part 1, section 3.3.3. Baseline information will also characterize the region al context of each of the paragraph 5(1)(c) elements to support the assessment of project related effects and cumulative effects. Baseline information will be sufficient to provide a comprehensive understanding of the current state of each VC. Baseline information for current use of lands and resources for traditional purposes will focus on the traditional activity (e.g., hunting, fishing, trapping, plant gathering) and include a characterization of all attributes of the activity that can be affected by environmental change. This includes not only identifying species of importance but also assessing the quality and quantity of preferred traditional resources and locations, timing (e.g., seasonality, access restrictions, distance from community), ambient/sensory environment (e.g., noise, air quality, visual landscape, presence of others) and cultural environment (e.g., historical/generational connections, preferred areas). Specific aspects that will be considered include, but are not limited to: - location of traditional territory (including maps where available); - location of reserves and communities; - location of permanent residences, hunting camps and cabins; - traditional uses currently practiced or practiced in recent history; - fish, wildlife, birds, plants or other natural resources of importance for traditional use; - places where fish, wildlife, birds, plants or other natural resources are harvested; - access and travel routes for conducting traditional practices; - frequency, duration or timing of traditional practices; - cultural values associated with the area affected by the project and the traditional uses identified; - areas of concentration of migratory animals, such as breeding, denning and/or wintering areas; - ungulates, furbearers, amphibians, small mammals, and their habitat; - existing or proposed protected areas, special management areas, and conservation areas in the regional study area; - wetlands most likely to be affected by project activities according to their location, size, type (wetland class and form), species composition and ecological function (Canadian Wetland Classification System, National Wetlands Working Group, 1997); - key plant communities and animals that rely on wetlands; and - submerged floating and emergent aquatic vegetation.	6.11 Indigenous Peoples App B Summary of Consultation	6.14 Indigenous Peoples	6.14 Mi'kmaq of Nova Scotia

[6] Proponents are encouraged to consult COSEWIC's annual report for a listing of the designated wildlife species: http://www.cosewic.gc.ca/eng/sct0/index_e.cfm#sar

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
	Baseline information for health[7] and socio-economic conditions will include the functioning and health of the socio-economic environment, encompassing a broad range of matters that affect communities in the study area in a way that recognizes interrelationships, system functions and vulnerabilities. Specific aspects that will be considered include, but are not limited to: - drinking water sources (permanent, seasonal, periodic, or temporary); - reliance on country foods (also known as traditional foods) including food that is trapped, fished, hunted, harvested or grown for subsistence or medicinal purposes, outside of the commercial food chain; - which country foods are consumed by which Aboriginal groups, how frequently and where these country foods are harvested; - commercial activities (e.g. fishing, trapping, hunting, forestry, outfitting); - recreational uses; Any other baseline information that supports the analysis of predicted effects on Aboriginal peoples will be included as necessary. The EIS will also indicate how input from Aboriginal groups was used in establishing the baseline conditions related to health and socio -economics, physical and cultural heritage and current use of lands and resources for traditional purposes.			6.14 Mi'kmaq of Nova Scotia 6.16 Socio-economic Conditions Appendix C.2
6.1.11. Other environmental changes arising as a result of a federal decision or due to effects on federal lands, lands in another province or lands outside Canada	Should there be the potential for a change to the environment arising as a result of a federal decision(s), or on federal lands, lands in another province or lands outside Canada, the EIS will include baseline information on the environmental component likely to be affected (if this information is not already covered in other subsections of these guidelines). For example, if an authorization provided under the Fisheries Act was to result in the flooding of key wildlife habitat, baseline information should be provided on the wildlife species likely to be affected.	6.14.5 Environmental Effects Incidental of Decisions Made by a Federal Authority	6.17.5 Environmental Effects Incidental of Decisions Made by a Federal Authority	6.17.6 Environmental Effects Incidental of Decisions Made by a Federal Authority
6.2. Predicted changes to the physical environment	The assessment will include a consideration of the predicted changes to the environment as a result of the project being carried out or as a result of any powers duties or functions that are to be exercised by the federal government in relation to the project. These predicted changes to the environment are to be considered in relation to each phase of the project (construction, operation, decommissioning, and abandonment) and are to be described in terms of the geographic extent of the changes, the duration and frequency of change, and whether the environmental changes are reversible or irreversible.	6.X.6 Subsections for each VC titled "Project Interactions and Effects"	6.X.X Subsections for each VC titled "Project Activities Interactions and Effects"	Subsections for each VC titled "Project Activities/Interactions and Effects" 6.1.7 Noise 6.2.7 Air 6.3.7 Light 6.4.7 Greenhouse Gases 6.5.7 Geology, Soil, and Sediment 6.6.7 Groundwater 6.7.8 Water Quantity and Quality 6.8.7 Wetlands 6.9.7 Fish and Fish Habitat 6.10.7 Habitat and Flora 6.11.7 Terrestrial Fauna 6.12.8 Avifauna 6.13.7 Species of Conservation Interest and Species at Risk 6.14.7 Mi'kmaq of Nova Scotia 6.15.7 Physical Cultural Heritage 6.16.10 Socio-economic Conditions

[7] The proponent should refer to Health Canada's Useful Information for Environmental Assessments document in order to include the appropriate baseline information relevant to human health. This document can be obtained at http://www.hc-sc.gc.ca/ewhsemt/pubs/eval/environ_assess-eval/index-eng.php

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
6.2.1. Changes to the atmospheric environment	- changes in air quality - changes in greenhouse gas emissions levels; - changes in ambient noise levels; and - changes in night-time light levels.	6.1.6 Project Activities Interactions and Effects	6.1.6 Project Activities and Noise Interactions and Effects 6.2.5 Project Activities and Air Interactions and Effects 6.3.6 Project Activities and Light Interactions and Effects 6.4.6 Project Activities and GHG Interactions and Effects	6.1.7 Project Activities and Noise Interactions and Effects 6.2.7 Project Activities and Air Interactions and Effects 6.3.7 Project Activities and Light Interactions and Effects 6.4.7 Project Activities and GHG Interactions and Effects
6.2.2. Changes to groundwater and surface water	- changes to turbidity, oxygen level, water temperature, ice regime, water quality; - changes to the hydrological and hydrometric conditions; - changes to groundwater flow regime (directions and rates of flow), groundwater recharge/discharge areas and any changes to groundwater infiltration areas; - changes to water quality attributed to acid rock drainage and metal leaching associated with the storage of waste rock, ore, low grade ore, tailings, overburden and potential construction material, including: - short term metal leaching properties; - longer term rates of acid generation (if any) and metal leaching; - estimates of the potential for mined materials (including waste rock, tailings and low grade ore) to be sources of acid rock drainage or metal leaching; - estimates of potential time to the onset of acid rock drainage or metal leaching; - quantity and quality of leachate from samples of tailings, waste rock, and ore; - quantity and quality of effluent to be released from the site into the receiving waters; - quality of humidity cell or column test liquid from acid rock testing; - sensitivity analysis to assess the effects of imperfect segregation of waste rock; - pit water chemistry during operation and post-closure, and pit closure management measures (e.g. flooding). This will include geochemical modelling of pit water quality in the post-closure period; - surface and seepage water quality and flow rates from the waste rock dumps, tailings/waste rock impoundment facility, stockpiles and other infrastructure during operation and post-closure; - drawings and/or figures showing groundwater contours (piezometric surfaces) to illustrate projected seepage conditions for the applicable project components; and - a discussion of the potential for and timing of off-site migration of impacted groundwater, and an analysis of contaminant attenuation capacities within the hydrogeological units within the project area.	6.3.6 Project Activities and Surface Water Interactions and Effects; 6.4.6 Project Activities and Groundwater Quality and Quantity Interactions and Effects	6.6.6 Project Activities and Groundwater Quality and Quantity Interactions and Effects 6.7.6 Project Activities and Surface Water Interactions and Effects	6.6.7 Project Activities and Groundwater Quality and Quantity Interactions and Effects 6.7.8 Project Activities and Surface Water Interactions and Effects
6.2.3. Changes to wetlands	- changes in wetland size, function, or resident flora or habitat; - changes to hydrological conditions; - identification of all direct and indirect effects on wetlands; and - if warranted, a preliminary wetland compensation plan as detailed in the Nova Scotia Wetland Conservation Policy.	6.5.6 Project Activities and Wetlands Interactions and Effects	6.8.6 Project Activities and Wetlands Interactions and Effects	6.8.7 Project Activities and Wetlands Interactions and Effects
6.2.4. Changes to the terrestrial landscape	- overall description of changes related to landscape disturbance; - changes to migratory bird habitat, including losses, structural changes, fragmentation of habitat and wetlands (cover types, ecological land unit in terms of quality, quantity, diversity, distribution and functions) used by migratory birds; - changes to critical habitat for provincially or federally listed species at risk; and - changes to key habitat for species important to Aboriginal current use of resources.	6.2.6 Project Activities Interactions and Effects; 6.7.6 Project Activities and Habitat and Flora Interactions and Effects; 6.8.6 Project Activities and Terrestrial Fauna Interactions and Effects	6.10.6 Project Activities and Habitat and Flora Interactions and Effects 6.11.6 Project Activities and Terrestrial Fauna Interactions and Effects	6.10.7 Project Activities and Habitat and Flora Interactions and Effects 6.11.7 Project Activities and Terrestrial Fauna Interactions and Effects

6.3. Predicted effects on valued components	Based on the predicted changes to the environment identified in section 6.2, the proponent is to assess the environmental effects of the project on VCs including those listed below. Additional VCs may be identified through the analysis of environmental effects and based on federal or provincial requirements.	6.X.6 Subsections for each VC titled "Project Interactions and Effects"	6.X.X Subsections for each VC titled "Project Interactions and Effects"	Subsections for each VC titled "Project Interactions and Effects" 6.1.7 Noise 6.2.7 Air 6.3.7 Light 6.4.7 Greenhouse Gases 6.5.7 Geology, Soil, and Sediment 6.6.7 Groundwater 6.7.8 Water Quantity and Quality 6.8.7 Wetlands 6.9.7 Fish and Fish Habitat 6.10.7 Habitat and Flora 6.11.7 Terrestrial Fauna 6.12.8 Avifauna 6.13.7 Species of Conservation Interest and Species at Risk 6.14.7 Mi'kmaq of Nova Scotia 6.15.7 Physical Cultural Heritage 6.16.10 Socio-economic Conditions
6.3.1. Fish and fish habitat	- the identification of any potential harmful alteration, disruption or destruction of fish habitat, including the calculations of any potential habitat loss (temporary or permanent) in terms of surface areas (e.g. spawning grounds, fry-rearing areas, feeding), and in relation to watershed availability and significance. The assessment will include a consideration of: - the geomorphological changes and their effects on hydrodynamic conditions and fish habitats (e.g. modification of substrates, dynamic imbalance, silting of spawning beds); - the modifications of hydrological and hydrometric conditions on fish habitat and on the fish species' life cycle activities (e.g. reproduction, fry-rearing, movements); - potential impacts on riparian areas that could affect aquatic biological resources and productivity taking into account any anticipated modifications to fish habitat; and - any potential imbalances in the food web in relation to baseline. - the effects of changes to the aquatic environment on fish and their habitat, including: - estimates of fish mortality for various species and life stage (e.g. egg, juvenile, adult); - the anticipated changes in the composition and characteristics of the populations of various fish species, included shellfish and forage fish; - any modifications in migration or local movements (upstream and downstream migration, and lateral movements) following the construction and operation of works (physical and hydraulic barrier); - any reduction in fish populations as a result of potential overfishing due to increased access to the project area; and - any modifications and use of habitats by federally or provincially listed fish species. - a discussion of how project construction timing correlates to key fisheries windows for freshwater and anadromous species, and any potential impacts resulting from overlapping periods; and - a discussion of how vibration caused by blasting may affect fish behaviour, such as spawning or migrations.	6.6.6 Project Activities and Fish and Fish Habitat Interactions and Effects	6.9.6 Project Activities and Fish and Fish Habitat Interactions and Effects	6.9.7 Project Activities and Fish and Fish Habitat Interactions and Effects
6.3.2. Migratory birds	- direct migratory bird mortality that could be caused by clearing of sites or birds and nests being in contact with contaminated waters (e.g., tailing impoundment area); - collision risk of migratory birds with any project infrastructures; and - indirect effects caused by increased disturbance (e.g. noise, light, presence of workers), relative abundance movements and changes in migratory bird habitat.	6.9.6 Project Activities and Birds Interactions and Effects	6.12.7 Project Activities and Birds Interactions and Effects	6.12.8 Project Activities and Avifauna Interactions and Effects

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
6.3.3. Species at risk	- for each habitat unit, the potential effects of the project on federally listed species at risk and those species listed by the Committee on the Status of Endangered Wildlife in Canada classified as extirpated, endangered, threatened or of special concern (flora and fauna) and their critical habitat. Also the potential effects to any species listed by the Nova Scotia Endangered Species Act and listed as S1, S2 or S3 by the Atlantic Canada Conservation Data Centre.	6.10.6 Project Activities and Species at Risk Interactions and Effects	6.13.6 Project Activities and Species at Risk Interactions and Effects	6.13.7 Project Activities and Species at Risk Interactions and Effects
6.3.4. Aboriginal peoples	With respect to Aboriginal peoples, a description and analysis of how changes to the environment caused by the project will affect each Aboriginal group's: - current use of land and resources for traditional purposes. This assessment will characterize the effect(s) on the use or activity (e.g., hunting, fishing, trapping, plant gathering) as a result of the underlying changes to the environment (i.e., how will the activity change if the project proceeds). The underlying changes to the environment will also be described, including, but not limited to: - any changes to resources (fish, wildlife, birds, plants or other natural resources) used for traditional purposes (e.g. hunting, fishing, trapping, collection of medicinal plants, use of sacred sites); - any changes or alterations to access into the areas used for traditional purposes, including development of new roads, deactivation or reclamation of access roads and changes to waterways that affect navigation; - any changes to the environment that affect cultural value or importance associated with traditional uses or areas affected by the project (e.g. values or attributes of the area that make it important as a place for inter-generational teaching of language or traditional practices, communal gatherings, integrity of preferred practice areas); - how timing of project activities that have the potential to affect Aboriginal peoples (e.g., construction, blasting, discharges) interacts with the timing of traditional practices, and any potential effects resulting from overlapping periods; - any changes to the alienation of lands from Aboriginal traditional use, including consideration of the regional context for traditional use, and the value of the project area in that regional context; - any changes to environmental quality (e.g. air, water, soil) or the sensory environment (e.g. noise, light, visual landscape), or perceived disturbance of the environment (e.g. fear of contamination of water or country foods) that could detract from Aboriginal use of the area or lead to avoidance of the area; and - an assessment of the potential to return affected areas to pre-disturbance conditions to support traditional practices. - human health, focusing on effects on health outcomes or risks in consideration of but not limited to potential changes in air quality, effects of vibration from blasting, quality and availability of country foods, water quality and quantity (drinking and recreational), and noise exposure. When risks to human health due to changes in one or more of these components are predicted, a complete Human Health Risk Assessment (HHRA) examining all exposure pathways for pollutants of concern may be necessary to adequately characterize potential risks to human health. Where adverse health effects are predicted, any incidental effects such as effects on current use of lands and resources for traditional purposes will also be assessed. The proponent must provide a justification if it determines that an assessment of the potential for contamination of country foods is not required or if some contaminants are excluded from the assessment.; - socio-economic conditions, including but not limited to: - the use of navigable waters; - forestry and logging operations; - commercial fishing, hunting, trapping, and gathering activities; - commercial outfitters; and - recreational use. - physical and cultural heritage, and structure, site or thing of historical, archaeological, paleontological or architectural significance to Aboriginal groups, including, but not limited to: - the loss or destruction of physical and cultural heritage; - changes to access to physical and cultural heritage; and - changes to the cultural value or importance associated with physical and cultural heritage. Other effects of changes to the environment on Aboriginal peoples should be reflected as necessary.	6.11.6 Project Activities and Indigenous Peoples Interactions and Effects	6.14.6 Project Activities and Indigenous Peoples Interactions and Effects	6.14.7 Project Activities and Mi'kmaq of Nova Scotia Interactions and Effects 6.15.7 Project Activities and Physical and Cultural Heritage Interactions and Effects Appendix C.2

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
6.4. Other valued components that may be affected as a result of a federal decision or due to effects on federal lands, lands in another province or lands outside Canada	If there is the potential for a change to the environment arising as a result of a federal decision(s), for example an authorisation under section 35 of the Fisheries Act, the EIS should include a description of the specific project components for which a federal authorisation/decision is required, and an assessment of any other VCs (not already covered in other subsections of these guidelines) that may be affected by the changes to the environment caused by these specific project components. If there is the potential for the project to result in environmental changes on federal lands, another province, or another country, then VCs of importance not already identified should be included. For example, if the project will result in the generation of greenhouse gas emissions, the EIS should include a description of the project's greenhouse gas emissions in a regional, provincial, national or international context if applicable. Suggested VCs are noted below for this project.	6.X.6 Subsections for each VC titled "Project Interactions and Effects"	6.X.X Subsections for each VC titled "Project Interactions and Effects"	Subsections for each VC titled "Project Interactions and Effects" 6.1.7 Noise 6.2.7 Air 6.3.7 Light 6.4.7 Greenhouse Gases 6.5.7 Geology, Soil, and Sediment 6.6.7 Groundwater 6.7.8 Water Quantity and Quality 6.8.7 Wetlands 6.9.7 Fish and Fish Habitat 6.10.7 Habitat and Flora 6.11.7 Terrestrial Fauna 6.12.8 Avifauna 6.13.7 Species of Conservation Interest and Species at Risk 6.14.7 Mi'kmaq of Nova Scotia 6.15.7 Physical Cultural Heritage 6.16.10 Socio-economic Conditions
6.4.1. Atmospheric environment	- effects on the atmospheric environment (e.g. air emissions, noise, light) that could occur within Beaver Lake Indian Reserve 17 and as a result of project components that could require a federal decision.	6.1.6 Project Activities Interactions and Effects	6.1.6 Project Activities and Noise Interactions and Effects 6.2.5 Project Activities and Air Interactions and Effects 6.3.6 Project Activities and Light Interactions and Effects 6.4.6 Project Activities and GHG Interactions and Effects	6.1.7 Project Activities and Noise Interactions and Effects 6.2.7 Project Activities and Air Interactions and Effects 6.3.7 Project Activities and Light Interactions and Effects 6.4.7 Project Activities and GHG Interactions and Effects
6.4.2. Water quality and quantity	- all direct and indirect effects on water quality and quantity in Beaver Lake Indian Reserve 17 and those affected by project components that could require a federal decision.	6.3.6. Project Activities and Surface Water Interactions and Effects 6.4.6 Project Activities and Groundwater Quality and Quantity Interactions and Effects	6.6.6. Project Activities and Groundwater Quality and Quantity Interactions and Effects 6.7.6 Project Activities and Surface Water Interactions and Effects	6.6.7 Project Activities and Groundwater Quality and Quantity Interactions and Effects 6.7.8 Project Activities and Surface Water Interactions and Effects
6.4.3. Wetlands	- all direct and indirect effects on wetlands in Beaver Lake Indian Reserve 17 and those affected by project components that could require a federal decision.	6.5.6 Project Activities and Wetlands Interactions and Effects	6.8.6 Project Activities and Wetlands Interactions and Effects	6.8.7 Project Activities and Wetlands Interactions and Effects
6.4.4. Plants	- all direct and indirect effects on plants in Beaver Lake Indian Reserve 17 and those affected by project components that could require a federal decision.	6.7.6 Project Activities and Habitat and Flora Interactions and Effects	6.10.6 Project Activities and Habitat and Flora Interactions and Effects	6.10.7 Project Activities and Habitat and Flora Interactions and Effects
6.4.5. Wildlife	- all direct and indirect effects on wildlife (e.g. furbearers) in Beaver Lake Indian Reserve 17 and those affected by components of the Project that could require a federal decision.	6.8.6 Project Activities and Terrestrial Fauna Interactions and Effects	6.11.6 Project Activities and Terrestrial Fauna Interactions and Effects	6.11.7 Project Activities and Terrestrial Fauna Interactions and Effects
6.4.6. Health and socio-economic conditions	- a description and analysis of how changes to the environment caused by project components that could require a federal decision could affect heath and socio-economic conditions of non-Aboriginal peoples (e.g. tourism, hunting and trapping, hiking).	6.13.6 Project Activities Interactions and Effects	6.16.7 Project Activities and Socioeconomic Interactions and Effects	6.16.10 Project Activities and Socioeconomic Interactions and Effects

6.4.7. Physical and cultural heritage and structures, sites or things of historical, archaeological, paleontological or architectural significance	- a description and analysis of how changes to the environment caused by project components that could require a federal decision could affect physical and cultural heritage and structuress, sites or things of historical, archaeological, paleontological or architectural significance of non-Aboriginal People.	6.12.6 Project Activities Interactions and Effect	6.15.6 Project Activities and Physical and Cultural Heritage Interactions and Effects	6.15.7 Project Activities and Physical and Cultural Heritage Interactions and Effects
6.5. Mitigation	Every EA conducted under CEAA 2012 will consider measures that are technically and economically feasible and that would mitigate any significant adverse environmental effects of the project. Each measure will be specific, achievable, measurable and verifiable, and described in a manner that avoids ambiguity in intent, interpretation and implementation. Mitigation measures may be considered for inclusion as conditions in the EA decision statement and/or in other compliance and enforcement mechanisms provided by other authorities' permitting or licensing processes. As a first step, the proponent is encouraged to use an approach based on the avoidance and reduction of the effects at the source. Such an approach may include the modification of the design of the project or relocation of project components. The EIS will describe the standard mitigation practices, policies and commitments that constitute technically and economically feasible mitigation measures and that will be applied as part of standard practice regardless of location (including the measures directed at promoting beneficial or mitigating adverse socio-economic effects. The EIS will then describe the project's environmental protection plan and its environmental management system, through which the proponent will deliver this plan. The plan will provide an overall perspective on how potentially adverse effects would be minimized and managed over time. The EIS will further discuss the mechanisms the proponent would use to require its contractors and sub-contractors to comply with these commitments and policies and with auditing and enforcement programs. The EIS will then describe mitigation measures that are specific to each environmental effect identified. Measures will be written as specific commitments that clearly describe how the proponent intends to implement them and the environmental outcome the mitigation is designed to address. Where mitigation measures have been identified in relation to species and/or critical habitat listed under the Species at Risk Act, the mitigation measures will be consistent with any applicable recovery strategy and action plans.	6.X.7 Subsections for each VC titled "Mitigation and Monitoring"	6.X.X Subsections for each VC titled "Mitigation"	Subsections for each VC titled "Mitigation" 6.1.8 Noise 6.2.8 Air 6.3.8 Light 6.4.8 Greenhouse Gases 6.5.8 Geology, Soil, and Sediment 6.6.8 Groundwater 6.7.9 Water Quantity and Quality 6.8.8 Wetlands 6.9.8 Fish and Fish Habitat 6.10.8 Habitat and Flora 6.11.8 Terrestrial Fauna 6.12.9 Avifauna 6.13.8 Species of Conservation Interest and Species at Risk 6.14.8 Mi'kmaq of Nova Scotia 6.15.8 Physical Cultural Heritage 6.16.11 Socio-economic Conditions
	The EIS will specify the actions, works, minimal disturbance footprint techniques, best available technology, corrective measures or additions planned during the project's various phases to eliminate or reduce the significance of adverse effects. The impact statement will also present an assessment of the effectiveness of the proposed technically and economically feasible mitigation measures. The reasons for determining if the mitigation measure reduces the significance of an adverse effect will be made explicit. The EIS will indicate what other technically and economically feasible mitigation measures were considered, and explain why they were rejected. Trade-offs between cost savings and effectiveness of the various forms of mitigation will be justified. The EIS will identify who is responsible for the implementation of these measures and the system of accountability. Where mitigation measures are proposed to be implemented for which there is little experience or for which there is some question as to their effectiveness, the potential risks and effects to the environment should those measures not be effective will be clearly and concisely described. In addition, the EIS will identify the extent to which technology innovations will help mitigate environmental effects. Where possible, it will provide detailed information on the nature of these measures, their implementation, management and the requirements of the follow-up program. Adaptive management is not considered as a mitigation measure, but if the follow-up program (refer to section 8) indicates that corrective action is required, the proposed approach for managing the action should be identified.			2.10 Alternative Means of Carrying out the Project 9 Summary of the Environment al Impact Statement, Table 9.1-1 Summary of Key Mitigation Measures by Valued Component

6.6. Significance of residual effects	After having established the technically and economically feasible mitigation measures, the EIS will present any residual environmental effects of the project on the VCs identified in section 6.3. The residual effects will be described, even if very small or deemed insignificant. The EIS will then provide an analysis of the significance of the residual environmental effects that are considered adverse, using guidance described in section 4 of the Agency's reference guide Determining Whether a Project is Likely to Cause Significant Adverse Environmental Effects12 . The EIS will identify the criteria used to assign significance ratings to any predicted adverse effects. It will contain clear and sufficient information to enable the Agency, technical and regulatory agencies, Aboriginal groups and the public to review the proponent's analysis of the significance of effects. The EIS will document the terms used to describe the level of significance. The following criteria should be used in determining the significance of residual effects: - magnitude; - geographic extent; - duration; - frequency; - reversibility; - ecological and social context; and - existence of environmental standards, guidelines or objectives for assessing the impact. In assessing significance against these criteria the proponent will, where possible, use relevant existing regulatory documents, environmental standards, guidelines, or objectives such as prescribed maximum levels of emissions or discharges of specific hazardous agents into the environment. The EIS will contain a section which explains the assumptions, definitions and limits to the criteria mentioned above in order to maintain consistency between the effects on each VC. Where significant adverse effects are identified, the EIS will set out the probability (likelihood) that they will occur, and describe the degree of scientific uncertainty related to the data and methods used within the framework of its environmental analysis.	6.X.8 Subsections for each VC titled "Residual effects and Significance"	6.X.X Subsections for each VC titled "Residual Effects and Significance"	Subsections for each VC titled "Residual Effects and Significance" 6.1.9 Noise 6.2.9 Air 6.3.9 Light 6.4.9 Greenhouse Gases 6.5.9 Geology, Soil, and Sediment 6.6.9 Groundwater 6.7.10 Water Quantity and Quality 6.8.9 Wetlands 6.9.9 Fish and Fish Habitat 6.10.9 Habitat and Flora 6.11.9 Terrestrial Fauna 6.12.10 Avifauna 6.13.9 Species of Conservation Interest and Species at Risk 6.14.9 Mi'kmaq of Nova Scotia 6.15.9 Physical Cultural Heritage 6.16.11 Socio-economic Conditions

6.7.1. Effects of potential accidents or malfunctions	The failure of certain works caused by human error or exceptional natural events (e.g. flooding, earthquake) could cause major effects. The proponent will therefore conduct an analysis of the risks of accidents and malfunctions, determine their effects and present a preliminary emergency measures. Taking into account the lifespan of different project components, the proponent will identify the probability of potential accidents and malfunctions related to the project, including an explanation of how those events were identified, potential consequences (including the environmental effects as defined in section 5 of CEAA 2012), the plausible worst case scenarios and the effects of these scenarios. This assessment will include an identification of the magnitude of an accident and/or malfunction, including the quantity, mechanism, rate, form and characteristics of the contaminants and other materials likely to be released into the environment during the accident and malfunction events and would potentially result in an adverse environmental effect as defined in section 5 of CEAA 2012. The EIS will describe the safeguards that have been established to protect against such occurrences and the contingency and emergency response procedures in place if such events do occur.	6.15 Accidents and Malfunctions	6.18 Accidents and Malfunctions	6.18 Accidents and Malfunctions
6.7.2. Effects of the environment on the project	The EIS will take into account how local conditions and natural hazards, such as severe and/or extreme weather conditions and external events (e.g. flooding, drought, ice jams, landslides, erosion, subsidence, fire, outflow conditions and seismic events) could adversely affect the project and how this in turn could result in impacts to the environment (e.g., extreme environmental conditions result in malfunctions and accidental events). These events will be considered in different probability patterns (i.e., 5-year flood vs. 100-year flood). Longer-term effects of climate change will also be discussed up to the projected post-closure phase of the project. This discussion will include a description of climate data used. For the provincial assessment the proponent will consider the Guide to Considering Climate Change in Environmental Assessments in Nova Scotia. The EIS will provide details of planning, design and construction strategies intended to minimize the potential environmental effects of the environment on the project.	7 Effects of the Environment on the Project	7 Effects of the Environment on the Project	7 Effects of the Environment on the Project
6.7.3. Cumulative effects assessment	The proponent will identify and assess the project's cumulative effects using the approach described in the Agency's Operational Policy Statement entitled Addressing Cumulative Environmental Effects under the Canadian Environmental Assessment Act, 2012 and the guide entitled Cumulative Effects Assessment Practitioners' Guide, 1999[8]. Cumulative effects are defined as changes to the environment due to the project combined with the existence of other past, present and reasonably foreseeable physical activities. Cumulative effects may result if: - implementation of the project being studied may cause direct residual adverse effects on the valued components, taking into account the application of technically and economically feasible mitigation measures; and - the same valued components may be affected by other past, present or reasonably foreseeable physical activities. Valued components that would not be affected by the project or would be affected positively by the project can, therefore, be omitted from the cumulative effects assessment. A cumulative effect on an environmental component may, however, be important even if the assessment of the project's effects on this component reveals that the effects of the project are minor. In its EIS, the proponent will: - identify and provide a rationale for the valued components that will constitute the focus of the cumulative effects assessment, emphasizing this assessment on the VCs most likely to be affected by the project and other project and activities. To this end, the proponent must consider, without limiting itself thereto, the following components likely to be affected by the project: - fish and fish habitat; - migratory birds; - species at risk; and - Aboriginal peoples.	8 Cumulative Effects Assessment	8 Cumulative Effects Assessment	8 Cumulative Effects Assessment

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
	- identify and justify the spatial and temporal boundaries for the cumulative effects assessment for each VC selected. The boundaries for the cumulative effects assessments will generally be different for each VC considered. These cumulative effects boundaries will also generally be larger than the boundaries for the corresponding project effects;			8 Cumulative Effects Assessment
	- identify the sources of potential cumulative effects. Specify other projects or activities that have been or that are likely to be carried out that could cause effects on each selected VC within the boundaries defined, and whose effects would act in combination with the residual effects of the project. This assessment may consider the results of any relevant study conducted by a committee established under section 73 or 74 of CEAA 2012; - assess the cumulative effects on each VC selected by comparing the future scenario with the project and without the project. Effects of past activities (activities that have been carried out) will be used to contextualize the current state of the VC. In assessing the cumulative effects on current use of lands and resources for traditional purposes by Aboriginal peoples, the assessment will focus on the cumulative effects on the activity (e.g., hunting, fishing, trapping, plant harvesting). - describe the mitigation measures that are technically and economically feasible. The proponent shall assess the effectiveness of the measures applied to mitigate the cumulative effects. In cases where measures exist that are beyond the scope of the proponent's responsibility that could be effectively applied to mitigate these effects, the proponent will identify these effects and the parties that have the authority to act. In such cases, the EIS will summarize the discussions that took place with the other parties in order to implement the necessary measures over the long term; - determine the significance of the cumulative effects; and - develop a follow-up program to verify the accuracy of the assessment or to dispel the uncertainty concerning the effectiveness of mitigation measures for certain cumulative effects. The proponent is encouraged to consult with key stakeholders and Aboriginal groups prior to finalizing the choice of VCs and the appropriate boundaries to assess cumulative effects.			8 Cumulative Effects Assessment
7. SUMMARY OF ENVIRONMENT EFFECTS ASSESSMENT	The EIS will contain a table summarising the following key information: - potential environmental effects; - proposed mitigation measures to address the effects identified above; and - potential residual effects and the significance of the residual environmental effects. The summary table will be used in the EA Report prepared by the Agency. An example of a format for the key summary table is provided in Appendix 1 of this document. In a second table, the EIS will summarize all key mitigation measures and commitments made by the proponent which will more specifically mitigate any significant adverse effects of the project on valued components (i.e., those measures that are essential to ensure that the project will not result in significant adverse environmental effects).	10 Summary of the Environmental Impact Statement	10 Environmental Impact Statement Summary and Conclusions	9 Summary of Environmental Effects Assessment Beaver Dam Mine Project Environmental Impact Statement Summary – May 2021
8. FOLLOW-UP AND MONITORING PROGRAMS	A follow-up program is designed to verify the accuracy of the effects assessment and to determine the effectiveness of the measures implemented to mitigate the adverse effects of the project. The goal of a monitoring program is to ensure that proper measures and controls are in place in order to decrease the potential for environmental degradation during all phases of project development, and to provide clearly defined action plans and emergency response procedures to account for human and environmental health and safety.	9 Compliance and Effects Monitoring Program	9 Compliance and Effects Monitoring Program	10 Follow-up and Monitoring Programs Proposed

Beaver Dam Mine Project Updated 2021 Environmental Impact Statement Guidelines (CEAA 2016) Concordance Table (continued)

Guidelines Section	Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act,* 2012 Beaver Dam Mine Project EIS Guidelines Descriptions	Applicable Corresponding 2017 EIS Section	Applicable Corresponding Revised 2019 EIS Section	Applicable Corresponding Updated 2021 EIS Section
8.1. Follow-up program	The duration of the follow-up program shall be as long as required for the environment to regain its equilibrium and to evaluate the effectiveness of the mitigation measures. The EIS shall present a preliminary follow-up program in particular for areas where scientific uncertainty exists in the prediction of effects. This program shall include: - objectives of the follow-up program and the VCs targeted by the program; - list of elements requiring follow-up; - number of follow-up studies planned as well as their main characteristics (list of the parameters to be measured, planned implementation timetable, etc.); - intervention mechanism used in the event that an unexpected deterioration of the environment is observed; - mechanism to disseminate follow-up results among the concerned populations; - accessibility and sharing of data for the general population; - opportunity for the proponent to include the participation of Aboriginal groups and stakeholders on the affected territory, during the development and implementation of the program; and - involvement of local and regional organizations in the design, implementation and evaluation of the follow-up results as well as any updates, including a communication mechanism between these organizations and the proponent.	9.1 Environmental Management Plans	9.1 Environmental Management Plans	10.1 Environmental Follow-up Programs
8.2. Monitoring	The proponent will prepare an environmental monitoring program for all phases of the project. This program will help ensure that the project is implemented as proposed, that the mitigation or compensation measures proposed to minimize the project's environmental effects are effectively implemented, and that the conditions set at the time of the project's authorization and the requirements pertaining to the relevant laws and regulations are met. The monitoring program will also make it possible to check the proper operation of works, equipment and facilities. If necessary, the program will help reorient the work and possibly make improvements at the time of construction and implementation of the various elements of the project. Specifically, the environmental impact statement shall present an outline of the preliminary environmental monitoring program, including the: - identification of the interventions that pose risks to one or more of the components and the measures and means planned to protect the environment; - description of the characteristics of the monitoring program where foreseeable (e.g., location of interventions, planned protocols, list of measured parameters, analytical methods employed, schedule, human and financial resources required); - description of the proponent's intervention mechanisms in the event of the observation of noncompliance with the legal and environmental requirements or with the obligations imposed on contractors by the environmental provisions of their contracts; and - guidelines for preparing monitoring reports (number, content, frequency, format) that will be sent to the authorities concerned.	9.2 Environmental Monitoring Plans	9.2 Environmental Monitoring Plans	10.2 Environmental Monitoring Plans
9. NOVA SCOTIA ENVIRONMENT REQUIREMENTS	The Government of Nova Scotia requires a Class I Registration under the Nova Scotia Environmental Assessment Regulations made under the Environment Act. Pursuant to Schedule A of the Environmental Assessment Regulations a facility that extracts or processes a metallic or non-metallic mineral is a Class I Undertaking.	-	-	Beaver Dam Mine Project Updated 2021 Environmental Impact Statement
	The undertaking will not be officially registered until the proponent submits all applicable fees prescribed under the Nova Scotia Environment Act and all the required information. When preparing a registration document for a Class 1 undertaking, the proponent must ensure that certain information is included in the document. Under Section 9 (1A) of the Environmental Assessment Regulations, a registration document must include, as a minimum, the following information:	-	-	Beaver Dam Mine Project Updated 2021 Environmental Impact Statement
	- the name of the undertaking;	1.2 Proponent Information	1.2 Proponent Information	1.4 Proponent Information
	- the location of the undertaking;	2.1 Project Location	2.1 Project Location	1.2.2 Project Location 2.3 Project Location

	The proponent also needs to address factors relevant to the Minister's decision. Under Section 12 of the Environmental Assessment Regulations, the Minister must consider the following information when making a decision: - the location of the proposed undertaking and the nature and sensitivity of the surrounding area; - the size, scope and complexity of the proposed undertaking; - concerns expressed by the public and Aboriginal people about the adverse effects or the environmental effects of the proposed undertaking; - steps taken by the proponent to address environmental concerns expressed by the public and Aboriginal people; - whether environmental baseline information submitted under subclause 9(1A)(b)(x) for the undertaking is sufficient for predicting adverse effects or environmental effects related to the undertaking; - potential and known adverse effects or environmental effects of the proposed undertaking, including identifying any effects on species at risk, species of conservation concern and their habitats; - project schedules where applicable; - planned or existing land use in the area of the undertaking; - other undertakings in the area; - whether compliance with licenses, certificates, permits, approvals or other documents of authorization required by law will mitigate the environmental effects; and - such other information as the Minister may require. For more information the proponent may refer to the Guide to Preparing an EA Registration Document for Mining Developments in Nova Scotia.	-	-	Beaver Dam Mine Project Updated 2021 Environmental Impact Statement

2.10.10 Mine Waste Management Facilities 2-22
2.10.10.1 Waste Rock Storage 2-22
2.10.10.2 Tailings Storage 2-23
2.10.11 The Preferred Approach 2-24
2.11 Conclusions 2-28
3 PUBLIC ENGAGEMENT 3-1
3.1 Introduction 3-1
3.1.1 Summary of Public Engagement Before the Updates 3-1
3.1.2 Summary of Updates to Public Engagement 3-1
3.2 Objectives 3-3
3.3 Spatial Boundary 3-3
3.4 Engagement Strategy 3-6
3.4.1 Adaptive Management 3-8
3.4.2 Community Liaison Committee 3-9
3.4.3 Open Houses and Town Hall Meetings 3-10
3.4.4 Presentations and Meetings with Local Community Groups 3-10
3.4.5 Community Bulletins (Newsletter) 3-10
3.4.6 Signage 3-11
3.4.7 Website, Email, Phone Line and other Digital Media 3-11
3.4.8 Media and Press Releases 3-12
3.4.9 Meetings with Local Residents and Landowners 3-12
3.4.10 Complaints Response Procedure 3-12
3.5 Regulatory Consultation 3-12
3.6 Public Engagement Activities 3-13
3.6.1 Community Open Houses 3-13
3.6.2 Community Liaison Committee 3-15
3.6.3 Stakeholder Meetings 3-16
3.6.3.1 Nova Scotia Salmon Association 3-16
3.6.3.2 Mooseland and Area Community Association 3-17
3.6.3.3 Sheet Harbour and Area Chamber of Commerce 3-17

3.6.3.4 All Terrain Vehicle Groups 3-18
3.6.4 Summary of Supplementary Engagement - 2020 3-18
3.7 Key Concerns Raised and Proponent Responses 3-20
3.7.1 Public Engagement 2015 to 2019 3-20
3.7.2 2020 Supplementary Engagement Strategy 3-20
3.8 Ongoing Public Engagement 3-31
4 INDIGENOUS PEOPLES ENGAGEMENT PROGRAM 4-1
4.1 Introduction 4-1
4.1.1 Summary of Indigenous Peoples Engagement Before the Updates 4-1
4.1.2 Summary of Updates to Indigenous Peoples Engagement 4-1
4.2 Objectives 4-2
4.3 Indigenous People in Nova Scotia 4-3
4.4 Key Engagement Activities 4-5
4.5 Mi'kmaq of Nova Scotia Engagement Activities 4-7
4.5.1 Community Open Houses 4-8
4.5.2 Community Liaison Committee 4-9
4.6 Key Concerns Raised by the Mi'kmaq of Nova Scotia and Proponent Responses 4-10
4.7 Ongoing Mi'kmaq of Nova Scotia Engagement 4-14
5 ENVIRONMENTAL EFFECTS ASSESSMENT METHODOLOGY 5-1
5.1 Introduction 5-1
5.1.1 Summary of Environmental Effects Assessment Methodology Before the Updates 5-1
5.1.2 Summary of Updates to Environment Effects Assessment Methodology 5-1
5.2 Scope of the Environmental Assessment 5-2
5.2.1 Designated Project 5-2
5.2.2 Factors to be Considered 5-4
5.2.3 Scope of Factors to be Considered 5-5
5.3 Overview of Approach 5-6
5.4 Valued Components Selection 5-6
5.5 Project Boundaries 5-9
5.5.1 Temporal Boundaries 5-9
5.5.2 Spatial Boundaries 5-9

5.5.2.1 Project Area (PA) 5-9
5.5.2.2 Local Assessment Area (LAA) 5-9
5.5.2.3 Regional Assessment Area (RAA) 5-9
5.5.3 Administrative Boundaries 5-13
5.5.4 Technical Boundaries 5-13
5.6 Standards or Thresholds for Characterizing and Determining Significance of Effects . 5-13
5.7 Baseline Conditions 5-13
5.8 Anticipated Project-Environment Interaction 5-14
5.9 Effects Prediction 5-18
5.10 Mitigation Measures 5-18
5.11 Residual Effects and the Determination of Significance 5-18
5.12 Follow-up and Effects Monitoring 5-23
5.13 Effects of the Environment on the Project 5-23
6 ENVIRONMENTAL EFFECTS ASSESSMENT 6-1
6.1 Noise 6-1
6.1.1 Introduction 6-1
6.1.1.1 Summary of Noise Before the Updates 6-1
6.1.1.2 Summary of Updates to Noise 6-1
6.1.2 Rationale for Valued Component Selection 6-2
6.1.3 Baseline Program Methodology 6-3
6.1.4 Baseline Conditions 6-5
6.1.4.1 Overview 6-5
6.1.4.2 Ambient Noise 6-5
6.1.5 Consideration of Engagement Results 6-8
6.1.6 Effects Assessment Methodology and Modelling 6-8
6.1.6.1 Boundaries 6-8
6.1.6.2 Thresholds for Determination of Significance 6-11
6.1.6.3 Noise Modelling Methodology 6-12
6.1.7 Project Activities, Noise Interactions, and Predicted Effects 6-18
6.1.7.1 Overview 6-18
6.1.7.2 Model Results: Prediction of Noise Effects, Construction 6-21

6.1.7.3 Model Results: Predicted of Noise Effects, Operations 6-23
6.1.7.4 Noise Effects Summary 6-25
6.1.8 Mitigation 6-26
6.1.9 Residual Effects and Significance 6-27
6.2 Air 6-30
6.2.1 Introduction 6-30
6.2.1.1 Summary of Air Before the Updates 6-30
6.2.1.2 Summary of Updates to Air 6-30
6.2.2 Rationale for Valued Component Selection 6-32
6.2.3 Baseline Program Methodology 6-32
6.2.4 Baseline Conditions 6-32
6.2.4.1 Climate and Meteorological Information 6-32
6.2.4.2 Ambient Air Quality Standards 6-33
6.2.4.3 Baseline Air Quality Monitoring Program 6-33
6.2.4.4 Regional Ambient Air Quality 6-34
6.2.5 Consideration of Engagement Results 6-39
6.2.6 Effects Assessment Methodology 6-39
6.2.6.1 Boundaries 6-39
6.2.6.2 Thresholds for Determination of Significance 6-42
6.2.6.3 Air Effects Modelling, Summary 6-43
6.2.7 Project Activities/Interactions with Air Quality 6-45
6.2.7.1 Prediction of Air Effects, Beaver Dam Mine Site 6-45
6.2.7.2 Prediction of Air Effects, Haul Road 6-83
6.2.7.3 Prediction of Air Effects, Touquoy Mine Site 6-85
6.2.8 Mitigation 6-87
6.2.9 Residual Effects and Significance 6-88
6.2.10 Proposed Follow-up and Monitoring Program 6-90
6.3 Light 6-91
6.3.1 Introduction 6-91
6.3.1.1 Summary of Light Before the Updates 6-91
6.3.1.2 Summary of Updates to Light 6-91

6.3.2 Rationale for Valued Component Selection 6-93
6.3.3 Baseline Program Methodology 6-93
6.3.4 Baseline Conditions 6-93
6.3.5 Consideration of Engagement Results 6-94
6.3.6 Effects Assessment Methodology Update 6-94
6.3.6.1 Boundaries 6-94
6.3.6.2 Light Assessment Modelling Methodology 6-96
6.3.6.3 Thresholds for Determination of Significance 6-99
6.3.7 Project Activities, Light Interactions, and Effects 6-100
6.3.7.1 Beaver Dam Mine Site and Haul Road 6-101
6.3.7.2 Touquoy Mine Site 6-105
6.3.8 Mitigation 6-105
6.3.9 Residual Effects and Significance 6-106
6.3.10 Proposed Compliance and Effects Monitoring Program 6-108
6.4 Greenhouse Gases 6-109
6.4.1 Introduction 6-109
6.4.1.1 Summary of Greenhouse Gases Before the Updates 6-109
6.4.1.2 Summary of Updates to Greenhouse Gases 6-109
6.4.2 Rationale for Valued Component Selection 6-110
6.4.3 Baseline Program Methodology 6-110
6.4.4 Baseline Conditions 6-110
6.4.4.1 Provincial and Federal Greenhouse Gas Limits 6-110
6.4.5 Consideration of Engagement Results 6-111
6.4.6 Effects Assessment Methodology 6-112
6.4.6.1 Boundaries 6-112
6.4.6.2 Thresholds for Determination of Significance 6-114
6.4.7 Project Activities/Interactions with Greenhouse Gas 6-115
6.4.7.1 Beaver Dam Mine Site and Haul Road 6-117
6.4.7.2 Touquoy Mine Site 6-117
6.4.7.3 Overall Project 6-118
6.4.8 Mitigation 6-118

6.4.9 Residual Effect and Significance 6-118
6.4.10 Proposed Compliance and Effects Monitoring Program 6-120
6.5 Geology, Soils, and Sediment Quality 6-121
6.5.1 Introduction 6-121
6.5.1.1 Summary of Geology, Soils, and Sediment Quality Before the Updates 6-121
6.5.1.2 Summary of Updates to Geology, Soils, and Sediment Quality 6-121
6.5.2 Rationale for Valued Component Selection 6-123
6.5.3 Baseline Program Methodology for Soil and Sediments 6-123
6.5.4 Baseline Conditions 6-126
6.5.4.1 Regional Overview 6-126
6.5.4.2 Local Baseline Study Results 6-133
6.5.5 Consideration of Consultation and Engagement Results 6-140
6.5.6 Effects Assessment Methodology 6-141
6.5.6.1 Boundaries 6-141
6.5.6.2 Thresholds for Determination of Significance 6-143
6.5.6.3 Metal Leaching and Acid Rock Drainage Assessment 6-143
6.5.7 Project Activities Interactions and Effects 6-147
6.5.7.1 Overview of Potential Project Interactions 6-147
6.5.7.2 Potential Project Interactions, Beaver Dam Mine Site 6-147
6.5.7.3 Potential Project Interactions, Haul Road 6-148
6.5.7.4 Potential Project Interactions, Touqouy Mine Site 6-149
6.5.8 Mitigation 6-149
6.5.9 Residual Effects and Significance 6-151
6.5.10 Proposed Compliance and Effects Monitoring Program 6-153
6.6 Groundwater Quality and Quantity 6-154
6.6.1 Introduction 6-154
6.6.1.1 Summary of Groundwater Quality and Quantity Before the Updates 6-154
6.6.1.2 Summary of Updates to Groundwater Quality and Quantity 6-154
6.6.2 Rationale for Valued Component Selection 6-157
6.6.3 Baseline Program Methodology 6-157
6.6.3.1 Beaver Dam Mine Site Baseline Program Methodology Update 6-158

6.6.3.2 Touquoy Mine Site Baseline Program Methodology 6-161
6.6.4 Baseline Conditions 6-161
6.6.4.1 Regional Baseline Conditions 6-161
6.6.4.2 Project Area Baseline Conditions 6-167
6.6.5 Consideration of Engagement Results 6-176
6.6.6 Effects Assessment Methodology Update 6-177
6.6.6.1 Boundaries 6-177
6.6.6.2 Beaver Dam Mine Site Groundwater Modelling Methodology 6-180
6.6.6.3 Touquoy Mine Site Groundwater Modelling Methodology 6-180
6.6.6.4 Thresholds for Determination of Significance 6-181
6.6.7 Project Activities/Interactions with Groundwater Quality and Quantity 6-182
6.6.7.1 Beaver Dam Mine Site 6-183
6.6.7.2 Haul Road 6-194
6.6.7.3 Touquoy Mine Site 6-195
6.6.7.4 Groundwater Project Effects Summary 6-202
6.6.8 Mitigation 6-204
6.6.9 Significance of Residual Effects 6-205
6.6.10 Proposed Compliance and Effects Monitoring Program 6-207
6.7 Surface Water Quantity and Quality 6-208
6.7.1 Introduction 6-208
6.7.1.1 Summary of Surface Water Quality and Quantity Before the Updates 6-208
6.7.1.2 Summary of Updates to Surface Water Quantity and Quality 6-208
6.7.2 Rationale for Valued Component Selection 6-210
6.7.3 Baseline Program Methodology 6-212
6.7.4 Water Quantity Baseline Conditions 6-220
6.7.4.1 Overview 6-220
6.7.4.2 Monitoring Results 6-223
6.7.5 Water Quality Baseline Conditions 6-232
6.7.5.1 Overview 6-232
6.7.5.2 Baseline Results 6-235
6.7.6 Consideration of Engagement Results 6-247

6.7.7 Effects Assessment Methodology 6-247
6.7.7.1 Boundaries 6-248
6.7.7.2 Thresholds for Determination of Significance 6-254
6.7.7.3 Surface Water Modelling: Methodology 6-256
6.7.8 Project Activities/Interactions with Surface Water Quantity and Quality 6-264
6.7.8.1 Overview of Potential Surface Water Interactions 6-264
6.7.8.2 Surface Water Effects: Beaver Dam Mine 6-266
6.7.8.3 Surface Water Quality Effects: Haul Road 6-292
6.7.8.4 Surface Water Effects: Touquoy Mine Site 6-298
6.7.9 Mitigation 6-303
6.7.9.1 Water Treatment and Project Discharges 6-303
6.7.9.2 Sedimentation and Erosion 6-304
6.7.10 Residual Effects and Significance 6-306
6.7.10.1 Beaver Dam Mine 6-306
6.7.10.2 Haul Road 6-307
6.7.10.3 Touquoy Mine Site 6-308
6.7.11 Proposed Compliance and Effects Monitoring Program 6-310
6.7.12 Summary of Residual Effects to Surface Water Quantity and Quality 6-310
6.8 Wetlands 6-312
6.8.1 Introduction 6-312
6.8.1.1 Summary of Wetlands Before the Updates 6-312
6.8.1.2 Summary of Updates to Wetlands 6-312
6.8.2 Rationale for Valued Component Selection 6-314
6.8.3 Baseline Program Methodology 6-315
6.8.3.1 Desktop Evaluation 6-315
6.8.3.2 Field Delineation 6-315
6.8.3.3 Wetlands of Special Significance 6-317
6.8.3.4 Wetland Functional Assessment 6-319
6.8.3.5 Touquoy Mine Site 6-319
6.8.4 Baseline Conditions 6-320
6.8.4.1 Functional Assessment Results 6-342

6.8.4.2 Touquoy Mine Site 6-370
6.8.5 Considerations of Engagement Results 6-372
6.8.6 Effects Assessment Methodology 6-372
6.8.6.1 Boundaries 6-372
6.8.6.2 Wetland Cumulative Effects Modeling 6-374
6.8.6.3 Thresholds for Determination of Significance 6-382
6.8.7 Project Activities/Interactions with Wetlands 6-383
6.8.7.1 Beaver Dam Mine Site and Haul Road Wetland Impacts 6-384
6.8.7.2 Wetland Cumulative Effects Modelling Results 6-415
6.8.8 Avoidance and Mitigation 6-418
6.8.8.1 Wetland Avoidance 6-418
6.8.8.2 Wetland Mitigation 6-420
6.8.9 Residual Effects and Significance 6-421
6.8.10 Proposed Compliance and Effects Monitoring Program 6-424
6.9 Fish and Fish Habitat 6-425
6.9.1 Introduction 6-425
6.9.1.1 Summary of Fish and Fish Habitat Before Updates 6-425
6.9.1.2 Summary of Updates to Fish and Fish Habitat 6-425
6.9.2 Rationale for Valued Component Selection 6-427
6.9.3 Baseline Methodology 6-428
6.9.3.1 Surface Water 6-430
6.9.3.2 Benthic Macroinvertebrate Sampling 6-430
6.9.3.3 Fish Habitat Assessment 6-432
6.9.3.4 Fish Collection 6-435
6.9.3.5 Environmental DNA 6-436
6.9.4 Baseline Results 6-439
6.9.4.1 Overview 6-439
6.9.4.2 Site Specific Study Results 6-443
6.9.5 Consideration of Engagement Results 6-473
6.9.6 Effects Assessment Methodology 6-473
6.9.6.1 Boundaries 6-473

6.9.6.2 Thresholds for Determination of Significance 6-475
6.9.7 Project Activities/Interactions with Fish and Fish Habitat 6-477
6.9.7.1 Overview of Potential Fish and Fish Habitat Interactions 6-477
6.9.7.2 Beaver Dam Mine Site, Fish and Fish Habitat Effects 6-480
6.9.7.3 Haul Road, Fish and Fish Habitat Effects 6-498
6.9.7.4 Indirect Effects to Adjacent Streams 6-509
6.9.7.5 Summary of Direct Effects to Fish and Fish Habitat 6-514
6.9.7.6 Summary of Indirect Effects to Fish and Fish Habitat 6-514
6.9.7.7 Fish and Fish Habitat Effects: Touquoy Mine Site 6-515
6.9.8 Avoidance and Mitigation 6-517
6.9.8.1 Avoidance 6-517
6.9.8.2 Mitigation 6-519
6.9.8.3 Offsetting 6-525
6.9.9 Significance of Residual Effects 6-526
6.9.10 Proposed Compliance and Effects Monitoring Program Update 6-530
6.10 Habitat and Flora 6-531
6.10.1 Introduction 6-531
6.10.1.1 Summary of Habitat and Flora Before the Update 6-531
6.10.1.2 Summary of Updates to Habitat and Flora 6-531
6.10.2 Rationale for Valued Component Selection 6-533
6.10.3 Baseline Program Methodology 6-533
6.10.3.1 Priority List Methodology and Desktop Evaluation 6-534
6.10.3.2 Habitat Survey 6-535
6.10.3.3 Vascular Plant Survey 6-540
6.10.3.4 Lichen Survey 6-541
6.10.3.5 Habitat Desktop Analysis 6-541
6.10.3.6 Old Forest and Interior Forest Desktop Analysis 6-542
6.10.4 Baseline Conditions 6-543
6.10.4.1 Desktop Evaluation 6-543
6.10.4.2 Habitat Survey Results 6-545
6.10.4.3 Vascular Plants 6-555

6.10.4.4 Lichens 6-556
6.10.4.5 Habitat Desktop Analysis 6-558
6.10.4.6 Old Forest and Interior Forest 6-564
6.10.5 Consideration of Engagement Results 6-564
6.10.6 Effects Assessment Methodology 6-566
6.10.6.1 Boundaries 6-566
6.10.6.2 Thresholds for Determination of Significance 6-568
6.10.7 Project Activities/Interactions with Habitat and Flora 6-568
6.10.7.1 Direct and Indirect Impacts of the Project on Habitat and Flora 6-570
6.10.7.2 Touquoy Mine Site 6-575
6.10.8 Mitigation 6-575
6.10.9 Residual Effects and Significance 6-577
6.10.10 Proposed Compliance and Effects Monitoring Program 6-579
6.11 Terrestrial Fauna 6-580
6.11.1 Introduction 6-580
6.11.1.1 Summary of Terrestrial Fauna Before the Updates 6-580
6.11.1.2 Summary of Updates to Terrestrial Fauna 6-580
6.11.2 Rationale for Valued Component Selection 6-582
6.11.3 Baseline Program Methodology 6-582
6.11.4 Baseline Conditions 6-588
6.11.4.1 Mammals 6-588
6.11.4.2 Herpetofauna 6-591
6.11.4.3 Summary of Fauna and Habitat within the Project Area 6-592
6.11.5 Consideration of Engagement Results 6-593
6.11.6 Effects Assessment Methodology 6-593
6.11.6.1 Boundaries 6-593
6.11.6.2 Thresholds for Determination of Significance 6-595
6.11.7 Project Activities/Interactions with Terrestrial Fauna 6-596
6.11.7.1 Habitat Use and Direct Loss 6-596
6.11.7.2 Habitat Fragmentation 6-600
6.11.7.3 Direct Mortality 6-601

6.11.7.4 Sensory Disturbance 6-602
6.11.7.5 Touquoy Mine Site 6-604
6.11.8 Mitigation 6-605
6.11.9 Residual Effects and Significance Update 6-606
6.11.10 Proposed Compliance and Effects Monitoring Program 6-608
6.12 Avifauna 6-609
6.12.1 Introduction 6-609
6.12.1.1 Summary of Avifauna Before the Updates 6-609
6.12.1.2 Summary of Updates to Avifauna 6-609
6.12.2 Rationale for Valued Component Selection 6-611
6.12.3 Desktop Review 6-611
6.12.3.1 Maritime Breeding Bird Atlas 6-612
6.12.3.2 Important Avifauna Areas 6-612
6.12.4 Baseline Program Methodology 6-613
6.12.4.1 Fall Migration 6-614
6.12.4.2 Winter Birds 6-620
6.12.4.3 Spring Diurnal Raptor Migration 6-620
6.12.4.4 Spring Nocturnal Owl 6-620
6.12.4.5 Spring Migration 6-621
6.12.4.6 Breeding Birds 6-621
6.12.5 Baseline Conditions 6-623
6.12.5.1 Winter Birds 6-630
6.12.5.2 Spring Diurnal Raptor Migration 6-630
6.12.5.3 Nocturnal Owl 6-630
6.12.5.4 Fall Migration 6-630
6.12.5.5 Spring Migration 6-631
6.12.5.6 Breeding Birds 6-632
6.12.5.7 Common Nighthawk 6-636
6.12.5.8 Discussion 6-636
6.12.6 Consideration Engagement Results 6-638
6.12.7 Effects Assessment Methodology 6-638

6.12.7.1 Boundaries 6-638
6.12.7.2 Thresholds for Determination of Significance 6-640
6.12.8 Project Activities/Interactions with Avifauna 6-641
6.12.8.1 Habitat Use and Direct Loss 6-643
6.12.8.2 Habitat Fragmentation 6-644
6.12.8.3 Direct Mortality 6-645
6.12.8.4 Sensory Disturbance 6-647
6.12.8.5 Touquoy Mine Site 6-649
6.12.9 Mitigation 6-649
6.12.10 Residual Effects and Significance 6-651
6.12.11 Proposed Compliance and Effects Monitoring Program Update 6-653
6.13 Species of Conservation Interest and Species at Risk 6-654
6.13.1 Introduction 6-654
6.13.1.1 Summary of Species of Conservation Interest and Species at Risk Before the Updates 6-654
6.13.1.2 Summary of Update to Species of Conservation Interest and Species at Risk 6-654
6.13.2 Rationale for Valued Component Selection 6-656
6.13.3 Baseline Program Methodology 6-657
6.13.3.1 Desktop Priority Species List Methodology 6-657
6.13.3.2 Field Program Methodologies 6-659
6.13.4 Baseline Conditions 6-676
6.13.4.1 Priority Fish Species 6-676
6.13.4.2 Priority Vascular Flora Species 6-683
6.13.4.3 Priority Lichen Species 6-690
6.13.4.4 Priority Terrestrial Mammal Species 6-695
6.13.4.5 Priority Terrestrial Mammal Summary 6-699
6.13.4.6 Priority Herpetofauna Species 6-700
6.13.4.7 Priority Invertebrate Species 6-701
6.13.4.8 Priority Avifauna Species 6-703
6.13.5 Consideration of Engagement Results 6-711
6.13.6 Effects Assessment Methodology 6-712
6.13.6.1 Boundaries 6-712

6.13.6.2 Thresholds for Determination of Significance 6-714
6.13.7 Project Activities/Interactions with Species of Conservation Interest and Species at Risk 6-717
6.13.8 Mitigation 6-724
6.13.8.1 Priority Fish Species 6-724
6.13.8.2 Priority Vascular Flora and Lichen Species 6-726
6.13.8.3 Priority Terrestrial Fauna Species 6-729
6.13.8.4 Priority Avifauna Species 6-731
6.13.9 Residual Effects and Significance 6-736
6.13.9.1 Priority Fish Species 6-737
6.13.9.2 Priority Vascular Plant and Lichen Species 6-737
6.13.9.3 Priority Terrestrial Fauna Species 6-737
6.13.9.4 Priority Avifauna Species 6-740
6.13.10 Proposed Compliance and Effects Monitoring Programs 6-742
6.14 Mi'kmaq of Nova Scotia 6-744
6.14.1 Introduction 6-744
6.14.1.1 Summary of Mi'kmaq of Nova Scotia Before the Updates 6-744
6.14.1.2 Summary of Updates to Mi'kmaq of Nova Scotia 6-744
6.14.2 Rationale for Valued Component Selection 6-745
6.14.3 Baseline Program Methodology 6-747
6.14.3.1 Beaver Dam Mine Site and Haul Road Baseline Program Methodology 6-747
6.14.3.2 Touquoy Baseline Program Methodology 6-750
6.14.4 Baseline Conditions 6-750
6.14.4.1 Regional Baseline Conditions and General Information Relating to Mi'kmaq Communities 6-750
6.14.4.2 Beaver Dam Mine Site and Haul Road Baseline Conditions 6-761
6.14.4.3 Touquoy Mine Site Baseline Conditions 6-769
6.14.5 Consideration of Engagement Results 6-769
6.14.6 Effects Assessment Methodology 6-770
6.14.6.1 Boundaries 6-770
6.14.6.2 Thresholds for Determination of Significance 6-771
6.14.7 Project Activities/Interactions with Mi'kmaq of Nova Scotia 6-772
6.14.7.1 Project Interactions with Mi'kmaq Traditional Use/Rights 6-780

6.14.7.2 Project Interactions and Mi'kmaq Health and Socio-economic Condition 6-786
6.14.8 Mitigation 6-792
6.14.9 Residual Effects and Significance 6-805
6.14.10 Proposed Compliance and Effects Monitoring Program 6-810
6.15 Physical and Cultural Heritage 6-811
6.15.1 Introduction 6-811
6.15.1.1 Summary of Physical and Cultural Heritage Before the Updates 6-811
6.15.1.2 Summary of Updates to Physical and Cultural Heritage 6-811
6.15.2 Rationale for Valued Component Selection 6-813
6.15.3 Baseline Program Methodology 6-813
6.15.4 Baseline Conditions 6-814
6.15.4.1 Beaver Dam Mine Site 6-814
6.15.4.2 Haul Road 6-816
6.15.4.3 Touquoy Mine Site 6-817
6.15.5 Consideration of Engagement Results 6-817
6.15.6 Effects Assessment Methodology 6-817
6.15.6.1 Boundaries 6-817
6.15.6.2 Thresholds for Determination of Significance 6-818
6.15.7 Project Activities/Interactions with Physical and Cultural Heritage 6-818
6.15.7.1 Touquoy Mine Site 6-820
6.15.8 Mitigation 6-820
6.15.9 Residual Effects and Significance 6-821
6.15.10 Proposed Compliance and Effects Monitoring Program 6-823
6.16 Socio-economic Conditions 6-824
6.16.1 Introduction 6-824
6.16.1.1 Summary of Socio-economic Conditions Before the Updates 6-824
6.16.1.2 Summary of Updates to Socio-economic Conditions 6-824
6.16.2 Rational for Valued Component Selection 6-824
6.16.3 Baseline Program Methodology 6-830
6.16.4 Baseline Conditions 6-831
6.16.4.1 The Nova Scotia Economy – Pre COVID 6-831

6.16.4.2 Baseline Conditions – Post COVID 6-832
6.16.4.3 Local Context and Population 6-835
6.16.4.4 Community Infrastructure 6-837
6.16.4.5 Recreational Facilities 6-840
6.16.4.6 Local Economy 6-842
6.16.4.7 Roads and Traffic 6-843
6.16.4.8 Parks and Open Space 6-844
6.16.4.9 Tourism 6-846
6.16.4.10 Health and Well-being 6-848
6.16.4.11 Emergency Services 6-849
6.16.4.12 Land and Resource Use 6-849
6.16.4.13 Natural Resource Use 6-851
6.16.5 Themes and Topic Areas 6-852
6.16.5.1 Workforce Development 6-852
6.16.5.2 Demographics 6-859
6.16.5.3 Healthy Communities 6-860
6.16.5.4 Land Use, Recreational and Indigenous 6-862
6.16.5.5 Parks and Open Space, Tourism 6-869
6.16.5.6 Roads and Traffic 6-871
6.16.5.7 Impact on Government Revenues 6-874
6.16.6 Viewshed Analysis 6-876
6.16.7 Reclamation and Closure 6-877
6.16.8 Consideration of Engagement Results 6-878
6.16.9 Effects Assessment Methodology 6-879
6.16.9.1 Boundaries 6-879
6.16.10 Project Activities/Interaction with Socio-economic Conditions 6-880
6.16.10.1 Touquoy Mine Site 6-882
6.16.11 Mitigation 6-882
6.16.12 Residual Effects and Significance 6-883
6.16.13 Proposed Compliance and Effects Monitoring Program 6-887
6.17 Assessment of Valued Components within Federal Jurisdiction 6-888

6.17.1 Introduction 6-888
6.17.1.1 Summary of Assessment of Valued Components within Federal Jurisdiction Before the Updates 6-888
6.17.1.2 Summary of Updates to Assessment of Valued Components within Federal Jurisdiction 6-888
6.17.2 Environmental Effects within Federal Jurisdiction 6-890
6.17.2.1 Fish and Fish Habitat 6-890
6.17.2.2 Migratory Birds 6-891
6.17.2.3 Species at Risk 6-891
6.17.3 Environmental Effects on Federal or Transboundary Lands 6-893
6.17.4 Environmental Effects on Indigenous Peoples 6-893
6.17.5 Power or Duty by Federal Authority 6-894
6.17.6 Environmental Effects Incidental of Decisions Made by a Federal Authority 6-895
6.18 Accidents and Malfunctions 6-897
6.18.1 Summary of Accidents and Malfunctions Before the Updates 6-897
6.18.2 Summary of Updates to Accidents and Malfunctions 6-897
6.18.3 Introduction 6-898
6.18.4 Assessment Methodology 6-899
6.18.5 Hazard Identification 6-900
6.18.6 Structural Failures 6-901
6.18.6.1 Open Pit Mine Slope Failure 6-901
6.18.6.2 Stockpile Slope Failure 6-904
6.18.6.3 Settling Pond Failure 6-907
6.18.6.4 Infrastructure Failure 6-911
6.18.7 Accidents 6-914
6.18.7.1 Fuel and/or Other Spills 6-914
6.18.7.2 Unplanned Explosive Event 6-919
6.18.7.3 Mobile Equipment Accident 6-921
6.18.7.4 Touquoy Mine 6-925
6.18.7.5 Tailings and Reclaim Water Pipelines Spills 6-925
6.18.7.6 Cyanide Release 6-927
6.18.8 Other Malfunctions 6-930
6.18.8.1 Forest and/or Site Fires 6-930

6.18.9 Risk Assessment 6-933
6.18.10 Discussion 6-940
7 EFFECTS OF THE ENVIRONMENT ON THE BEAVER DAM MINE PROJECT 7-1
7.1 Introduction 7-1
7.1.1 Summary of Effects of the Environment on the Beaver Dam Mine Project Before the Updates 7-1
7.1.2 Summary of Updates to Effects of the Environment on the Beaver Dam Mine Project 7-1
7.2 Environmental Considerations 7-2
7.2.1 Climate 7-3
7.2.1.1 Temperature 7-3
7.2.1.2 Precipitation 7-3
7.2.1.3 Wind 7-4
7.2.2 Extreme Weather 7-5
7.2.2.1 Flood and Drought Conditions 7-5
7.2.2.2 Extreme Temperatures, Storms, and Wind 7-5
7.2.2.3 Lighting Strikes 7-5
7.2.3 Climate Change 7-6
7.2.3.1 Regional Future Projections 7-6
7.2.3.2 Effects of Climate Change on the Project 7-7
7.2.3.3 Forest Fires 7-7
7.2.3.4 Climate Change Mitigation and Adaptation 7-7
7.2.4 Slope Stability 7-8
7.2.5 Seismic Events 7-9
7.3 Mitigation 7-10
7.4 Summary 7-11
8 CUMULATIVE ENVIRONMENTAL EFFECTS ASSESSMENT 8-1
8.1 Introduction 8-1
8.1.1 Summary of the Cumulative Effects before Updates 8-1
8.1.2 Summary of Updates to the Cumulative Effects 8-1
8.1.3 Summary of Approach to Cumulative Effects Assessment 8-2
8.2 Types of Cumulative Effects 8-2
8.3 Cumulative Assessment Methodology 8-3

8.3.1 Scoping Approach 8-3
8.3.2 Assessment Approach 8-6
8.3.2.1 Baseline Conditions 8-6
8.3.2.2 Identification and Assessment of the Cumulative Effects 8-7
8.3.2.3 Mitigation 8-7
8.3.2.4 Residual Cumulative Effects and Significance Assessment 8-7
8.3.2.5 Follow-up and Monitoring 8-7
8.3.3 Consideration of Engagement Results and Indigenous Traditional Knowledge 8-8
8.4 Scoping of the Valued Components 8-8
8.4.1 Identification of the Valued Components 8-8
8.4.2 Determining the Spatial and Temporal Boundaries 8-9
8.4.2.1 Spatial Boundaries 8-9
8.4.2.2 Temporal Boundaries 8-9
8.4.3 Identification, Selection and Description Past, Present and Future Physical Activities 8-14
8.4.3.1 Current and Past Projects 8-15
8.4.3.2 Future Physical Activities (Certain, Reasonably Foreseeable or Hypothetical) 8-22
8.4.4 Confirmation of Valued Components to be Carried Forward Cumulative Effects Assessment 8-26
8.5 Cumulative Effects Assessment of the Valued Components 8-33
8.5.1 Noise Cumulative Effects Assessment 8-33
8.5.1.1 Baseline Conditions 8-33
8.5.1.2 Analysis of Effects 8-34
8.5.1.3 Mitigation 8-38
8.5.1.4 Residual Cumulative Effects and Significance Assessment 8-38
8.5.1.5 Follow-up and Monitoring Programs 8-40
8.5.2 Air Cumulative Effects Assessment 8-40
8.5.2.1 Baseline Conditions 8-40
8.5.2.2 Analysis of Effects 8-41
8.5.2.3 Mitigation 8-49
8.5.2.4 Residual Cumulative Effects and Significance Assessment 8-49
8.5.2.5 Follow-up and Monitoring Programs 8-51
8.5.3 Light Cumulative Effects Assessment 8-51

8.5.3.1 Baseline Conditions 8-51
8.5.3.2 Mitigation 8-55
8.5.3.3 Residual Cumulative Effects and Significance Assessment 8-55
8.5.3.4 Follow-up and Monitoring Programs 8-57
8.5.4 Surface Water Quality and Quantity Cumulative Effects Assessment 8-57
8.5.4.2 Analysis of Effects 8-61
8.5.4.3 Mitigation 8-70
8.5.4.4 Residual Cumulative Effects and Significance Assessment 8-70
8.5.4.5 Follow-up and Monitoring Programs 8-72
8.5.5 Fish and Fish Habitat Cumulative Effects Assessment 8-72
8.5.5.1 Baseline conditions 8-72
8.5.5.2 Analysis of Effects 8-74
8.5.5.3 Mitigation 8-78
8.5.5.4 Residual Cumulative Effects and Significance Assessment 8-78
8.5.5.5 Follow-up and Monitoring Programs 8-78
8.5.6 Species of Conservation Interest and Species at Risk Cumulative Effects Assessment 8-80
8.5.6.1 Baseline conditions 8-80
8.5.6.2 Analysis of Effects 8-84
8.5.6.3 Mitigation 8-98
8.5.6.4 Residual Cumulative Effects and Significance Assessment 8-98
8.5.6.5 Follow-up and Monitoring Programs 8-98
8.5.7 Mi'kmaq of Nova Scotia Cumulative Effects Assessment 8-100
8.5.7.1 Baseline conditions 8-100
8.5.7.2 Analysis of Effects 8-104
8.5.7.3 Mitigation 8-111
8.5.7.4 Residual Cumulative Effects and Significance Assessment 8-112
8.5.7.5 Follow-up and Monitoring Programs 8-114
8.6 Cumulative Effects Summary 8-114
9 SUMMARY OF ENVIRONMENTAL EFFECTS ASSESSMENT MITIGATIONS AND ENVIRONMENTAL RESIDUAL EFFECTS 9-1
9.1 Summary of the Environmental Impact Statement 9-1

10 FOLLOW-UP AND MONITORING PROGRAMS PROPOSED 10-1

10.1 Environmental Follow-Up Program 10-1

10.2 Environmental Monitoring Plans 10-1

1 INTRODUCTION

1.1 Purpose of the Environmental Impact Statement 2021 Update

The Environmental Impact Statement (EIS) was submitted in 2017 (AGC 2017) and resubmitted as the Revised 2019 EIS (AMNS 2019) to address Information Requests (Round 1) from the Impact Assessment Agency of Canada (IAAC; formerly the Canadian Environmental Assessment Agency [formal change of name August 2019]) and Nova Scotia Environment (NSE) (CEAA 2017 and NSE 2017). This Updated 2021 EIS has been developed to support Information Requests (Round 2; CEAA 2019 and NSE 2019). The Updated 2021 EIS also addresses advances in the Project Descriptions as well as additional Regulatory, Public and Indigenous Peoples engagement that has been undertaken since the Revised 2019 EIS. The Project Description updates coupled with engagement has resulted in changes to Valued Component (VC) Sections (Section 6). Each section of the EIS includes a summary of changes before and after the 2021 updates. **Changes to Updated 2021 EIS from the Revised 2019 EIS are HIGHLIGHTED.** Sections that have been completely replaced from the Revised 2019 EIS version **do not** include highlighting. The completely replaced sections are:

- Section 2 Project Description;
- Section 6.7 Surface Water Quantity and Quality;
- Section 6.9 Fish and Fish Habitat;
- Section 6.14 Mi'kmaq of Nova Scotia;
- Section 6.16 Socio-economic Conditions;
- Section 8 Cumulative Effects;
- Sections 9 Summary of Environmental Effects Assessment Mitigations and Environmental Residual Effects; and
- Section 10 Follow-up and Monitoring Programs Proposed.

The ownership of the company has also changed since the Revised 2019 EIS, which is presented in the Introduction (Section 1.4) as well as the Project Description (Section 2).

1.1.1 Summary of Updates to Introduction

Atlantic Mining NS Inc. (AMNS; the Proponent), a wholly owned subsidiary of St Barbara Limited (St Barbara), is a well-financed, growth-oriented gold development group with a long-term strategy to create a mid-tier gold production group focused on manageable, executable projects in mining-friendly jurisdictions. Its board and management team, with extensive experience in geology, mining and mine development, process and metallurgy and project financing, has been updated to reflect new company ownership and organizational structure. The Beaver Dam Mine Project (the Project) is proposing to construct (1 year), operate (5 years) and reclamation (active closure 2 years and post-closure monitoring 10+ years). The operation period has been extended from 3.5 years to 5 years, which is reflected in the ore production schedule and number of trucks needed to transport ore to Touquoy for processing. The Project layout has been altered to reflects more advanced engineering while ensuring that infrastructure avoids critical habitat (e.g., blue felt lichen). Additional engagement undertaken in 2020 to 2021 resulted in the need to allow for continued access along the haul road and around the Beaver Dam Mine site, which is addressed through the construction of bypass roads. Additional baseline data collection improved the overall assessment by reducing uncertainty and providing for improved clarity to address Round 2, Information Requests (IR2). Table 1.1-1 provides a summary of the Introduction subsections that have been updated from the Revised 2019 EIS.

Table 1.1-1: Updated Subsections from the 2019 Revised Environmental Impact Statement – Introduction

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
-	-	1.1 Purpose of the Environmental Impact Statement 2021 Update	• New
1.1 Project Overview	Yes	1.2 Project Overview	• Updates to reflect changes in the Project Description, Project Schedule, and Project Layout
1.2 Proponent Information	Yes	1.4 Proponent Information	• Section moved for section layout organization • Updates to reflect changes in ownership and organizational structure
1.3 Regulatory Framework and Role of Government	Yes	1.5 Regulatory Framework and Role of Government	• Section moved for section layout organization • Updates to reflect current regulatory regime
1.4 Purpose of the Project	Yes	1.3 Purpose of the Project	• Section moved for section layout organization • Minor updates
1.5 Guiding Principals	Yes	1.6 Guiding Principals	• Minor updates to include recent engagement with pubic and the Mi'kmaq of Nova Scotia
1.6 Benefits of the Project	Yes	1.7 Benefits of the Project	• Updated to include bypass roads
-	-	1.8 Report Organization	• New • includes high-level tables summarizing changes of EIS sections and Appendices from 2017 to 2019 and to 2021

1.2 Project Overview

1.2.1 Name of Designated Project

The designated Project will be known as the "Beaver Dam Mine Project" (the Project).

1.2.2 Project Location

1.2.2.1 Beaver Dam Mine Site

The Beaver Dam Mine property is in Marinette, Regional Municipality of Halifax Area, Nova Scotia, which is approximately 85 km northeast of Halifax. The approximate centre point of the Beaver Dam Mine Site is 521319 E 4990700 N (UTM Zone 20 NAD83 CSRS).

1.2.2.2 Haul Road

The Haul Road extends from the Beaver Dam Mine Site to the Touquoy Mine site (Figure 1.2-1). By-pass roads to allow light truck traffic and recreational vehicles (e.g., ATV and snowmobiles) to maintain access during operations will be constructed adjacent and parallel to portions of the Haul Road. The total disturbance of Haul Roads is 25 ha and by-pass roads are expected to disturb approximately 10 ha with 25 ha on crown land.

1.2.2.3 Touquoy Mine

The Touquoy property is located 60 km northeast of t Halifax, Nova Scotia, which is centered on the former mining village of Moose River Gold Mines. The closest population centres are Middle Musquodoboit located 20 km to the northwest and approximately 12

km from the community of Mooseland which is located to the southeast. The approximate centre point of the Touquoy property is 505280.58E 505280.58N UTM Zone20 NAD83 CSRS.

1.2.3 Overview

The Beaver Dam Mine Project (the Project) proposed by Atlantic Mining NS Inc. (AMNS), a wholly owned subsidiary of St Barbara or the Proponent, will operate as a satellite open pit mine with total ore extracted over five years will range from 0.7 to 2.1 million tonnes per year (Mt/year). Crushed ore from the Beaver Dam Mine Site will be transported by an average of 190 trucks (i.e., round trip) approximately 31 kilometers (km) to the existing and fully permitted Touquoy Mine. Processing of ore from the Beaver Dam gold deposit at the existing Touquoy plant will begin upon completion of mining activities from the Touquoy open pit. The Project is anticipated to begin construction in 2022, come into production in 2023, cease operations in 2027 and then be reclaimed. The Project timelines, however, is subject to environmental assessment and associated permitting approvals.

The Project is subject to both federal and provincial environmental assessment (EA) processes. This document forms both the Environmental Impact Statement (EIS) and EA Registration Document (EARD) under the federal and provincial processes.

This EIS/EARD for the Project has been prepared to facilitate the approval of the Project in accordance with the *Canadian Environmental Assessment Act,* 2012 (CEAA 2012) and Environmental Assessment Regulations made under the *Nova Scotia Environment Act*. The EIS Guidelines (CEA Agency 2016) prepared by Canadian Environmental Assessment Agency (CEA Agency) have provided a framework for the organization of this EIS. No public money is being sought to undertake the Project.

The Project consists the **Beaver Dam Mine Property** (i.e., mining and storing of waste rock), an approximately 31-kilometre (km) **Haul Road** that connects to the two sites and the **Touquoy Property** (i.e., processing, and depositing tailings) (Figure 1.2-1). The Project is bound within a Project Area (PA). The PA will result in approximately 243 hectares (ha) of disturbance with 34 ha or 14% occurring on crown land. The Beaver Dam Mine site is shown on Figure 1.2-2 and Touquoy Mine site is shown on Figure 1.2-3.

1.2.4 Beaver Dam Mine

The Beaver Dam Mine is in Marinette, Regional Municipality of Halifax Area, Nova Scotia, which is approximately 85 km northeast of Halifax. The Beaver Lake IR 17 is located approximately 6 km of the Beaver Dam deposit and 5 km from the intersection of the Beaver Dam Mine Road and Highway 224. The community of Mooseland is approximate 1 km from the intersection of the Beaver Dam Haul Road and the Mooseland Road. The Beaver Dam mine footprint approximately 208 ha with 26 ha or 14% on Crown land. Physical activities specific to the operation of the Beaver Dam Mine will include mining of ore, crushing of ore, operation of till and waste rock storage facilities, and treatment of surface water runoff and mine discharge water through collection and settling ponds. No ore processing or tailings management will occur at the Beaver Dam Mine Site. Operational infrastructure will be minimal as those Project activities will use infrastructure at the Touquoy Mine in Moose River. Electrical power demand required for the Beaver Dam Mine Site is not anticipated to be substantial and will be supplied by on site generators. Petroleum products will be stored on-site for use in generators, operational equipment, and haul trucks.

Beaver Dam Mine site will be reclaimed following operations, which will include two years of active closure (i.e., decommissioning and earthworks) and 10+ years of monitoring. The length of time of reclamation monitoring will be informed by successive reclamation plans as well as ongoing monitoring.

McCallum Environmental Ltd.

Document Name: BD_EIS_Fig2.1-X General Touquoy Arrangement

1.2.5 Haul Road

The Haul Road extends from the Beaver Dam Mine Site to the Touquoy Mine site (Figure 1.2-1). Transporting ore from the Beaver Dam Mine Site to the existing Touquoy Mine facilities is required for processing the ore and managing tailings in the exhausted Touquoy pit. Portions of the Haul Road route (approximately 16 km) will be upgraded to a dual lane road to facilitate the safe passage of two-way truck traffic at a maximum speed of 70 kilometres per hour (km/h). By-pass roads to allow light truck traffic and recreational vehicles (e.g., ATV and snowmobiles) to maintain continued access during operations will be constructed adjacent and parallel to portions of the Haul Road. The total disturbance of Haul Roads is 25 ha and by-pass roads are expected to disturb approximately 10 ha with 25 ha on crown land. Where possible, the upgrades will follow the course of the existing roadway; however, some adjustments to existing road alignment will be required to fulfill safe design standards.

The Haul Road consists of the following four main segments:

- 7.2 km existing Beaver Dam Mines road, that extends east from the proposed mine site to highway 224, which will be upgraded to support ore transport and will include bypass road.
- 4 km of new constructed road west of Highway 224 to connect the Haul road to an existing forestry road, this section will not include bypass road.
- 8.2 km existing forestry road that extends east to the Mooseland Road, referred to locally as the Dump Road, will be upgraded to support ore transport truck and will include bypass road.
- 10.7 km Mooseland Road that will be upgraded by Department of Transportation and Infrastructure Renewal (TIR) extends north along the Mooseland Road to the existing Touquoy Mine. Bypass roads crossing and parking area is currently being considered in the design to address safety concerns by local residents.

1.2.6 Touquoy Gold Mine

The Touquoy Mine, is centered in former mining village of Moose River Gold Mines, will process ore and manage tailings in the exhausted or mined-out pit at the Touquoy facilities currently operating as part of the fully permitted Touquoy Mine.

The Touquoy Gold Project underwent a review in 2007 to determine if an EA was required under the existing provincial and federal legislation. It was determined by Nova Scotia Environment (NSE) and the CEA Agency that only a provincial EA was required in accordance with the Nova Scotia Environmental Assessment Regulations. Under the *Canadian Environmental Assessment Act* (1992) and its pursuant regulations, there were no triggers for a federal EA when the Touquoy Gold Project was reviewed in 2007. The CEA Agency file number for the review is 10700-40. The Touquoy Gold Project obtained EA approval in 2008 and has since obtained additional approvals through the applicable provincial regulatory processes, including the Industrial Approval (IA); the Touquoy Gold Mine has been in in operation as per the associated approvals since 2018.

Changes to the Touquoy Gold Mine as a result of the Project will be assessed through this EIS. They include: an increase in the duration of ore processing (approximately four additional years); minor adjustments to the ore processing facility; and disposal of Beaver Dam Mine tailings in the exhausted Touquoy Mine open pit. There is not anticipated disturbance to the exiting Touquoy Mine site that will result from processing Beaver Dam ore.

Due to the timing of the Beaver Dam Mine ore being processed at the Touquoy Mine site, the Beaver Dam tailings will not be stored in the Touquoy tailings management facility, but instead would be permanently stored in the pit after the Touquoy gold deposit has been mined. This allows the Touquoy Mine Site footprint to be maintained as permitted and no tailings management facility will need to be constructed at the Beaver Dam Mine Site (Section 2). Other aspects of the Touquoy Gold Mine will remain

as assessed and approved through the Nova Scotia EA process in 2008 (NSE 2008) and/or currently being assessed as part of the Touquoy Mine Expansion that is currently planned to be submitted in June 2021.

Updates to the current reclamation plan for the Touquoy Gold Mine, as a result of the Project, would require approval by the Province of Nova Scotia as a condition of Mineral Lease (MLE11-1) and Industrial Approval (#2012-084244-08).

1.3 Purpose of the Project

The implementation of the Project will provide additional ore to the existing Touquoy Mine processing plant. This will extend the life of the Touquoy Mine Site to continue to provide economic and social benefits with minimal additional infrastructure. Completing the Project with safe production, environmental stewardship and community engagement is key for the Proponent to ensure that the Province, the community, and the Mi'kmaq of Nova Scotia receive optimum benefit.

Worldwide annual gold production is about 3,200 tonnes (NRCan 2019). Gold is used primarily for jewelry and as a storage form of wealth with China and India forming the majority of the demand. Canada produced about 5% of the world total in past years. With the Proponent's four gold development projects in Nova Scotia, there is much opportunity to supply gold with existing and expected future demand.

The Proponent has recognized that the quantity and unusual style of gold mineralization at the Beaver Dam Mine Site will support a commercially viable surface mining operation with on-site crushing and off- site processing of ore. The amount of gold expected to be recovered will represent more than one-third of the gold produced from the historic goldfields of Nova Scotia since the 1860s.

The Proponent is proposing to develop this resource in line with all applicable regulatory requirements and recognizes the significant potential benefits to the local economy, the Province of Nova Scotia, the Mi'kmaq of Nova Scotia and the AMNS in completing this Project. The Proponent has designed a project that is in line with the intent of NSL&F for efficient use of mineral resources and to "*promote the concepts of environmental responsibility and sustainable development, stewardship of the mineral resource sector, and integrated resource planning*."

All phases of the Project will provide employment opportunities for local residents and Indigenous Peoples, as well as provide tax revenue for the municipal, provincial, and federal levels of government. It is anticipated that additional labour force will be required during construction and a smaller, but still significant, labour force will be required during operation. Indirect employment will be generated by the Project through the use of external contractors and suppliers. Tax revenue in the millions of dollars per year will be generated through corporate income taxes paid by the Proponent, as well as its contractors and suppliers. Socio-economic benefits that will occur as a result of the Project are discussed further in Section 1.7.2.

1.4 Proponent Information

1.4.1 Proponent Profile

Atlantic Mining NS Inc. (the Proponent), a wholly owned subsidiary of St Barbara, is a well-financed, growth-oriented gold development group with a long-term strategy to create a mid-tier gold production group focused on manageable, executable projects in mining-friendly jurisdictions. Its board and management team, with extensive experience in geology, mining and mine development, process and metallurgy and project financing, are currently focused on the development of its project portfolio of advanced gold development properties located in Nova Scotia, Canada.

Currently, the Proponent holds four gold development projects in Nova Scotia: the Touquoy Gold Project, the Beaver Dam gold deposit, the Fifteen Mile Stream gold deposit and, the Cochrane Hill gold deposit. The Touquoy Gold Project has been in operation since October 2017. The Beaver Dam Mine Project Environmental Impact Statement has been submitted to IAAC and is in the information request phase.

Environmental data collection for the Project commenced in November 2016 when exploration drilling began to clearly define the gold resource. In January 2018, Ausenco Engineering Canada Inc. (Ausenco) was commissioned by the Proponent to complete a Project Pre-Feasibility Study and the NI 43-101 Technical Report for the development of the Moose River Consolidated Project Phase I (Touquoy and Beaver Dam deposits), and Phase II expansion (Fifteen Mile Stream and Cochrane Hill deposits) (Ausenco 2019). A Feasibility Report is currently being updated for the Beaver Dam Mine by Ausenco that included updates to the Project Description including the Project Layout (Figure 1.2-2 and 1.2-3).

Regulatory consultation on the Beaver Dam Mine Project began in October 2014 with a Provincial "One Window Process: Mineral Development in Nova Scotia" meeting to present the planned Project and to receive feedback on the regulatory regime and regional expertise. The EIS was submitted to CEA Agency in June 2017 and a Revised EIS was submitted in February 2019 to address Round 1 of Information Requests. This Updated 2021 Beaver Dam Mine EIS along with responses to Round 2 IRs forms the next step in the permitting process. The Fifteen Mile Stream Project EIS was submitted in February 2021 and is currently awaiting Round 1 of Information Requests. The Cochrane Hill projects is in the pre-submission phase of the EIS/EARD review process.

Mineral exploration and mining licences are issued by the Nova Scotia Department of Energy and Mines (NSDEM) under the Mineral Resources Act of 2016 (amended in 2018). Exploration licences are granted for two-year terms, and are renewable indefinitely, provided certain annual conditions are met. Exploration licences can contain a maximum of 80 bordering mineral claims. Mining licences are granted for 20-year terms and can be renewed an indefinite number of times at the discretion of the Minister for Natural Resources.

The Beaver Dam property is held under two exploration license EL50421 and EL51852. The EL EL50421 comprises 76 contiguous claims that cover an area of approximately 1,230 ha and EL51852 comprises 7 claims and covers 113 ha. Exploration Licence 50421 is an amalgamation of EL 05920 and EL 06175 which was reissued as EL 50421 in August 2014. Exploration Licence 05920 represented the amalgamation of three pre-existing Exploration Licences 00047, 04790 and 04516. The Exploration Licences were regrouped in 2003 as EL 05920 and reissued by the NSDEM in 2005 .

Mineral rights to the Touquoy Property are wholly owned by AMNS and consist of one mineral lease (MLE11-1) comprising 49 claims and covering 793 ha, and one adjoining Exploration License (EL10377) comprising 64 claims and covering 1,036 ha.

1.4.2 Corporate Governance and Management Structure

The Proponent is committed to the highest practical standards of corporate governance and to being a responsible corporate citizen. Safe production and environmental stewardship are keys to the Proponent's organization. The guiding principles, including the purpose, commitments and core values of St Barbara, are detailed on their company website: https://stbarbara.com.au/about-us/our-vision-and-values/.

The company relies upon its senior management team and Board of Directors who have extensive experience with past mining developments worldwide.

The current senior management team of St Barbara:

- Craig Jetson – Managing Director and Chief Executive Officer (CEO);
- Garth Campbell-Cowan– Chief Financial Officer (CFO);
- Rowan Cole – Corporate Secretary;
- Laird Brownlie – Head of External Affairs and Business Continuity;
- Craig Hudson – Head of Permitting and Projects;
- Andrew Taylor General Manager, Atlantic Operations; and
- Neil Schofield – Consulting Resource Geologist.

The CEO reports to the six-member Board of Directors:

- Craig Jetson – Managing Director and CEO;
- Tim Netscher – Independent Non-Executive Chairman;
- Kerry Gleenson – Independent Non-Executive Director;
- David Moroney - Independent Non-Executive Director;
- Stef Loader – Independent Non-Executive Director; and
- Steven Dean – Independent Non-Executive Director.

Traded on the Australian Securities Exchange (ASX) as SBM, St Barbara committed to maintaining high standards of ethics, integrity and statutory compliance in all Company dealings and conformance with the ASX Corporate Governance Principles and Recommendations (3rd Edition). The Proponent has a Nominating and Corporate Governance Committee, an Audit Committee and a Compensation Committee, as well as policies and codes, such as Code of Conduct which includes obligations regarding environmental standards, health and safety, contributions to local communities, and respect and tolerance. Any breaches of this Code must be immediately reported to the Chair of the Nominating and Corporate Governance Committee.

As part of its commitment to corporate responsibility and incorporation of best practices, the proponent has established a Geotechnical and Tailings Dam Review Board (Review Board) for design, construction and operation phases of the AMNS projects. This includes tailings management, waste rock storage and open pit mining activities. Reporting to AMNS's General Manager Atlantic Operations, the Review Board is established to provide ongoing, independent confirmation to the proponent by internationally-recognized experts that the design, construction, operation and closure of the AMNS projects conform with international best practice and to minimize impact in compliance with its permits and licenses. The Review Board is independent, and its scope includes reviewing, commenting, questioning, critiquing and advising on all aspects of including, but not limited to:

- Engineering design;
- Construction practices;
- Operation and maintenance practices;
- Closure and post-closure requirements;
- Stability;
- Water management and treatment, including both surface and ground water;

- Geochemical considerations;
- Management systems;
- Budget and staffing;
- Emergency preparedness and response planning; and
- Community interaction.

AMNS intends to maintain suitable insurance and bonding to ensure its commitments are met. This includes maintaining financial bonding to ensure that adequate reclamation security is in place at all times during the construction, development and operational phases of the Company's mining projects, as well as appropriate environmental impairment liability insurance. As part of the existing Touquoy Gold Project, both reclamation security and environmental liability insurance are maintained as per requirements of the Province of Nova Scotia.

Further AMSN commits to completing its operations in adherence with best available practices (BAPs) and industry standards as per guides developed by Mining Association of Canada, such as the Towards Sustainable Mining initiative, and the Canadian Dam Association.

1.4.3 Proponent Personnel Details

A corporate office in Melbourne, Victoria, Australia and a local office in Moose River Gold Mines, Nova Scotia are maintained in support of the AMNS projects. Key management and technical staff will be located in both locations for the duration of the Beaver Dam Mine Project. The addresses for both office locations are provided in Table 1.4-1.

Table 1.4-1: Office Locations

Corporate Office	Local Office
Level 10, 432 St Kilda Road, Melbourne, VIC 3004 Locked Bag 9, Collins Street East, VIC 8003 Tel: +61 (3) 8660 1900 Fax: +61 (3) 8660 1999	6749 Moose River Road Moose River Gold Mines RR2 Middle Musquodoboit, Nova Scotia Canada B0N 1X0 Phone: (902) 384-2772

All communications regarding the EA for the Project should be sent to the Head of Permitting and Projects as directed by the CEO. The contact information for these two roles is outlined in Table 1.4-2.

Table 1.4-2: Proponent Contacts

Position	Proponent
Environment Permitting Project Manager	Barb Bryden Middle Musquodoboit, Nova Scotia Phone: (902) 384-2772 Email: Barb.Bryden@Atlanticgold.ca
Head of Permitting and Projects	Craig Hudson Middle Musquodoboit, Nova Scotia Phone: (902) 384-3641 Email: Craig.Hudson@atlanticgold.ca
General Manager Atlantic Operations	Andrew Taylor Middle Musquodoboit, Nova Scotia Phone: (902) 384-3603 Email: Andrew.Taylor@atlanticgold.ca

1.4.4 Environmental Assessment Consulting Team

The EIS was prepared by a consulting team that is provided in Table 1.4-3

Table 1.4-3: Environmental Assessment Consultant Team Contributions

Consultant	Contributing Role
Allnorth Engineering, Consulting, Project Management, and Surveying	• Reviewed the engineering feasibility of the new construction portion of the Haul Road, 2019 Moose River Consolidated NI 43-101 (Ausenco 2019)
Ausenco Engineering Canada Incorporated	• Preparation of the 2021 feasibility study for the Project (In Progress)
Brighter Community Planning & Consulting	• Public Engagement and Socio-Economic (Section 3, Section 6.16 and Appendix A.6 [draft Public Engagement Plan])
Confederacy of Mainland Mi'kmaq – Mainland Mi'kmaq Development inc.	• Prepared a Mi'kmaq Ecological Knowledge Study report for the Project (Appendix M.1)
Cultural Resource Management Group Limited	• Prepared archaeological screening and reconnaissance reports for the Project (Appendices N.1 to N.7)
GHD	• Noise environmental effects assessment and Noise Impact Assessment Technical Report (operations) and Memorandum (construction) (Section 6.1 and Appendices B.1 and B.2) • Air environmental effects assessment and Air Emissions Technical Report (Section 6.2 and Appendix C.1) • Light environmental effects assessment and Light Impact Assessment (Section 6.3 and Appendix D.1) • Surface Water Quantity and Quality environmental effects assessment, additional water quality modelling, water balance analysis, stormwater management, erosion and sediment control plan, predictive water quality, water treatment assessments, and baseflow mitigation assessment (Section 6.7 and Appendices G.1, G.3, G.4 and P.4) • Groundwater Quality and Quantity environmental effects assessment, field activities, baseline groundwater program, hydrogeological modelling report, and potential impacts from metals COCs to groundwater and surface water from dust deposition along the Haul Road (Section 6.6 and Appendices F.3, F.4, F.5 and F.9)
Golder Associates Ltd.	• Mine Waste Stockpile Geotechnical Design and Geotechnical Investigation: Data Report (Appendices A.2a and A.2c) • Preparation of a Geotechnical Assessment of the Beaver Dam Mine Open Pit (In Progress)
Intrinsik	• Prepared an evaluation of exposure and risks related to emissions from the Project onto recreational water usage and country foods and an aquatic effects assessment (reassessment) for the Killag and Moose rivers (Appendices C.2 and G.2)
KPMG	• Economic Impact Assessment Reports for the Project and the Moose River Consolidated Project (Appendices O.1 and O.2)
Lorax Environmental	• Prepared geochemical source term predictions and an ML/ARD assessment report, geochemical source terms update, kinetic test update and a draft ML/ARD management plan and nitrogen source control monitoring plan for Touquoy Mine (Appendices E.2 to E.5 and E.10)

Table 1.4-3: Environmental Assessment Consultants (continued)

Consultant	Contributing Role
McCallum Environmental Ltd.	• Wetlands environmental effects assessment, wetlands functional assessment, characterization and preliminary Wetlands Compensation Plan (Section 6.8 and Appendices H.1 to H.3) • Fish and Fish Habitat environmental effects assessment, photographic log, and Fish and Fish Habitat baseline (2015 to 2017 and 2019 to 2020) (Section 6.9 and Appendices J.1, J.2, and J.4) • Habitat and Flora environmental effects assessment, master species list, preliminary Lichen Mitigation and Management Plan, (Section 6.10 and Appendices K.1 and P.6) • Terrestrial Fauna environmental effects assessment, draft Wildlife Mitigation and Monitoring Plan and Landbird SAR Mitigation and Monitoring Plan (Section 6.11 and Appendix P.7) • Avifauna environmental effects assessment, relative abundance of avian species and Landbird SAR Mitigation and Monitoring Plan (Section 6.12 and Appendices L.2 and Appendix A of Appendix P.7 [draft Wildlife Mitigation and Monitoring Plan]) • Species of Conservation Interest and Species at Risk environmental effects assessment (Section 6.13) • Mi'kmaq of Nova Scotia engagement and environmental effects assessment (Section 4 and Appendix A.5 [Mi'kmaq of Nova Scotia engagement log], and Section 6.14) • Review and update of physical and cultural heritage environmental effects assessment and assessment of valued components within Federal jurisdiction (Sections 6.15 and 6.17) • Cumulative effects assessment (Section 8)
Moose Mountain Technical Services	• Preparation of Beaver Dam Mine Planning component of the Feasibility for the Project 2019 Moose River Consolidated NI 43-101 (Ausenco 2019) and 2021 Feasibility Study NI 43-101 2021 (In Progress)
Nortek Resource Solutions Inc.	• Prepared the visual simulations (zone of influence) for the Project (Appendix M.2)
Wood Environment & Infrastructure Solutions	• Senior review of Fish and Fish Habitat environmental effects assessments (Section 6.9), review of Air (Section 6.2), Geology, Soils and Sediment Quality (Section 6.5) and Surface Water Quantity and Quality (Section 6.7) environmental effects assessments and development of the draft Fish Habitat Offset Plan (Appendix J.3)
Stantec	• Prepared Phase I and Phase II's (limited and extended) environmental site assessments for the Project (Appendices E.6 to E.8) • Review of Geology, Soil, and Sediment Quality environmental effects assessment (Section 6.5) • Prepared the following studies at the Touquoy Mine Site; a water and tailings management plan, groundwater flow and solute transport model, an assimilative capacity study of Moose River, and a simulation of cumulative effects of deposition of tailings (Appendices F.6 to F.8, and F.10) • Prepared assessment of water quality downstream of tailings facility and water balance report (Rev. 2) for tailing management – Touquoy Mine (Appendices G.5a and G.5b)
WSP	• Preliminary Design of Haul Road including By-pass Roads (2021 Feasibility Study NI 43-101 2021[In Progress])

1.5 Regulatory Framework and Role of Government

The federal, provincial, and municipal regulatory framework outlines requirements for the EA process, the permits required for construction, operation and reclamation, and the conditions under which the Project will be operated. General legislation that may be applicable to the Project is outlined in Table 1.5-1, while key legislation which directly drives the development of the EIS is explained in more detail in the coming sections.

Table 1.5-1: Legislation Potential Applicable to the Beaver Dam Mine Project

Legislation	Physical Activity and/or Trigger	Regulatory Authority
Federal		
CEAA 2012	Assessment due to the construction, operation, decommissioning of a gold mine with an ore production capacity greater than 600 tonnes per day.	IAAC
Fisheries Act	Authorization and compensation due to physical activities in wetlands, watercourses, and water bodies.	DFO
Fisheries Act – Metal and Diamond Mining Effluent Regulations	Environmental Effects Monitoring program due to mining effluent discharge to aquatic habitat.	ECCC
Migratory Birds Convention Act – Migratory Bird Regulations	Potential authorization due to physical activities potentially relocating birds and altering their habitat.	ECCC
Species at Risk Act	Potential authorization due to physical activities destroying SARA listed species and/or their habitat.	DFO/ECCC
Canadian Navigable Waters Act	Potential authorization due to physical activities diverting water or activities that may interfere with navigation of non-scheduled waterways. Requirements to be ascertained following submission of a Notice of Work.	TC
Canadian Environmental Protection Act	Promotes sustainable development through pollution prevention and the protection of the environment and human health from risks associated with toxic substances.	ECCC
Transportation of Dangerous Goods Act	The movement of dangerous foods to, from, and within the site must comply with applicable regulations.	TC
Provincial		
Environment Act – EA Regulations – Schedule A	Assessment due to the construction, operation, decommissioning of a facility that extracts of processes metallic or non-metallic minerals.	NSE
Environment Act – Activities Designation Regulations	Industrial Approval for the construction, operation, or reclamation of a surface mine using explosives and procuring mineral bearing ore.	NSE
Environment Act – Activities Designation Regulations	Water approval and/or notification for water withdrawal, alteration of water bodies, watercourses, and/or wetlands.	NSE
Environment Act – Air Quality Regulations	Ambient air quality standards for baseline environmental conditions discussion.	NSE
Special Places Protection Act and Regulations	Authorization required prior to conducting intrusive archaeological work.	NSCCH
Wildlife Act	Prohibits taking, hunting, killing, or possessing eagles, osprey, falcons, hawks, owls, and any other protected wildlife.	NSL&F
Endangered Species Act	Prohibits killing, injuring, disturbing, taking or interfering with endangered or threatened species and/or their habitat.	NSL&F
Crown Lands Act	Crown Lands Lease due to exploration and/or construction occurring on Crown Lands.	NSL&F
Municipal Government Act	Authorizes municipalities to develop Municipal Planning Strategies and Land Use By-laws.	NSDMA
Municipal		
National Building Code of Canada	Approval for construction and occupation of buildings.	HRM

Source: Atlantic Gold 2017 and 2019.

Note: SARA = *Species at Risk Act*; NPA = *Navigation Protection Act*; NWPA = *Navigable Waters Protection Act*; CEA Agency = Canadian Environmental Assessment Agency; DFO = Fisheries and Oceans Canada; ECCC = Environment and Climate Change Canada; TC = Transport Canada; NSE = Nova Scotia Environment; NSCCH = Nova Scotia Communities, Culture and Heritage; NSDNR = Nova Scotia Department of Natural Resources; NSL&F = Nova Scotia Department of Lands and Forestry; NSDMA = Nova Scotia Department of Municipal Affairs and Housing; HRM = Halifax Regional Municipality.

The Project is also driven by guidelines, policies, and standards that may be applicable during design, construction, operation, and reclamation. Those that may potentially be applicable to the Project are listed below, while key guidance documents which are directly applicable to the development of the EIS are listed in the coming sections.

- Federal
  - Canadian Council of Ministers of the Environment (CCME) Canadian Water Quality Guidelines for the Protection of Freshwater Aquatic Life (FWAL) (CCME 1999a);
  - CCME Canadian Soil Quality Guidelines for the Protection of Environmental and Human Health (CCME 1999b);
  - CCME Canadian Sediment Quality Guidelines for the Protection of Aquatic Life (CCME 2001);
  - CCME Canada Wide Standards for Particulate Matter (PM) and Ozone (CCME 2010);
  - Environmental Codes of Practice for Metal Mines (EC 2012c);
  - Guidelines for the Assessment of Alternatives for Mine Waste Disposal (EC 2011);
  - Streamlining the Approvals Process for Metal Mines with Tailings Impoundment Areas (EC 2012a);
  - Guidance Document for Flow Measurement of Metal Mining Effluents (EC 2001);
  - Guidance Document for Sampling and Analysis of Metal Mining Effluents (EC 2002);
  - Federal Environmental Quality Guideline (FEQG): Cobalt. May 2017. (ECCC 2017a);
  - Fisheries Protection Policy Statement (DFO 2013a);
  - Fisheries Productivity Investment Policy: A Proponent's Guide to Offsetting (DFO 2013b);
  - Assessing Cumulative Environmental Effects under the Canadian Environmental Assessment Act, 2012: Interim Technical Guidance (CEAA 2018);
  - Guide for Reporting to the National Pollutant Release Inventory (NPRI) 2016 and 2017 (ECCC 2016a); and
  - Federal Policy on Wetland Conservation (EC 1991).
- Provincial
  - Guidelines for Environmental Noise Measurement and Assessment (NSE 1990);
  - Toward a Greener Future: Nova Scotia's Climate Change Action Plan (NSE 2009a);
  - Guide to Consider Climate Change in Project Development in Nova Scotia (NSE 2011a);
  - Nova Scotia Wetland Conservation Policy (NSE 2019);
  - The Path We Share: A Natural Resource Strategy for Nova Scotia 2011-2020 (NSDNR 2011);
  - Water for Life: Nova Scotia's Water Resource Management Strategy (NSE 2010a);
  - Environmental Quality Standards (NSEQS) for Contaminated Sites (Tier 1) for Groundwater, Surface Water (fresh water), Soils and Sediment (NSE 2013b);
  - Remediation Levels Protocol. Table 3, Pathway Specific Standards for Groundwater (NSE 2013a);
  - Nova Scotia Standard Specifications: Highway Construction and Maintenance (NSTIR 1997);

- Erosion and Sediment Control Handbook for Construction Sites (NSE 1988);
- Guide to Altering Watercourses (NSE 2015a);
- Nova Scotia Watercourse Alterations Standard (NSE 2015b);
- Generic Environmental Protection Plan for Construction of 100 Series Highways (NSTIR 2007);
- Storm Drainage Works Approval Policy (NSE 2002a);
- Pit and Quarry Guidelines (NSDEL 1999);
- Blasting Safety Regulations made under Section 82 of the *Occupational Health and Safety Act* S.N.S. 1996, c. 7 O.I.C. 2008-65 (February 26, 2008, effective April 1, 2008), N.S. Reg. 89/2008 as amended by O.I.C. 2013-65 (March 12, 2013, effective June 12, 2013), N.S. Reg. 54/2013;
- Air Quality Regulations (NSE 2007); and
- Greenhouse Gas Emissions Regulations (NSE 2018).

- Municipal
  - Musquodoboit Valley/Dutch Settlement Municipal Planning Strategy (HRM 1996a);
  - Musquodoboit Valley/Dutch Settlement Land Use By-law (HRM 1996b);
  - Eastern Shore (East) Municipal Planning Strategy (HRM 1996c); and
  - Eastern Shore (East) Land Use By-law (HRM 1996d).

1.5.1 Federal Regulatory Framework

1.5.1.1 Canadian Environmental Assessment Act, 2012

The *Impact Assessment Act* 2019 (IAA) and its regulations establish the current legislative basis for the federal impact assessment process. CEAA 2012 regulates the Government of Canada's EA process and the Regulations Designating Physical Activities (amended December 31, 2014) specify the physical activities to which CEAA 2012 applies. The Project is a designated project in accordance with Section 16(c) of these Regulations, as it is a project which states:

> *The construction, operation, decommissioning, and abandonment of a new rare earth element mine or gold mine, other than a placer mine, with an ore production capacity of 600 t/day or more.*

Key regulatory events in accordance with CEAA 2012 which have given rise to the completion of this EIS are provided in Table 1.5-2. Additional details for all of these events can be found on the Canadian Environmental Assessment Registry (CEAR).

Table 1.5-2: Timeline of Events in Accordance with Canadian Environmental Assessment Agency 2012

Date	Event
October 16, 2015	AMNS and GHD submit a Project Description document to CEAA in order to initiate the EA determination process (GHD 2015)
October 19, 2015	CEAA releases a public notice inviting comments on the Project Description document in order to acquire assistance in the EA determination process. The public has 20 days to comment
December 3, 2015	CEAA releases the Notice of EA Determination indicating that a federal EA is required for the Beaver Dam Mine Project
December 7, 2015	CEAA releases the Notice of Commencement of an EA.
December 7, 2015	CEAA releases the draft EIS Guidelines and a public notice inviting comments on the guidelines in order to ensure they reflect which aspects of the environment may be affected and should be examined during the EA. The public has 37 days to comment
January 19, 2016	CEAA releases the final EIS Guidelines specific to the Beaver Dam Mine Project.
January 25, 2016	CEAA releases a public notice inviting eligible individuals and groups to apply for federal funding in order to enable their participation in the upcoming steps of the environmental assessment
April 29, 2016	CEAA releases the results of funding allocation for participation in the upcoming steps of the environmental assessment.
Project Initiation to March 2017	Baseline data collection, engagement with regulators, stakeholders, and Mi'kmaq, and drafting of the EIS
March 27, 2017	AMNS submits the Beaver Dam Mine Project EIS for conformity review
April 27, 2017	CEAA issues a letter providing the outcome of the Beaver Dam Mine Project EIS conformity review
June 2, 2017	AMNS re-submits the Beaver Dam Mine Project EIS for conformity review
June 28, 2017	Beaver Dam Mine Project meets conformity and commences formal review process under CEAA
August 9 and 21, 2017	CEAA provided Round 1, Information Requests to AMNS (CEAA 2017 and NSE 2017)
February 28, 2019	AMNS submits the Beaver Dam Mine Project Revised 2019 EIS
March 31, 2019	Beaver Dam Mine Project meets conformity and commences formal review process under CEAA
May 8 and June 12, 2019	CEAA provided Round 2, Information Requests to AMNS (CEAA 2019 and NSE 2019)
June 4, 2021	AMNS submits Responses to Round 2, Information Requests
June 11, 2021	AMNS submits Updated 2021 EIS to support Responses to Round 2, Information Requests

Following submission of this EIS to IAAC, another public notice will be released inviting public comment. The provincial and federal government reviews will be completed in conjunction with this public review period. The IAAC will then prepare and publish a draft EA report which considers all public and government comments, and detail conclusions regarding the potential for environmental effects from the Project. The Project is contingent upon receipt of an approved EA decision statement.

1.5.1.2 Fisheries Act, 1985

The *Fisheries Act* is administered by Fisheries and Oceans Canada (DFO) and generally protects the sustainability and productivity of recreational, commercial, and indigenous fisheries in Canada.

Under Section 35(1) The Minister may designate, as a work, undertaking, or activity that is associated with a designated project, any work, undertaking or activity, that the Minister considers likely to result in the death of fish or the harmful alteration, disruption or destruction [HADD] of fish habitat unless authorized by or carried on in accordance with regulations issued in accordance with the Fisheries Act. In addition, Section 36(3) prohibits the discharge or deposition of a deleterious substance of any type in water frequented by fish or in any place under any conditions where the deleterious substance or any other deleterious substance that

results from the deposit of the deleterious substance may enter such water unless authorized or carried on in accordance with those same regulations.

As a result of anticipated physical activities potentially occurring in wetlands, watercourses, and water bodies, authorization in accordance with Section 35(2) of the *Fisheries Act* may be required.

1.5.1.2.1 Metal and Diamond Mining Effluent Regulations

The Metal and Diamond Mining Effluent Regulations (MDMER) are made under the *Fisheries Act* and apply to mines that exceed an effluent flow rate of 50 m^3 per day, based on effluent deposited from all final discharge points of the mine and deposit a deleterious substance in any water or place referred to in subsection 36(3) of the *Fisheries Act*.

As a result of anticipated collection and discharge of surface water runoff and mine discharge water through water management ponds, effluent monitoring in accordance with the Section 2(1) of the MDMER may be required.

In addition to likely residual impacts that constitute a HADD, any fish and fish habitat that may be subject to a MDMER Schedule 2 designation and accordingly a fish habitat compensation process for these residual impacts has also been included in the draft Fish Habitat Offset Plan (Appendix J.3).

1.5.1.3 Migratory Birds Convention Act, 1994

Section 5 of the Migratory Birds Convention Act (MBCA) protects migratory birds, their nests, and their eggs from hunting, trafficking, and commercialization. A permit is required to disturb, destroy, or take a nest, egg, nest shelter, eider duck shelter, or duck box of a migratory bird.

In addition, Section 5.3 of the MCBA prohibits the discharge or deposition of a substance harmful to migratory birds in waters or an area frequented by migratory birds or in a place from which the substance may enter such waters or such an area. The discharge or deposition of a substance that may combine with a substance already present to create a harmful substance is also prohibited in Section 5.3.

1.5.1.3.1 Migratory Birds Regulations

The Migratory Birds Regulations (MBR) is made under the *MBCA* and may apply to the Project as a result of anticipated physical activities potentially relocating birds and destroying their habitat. An authorization in accordance with Section 4(1) of the MBR may be required.

1.5.1.3.2 Species at Risk Act, 2002

The *Species at Risk Act* (SARA) protects wildlife species from becoming extinct through prohibitions against killing, harming, harassing, capturing or taking species at risk (SAR), and against destroying their critical habitats. The Committee on the Status of Endangered Wildlife in Canada (COSEWIC) identifies species of special concern that may then qualify for legal protection and recovery in accordance with SARA. SARA's mandate is to provide for the recovery of SAR and to ensure through sound management that species of concern do not require SARA listing. DFO is responsible for aquatic SAR, while ECCC is responsible for terrestrial SAR.

As a result of anticipated physical activities potentially occurring in wetlands, watercourses, and water bodies, as well as the potential destruction of sensitive terrestrial habitat, authorization in accordance with SARA may be required.

1.5.1.4 Navigation Protection Act, 1985

The *Navigation Protection Act* (NPA), formerly the *Navigable Waters Protection Act* (NWPA), was amended in April 2014 and effectively changed the definition of navigable waters under this legislation. Prior to the last amendment of the NPA, navigable waters included all bodies or courses of water that were capable of being navigated by any type of floating vessel for transportation, recreation, or commerce. This definition created the need for works in, on, under, or over any water body or watercourse to obtain a Navigable Waters Protection Approval.

The last amendment added a schedule to the NPA that listed scheduled waters for which regulatory approval is required for works that risk a substantial interference with navigation. The schedule listed three oceans, 62 rivers, and 97 lakes, none of which are located in the area of the Project.

The federal government recently made changes to these regulations and the *Canadian Navigable Waters Act (CNWA)* that replaced the *Navigation Protection Act* came into effect August 28, 2019. There is potential that, under this new regulation, waterways within the Project Area could require permitting. Further consultation with Transport Canada (TC) will be required as permitting proceeds. The Proponent has consulted with TC and confirmed that no pre-existing permits are in place within the PA under the repealed NWPA or the schedule of waterways that has been retained from the NPA in the new CNWA. Based upon the absence of any designations of local waterways, the requirement of permits for navigable waters is not anticipated for the Project under the CNWA. However, the Project involves diverting water and upgrades or construction of new works that may restrict navigation of a non-scheduled waterway (e.g., installation or upgrades of bridges, culverts, etc.). This requirement can only be ascertained once the Proponent submits a Notice of Work to TC.

AMNS will identify to TC the existing crossings on which alterations/work are being proposed and will opt out of the NPA regime as required. A full list of watercourses and waterbodies located within the Beaver Dam Mine Site and Haul Road are discussed in Section 6.7 (Surface Water Quantity and Quality) and Appendix G.4 (Physical Characterization of Watercourses and Waterbodies).

1.5.1.5 Federal Guidance Applicable to the Project

In addition to the EIS Guidelines developed for the Project (CEAA 2016), other guidance documents from CEAA that have been consulted include but are not limited to:

- Operational Policy Statement Assessing Cumulative Environmental Effects under the *Canadian Environmental Assessment Act*, 2012 (CEAA 2013a);
- Operational Policy Statement Addressing "Purpose of" and "Alternative Means" under the *Canadian Environmental Assessment Act*, 2012 (CEAA 2013b);
- Operational Policy Statement Determining Whether a Designated Project is Likely to Cause Significant Adverse Environmental Effects under the *Canadian Environmental Assessment Act*, 2012 (CEAA 2015a);
- Draft Technical Guidance for Assessing Cumulative Environmental Effects Under the *Canadian Environmental Assessment Act*, 2012 (CEAA 2014a); and

- Technical Guidance for Assessing Physical and Cultural Heritage or any Structure, Site, or Thing that is of Historical, Archaeological, Paleontological, or Architectural Significance under the *Canadian Environmental Assessment Act*, 2012 (CEAA 2014b).

1.5.2 Provincial Regulatory Framework

1.5.2.1 Nova Scotia Environment Act, 1995

1.5.2.1.1 Environmental Assessment Regulations

The Environmental Assessment Regulations made under Section 49 of the *Nova Scotia Environment Act* regulates the Government of Nova Scotia's EA process. Projects that trigger the EA process are sub-divided into two classes - Class I and Class II. The Project triggers a Class I EA in accordance with Schedule A, Section B(1a) of these regulations, as it is a project which involves:

- A facility that extracts or processes metallic or non-metallic minerals.

This EIS will substitute and fulfill all the requirements of a provincial EARD.

1.5.2.1.2 Activities Designation Regulations

Many of the provincial permits anticipated to be required for the Project are regulated in accordance with the Activities Designation Regulations made under Section 66 of the *Nova Scotia Environment Act*. An Industrial Approval (IA) will be required in accordance with Section 16(2d) of these regulations, as it is a project that involves:

- A surface mine where an opening or excavation is made in the ground from the surface which may require the use of explosives for the purpose of procuring any mineral bearing ore, including coal, and any associated infrastructure.

The IA process, known as Part V of the *Nova Scotia Environment Act* seeks to guide the proponent in determining the way in which a project, after EA Approval, is to be monitored for compliance targets, objectives set through the EA process, and commitments made by proponents through various means such as public and Indigenous Peoples engagement. It is a well understood process by the Proponent, having been part of the process for the existing Touquoy operation that has an IA.

Activities required to facilitate the Project, including wetland and watercourse alteration and groundwater and surface water withdrawals, may require approvals in accordance with these regulations as well. These permitting requirements will be initiated once EA approval has been received from the province.

1.5.2.2 Nova Scotia Endangered Species Act, 1999

The Nova Scotia Endangered Species Act (NSESA) prohibits the killing or disturbing species at risk, destroying or disturbing its residence, and destroying or disturbing of core habitat.

As a result of anticipated physical activities potentially occurring in wetlands, watercourses, and water bodies, as well as the potential destruction of sensitive terrestrial habitat, authorization in accordance with NSESA may be required.

1.5.2.3 Provincial Guidance Applicable to the Project

Provincial guidance documents that have been consulted in preparation of this EIS include:

- A Proponents Guide to Environmental Assessment (NSE 2001);
- Guide to Preparing an EA Registration Document for Mining Developments in Nova Scotia (NSE 2002b);
- Guide to Considering Climate Change in Environmental Assessment in Nova Scotia (NSE 2011c); and
- Guide to Addressing Wildlife Species and Habitat in an EA Registration Document (NSE 2005).

1.5.3 Municipal Regulatory Framework

The Halifax Regional Municipality is divided into 21 community plan areas that have their own set of land use strategies and by-laws. The Project straddles the boundary of the Musquodoboit Valley/Dutch Settlement Plan Area and the Eastern Shore (East) Plan Area.

The Beaver Dam Mine Site and Touquoy Mine Site are located in the Musquodoboit Valley and Dutch Settlement Plan Area. The Land Use By-law and Municipal Planning Strategy for this area were last amended in October 2014. The area is zoned mixed use, and extractive facilities, of which mining related infrastructure is one, are permitted within this zoning designation. The by-law for mixed use land use prescribes minimum separation distances from features such as lot lines, dwellings, watercourses, domestic wells, and residential zones. The physical activity of mining or extraction is not specified in the by-law as it is governed in the provincial and federal regulatory regime. The Municipal Planning Strategy (HRM MPS 2014) describes mining as an important land use within the Plan Area from an economic perspective; however, extractive operations can potentially create harmful environmental effects. The Municipal Planning Strategy also states these concerns are addressed by the provincial Department of Environment through their permitting process (HRM MPS 2014).

The majority of the Haul Road is located in the Eastern Shore (East) Plan Area, while a minor portion is located in the Musquodoboit Valley and Dutch Settlement Plan Area. The Municipal Planning Strategies describe extraction as an important land use within the Plan Area from an economic perspective; but also acknowledge that extractive operations can potentially create harmful environmental effects.

1.5.4 Indigenous Peoples

In 2004 and 2005, the Supreme Court of Canada decided the Crown (provincial and federal) has a duty to consult with Indigenous Peoples when contemplating decisions or actions that may adversely affect their established or potential Indigenous rights and treaty rights. The provincial government typically delegates certain procedural aspects of this consultation to the Proponent of a project. The federal government always acts as the consultation coordinator to integrate the Government of Canada's indigenous consultation activities into the EA process. This duty cannot be delegated to proponents.

The Made-in-Nova Scotia Process is the forum for the Mi'kmaq, Nova Scotia and Canada to resolve issues related to Mi'kmaq treaty rights, Aboriginal rights, including Aboriginal title, and Mi'kmaq governance. The process involves the Mi'kmaq of Nova Scotia as represented by the Assembly of Nova Scotia Mi'kmaq Chiefs and the provincial and federal governments.

Through the provincial Indigenous Peoples engagement process, AMNS and the consulting team undertook engagement. This engagement with the Mi'kmaq of Nova Scotia by AMNS referenced two key guidance documents which have influenced the EA process for the Project:

- Proponents' Guide: The Role of Proponents in Crown Consultation with the Mi'kmaq of Nova Scotia (Province of Nova Scotia 2012); and
- Mi'kmaq Ecological Knowledge Study Protocol, 2nd Edition (KMKNO 2007).

Other pertinent guidance in the federal regulatory framework which has influenced the EA process for the Project includes:

- Aboriginal Consultation and Accommodation – Updated Guidelines for Federal Officials to Fulfill the Duty to Consult (AANDC 2011);
- Technical Guidance for Assessing the Current Use of Lands and Resources for Traditional Purposes under the *Canadian Environmental Assessment Act*, 2012 (CEAA 2015b);
- Reference Guide Considering Aboriginal Traditional Knowledge in Environmental Assessments Conducted Under the *Canadian Environmental Assessment Act*, 2012 (CEAA 2014c); and
- In Nova Scotia, treaty rights following the 1999 decision in the Donald Marshall Jr. case confirms the right of the Mi'kmaq to hunt, fish, and gather to earn a moderate livelihood. These are protected under Section 35 of the *Constitution Act*, 1982.

1.6 Guiding Principles

1.6.1 Planning Tool

At its foundation, EA is a planning tool used to ensure that projects are carefully planned to avoid or mitigate possible negative environmental effects and to maximize potential benefits. Use of the EA process early in a project's planning phase can be used to encourage proponents to develop their projects in the most sustainable manner. The use of the EIS Guidelines (CEAA 2016) required the Proponent to carefully review and consider the Project, including its alternatives, and the potential effects on valued components

1.6.2 Public Participation

The EIS Guidelines require that the Proponent provide current information about the Project to the general public and especially the communities likely to be most affected by Project activities (CEAA 2016). Within the provincial and federal EA processes, there are distinct public comment periods, including the opportunity to comment on the EIS. To maximize public participation, proponents are required engage the public directly and early on in the EA process.

The Proponent has been engaging stakeholders, including the local community, non-governmental organizations, governmental departments, and the local community since planning and permitting began on the Touquoy Mine over a decade ago. More specific to the Project, specific engagement activities occurred in past year to facilitate public participation. This included open houses in May 2016, presentations and meeting with community organizations and expansion of the existing Community Liaison Committee (CLC). Additional engagement was undertaken in 2020 to 2021 with residents, key stakeholders, and members of the public, which is described in Section 3. It should be noted that concerns related to access are addressed through the construction of bypass roads that will allow for continued access during operations.

Comments from the public were considered in the development of the EIS in terms of planning the Project and its assessment for each Valued Component (VC); responses from the Proponent are documented in this EIS. Additional public engagement details are discussed in Section 3 and Appendix A.4a.

1.6.3 Mi'kmaq of Nova Scotia Engagement

The EIS Guidelines require that the Proponent engage with Indigenous Groups, Mi'kmaq of Nova Scotia, that may be affected by the Project (CEAA 2016).

Within the provincial and federal EA processes and as part of the Made-in-Nova Scotia Process, there are distinct consultation processes completed by the Crown. To maximize engagement of Indigenous Peoples in the EA process, proponents are required to engage Indigenous Peoples directly and early on in the EA process (CEAA 2016).

The Proponent engaged with the Mi'kmaq of Nova Scotia to obtain views on:

- Effects of changes to the environment on the Mi'kmaq of Nova Scotia, specifically: health and socio- economic conditions; physical and cultural heritage, including any structure, site or thing that is of historical, archaeological, paleontological or architectural significance, and current use of lands and resources for traditional purposes; and
- Potential adverse impacts of the Project on potential or established Indigenous Peoples rights or Treaty rights, title and related interests, in respect of the Crown's duty to consult, and where appropriate, accommodate the Mi'kmaq of Nova Scotia.

The information gathered by the proponent during its engagement with Indigenous Peoples helps to contribute to the Crown's understanding of any potential adverse impacts of the Project on potential or established Aboriginal or treaty rights, title and related interests, and the effectiveness of measures proposed to avoid or minimize those impacts.

AMNS has been engaging the Mi'kmaq of Nova Scotia since planning and permitting began on the Touquoy Gold Mine over a decade ago. More specific to the Project, specific engagement activities occurred in past year to engage the Mi'kmaq of Nova Scotia. This included open houses in May 2016, many presentations and meetings with different Mi'kmaq groups, and expansion of the existing CLC to include representatives of the two nearest Mi'kmaq communities, Millbrook First Nation and Sipekne'katik First Nation. Recent engagement efforts through 2018 and 2019 have taken place with Millbrook, Sipekne'katik and KMKNO relating to project technical updates, mitigation and monitoring plans, changes to Project infrastructure including waste rock stockpiles and the Preferred Alternative Haul Road, and discussions relating to thresholds of significance with Millbrook First Nation.

Additional engagement has been undertaken since the 2019 Revised EIS, which are documented in Section 4. Comments from the Mi'kmaq of Nova Scotia were considered in the development of the EIS in terms of planning the Project and the assessment for each VC; responses from the Proponent are documented in this EIS (Section 4 and Appendix A.5).

1.6.4 Precautionary Approach Application

The EIS Guidelines require that the Proponent demonstrate how all aspects of the Project have been examined and planned in a precautionary manner to avoid serious or irreversible environmental effects (CEAA 2016). This EIS applies the precautionary approach through the following assessment methodologies:

- provide extensive detail about the existing environment and develop mitigation measures to eliminate, reduce, or control the effect Project activities have on the environment;
- consider project designs that will minimize disturbance to the existing environment;
- outline contingency plans that address worst-case accidents and malfunctions;
- outline follow-up and monitoring programs to verify project activity related impact predictions; and
- anticipate other projects in the area in an effort to assess cumulative effects.

The application of a precautionary approach in developing this EIS will allow the EA to act as a planning tool which will be used to ensure the Project avoids or mitigates potential environment effects and promotes sustainable development.

1.7 Benefits of the Project

1.7.1 Environmental Benefits

The environmental benefits of the Project to Nova Scotia are numerous to correct past practices with respect to the environment. Given the area has been subjected to extensive exploration, mining, and logging activity over several decades, baseline conditions show obvious effects from these historic activities (Section 6.5 Geology, Soil, and Sediment Qualtiy). The current condition at the Beaver Dam Mine Site is disturbed, and fragmented habitat based on significant timber harvesting, associated road building and yarding areas and historic exploration/mining activity. The PA contains a diversity of habitat types and landscape features but has experienced a considerable amount of disturbance and habitat fragmentation as a result of these activities. The level of disturbance within the Beaver Dam mine site disproportionately affects uplands, over wetlands. The level of new fragmentation associated with the Project is anticipated to be moderate, given the existing disturbance. Historic tailings and waste rock will be removed from the site and encapsulated in the Touquoy exhausted pit. Water will be treated during construction to remove metals associated with historic tailings.

The poor condition of the majority of existing Haul Road culvert crossings directly contributes to poor surface water quality and fish passage in watercourses and wetlands along the Beaver Dam Mines Road and the Moose River Cross Road (Figure 1.2-1) Upgrades to this existing Haul Road will include culvert replacements at over 20 locations and 3 new bridges, where determined to be necessary (Section 2 and Section 6.9). It is expected that correctly installed culverts will increase fish passage and positively affect fish habitat through improved surface water quality.

All environmental baseline investigations for the Project have added to the scientific understanding of the area and improved background data held by the province. Background data helps increase the knowledge base of its users and increases public ecological awareness and promotes conservation of natural ecosystems.

At closure, reclamation will occur at the Project Site and Touquoy Mine Site. The reclamation plan will be secured with a bond held by the Province of Nova Scotia to ensure there are sufficient funds to reclaim the site at any point during the Project. The plan for reclamation requires approval of the Nova Scotia Department of Lands and Forests.

1.7.2 Socio-economic Benefits

KPMG International completed an Economic Impact Assessment of the Moose River Consolidated (MRC) Project to evaluate the economic benefits stemming from the Proponent's mining projects in Nova Scotia (KPMG 2015). This assessment considered the Touquoy and Beaver Dam Mine Projects together and found that socio-economic benefits will stem primarily from the construction and operation phases of the Project.

Construction activities will involve preparing the Project Site, setting up infrastructure and facilities, and purchasing mining processing equipment to enable the MRC Project to reach full production. Much of the spending associated with these activities will be incurred in Nova Scotia and Canada. As per the KPMG report, it was projected that construction costs will be approximately $146 million, with approximately $97.6 million, or 67%, being spent in Nova Scotia, and approximately $111.9 million, or 77%, being spent in Canada. As a result of this spending, it is anticipated that 391 full time equivalent jobs will be created in Nova Scotia per year during construction. For Canada as a whole, the construction phase will create 437 full time equivalent jobs per year. Tax revenues stemming from the construction phase are expected to be $4.1 million for the Government of Nova Scotia and $5.5 million for the Government of Canada. This is a conservative estimate as corporate income taxes paid by contractors and suppliers cannot be estimated.

Operational mining and processing activities will involve the deployment and operation of new mining production capacity. Similar to the construction phase, much of the spending associated with operation of the MRC Project will be incurred in Nova Scotia and Canada. As per the KPMG report, it was projected that annual operating costs will be approximately $52.3 million, with approximately $38.1 million, or 73%, being spent in Nova Scotia, and approximately $39.4 million, or 75%, being spent in Canada. The costs include several spending components, the most important being:

- salaries and benefits for 27% of total annual operating costs;
- cyanide, lime, and reagents for 24% of total annual operating costs;
- diesel for 22% of total annual operating costs;
- wear parts and spare parts for 15% of total annual operating costs; and
- electricity (Touquoy only) for 7% of total annual operating costs.

As a result of this spending, it was anticipated in the KPMG report that 228 yearly and recurrent full-time equivalent jobs will be created in Nova Scotia during operation. For Canada as a whole, the operation phase will create 278 yearly and recurrent full-time equivalent jobs during operation. Tax revenues stemming from the operation phase are expected to be $10.2 million annually for the Government of Nova Scotia and $8.1 million annually for the Government of Canada. These represent conservative estimates as corporate income taxes paid by suppliers cannot be estimated.

The Province of Nova Scotia's unemployment rate is higher than the national average (8.8%>6.9%) and its gross domestic product (GDP) growth was the slowest of all Canadian provinces the last few years. In addition, the GDP per capita is the second lowest in Canada. The MRC Project would greatly benefit the Province of Nova Scotia due to substantial upfront investments and significant annual operation costs contributing to job creation and government tax revenue.

AMNS is committed to working with local communities and the Mi'kmaq of Nova Scotia to maximize socio-economic benefits as the Company developments its projects in the Province, including the Beaver Dam Mine Project.

1.8 Environmental Impact Statement Organization

The Updated 2021 EIS for the Project has retained most of the primary structure of the Revised 2019 EIS (AMNS 2019) (i.e., most major headings match between the two documents). An overview of the contents of each section of the Updated 2021 EIS are provided in the following text:

- Section 1 Introduction introduces the Project and the 2021 EIS Update. It provides summary information and updates, where relevant, to details provided in Section 1 of the 2017 EIS (AGC 2017) and the Revised 2019 EIS (AMNS 2019) relating to the Proponent, Project Overview, and Regulatory Process.
- Section 2 Project Description has been updated to include changes to the Project Layout, Mine Infrastructure Layout, Project Production Schedule, inclusion of bypass roads due to advances in project engineering and resulting from recent engagement regarding land use access. The effects of Project Description Updates are documented in Sections 6 through 10 of the EIS.
- Section 3 Public Engagement has been updated to include engagement activities post the Revised 2019 EIS submission. A public engagement log and supporting documentation are included in Appendices A.4a to A.4c.
- Section 4 Indigenous Peoples Engagement Program has been expanded to include Mi'kmaq of Nova Scotia engagement activities post the Revised 2019 EIS submission. The engagement log is presented in Appendix A.5.
- Section 5 Environmental Effects Assessment Methodology provides a summary of the environmental assessment methodology used for the EIS. The methodology has been updated for clarification on significance thresholds (i.e., magnitude and significance).
- Section 6 Environmental Effects Assessment – Updates to each of the Valued Component sections are based on changes to infrastructure and Project Description for the Beaver Dam Mine Site and in response to IR2s.
- Section 7 Effects of the Environment on the Project has been updated with relevant climate data sets.
- Section 8 Cumulative Effects Assessment has been updated to reflect existing developments/projects, current future developments/projects, changes to infrastructure and Project Description for the Beaver Dam Mine Site and in response to IR2s.
- Section 9 Summary of Environmental Effects and Conclusions has been updated to reflect changes to infrastructure and Project Description for the Beaver Dam Mine Site and in response to IR2s.
- Section 10 Summary of Proposed Follow-up Monitoring Programs has been updated to reflect changes to infrastructure and Project Description for the Beaver Dam Mine Site and in response to IR2s.
- Section 11 References has been updated to reflect any additional cited information.
- Section 12 Acronyms, Abbreviations, Units and Glossary has been updated to reflect additional terms.

Table 1.8-1 identifies the sections of the 2017 EIS (AGC 2017) and specifies whether they are unchanged or updated within the 2019 Revised EIS (AMNS 2019) and/or this 2020 EIS Update. If they are unchanged, the text will reflect what was presented in the 2019 Revised EIS (AMNS 2019). If the text in the subsection required updates, the changes will be highlighted in yellow.

Table 1.8-1: Summary of Updates to Sections from the 2017 Environmental Impact Statement through to the Updated 2021 Environmental Impact Statement

Section from the 2017 EIS		Updated in 2019	Updated in 2021	Nature of Update in 2021
1	Introduction	Yes	Yes	Updated to reflect changes in the Project Description and Regulatory changes since previous submission
2	Project Description	Yes	Yes	Updated to reflect changes in the Project Description (i.e., infrastructure and layout)
3	Public Engagement Program	No	Yes	Updated to reflect engagement undertaken since 2019
4	Indigenous Peoples Engagement Program	Yes	Yes	Updated to reflect engagement undertaken since 2019
5	Environmental Effects Assessment Methodology	No	Yes	Updated based on clarification on significance thresholds and related indices
6	Environmental Effects Assessment	Yes	Yes	Updated based on changes in Project Description, Beaver Dam Mine Layout, additional baseline information, and in response to Information Requests
6.1	Noise	Yes	Yes	Updated modelling based on changes to Project Description and in response to Information Requests
6.2	Air	Yes	Yes	Updated modelling based on changes to Project Description and in response to Information Requests
6.3	Light	Yes	Yes	Updated modelling based on changes to Project Description and in response to Information Requests
6.4	Greenhouse Gases	Yes	Yes	Updated modelling based on changes to Project Description and in response to Information Requests
6.5	Geology, Soil, and Sediment Quality	Yes	Yes	Updated modelling based on changes to Project Description/project layout. Additional baseline information collected on source terms, and historic mining activities including additional information on sediments.
6.6	Ground Water Quality and Quantity	Yes	Yes	Updated modelling based on changes in Project Descriptions/project layout including details additional details on water management structures. Updated modelling was undertaken to document as inputs to surface water quantity and wetlands. Mitigation and Monitoring updates.
6.7	Surface Water Quality	Yes	Yes	Updated modelling based on changes in Project Descriptions/project layout including details additional details on water management structures. Additional water modelling was undertaken to document changes in baseflow and water quality. Mitigation and Monitoring updates.
6.8	Wetlands	Yes	Yes	Updates based on changes in Project Descriptions/project layout. Updates to Air, Surface Water and Groundwater Section resulted in changes to indirect impacts. Mitigation and Monitoring updates.
6.9	Fish and Fish Habitat	Yes	Yes	Updates based on changes in Project Descriptions/project layout. Updated baseline data. Updates to Air, Surface Water and Groundwater Section resulted in changes to indirect impacts. Mitigation and Monitoring updates
6.10	Habitat and Flora	Yes	Yes	Updates based on changes in Project Descriptions/project layout. Updates to Air, Surface Water and Groundwater Section resulted in changes to indirect impacts. Mitigation and Monitoring updates

Table 1.8-1: Summary of Updates to Sections from the 2017 Environmental Impact Statement through to the Updated 2021 Environmental Impact Statement (continued)

Section from the 2017 EIS		Updated in 2019	Updated in 2021	Nature of Update in 2021
6.11	Terrestrial Fauna	Yes	Yes	Updates based on changes in Project Descriptions/project layout. Updates to Air, Surface Water and Groundwater Section resulted in changes to indirect impacts. Mitigation and Monitoring updates
6.12	Birds	Yes	Yes	Section title change to Avifauna Updates based on changes in Project Descriptions/project layout. Updates to Air, Surface Water and Groundwater Section resulted in changes to indirect impacts. Mitigation and Monitoring updates
6.13	Species of Conservation Interest and Species at Risk	Yes	Yes	Updates based on changes in Project Descriptions/project layout. Updates to Air, Surface Water and Groundwater Section resulted in changes to indirect impacts. Mitigation and Monitoring updates
6.14	Indigenous Peoples	Yes	Yes	Section title change to Mi'kmaq of Nova Scotia Updates based on additional engagement and feedback received since the Revised 2019 EIS.
6.15	Physical and Cultural Heritage	Yes	Yes	Updates based on Project Descriptions additional baseline reporting
6.16	Socio-economic Conditions	Yes	Yes	Updates based on Project Descriptions, additional linkages key Provincial Socio-Economic Policies and Documents as well as AMNS policies
6.17	Assessment of Valued Components within Federal Jurisdiction	Yes	Yes	Minor Updates to reflect changes in legislation and regulations
6.18	Accidents and Malfunctions	Yes	Yes	Updates to address Information Requests (Round 2 Part 1 and Part 2)
7	Effects of the Environment on the Project	Yes	Yes	Updated to reflect current data sets and additional available information
8	Cumulative Effects Assessment	Yes	Yes	Updated based changes to Project Description/project layout as well as additional corresponding changes to VCs
9	Summary of Compliance and Effects Monitoring Programs	Yes	Yes	Updated based on changes to VC
10	Environmental Impact Statement Summary and Conclusions	Yes	Yes	Updates based on outcomes from VC sections
11	References	No	Yes	Expanded
12	Acronyms, Abbreviations, Units and Glossary	No	Yes	Expanded acronym, abbreviation and unit lists and included Glossary

Appendices associated with the 2017 EIS (AGC 2017) are summarized in Table 1.8-2, together with cross-references to those appendices revised and presented within the 2019 Revised EIS (AMNS 2019) and this submission (Updated 2021 EIS). Appendices that are new in the 2021 EIS Update have also been identified (e.g., Appendix P.4 Mine Water Management Plan) in Table 1.8-2.

Table 1.8-2: Revisions to Appendices

Appendices from the 2017 EIS		Updated in 2019	Appendices from 2019 Revised EIS		Updated in 2021	Appendix Number within the 2021 EIS Update	
Appendix A	Community Liaison Committee draft Terms of Reference	yes	Appendix A.1	Terms of Reference for the Community Liaison Committee (CLC)	Yes	A.1	Plain Language Summary Beaver Dam Mine Project
Appendix B	Summary of Stakeholder and Mi'kmaq Engagement	Yes	Appendix A.2	Summary of Stakeholder and Mi'kmaq Engagement as Completed for the Project as of January 2018	New	A.2a	Mine Waste Stockpile Geotechnical Design - April 1, 2021
Appendix C	Sediment Baseline Analytical Results	New	Appendix B.1	Noise Impact Study Beaver Dam Mine Project	New	A.2b	Beaver DAM Project – Conceptual PAG Closure Options - December 1, 2021
Appendix D	Surface Water Balance Analytical Results	New	Appendix C.1	Air Dispersion Modelling and Air Emission Estimate Technical Memorandum	New	A.2c	Geotechnical Investigation: Data Report - Beaver Dam Mine, January 15, 2021
Appendix E	Hydrogeological Reports	New	Appendix C.2	Evaluation of Exposure Potential Related to Dust Deposition from Haul Road Traffic onto Soils, Berries, and Vegetation	No	A.3	Terms of Reference for the Community Liaison Committee (CLC)

2 PROJECT DESCRIPTION

2.1 Introduction

2.1.1 Summary of the Project Description Before the Updates

The **proposed Beaver Dam Mine Project** includes construction, operation, decommissioning, and reclamation of an open pit gold mine in Marinette, Nova Scotia. As proposed, the Beaver Dam Mine Project would have an ore production rate of 2.1 million tonnes per year, over a four-year period. Ore from the project would be crushed and transported approximately 31 kilometres by road to the Moose River (Touquoy) mine for processing. Beaver Dam mine tailings will be deposited sub aqueously in the mined-out Touquoy pit. The Beaver Dam mine site includes an open pit, mine site haul roads, waste material storage areas, primary crusher and administrative.

The Project Area (PA), therefore, includes:

- Beaver Dam Mine Site –mining, waste rock and water management;
- Haul Road – transport of ore to Touquoy Mine Site; and
- Touquoy Mine Site – processing ore and tailings disposal in the mined-out pit.

2.1.2 Summary of Updates to Project Description

AMNS has updated the project description to include five years of operations. The maximum ore production rate is 2.1 million tonnes per year (Mt/y) that will range from 0.75 to 2.1 Mt/y over the five years. Components of the project still include an open pit, mine site haul roads, waste material storage piles, ore stockpiles, optional primary crusher and operational facilities, and water management. Addition geochemical work indicated that there is potential for potential acid generative (PAG) material that requires segregation into a separate stockpile that will require an engineered cover at closure. Advances in detailed engineering include an option to undertake the operations without a primary crusher, using mine equipment within the pit (e.g., jawbreaker) to crush ore for transport. This assessment considers options with and without a primary crusher is described. Water management structures have been updated to include ponds that are sized to consider extreme weather events (i.e., Hurricane Beth) and climate change. Overall updates to the project footprint have been undertaken to avoid and/or minimize direct impacts to lichens, wetlands, and water bodies courses.

Additional studies on haul trucks have been undertaken to reduce to overall number of truck trips to an average of 200 return truck trips a day over the life of mine. The Preferred Alternative Road, which would require additional disturbance, is no longer considered in the updated as part of the Haul Road design. It may be necessary to use the Public Roads during start-up (i.e., 6 to 8 months) depending on approval and permitting timelines and construction restrictions.

Engagement undertaken in 2020 and 2021 indicated there was considerable concern regarding limitation of access along the Haul Road. A by-pass road will be constructed parallel and adjacent to proposed Haul Road to mitigate concerns raised by both the Mi'Kmaq of Nova Scotia and members of the public. The bypass road will be constructed to allow light truck and recreational vehicles access while the haul road is in operation.

The Project Area (PA), therefore, includes:

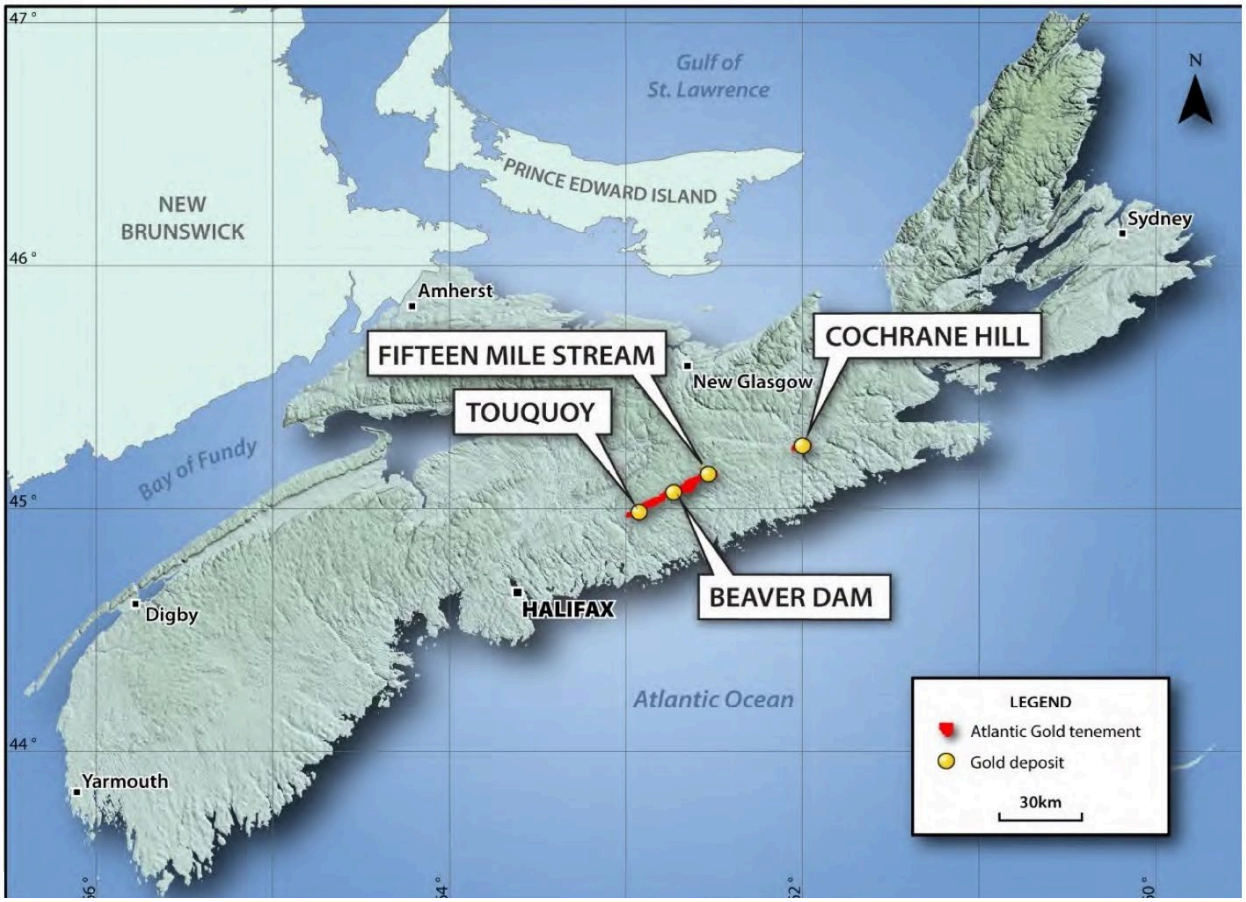
- Beaver Dam Mine Site – mining ore, managing waste rock storage, and water management;
- Haul Road – transport of ore to Touquoy Mine Site and will include; and
- Touquoy Mine Site – processing ore and tailings disposal in the mined-out pit.

St. Barbara Limited is committed to carbon neutrality across its mining operations by 2050. AMNS is continually looking for opportunities target carbon neutrally by 2025. Although advances in technologies including hydrogen cells in mine fleets are being developing, they are currently not technically and commercially viable option at the Beaver Dam Mine Site. Other assessments are being undertaken is evaluating if wind energy can be used to supply energy to Touquoy mill.

2.1.3 Overview of Updates

An overview of updates to the Project Description and corresponding sections is provided in Table 2-1.1.

Table 2.1-1: Updated and Unchanged Subsections from the 2019 Revised Environmental Impact Statement – Project Description



Project Description from the 2019 Revised EIS Submission	Updated in 2021	Reason for Update
2.1 Introduction	New	Project Summary based on 2019 Revised EIS and Summary based on Updated 2021 EIS
2.2 Ownership and Tenements	Update	New ownership; lease boundary updates due in changes in Project layout
2.3 Project Location	Limited Update	Updates Description of Project and included new figures
2.4 Ecological Setting	Limited Update	Updated description
2.5 Project History	Limited Update	Updated based on new Phase I and II information on historic mining activities
2.6 Geology and Resources	New	Additional information on geology and resources
2.7 Project Components	Updated	Updates to reflect updates to mining components at Beaver Dam Mine; Removal of the Preferred Alternative Haul Road Route and updates to Touquoy processing and tailings disposal
2.8 Project Schedule	Updated	Increase in Project Operations from 3.5 Years to 5 Years and updates to Active and Post-Closure
2.9 Active and Post Closure	Updated	Updated to reflect draft Reclamation and Closure Plan
2.10 Preferred Means of Carrying Out Project	No Change	
2.11 Conclusion	Limited Updates	Updates based on Socio-Economic Information

2.2 Ownership and Tenements

2.2.1 Ownership

Atlantic Mining NS Inc. (AMNS), formerly Atlantic Gold, is wholly owned by St Barbara Limited (St Barbara) that completed the acquisition of Atlantic Corporation on July 19, 2019. The proposed Beaver Dam Mine and existing Touquoy Mine are 100% owned by AMNS. The company is focused on growing gold production in Nova Scotia beginning with its Moose River Consolidated phase one open pit gold mine at Touquoy, which declared commercial production in March 2018. The life of mine expansion involves satellite deposits at Beaver Dam, Fifteen Mile Stream and Cochrane Hill (Figure 2.2-1).

Figure 2.2-1: Atlantic Mining NS Inc. Projects

2.2.2 Mineral Tenures

2.2.2.1 Beaver Dam Property

Mineral exploration and mining licences are issued by the Nova Scotia Department of Energy and Mines (NSDEM) under the *Mineral Resources Act* of 2016 (amended in 2018). Exploration licences are granted for two-year terms, and are renewable indefinitely, provided certain annual conditions are met. Exploration licences can contain a maximum of 80 bordering mineral claims. Mining licences are granted for 20-year terms and can be renewed an indefinite number of times at the discretion of the Minister for Natural Resources.

The Beaver Dam property is held under two exploration license EL50421 and EL51852. The EL EL50421 comprises 76 contiguous claims that cover an area of approximately 1, 230 ha and EL51852 comprises 7 claims and covers 113 ha. Exploration Licence 50421 is an amalgamation of EL 05920 and EL 06175, which was reissued as EL 50421 in August 2014. Exploration Licence 05920 represented the amalgamation of three pre-existing Exploration Licences 00047, 04790 and 04516. The Exploration Licences were regrouped in 2003 as EL 05920 and reissued by the NSDEM in 2005. The Mineral Tenure details are provided in Table 2.2-1 and Figure 2.2-2.

Haul Road does not require mineral leases because not extracting materials.

2.2.2.2 Touquoy Property

Mineral rights to the Touquoy Property are wholly owned by AMNS and consist of one mineral lease (MLE11-1) comprising 49 claims and covering 793 hectares (ha), and one adjoining Exploration License (EL10377) comprising 64 claims and covering 1,036 ha.

2.2.3 Surface Rights

2.2.3.1 Beaver Dam Property

Under the current *Mineral Resources Act*, prospectors and exploration companies must obtain permission from the landowner (whether private or Crown) prior to accessing licences.

At the Beaver Dam Mine Site, AMNS is in process of negotiation surface titles with Northern Timber Nova Scotia Corporation (Northern Timber) as well as applying for crown land lease parcels. Surface leases have been negotiated on portion of the haul road (i.e., near the intersection of the Mooseland Road). The remaining surface rights are currently under negotiations with Northern Timber and applications crown lease parcels.

2.2.3.2 Haul Road

The Haul Road will be under lease from Forestry companies and/or part of a purchasing arrangement, which is currently being negotiated.

2.2.3.3 Touquoy Property

At Touquoy, AMNS Atlantic holds (i.e., holds fee simple title to and possesses) of the private land required for the operation of the Touquoy mining operation. A Crown land lease to seven parcels of Crown land was granted in June 2014. The lease is for a 10-year term, renewable for a further 10 years.

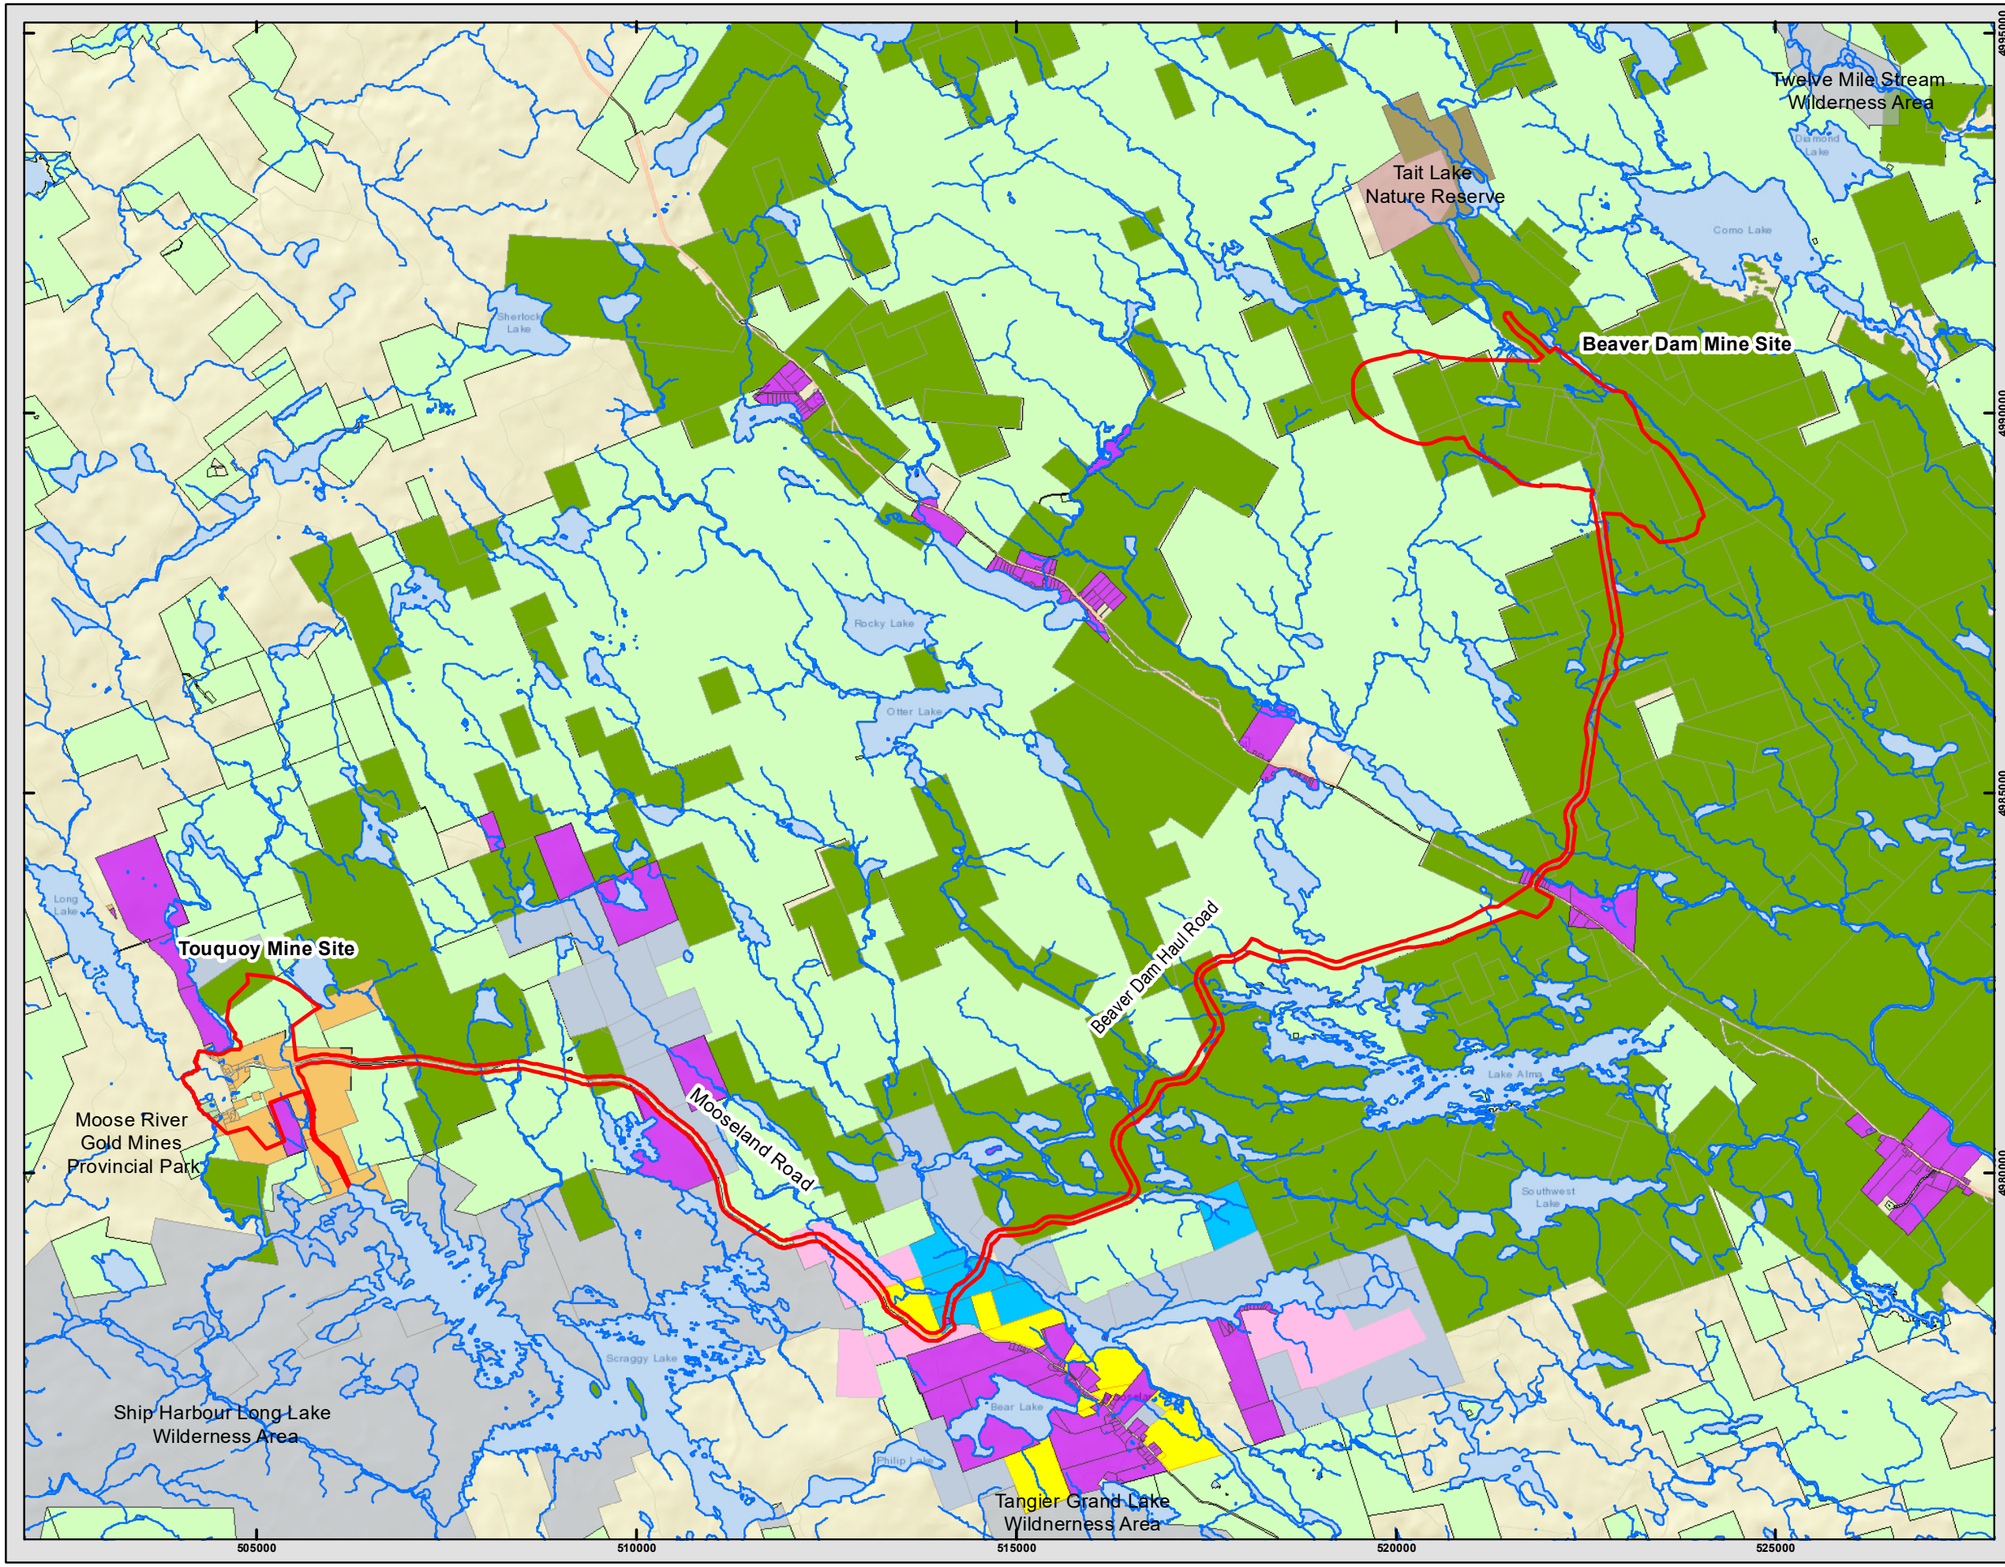
2.3 Project Location

The Project consists the Beaver Dam Mine Property (i.e., mining and storing of waste rock), a 31-kilometre (km) haul road that connects to the two sites and the Touquoy Property (i.e., processing, and depositing tailings) (Figure 2.3-1). The Project is bound within a Project Area (PA). The PA will result in approximately 244 hectares (ha) of disturbance with 34 ha or 14% occurring on crown land.

2.3.1 Beaver Dam Mine

The Beaver Dam Mine property is in Marinette, Regional Municipality of Halifax Area, Nova Scotia, which is approximately 85 km northeast of Halifax. The Beaver Lake IR is located approximately 6 km of the Beaver Dam deposit and 5 km from the intersection of the Beaver Dam Mine Road and Highway 224. The community of Mooseland is approximate 1 km from the intersection of the Beaver Dam Haul Road and the Mooseland Road. Goods and services needed are generally sourced from Halifax/Dartmouth. The Beaver Dam Mine Project layout is provided in Figure 2.3-2. The Beaver Dam mine footprint approximately 208 ha with 26 ha or 14% on Crown land. The approximate centre point of the Beaver Dam Mine Site is 521319 E 4990700 N (UTM Zone 20 NAD83 CSRS).

2.3.2 Haul Road



The Haul Road extends from the Beaver Dam Mine Site to the Touquoy Mine site (Figure 2.3-3). Bypass roads to allow light truck traffic and recreational vehicles (e.g., ATV and snowmobiles) to maintain access during operations will be constructed adjacent and parallel to portions of the Haul Road. The total disturbance of Haul Roads is 25 ha and by-pass roads are expected to disturb approximately 10 ha with 25 ha on crown land. The Haul Road consists of the following four main segments:

- 7.2 km existing Beaver Dam Mines road, that extends east from the proposed mine site to highway 224, which will be upgraded to support ore transport and will include bypass road.
- 4 km of new constructed road west of Highway 224 to connect the Haul road to an existing forestry road, this section will not include bypass road.
- 8.2 km existing forestry road that extends east to the Mooseland Road, referred to locally as the Dump Road, will be upgraded to support ore transport truck and will include bypass road.
- 10.7 km Mooseland Road that will be upgraded by Department of Transportation and Infrastructure Renewal (TIR) extends north along the Mooseland Road to the existing Touquoy Mine. By-pass roads crossing and parking area is currently being considered in the design to address safety concerns by local residents.

It may be necessary to use the Public Roads during start-up (i.e., 6 to 8 months) depending on approval and permitting timelines and construction restrictions.

2.3.3 Touquoy Mine

The Touquoy property is located 60 km northeast of t Halifax, Nova Scotia, which is centered on the former mining village of Moose River Gold Mines. Halifax provides the majority of goods and services required by the Project The closest population centres are Middle Musquodoboit located 20 km to the northwest and approximately 12 km from the community of Mooseland which is located to the southeast. The Touquoy Mine Site is shown in Figure 2.3-4. There is no anticipated disturbance to the exiting Touquoy Mine site that will result from processing Beaver Dam ore. The approximate centre point of the Touquoy property is 505280.58E 505280.58N UTM Zone20 NAD83 CSRS.

McCallum Environmental Ltd.

Document Name: BD_EIS_Fig2.1-X General Touquoy Arrangement

2.4 Ecological Setting

2.4.1 Physiography and Drainage

The proposed Beaver Dam Mine and Touquoy Mine is located within the Eastern Drumlins ecodistrict, a further subdivision of the Eastern ecoregion of NS. The ecodistrict is characterized by drumlin fields with generally north-south oriented drumlins. Beaver Dam is an area of low topographic relief with most of the area being around 140 metres above sea level (masl) with scattered drumlins reaching 160 masl.

At the Beaver Dam Mine drainage is to the southeast along a number of poorly drained streams and shallow lakes. Drainage in the area generally flows to the southeast along poorly drained streams, shallow lakes, and wetlands that eventually drain into Cameron Flowage and the Killag River. A drainage divide is present within the proposed Beaver Dam Mine Site, with drainage towards the south through Paul Brook (AMNS 2021). Locally, water in the eastern portion of the Site is directed toward an artificial historical settling pond with the remains of a dam that is maintaining the water level in the pond. Overflow from the historical settling pond is directed into Cameron Flowage and the Killag River. There are a number of boggy areas within the property. The Cameron Flowage/Killag River, Crusher Lake, Mud Lake, Tent Brook and Cope Brook (Beaver Dam Mine Site area) and associated drainage are the watercourses that will receive direct discharge and/or their catchment area. The vegetation consists of spruce, fir, and some hardwood. Logging has been widely carried out more recently including clear cutting in the immediate area of the deposit. Historic mining has occurred within the proposed Beaver Dam Mine property, which is detailed in Section 2.5 and Section 6.5 (Geology, Soils and Sediment Quality).

The Haul road is located in generally low-lying area with a mosaic of upland forests and wetlands. Forestry is the main land use that continues in the area and the existing road was constructed to allow access for logging. There is evidence of historic mining along the haul road.

At Touquoy Mine catchment areas drain mainly to the Moose River and its tributaries with the southern area of the property draining to Scraggy Lake. The runoff from the site infrastructure areas has been altered and is managed and controlled by means of collection ditches and ponds with collected water being discharged to Scraggy Lake. Fish River drains Square Lake to Scraggy Lake and both lakes are part of the Fish River Watershed that flows west and then south into Lake Charlotte, eventually draining to Ship Harbour.

2.4.2 Climate

The Project is located inland and somewhat removed from the immediate climatic influence of the Atlantic Ocean. It is characterized by warmer summers and cooler winters. Daily rainfall, snowfall and mean temperature data were obtained from the Environment Canada Middle Musquodoboit Climate Station (Climate ID 8203535) for a 41-year period between 1968 to 2016. Monthly lake evaporation normals were obtained from the Environment Canada Truro Climate Station (Climate ID 8205990), which is the closest climate station to the Project that collects lake evaporation data.

The average monthly temperature at the Site ranges from a low of -6.2°C in January to a high of 18.5°C in July. The lowest average total monthly precipitation occurs in June (94.8 millimetres [mm]), while the highest occurs in November (137.1 mm). Hurricanes are also possible in this region. The largest hurricane on record, recorded at Halifax International Airport (approximately 80 km west of the Site), was Hurricane Beth in 1971 with 296.4 mm of rainfall over 48 hours. This has been considered in the development of water management structures (i.e., settling ponds and diversion ditches) at the Beaver Dam Mine Site (Section 2.7.2.9).

Nova Scotia Environment and Climate Change (NSECC) provides climate change projections across the province (NSE 2020). The two climate regions nearest the Project (i.e., Halifax Regional Municipality and Truro, NS) project a 5% increase in short period rainfall intensity for the 2020s according to NSE (2020). As such, a 5% increase to the historic Intensity, Duration and Frequency (IDF) curve was incorporated into the design of water management structures at Beaver Dam Mine site and are therefore sized to consider climate change Appendix P.4 Mine Water Management Plan).

2.4.3 Current Land Use

The Project occurs within an area used for forestry with existing road used to access logging areas. The area is used by recreational hunters and fishers. The existing roads are used by light vehicles and recreational vehicles to access areas lakes and rivers as well as access east of the Killag River where there are camps and gathering sites. AMNS has and continues to undertake geological and geotechnical drilling to support the EIS and mine plans. Environmental monitoring is ongoing to support the Project.

The Nova Scotia Salmon Association (NSSA) leads the West River Sheet Harbour Acid Mitigation Project, which involves the operation and maintenance of automated lime dosers on both the Killag River and the West River (NSSA 2020). The lime doser on the Killag River is situated downstream from the proposed Project. The lime dosers are intended to buffer the naturally low pH of river water downstream to a more suitable pH to support Atlantic salmon and brook trout (NSSA 2020). In addition to these liming efforts, the NSSA conducts monitoring of Atlantic salmon (e.g., annual smolt monitoring, adult monitoring, electrofishing surveys) as well as other ecosystem components, such as invertebrates and water chemistry (NSSA 2020).

Touquoy Mine is currently an operating mine and land use in the area includes recreation, hunting and fishing as well as traditional land pursuits.

2.4.4 Traditional Land Use

The Confederacy of Mainland Mi'kmaq (CMM) was retained in 2009 by GHD Limited on behalf of the AMNS to complete a Mi'kmaq Ecological Knowledge Study (MEKS) for the proposed Project at the Beaver Dam Mine Site. In 2015, CMM was retained to update the MEKS, due to changes in the Haul Road to include approximately 4 km of new construction. CMM was then retained again in 2016 to finalize the MEKS to include the revised Project Area (PA) and any additional information.

In addition to the MEKS cited above, in 2018, a Traditional Land and Resource Use Study (TLRUS; MFC 2019) was undertaken by Millbrook First Nation to document historical and current use of the Project Area and surrounding areas by the Millbrook First Nation. This document was shared with AMNS under a confidentiality agreement. AMNS has integrated information obtained from the TLRUS, with permission from Millbrook First Nation, in appropriate sections of the EIS.

There are a number of activities associated with the harvest and use of plants, animals and fish within the PA and in the Local Assessment Area (LAA) that relate to historical traditions and customs of the Mi'kmaq that are still practiced today. As described, the TLRUS (MFC 2019), the MEKS and residents of the Beaver Lake IR 17 identify trapping and hunting activities, plant and berry gathering, and fishing in, near and surrounding the PA for purposes of sustenance, spiritual and cultural practice. The TLRUS (MFC 2019) described the frequency of use within the LAA which can be summarized as regular: weekly to annually across all seasons. This means the area was, and still is, an important resource area for the Millbrook First Nation community members and by extension, all Mi'kmaq of Nova Scotia, and any Project activities may have potential impacts on the ability of the Mi'kmaq of Nova Scotia to access certain areas to practice their rights where species with important cultural relevance may be found. Wild meat was traditionally a staple of the Millbrook First Nation diet, and a few of the harvesters interviewed for the TLRUS (MFC 2019) indicated they rely mainly on this food source and they share their food with other community members, rather than purchase their meat at a local supermarket.

2.4.5 Significant Areas

Some Mi'kmaq community members have camps on Crown land where they go to enjoy peaceful recreational and traditional activities with family and community members. There camps are documented within 1 km of the Haul Road and multiple other camp locations throughout the LAA (MFC 2019) The approximate distances of these areas from the PA (i.e., Beaver Dam Mine Site, Haul Road, and Touquoy Mine Site) is summarized in Table 2.4-1.

Table 2.4-1: Protected Areas with Provincial Designation

Provincially Designated Areas	Approximate Distance (From Beaver Dam Mine Project Area)	Direction	Type of Designation
Tait Lake Nature Reserve	1 km from Beaver Dam Mine Site	North	Nature Reserve
Cowan Brook Nature Reserve	9.5 km from Touquoy Mine Site	South	Nature Reserve
Twelve Mile Stream Wilderness Area	4.5 km from Beaver Dam Mine Site	Northeast	Wilderness Area
Liscomb Game Sanctuary	7.3 km from Beaver Dam Mine Site	East	Game Sanctuary
Tangier Grand Lake Wilderness Area	2.2 km from intersection of Moose River Cross Road and Mooseland Road	South	Nature Reserve
Ship Harbour Long Lake Wilderness Area	Adjacent to Mooseland Road	West	Nature Reserve

2.5 Project History

2.5.1 Beaver Dam Mine

The proposed Beaver Dam mine site has been subject to exploration and mining activity since gold was first discovered in 1868. Between 1871 and 1949, there were intermittent attempts to develop and mine the area, initially focused on the Austen Shaft area and later the Mill Shaft area located approximately 1.2 km west of the Austen Shaft. The small Papke Pit located approximately 400 m west of the Austen Shaft was excavated in 1926; however, the majority of development was focused on a belt of quartz veins in greywacke and slates that was approximately 23 m wide where intersected from the Austen Shaft. Approximately 967 ounces (oz) of gold production is recorded for Beaver Dam between 1889 and 1941. From 1978 until 1988, several companies drilled a combined 251 diamond drill holes for 47,935 metres (m). Some of these drill holes were completed underground via an exploration decline installed in the mid-1980s that reached a maximum depth of 100 m below surface. In 1987, a small open pit was also excavated in the Austen Shaft zone. Approximately 2,445 oz of gold production was also recorded for Beaver Dam between 1986 and 1989. Between 2005 and 2009 two companies drilled a combined 153 diamond drill holes for 22,010 m and completed several other exploration programs including an aeromagnetic survey, a till survey, and a follow-up reverse circulation drilling program for geochemical purposes. Additional details on historic mining at the Beaver Dam Mine Site is provided in Section 6.5 (Geology, Soil, and Sediment Quality).

AMNS secured rights to the property in 2014 and executed an exploration program whereby 38 diamond drill holes for 7,810 m were completed over the proposed surface mine area with the goal of increasing subsurface knowledge of the site and converting inferred gold resources to measured or indicated resources

There is evidence of historical mining at the site, including access roads/laydown areas, abandoned cabins, hunting blinds, old mine workings, dam structures, apparent building foundations, waste rock piles, and an old mining excavation. There are currently no permanent buildings in use and the site is not serviced. AMNS is committed to removing the historic tailings and waste rock from the site and disposing in the mined-out pit at Touquoy.

AMNS has undertaken exploration activities with the proposed Beaver Dam Mine Site. A project description was submitted to IAAC in 2015 (Atlantic Corporation 2015) with an Environmental Impact Statement (EIS) submitted in 2017 (AGC 2017). A revised EIS was submitted in February 2019 to address the first-round information requests (IR1). This updated Project Description and EIS is submitted to address changes in the Project Description and advances in detailed engineering as well as to address IR2 (AMNS 2021a).

2.5.2 Touquoy Mine

In 2012, an application for Industrial Approval (IA) and supporting documentation was prepared by Conestoga-Rovers & Associates (CRA) (CRA 2012) and submitted to NSE on behalf of AMNS. The application was based on the feasibility level design completed by Golder Associates Ltd. (Golder) in 2007 and revised in 2010. The 2011 Preliminary Reclamation plan (CRA 2011) was submitted as part of the IA Application. The IA application was approved on March 24, 2014, under Approval No. 2012- 084244.

Following receipt of the initial IA in March 2014, an update to the project feasibility level design was completed in July 2015 by Stantec (Stantec, July 7, 2015) to include updates to the mine development plan primarily relating to design changes for the TMF. The design was finalized, and drawings issued for construction in 2016 by Stantec.

The Project has and is currently in the process of applying for amendments with the NSE for modifications of infrastructure. A Class 1 Provincial Environmental Assessment for the site will be submitted later in June 2021. This will be followed by IA amendment applications.

2.6 Geology and Resources

2.6.1 Regional Geology

In Nova Scotia, two distinct geological terranes, the Avalon Terrane to the north and the Meguma Terrane to the south, are juxtaposed along the Cobequid–Chedabucto Fault Zone (CCFZ).

The Avalon Terrane comprises multiple successions of sedimentation and volcanism, together with felsic to mafic igneous intrusion. A number of metalliferous deposits have been recognized in the Avalon Terrane, mostly within Pre-Cambrian rocks, including carbonate hosted zinc skarn deposits, stratabound massive sulphide deposits, quartz-vein hosted high-grade gold mineralization in gneiss and diorite, polymetallic volcanic-hosted massive sulphide deposits in volcanic rocks and porphyry-style mineralization (Donohoe, 1996).

The Meguma Terrane consists of marine sedimentary and volcaniclastic rocks together with bimodal volcanic rocks. The terrane has hosted most of the gold mineralization exploited historically (from 1860 onward) in Nova Scotia with approximately 1.2 Moz Au produced (Bierlein and Smith, 2003).

Post juxtaposition, a series of shallow basins developed on both sides of the CCFZ. These are infilled by slate, quartzite and volcanic rocks of the Rockville Notch Group, and range in age from Early Silurian to Early Devonian (White and Barr, 2012).

Numerous, late syntectonic to post-tectonic, mainly Middle to Late Devonian, peraluminous, granitic plutons have intruded the earlier sequences (White and Barr, 2012).

The oldest known rocks of the Meguma Terrane are the greywackes and argillites of the Cambrian to Ordovician-aged Meguma Supergroup. The Meguma Supergroup is divided into two stratigraphic units, the basal greywacke dominated Goldenville Group and the overlying, finer-grained, argillite-dominated Halifax Group (Figure 2.6-1).

The basal contact of the Goldenville Group is not known, but the Goldenville Group is at least 5,600 m thick while the overlying Halifax Group averages approximately 4,400 m. These sediments were uplifted and deformed into a series of tightly-folded, subparallel, northeast-trending anticlines and synclines during the Acadian Orogeny (ca. 410–380 Ma). The sediments have been metamorphosed to greenschist to amphibolite (staurolite) facies and have been intruded by granites and minor mafic intrusions.

The Goldenville Group comprises, from oldest to youngest:

- Moose River Formation;
- Tangier Formation; and
- Taylors Head Formation.

2.6.2 Beaver Dam Deposit (Resource)

The Beaver Dam deposit is hosted in the southern limb of a north-dipping overturned anticlinal fold. The Moose River Formation is relatively thick in the vicinity of the Beaver Dam deposit (Figure 2.6-1 and Figure 2.6-2). The host stratigraphy is offset into segments by two northwest trending faults; the sinistral Mud Lake Fault and the dextral Cameron Flowage Fault. The Mud Lake Fault truncates, and forms the eastern boundary to, the Main Zone mineralization.

Lithologies at Beaver Dam have been metamorphosed to amphibolite facies (biotite grade) increasing to higher (staurolite) grade with proximity to the River Lake Pluton, the contact of which is about 2 km west of the Beaver Dam deposit.

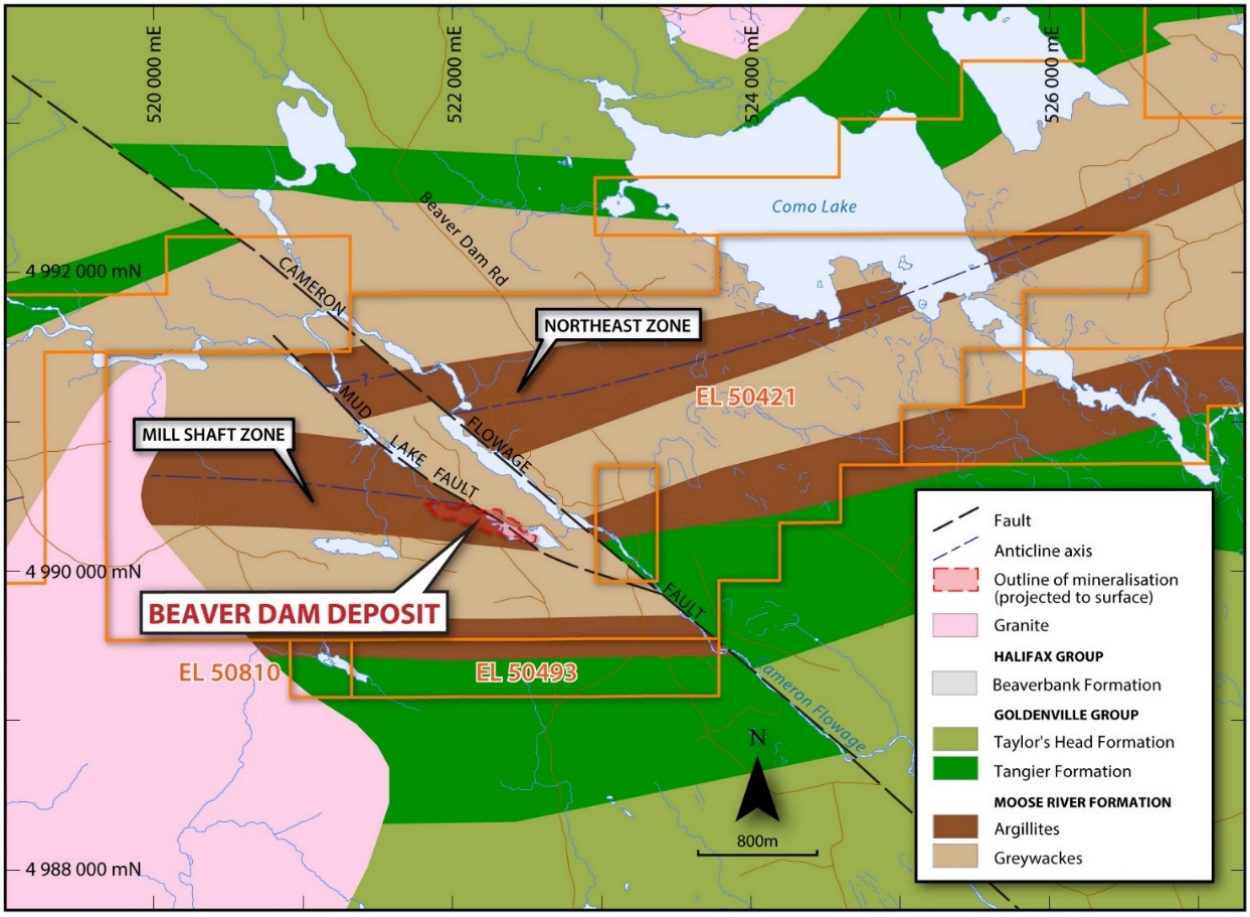
Gold mineralization at Beaver Dam has been recognised over a strike length of approximately 1.4 km, extending from the Main Zone northwest to the Mill Shaft Zone. Historic drilling has shown that mineralization weakens between the Main Zone and Mill Shaft Zone. The eastern end of the main zone is controlled by the Mud Lake Fault and possible offsets to the mineralization have been identified between the Mud Lake and Cameron Flowage faults and in the Northeast Zone, immediately east of the Cameron Flowage Fault.

The mineralised zone can reach as much as 100 m in width with better gold grade (e.g., >0.5 gpt) material typically confined to 5 m to 40 m widths within that zone. Mineralization has been identified in historical drill holes at vertical depths of >600 m below surface and remains open below that depth.

Gold mineralization is hosted within quartz veins and within the argillite and greywacke host rocks. Mineralized quartz veins are typically 0.5–20 cm in thickness, are commonly bedding parallel, but can also include cross-cutting veins. Sulphide assemblages include pyrrhotite, pyrite and/or arsenopyrite with lesser chalcopyrite, galena or sphalerite. Gold commonly occurs within quartz veins as coarse (>1 mm) grains and clusters of finer, but still visible (<1 mm), grains. Coarse gold grains are more likely to be found at vein-wall rock contacts and are often spatially associated with sulphides.

In the immediate vicinity of the deposit the host stratigraphy has been subdivided into several mappable units, from oldest to youngest: the Crouse Mudstone, Hangingwall Greywacke, Papke Mudstone, Millet Seed Sandstone and Austen Mudstone. The mineralized zone appears to gently cross-cut this macro-stratigraphy. Gold mineralization is often associated with sulphides including pyrrhotite, pyrite, arsenopyrite, and chalcopyrite.

Figure 2.6-1: Beaver Dam Deposit



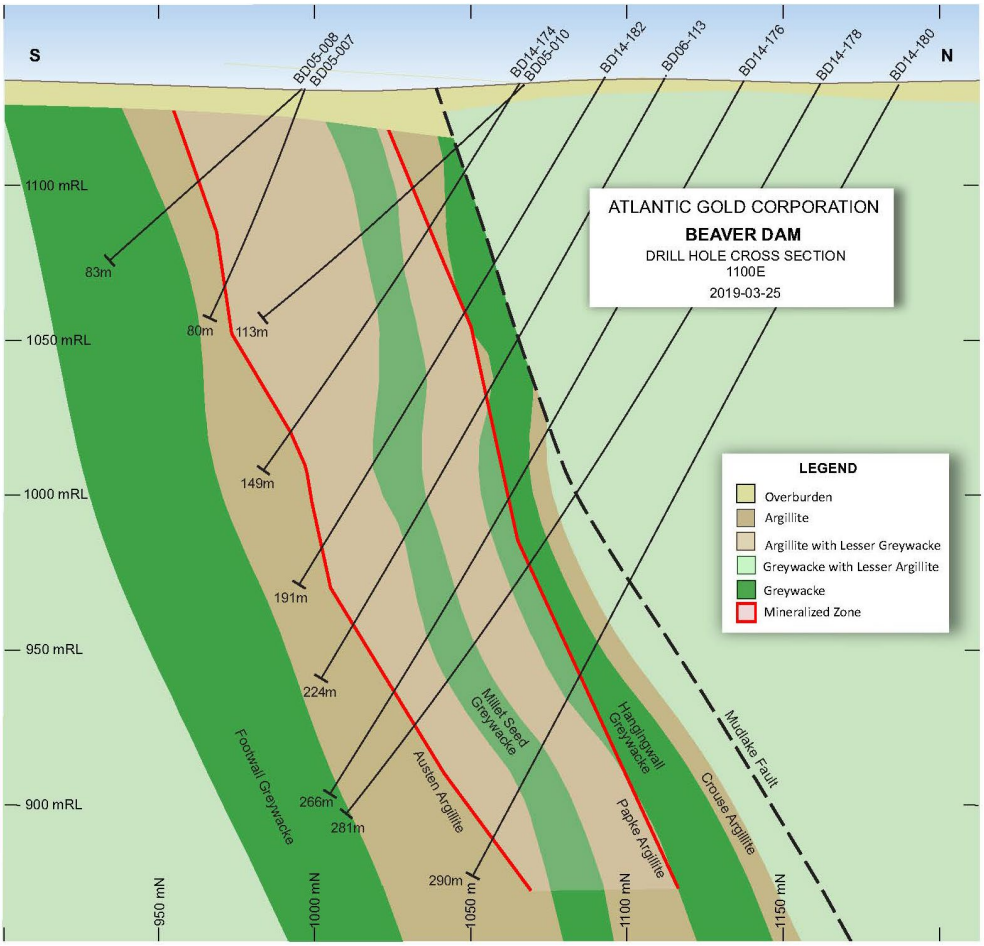


Figure 2.6-2: Cross Section of Beaver Dam Deposit

2.7 Project Components

The Beaver Dam Mine Project will operate as a satellite surface mine that will transport crushed ore along an approximately 31 km Haul Road to the Touquoy Mine in Moose River. Tailings will be disposed of in the exhausted Touquoy open pit.

The primary components associated with the Beaver Dam Mine Project include the following:

- Beaver Dam Mine Site:
  - Open pit for extracting ore and waste rock;
  - Mine site Haul Roads;
  - Waste material storage piles for waste rock (non-acid generating (NAG) and potential acid generating (PAG), one topsoil, three till and one organics stockpiles;
  - Run of mine (ROM), and low-grade ore (LGO) stockpiles;
  - Optional primary crusher;

  - Operational facilities; and
  - Water management.
- Haul Road any bypass roads for transporting ore; and,
- Existing Touquoy Mine Site.

The location of components at the Beaver Dam Mine Site, the Haul Road, and the location of the relevant components of the Touquoy Mine Site related to the Beaver Dam Mine Project are shown in Figures 2.3-1 to 2.3-4.

2.7.1 Summary of 2021 Updates

Geographical restrictions have been applied to the Beaver Dam Mine infrastructure layout to minimize disturbance to environment. The open pit, for example is at least 50 m away from the Cameron Flowage/Killag River to the north. Waste and till storage facilities, as described in Section 2.7.2 are distant from lakes and property boundaries, 500 m from all surveyed Boreal Felt Lichen, 50 m from all surveyed Boreal Felt Lichen habitats, and 100 m from all surveyed Frosted Glass Lichen (Section 6.13 Species of Conservation Interest and Species at Risk). Wetland disturbance at Beaver Dam by waste storage piles is minimized, wherever possible (Section 6.8 Wetlands).

Project components of the Beaver Dam Mine Project have been altered since the February Revised 2019 EIS (AMNS 2019) and in consideration of the geographical restrictions defined above are shown on Figure 2.7-1 that include the following:

- Adjustment in the location of the Waste Rock Storage and Low -Grade storage area to the west and away from critical habitat including blue felt lichen and frosted glass lichen.
- High Grade Stockpile will form part of the ROM Stockpile.
- Inclusion of a PAG stockpile south of the pit.
- Adjustment in the location of temporary stockpiles (i.e., topsoil, till and organic) to avoid critical habitat and minimize impacts to wetlands. The organic stockpile was not included in the 2019 revised EIS Project Description.
- Adjustments in the location of mine site haul roads to avoid critical habitat and minimize impacts to wetlands.
- Adjustments and more detailed engineering on administrative and ancillary areas that include the following:
  - Administration/Security Building;
  - Truck Shop/Truck Wash;
  - Crusher Structure and Conveyor (optional);
  - Stormwater/Evaporation Retention Pond;
  - Various Trailers;
  - Septic and Propane Tanks;
  - Petroleum and Hazardous Material Storage; and
  - Explosive Storage Area.
- Detailed water management structures including water management settling ponds, diversion ditches and water treatment.

2.7.2 Beaver Dam Mine Site

2.7.2.1 Open Pit

Mining is based on conventional open pit methods suited for the project location and local site requirements. The mining fleet will include diesel powered down the hole (DTH) drills with 144 mm bit size for production drilling, diesel-powered RC drills for bench-scale grade control drilling, 5.0 cubic metres (m^3) bucket size diesel hydraulic excavators and 9.0 m^3 bucket sized wheel loaders for production loading, and 64 tonne (t) payload rigid-frame haul trucks and 41 t articulated trucks for production hauling, plus ancillary and service equipment to support the mining operations. In-pit dewatering systems will be established for the pit. All surface water and precipitation in the pits will be handled by submersible pumps.

Holes will be drilled into the host rock to receive explosives used for blasting. Previous exploration drilling has mapped the host rock for ore-bearing potential. Further grade control drilling will be undertaken to confirm any local variation in ore distribution allowing blast patterns to be executed to maximize production of ore and minimize production of non-ore bearing waste rock. All blasting activities will be conducted by a licensed contractor.

The open pit will remove approximately 56.6 million tonnes (Mt) of material (i.e., ore, non-ore bearing waste rock, till, and organic material) over the life of mine. The production schedule for the Beaver Dam Mine is shown in Table 2.7-1 and Figure 2.7-2. The pit will be mined in a west/east phases. Ultimate pit limits are split into phases or pushbacks to target higher economic margin material earlier in the mine life. The ultimate pit is subdivided into two phases, west and east, but for considerations of vertical advance the pit is mined as one phase from top to bottom. A small starter pit phase is also planned for the northwest corner of the pit to provide construction materials early in the mine life. The ore mined from the pit will range from 0.75 Mt to 2.1 Mt per year over the life of mine with approximately 0.5 Mt to a maximum of 14.9 Mt of waste being generated over life of mine. The open pit will be advanced from the surface at 130 to 155 masl down to 45 masl. At completion, the open pit will measure approximately 900 m along its east-west axis, approximately 500 m along its north-south axis, with a depth of ranging approximately 175 to 200 m based on the current ore delineation. The total area comprising the open pit will be approximately 31 ha.

Table 2.7-1: Summary of Mine Production Schedule

Materials	Unit	LOM	2022	2023	2024	2025	2026	2027

Gold Grade	g/t	1.03	0.00	1.59	1.38	1.27	1.19	0.65

Source: Aucenco 2021

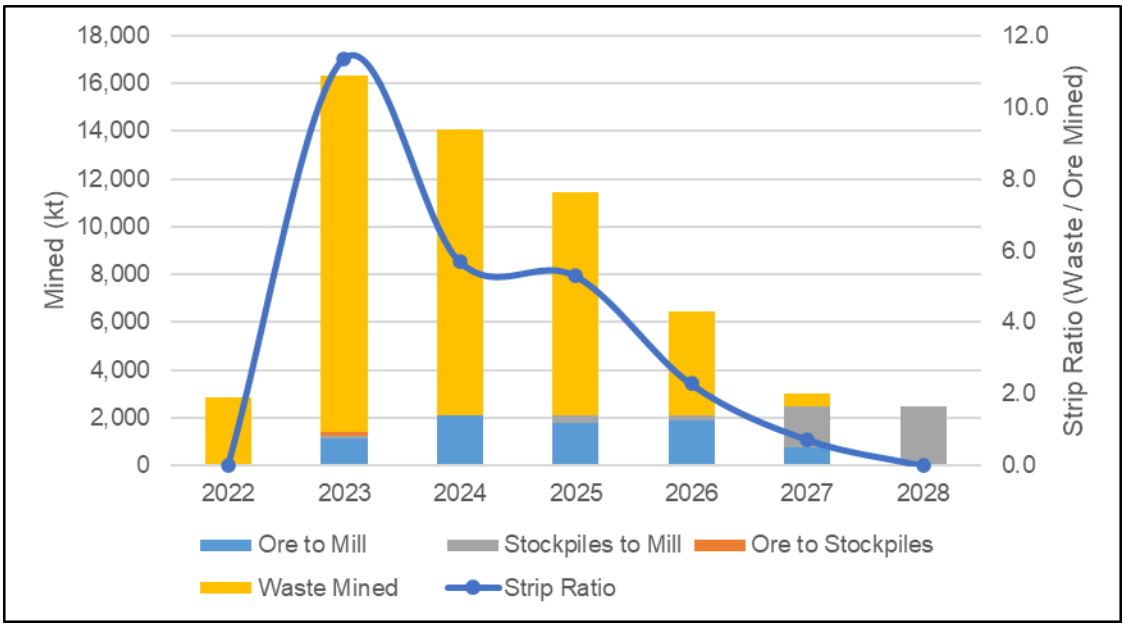
Note: LOM – Life of Mine; Differences in (LOM) totals are attributed to rounding between Kilotonnes to Milltion tonnes

Note: Milled includes ore includes from other operations

At Beaver Dam, ore will be hauled to a ROM pad that will be located 600 m south of the pit, and then ROM ore will be hauled by on-highway haulers from Beaver Dam to the process plant at Touquoy operations. Waste rock from Beaver Dam will be deposited into PAG and NAG Waste Rock Storage Facilities (WRSFs) to be situated 200 m south and 1,500 m west of the pit, respectively. The high grade ore will be stored on ROM stockpile.

Mining operations will be based on 365 operating days per year with two 12 hour shifts per day. An allowance of 12 days of no mine production has been built into the mine schedule to allow for adverse weather conditions.

Maintenance on mine equipment will be performed in the field with major repairs to mobile equipment in the shops located near the ROM pad.



Clearing, grubbing, grading, and stockpiling of vegetation, topsoil, and till in the pit area will be conducted progressively prior to accessing bedrock for mining purposes, to avoid erosion. All topsoil and till will be stored in stockpiles for use in reclamation and construction of berms, impoundments, mine site roads, and/or general site grading. Stockpile locations are shown on Figure 2.3-2 and detailed in Section 2.7.2.3. Once vegetation, topsoil, and till have been removed, drilling and blasting will be used to mine ore and non-ore bearing waste rock, as well as establish benches along rock walls.

2.7.2.2 Waste Material Stockpiles

The stockpiles on the Beaver Dam Mine site consist of the following:

- Waste Rock Storage Area (NAG and LGO stockpiles);
- Potential Acid Generating (PAG) Stockpile;
- Topsoil Stockpiles (TSS);
- Till Stockpiles (TLS); and
- Organic Material Stockpile (OMS).

Figure 2.7-2: Mine Production Schedule

The proposed stockpile locations including the waste rock storage area, potential acid generating stockpile and reclamation material stockpiles is summarized in Table 2.7-2. Stockpiles are located to minimize impacts to wetlands, water courses, surveyed lichen and lichen habitat buffer zones and the Crusher Lake buffer zone.

Table 2.7-2: Waste Material Stockpile Location and Design Criteria

Stockpile	General Description	Design Criteria				Bulk Density (t/m^3)	Swell Factor	Placed Density
		Area (ha)	Maximum Crest Height (m)	Weight (Mt)	Volume (Mm^3)			
Waste Rock Storage Area								
Non-Acid Generating Stockpile (NAG)	One NAG Stockpile located in the most Western extent of site, accessed by existing public roadways off Beaver Dam Road.	60	190	34.28	16.32	2.73	30%	2.10
Low Grade Ore Stockpile (LGO)	One LGO located in the Western portion of site directly East in near proximity to the NAG stockpile, accessed by existing public roadways off Beaver Dam Road.	12	170	2.45	1.17	2.73	30%	2.10
Potential Acid Generating Stockpile Area								
Potential Acid Generating Stockpile (PAG)	One Pag Located in the North-Central section of site, directly North of the originally proposed crusher pad, accessed by Beaver Dam Road.	10	180	2.50	1.19	2.73	30%	2.10
Temporary Stockpiles								
Topsoil Stockpiles (TSS)	Four small topsoil stockpiles are planned for the site. They are spaced across the site near areas requiring topsoil stripping.	15	165	1.10	0.55	2.00	-7%	2.00
Till Stockpiles (TLS)	Two till stockpiles are planned. They are both located East of the in the Central-East end of site.	15	165	2.66	1.73	2.00	30%	1.54
Organic Material Stockpile (OMS)	Located on the South-East section of site, accessed by public roads off Beaver Dam Road.	31	165	2.29	1.49	N/A	N/A	N/A

Source: Golder 2021 included in Appendix A.2a (Mine Wasted Stockpiles Geotechnical Design) .

ha = hectares; m =meters Mt = million tonnes; Mm^3 = million cubic metres; t/m^3 = tonnes per cubic metre; % = percent; N/A = not applicable.

2.7.2.3 Waste Rock Storage Area

Waste rock is generated during open pit development and used during operations for grading and construction of embankments and other infrastructure. The waste rock (NAG and PAG) stockpiles locations are within areas to avoid water courses, surveyed lichen and lichen habitat buffer zones and the crusher lake buffer zone (AMNS 2021). Stockpiles are also sited to minimize disturbance of surveyed wetland area. Waste rock not used for site development is stored permanently in the Waste Rock Storage Area (WRSA) to be reclaimed at closure. The WRSA (i.e., NAG rock stockpile, and the LGO stockpile), is located to the northwest of the Beaver Dam Mine Site as shown on Figure 2.3-2. A PAG stockpile, situated immediately south of the pit (Figure 2.3-2), described below, to allow for closure drainage to be directed towards the pit. Preliminary waste rock characterization has been completed, with pit excavated materials tagged as PAG vs. NAG based on block model codes defined by 3D solids delineating PAG materials (AMNS 2021).

2.7.2.3.1 Non-Acid Generating Stockpiles

The NAG rock stockpile will consist of benches 10 m in height with approximate with 15 m horizontal benches between each lift during construction (Table 2.7-3). During placement, waste rock is end-dumped at angle of repose of the waste rock. As construction proceeds to a higher lift, the preceding lift will be progressively recontoured during operations to a closure slope of 2.7H:1V, with benches left between each lift to allow a final overall slope from toe to crest of 3.0H:1V. The bench widths in some areas may vary between 3 to 4 m. The waste rock areas will have a 21 m dual lane haul road wrapping around the sides of facility for progressive access to all lifts, suitable for 64 t payload haulers. A 10% maximum grades on access haul ramps is included in the design. Table 2.7-3 provides the lift capacities.

Table 2.7-3: Waste Rock (NAG LGO and PAG) Lift Capacities

Lift top Elevation (m)	NAG Volume (MLCM)	NAG Capacity (Mt)	NAG Cumulative Capacity (Mt)	Low Grade Ore Volume (MLCM)	Low Grade Ore Capacity (Mt)	Low Grade Cumulative Capacity (Mt)	PAG Volume (MLCM)	PAG Capacity (Mt)	PAG Cumulative Capacity (Mt)
150	0.38	0.80	0.80	0.26	0.54	0.54

170	4.84	10.17	18.38	0.32	0.68	2.45	0.59	1.24	1.67
180	4.16	8.73	27.11				0.25	0.52	2.19
190	3.41	7.17	34.28						

Source AMNS 2021.

m = metre; Mt = million tonnes; NAG = non-acid generating; PAG = potential acid generating.

Slope stability analysis of the WRSA was completed by Golder Associates Ltd. (Golder 2021, Appendix A.2a). The slope stability report recommended that the stockpile could be constructed to elevation 190 m using the geometry above and satisfy the stability requirements. In accordance with the Golder recommendations (Golder 2021, Appendix A.2a), further construction to the final design elevation is based on monitoring and surveillance results during construction. Stability analysis will be completed by a professional engineer and provided to NSECC/DEM prior to exceeding elevation 190 m (Table 2.7-3).

2.7.2.3.2 Potential Acid Generating Stockpile

The PAG stockpile is located in the north-central section of site south of the open pit (Figure 2.3-2). As noted above, preliminary waste rock characterization has been completed, with pit excavated materials tagged as PAG vs. NAG based on block model codes defined by 3D solids delineating PAG materials. The PAG stockpile has been designed to store 2.5 Mt of PAG within 10 ha footprint (Table 2.7-3). The design includes a 180 m maximum height crest (Table 2.7-3). The lift capacities for PAG are provided in Table 2.7-3.

During construction, historic tailings and waste rock designated as PAG will be either temporarily or permanently stored in the PAG area depending on final quantities. It is anticipated that the majority of historic tailings will be removed from the Beaver Dam Mine site and stored sub-aqueously in mined-out Touquoy Pit. Appendix A.2b (Conceptual PAG Closure Options) additional details on historic tailings assessment of disposal options and is discussed in Section 6.5 (Geology, Soils and Sediment Quality) as well as the draft Reclamation and Closure Plan (Appendix P.2).

2.7.2.3.3 Ore Stockpiles

The LGO stockpile is located adjacent to the NAG Stockpiles with a footprint of 12 ha and is designed to achieve a maximum height of 170 m (Table 2.7-3) and Figure 2.3-2. The ROM stockpile is located near the pit. When ore is mined from the pit it will either be delivered to the ROM pad or the "low grade waste" stockpile in accordance with the following sequence:

- The ROM stockpile is for storing ore for delivery to Touquoy within the coming weeks. There is up to a 4-week capacity that can be stored during short-term periods of ore mining from the pit that exceed capacity to haul off site.
- During the construction period of the mine, any ore encountered in planned pit excavation will be stockpiled within the "low grade waste" NAG waste rock stockpile footprint. This material, less than 200 kilo tonnes (kt) estimated, is planned to be directed to the ROM pad before this area gets covered over by waste rock mined later in the mine life.
- The "low grade waste" stockpile is also planned to store all inferred resource and any mineralized materials that the short to medium term mine planning may want segregated from the bulk NAG waste rock. While this material is not considered ore for the purposes of the Feasibility Study (AMNS Internal, *In Progress*), experience at the Touquoy Mine operations would suggest that a dedicated area should be planned for segregating additional mineralization identified during operations.

2.7.2.3.4 Topsoil Stockpiles

Four topsoil stockpiles are planned for the site and are spaced across the site near areas requiring topsoil stripping (Figure 2.3-2). Topsoil will be salvaged as required from all disturbed areas and stockpiled in designated areas. An average topsoil thickness of 0.3 m has been assumed for all disturbed areas. The total disturbance for topsoil stockpiles is 15 ha with a design crest height maximum of 165 m and total storage capacity of 1.10 Mt and 0.55 Mm^3 (Table 2.7-4). The topsoil lifts will be 5 m and 3:1 slope. A 17 to 20 m berm allowance is included in the design. An overall slope range of 3:1 will be established once berms and ramps are completed. A summary of the amount of topsoil lift capacities for each stockpile during construction is provided in Table 2.7-4.

Additional topsoil piles with the following capacities are designed to store materials salvaged from the waste and ore stockpile footprints, as well as from the haul road footprints. Where possible, the topsoil materials will be windrowed directly outside the design footprints, rather than hauled to these stockpiles. An annual or light seeding will be applied to limit erosion and potential suspended solids. Drainage ditches will be established around the stockpile and water collect will be directed to settling ponds, which are described in Water Management (Section 2.7.2.9).

Table 2.7-4: Topsoil Storage Capacities

Source	Area (m^2)	Topsoil Volume (BCM)	Placed Volume (MLCM)	Planned Pile
Open Pit	314,000	94,200	0.11	North Pit Pile
Non-acid generating stockpile Haul Roads	829,000	248,700	0.34	North SP Pile
PAG SP	98,000	29,400	0.07	South Pit Pile
Crusher Area	120,300	36,100	0.03	South Site Pile

m^2 = square metres; BCM = bank cubic metres; MLCM = million loose cubic metres; SP = stockpile; PAG = potential acid generating.

2.7.2.3.5 Till Stockpiles

Two till stockpiles are planned (i.e., west and east) and they are both located east of the in the Central-East end of site (Table 2.7-5 and Figure 2.3-2). Till is defined as all materials between the topography surface and the bedrock contact surface, minus estimates for topsoil. Updates to bedrock contact surface have recently been made that will be included in design. The altered surface will be incorporated into an updated till quantity estimate during the detailed mine planning stage of the Project. The planned lifts for till stockpiles will be 10 m and a 20 m berm allowances for access around each lift. An overall slope range of 3:1 will be established once berms and ramps are completed. The lift top elevation, volume, and capacity is provided in Table 2.7-5. A portion of the till materials, related to the historic tailings and contamination from historic workings, is planned to be stored in the PAG stockpile location, however, the majority of historic tailings, as discussed below and in Section 6.5 (Geology, Soil and Sediment Quality), will disposed sub-aqueously in the mined-out pit at the Touquoy Mine.

An annual or light seeding will be applied to limit erosion and potential suspended solids. Drainage ditches will be established around the stockpile and water collect will be directed to settling ponds, which are described in Water Management (Section 2.7.2.9 and Appendix P.4 Mine Water Management Plan).

Table 2.7-5: Till Storage Capacities

Lift top Elevation (m)	West Till Capacity (Mt)	West Till Cumulative Capacity (Mt)	East Till Capacity (Mt)	East Till Cumulative Capacity (Mt)
150	0.15	0.15		
160	0.30	0.45	0.27	0.27
170	0.24	0.69	0.96	1.24
180			0.73	1.97

m = metre; Mt = million tonne.

2.7.2.3.6 Organic Stockpile

One organic stockpile is planned for the site, which is located on the south-east section of site. Organics will be salvaged as required from all disturbed areas and stockpiled in designated areas. The total disturbance for topsoil stockpiles is 31 ha with a design crest height maximum of 165 m (Table 2.7-6). The organic lifts will be 5 m and 7:1 slope. A 17 to 20 m berm allowance is included in the design. A summary of the organic lift capacities is provided in Table 2.7-6.

An annual or light seeding will be applied to limit erosion and potential suspended solids. Drainage ditches will be established around the stockpile and water collected will be directed to settling ponds, which are described in Water Management (Section 2.7.2.9).

Table 2.7-6: Organic Storage Capacities

Lift top Elevation (m)	Organic Till Capacity (Mt)	Organic Till Cumulative Capacity (Mt)
160	0.85	0.85
165	1.45	2.30

m = metre; Mt = million tonne.

2.7.2.4 Historic Tailings and Waste Rock

Historic tailings have been deposited within the footprint of the open pit and will be excavated early in the mine life. Estimated quantities of 50,000 t of historic tailings are described in Historic Tailings Quantities Estimate (Appendix A.2b) . This quantity occurs above the bedrock contact surface and therefore has been measured as part of the overall till quantities coming out of the open pit. A further 350,000 t of till materials is estimated to be affected by the historic tailings and historic mine operations.

These materials will not be sent to the till stockpiles, but rather to the PAG storage area. The historic tailings are planned to be directed off site from Beaver Dam to Touquoy for final deposition. An Historic Tailings Management Plan and a Potential Acid Generating Management Plan have been prepared for the Project to monitor and update estimates when construction and operations commence.

2.7.2.5 Mine Site Roads

Mine site roads will be constructed to enable the mining fleet (loaders, dozers, off-highway haul trucks) to access the stockpile locations and site facilities. The primary use of mine site roads will be the transportation of ore and non-ore bearing waste rock from the open pit to stockpile locations. Mine site Haul Roads will be dual lane and connect the pit exit with the topsoil, till, non-ore bearing waste rock stockpiles and ROM stockpiles.

The roads will be constructed out of non-ore bearing waste rock from the open pit and be approximately 27 m wide, including berms and drainage, with a maximum speed limit of 40 km/h. The density for cut and fill is provided in Table 2.7-7. Specifically, the mine haul road designs include the following inputs:

- 27 m wide haul roads that incorporate dual lane running width and berms on both edges of the haul road;
- 10% maximum grade;
- primarily constructed using pit run waste rock, hauled from pit, then dumped out, with final contouring done by dozers;
- running surface capped by 0.5 m crushed rock layer;
- balanced cut and fill areas built by dozers; and
- areas with excess cut handled by excavators and construction haulers.

Table 2.7-7: Density for cut and fill

Material	Bank Cut Density (t/m^3)	Swell Factor	Placed Density (t/m^3)
Haul Road Rock	2.78	30%	2.10

Additional roads surround the west, north and east limits of the open pit, as well as out to the explosives and magazine storage pads. A pit perimeter road on top of the berm surrounding the pit will be a gravel base and be 12 m wide. The general location of the mine site roads is displayed on Figure 2.3-2. Mine site Haul Roads will be dual lane and connect the pit exit with the topsoil, till, organic and non-ore bearing waste rock stockpiles and ROM stockpiles.

The following design criteria is used for these additional roads.

Pit perimeter road:

- 2 m in height;
- 12 m wide top surface to fit berms on both sides, and sized for travel by highway class vehicles as well as one way travel for articulated hauler;
- 10% maximum grade; and
- primarily fill constructed using pit run waste rock, hauled from pit, then dumped out, with final contouring done by dozers.

Explosive access road and pads:

- 6 m wide for on-highway class vehicle traffic;
- following existing on-site road paths;
- magazine pad dimensions of 20 m x 15 m as per supplier recommendations;
- explosive storage pad dimensions of 50 m x 50 m as per supplier recommendations; and
- balanced cut/fill construction by dozers.

The haul roads run from the open pit entrances on the west side of the pit:

- west of the NAG and low-grade WRSA;
- switchbacking southeast at the exit towards the ROM pad and PAG; and
- till will come out of the east side of the pit onto the haul road to the east and south towards the till stockpiles. The depth of the pit during till excavation will not require exiting to the west.

The pit haul roads at the Beaver Dam Mine Site will be built during the construction phase of the Project. The following table lists the cut and fill quantities estimated to construct the designed Beaver Dam mine haul roads, as well as the pit perimeter berm and the explosives access roads. Fill volumes for the haul road and pit perimeter berms are sourced as NAG rock from the open pit and quantities are provided in Table 2.7-8. The explosives storage road and pad are balanced cut to fill.

Table 2.7-8: Haul Road Construction Quantities

Road	Cut Volume (kBCM)	Fill Volume (kLCM)
Ex-Pit Haul Roads	42	140
Pit Perimeter Berm	0	43
Explosives Roads and Pads	1	2

Source: AMNS (2021).

kBCM = kilo bank cubic metre; kLCM = kilo loose cubic metre.

A pit perimeter road on top of the berm surrounding the pit will be a gravel base and be 12 m wide. The general location of the mine site roads is displayed on Figure 2.3-2.

Mine site Haul Roads will be dual lane and connect the pit exit with the topsoil, till, organic and non-ore bearing waste rock stockpiles and ROM stockpiles.

2.7.2.5.1 In-Plant Roads

One In-Plant Road is identified:

- Mining Infrastructure Area (MIA) In-Plant Access Road.

The road will be designed to a 30 km/hr design and posted speed limit and use the following design criteria: maximum longitudinal grade 12%, two lanes per road with lane width of 3.0 m per lane, 3% road cross-slope. Batter slopes shall be 1 vertical (V) to 3 horizontal (H) fill slopes and 1 V:2H back slopes and 1 vertical to 3 horizontal side slopes with a trapezoidal ditch shape.

2.7.2.5.2 Low-Volume Haul Road

One Low-Volume Haul Roads is identified:

- ROM to MIA Haul Road.

The road will be consistent with a 30 km/hr design and posted speed limit and use the following design criteria: maximum longitudinal grade 8%, two lanes per road with lane width of 15.0 m per lane, 2% road cross-slope. Batter slopes shall be 1 vertical to 3 horizontal fill slopes and 1 vertical to 2 horizontal back slopes and 1 vertical to 3 horizontal side slopes with a v-ditch shape.

At the entrance of the site, the road design modifications will allow for separation of the lanes, so that a gatehouse will be situated between the two lanes.

2.7.2.5.3 Dosing Station Bypass Road

The Dosing Station Bypass Road will be constructed to allow external traffic to access the Nova Scotia Salmon Association (NSSA) Lime Dosing station located along the Cameron Flowage to the east of the project site.

The road will be designed to a 30 km/hr design and posted speed limit and use the following design criteria: maximum longitudinal grade 12%, single lane per road with a lane width of 5.0 m per lane, 3% road cross-slope. Batter slopes shall be 1 vertical to 3 horizontal fill slopes and 1 vertical to 2 horizontal back slopes and 1 vertical to 3 horizontal side slopes with a trapezoidal ditch shape.

2.7.2.6 Infrastructure and Facilities

2.7.2.6.1 Earthworks Platforms

The following earthworks platforms will be constructed for the Beaver Dam Mine Site:

All new facility areas and surrounding areas are graded to ensure stormwater drains away from the facilities during rainfall. Drainage ditches, where necessary, along roadways are 0.6 m bottom channels with a minimum longitudinal grade of 0.5%. At the intersection of drainage paths and access roads or site roads, water will be conveyed across the road via a culvert crossing. Culverts will be installed with rip-rap erosion protection at inlets and outlets and will require regular maintenance to keep them sediment free and free-flowing during rainfall.

2.7.2.6.2 Buildings Administration, Mine Dry and Security

The principal buildings at the Project Site will include a truck shop, a combined building consisting of mine dry, offices and security administration, a gatehouse, and lunch/breakout room building. Where practical, buildings will be modular type construction to reduce construction costs. The truck shop building will be a fabric type construction with 3 haul truck bays and two maintenance bays for lube handling and a warehouse and workshop.

Figure 2.3-2 illustrates the overall site layout and Figure 2.7-3 illustrates the general layout of the plant and ancillary facilities.

The building list including WBS Area, name, building type and size is show in Table 2.7-9.

Table 2.7-9: Beaver Dam Mine Building List

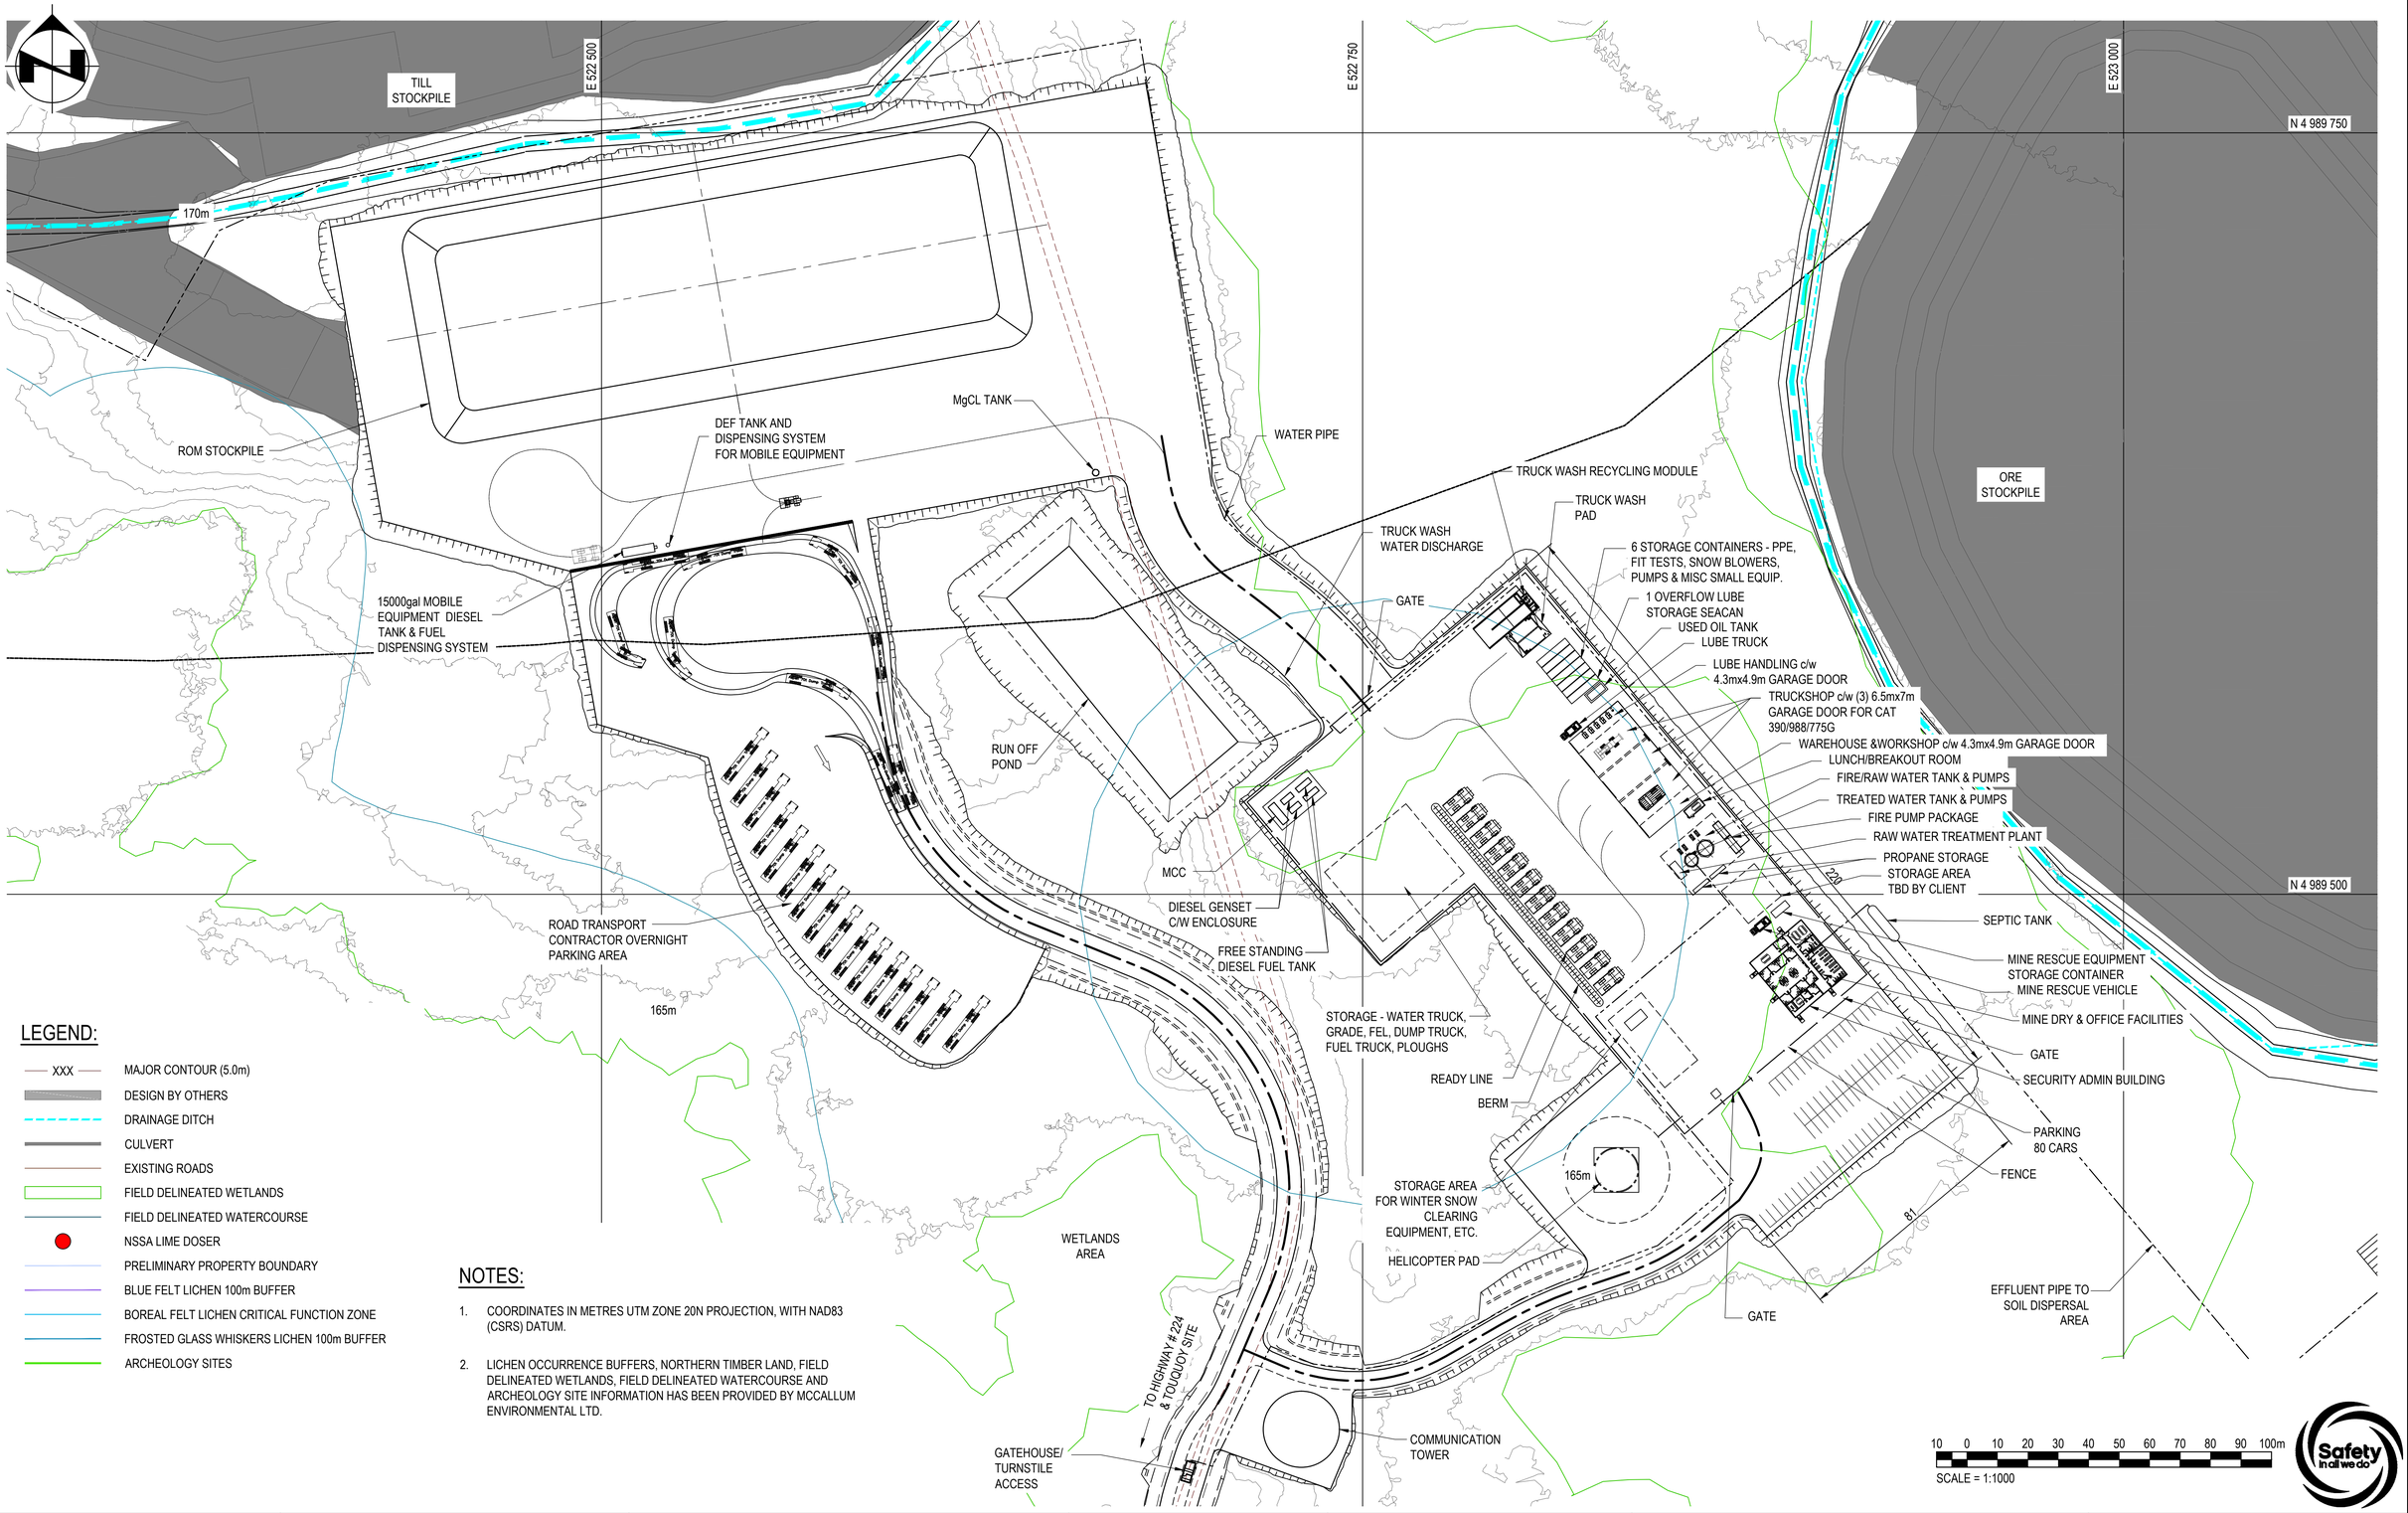
Item	WBS Area	Building Description	Building Type	Building Area (m^2)
1	1311	Truck Shop	Fabric Building	882
2	1330	Mine Dry and Offices	Modular Complex	407
3	1330	Security Administration	Modular Complex	60
4	1330	Lunch / Breakout Room	Modular Complex	21
5	4230	Gate House	Security Trailer	20

2.7.2.6.3 Truck Shop Building

The maintenance shop facility will be a pre-engineered fabric structure with a roof and low walls and limited interior support steel structures. The building will be supported on pre-cast concrete footings.

The facility will house a lube handling bay, warehouse/workshop bay and 3 haul truck bays with 7 m wide door openings. The facility is designed to service and maintain both the mining fleet and the process plant/site services fleet.

2.7.2.6.4 Mine Dry, Office & Security Administration Building



The mine dry, offices and security administration building will be a single-story, modular complex. The building will be supported on timber sleepers sitting above the finished grade level. This security administration building will have separate entry from the mine dry and office building, though it will share common walls.

2.7.2.6.5 Lunch / Breakout Building

The lunch / breakout room building will be a standalone modular building situated south-west of the truck shop. The building will be supported on timber sleepers sitting above the finished grade level.

2.7.2.6.6 Gate House

The gatehouse will be a security trailer situated at the entrance to the Project Site between the two road lanes. The building will be supported on timber sleepers sitting above the finished grade level.

2.7.2.7 Fuel Storage and Distribution

The site will be serviced by both propane and diesel. Diesel will be stored primarily at the mobile equipment fuelling station meant to serve both the mining fleet and the transport fleet. The fueling station consists of a 3,000 heated and insulated tank with a hybrid pump. The fueling system will supplied and owned by a third party vendor who will rent to the site as part of the fuel contract.

The generators will also be supplied with fuel tanks at 13,200 litres each and will be filled by the 3rd party vendor. Propane will be stored at site in two 7,500 L tanks which will be owned by the same vendor as the diesel fuel supplier. Propane will then be plumbed to the various buildings for heating.

2.7.2.8 Power Generation and Distribution

There is no external power supply being considered for the beaver dam site. All power will be generated on site via a diesel fueled generating plant. The generating plant will consist of two low voltage generators rated for 250 kW at 600 V. The plant design includes load shedding in the event of a failure of either generator.

Distribution is accomplished via cabling as there are no significant loads at a distance sufficient to warrant an overhead power line.

2.7.2.9 Water Management

2.7.2.9.1 Mining Infrastructure Area Collection Pond

The Mining Infrastructure Collection Pond is located adjacent to the Mining Infrastructure Area (MIA) and south of the ROM Pad. Contact water run-off from the plant pads will be collected and diverted to the collection pond. Stormwater run-off that does not come in contact with the plant pads, is considered clean, and is directed away from the plant site.

The MIA Collection Pond is sized to contain the run-off from the MIA Pad, Loading Pad and Trucking Contractor's Laydown. The pond will comprise of a Geosynthetic Clay Liner (GCL), HDPE geomembrane along with rock ballast.

The MIA Collection Pond for the plant site follows a wet pond design concept and delays the peak flow into the project's overall water management network. The MIA Collection Pond is sized to contain and convey the 100-year, 24-hour event storm.

2.7.2.9.2 Contact Water Treatment/Disposal System

The Mine Water Management Plan (Appendix P.4) and associated design measures have been developed based on the proposed feasibility level mine site arrangement with inputs from AMNS, Moose Mountain Technical Services (MMTS) and Ausenco. The Mine Water Management Plan will be implemented during the initial mine development phase and will be adjusted as necessary throughout the mine operations and closure phase.

Site contact water will be managed to meet the following regulatory discharge requirements prior to discharge to the natural environment:

- Metal and Diamond Mining Environmental Regulations (MDMER) Objectives.
- Canadian Council of Ministers of the Environment (CCME) Guidelines for the Protection of Aquatic Life.
- Tier 1 Nova Scotia Environment Quality Standards (EQS) for Surface Water.
- Site specific criteria (based on background).

Based on predictive water quality modelling, it is understood that the water quality at some locations may be acceptable for discharge to the environment with TSS removal as the only form of treatment. Where this is not the case, contingency measures (shutoff valves and pumps etc.) will be put in place to redirect water towards the north water treatment system (WTS) in case of exceedances. The primary objectives of the Mine Water Management Plan are as follows:

- Provide mechanism to dewater and treat ponded water within the project area (including the historic tailings area) to allow for development and excavation of mine infrastructure (e.g., pit, waste piles, haul road etc.).
- Capture, treat and provide controlled discharge for all site contact water during construction and operations.
- Divert all off-site clean water away from the mine site infrastructure to maintain existing drainage features (e.g., Mud Lake) and reduce the total volume of water entering the settling ponds for treatment.

2.7.2.9.3 Design Basis Criteria

The criteria used for the design of the water management infrastructure are based on the feasibility level design site arrangement, regulatory discharge water quality requirements, operational requirements, and environmental site conditions. The design basis criteria for storm events utilized for the Mine Water Management Plan (Appendix P.4) design are summarized in Table 2.7-10.

Table 2.7-10: Water Management Design Basis Criteria

Item	Design Basis
Contact Water. Non-contact Water Ditches and Culverts	Designed to convey stormwater runoff resulting from the 1 in 100 year, 24-hour, climate change adjusted storm event (113 mm).
Collection Ponds	Designed to contain runoff resulting from the 2 5 mm 4-hour storm event, 1 in 10-year 24-hour climate change adjusted storm event (87 mm) and 1 in 100-year 24-hour climate change adjusted storm event (113 mm) for a minimum of 24 hours to allow for TSS removal due to settling. Designed to convey runoff resulting from the 1 in 100-year 24-hour climate change adjusted storm event (113 mm) to Cameron Flowage via a concrete outlet structure. Designed to convey runoff from Hurricane Beth, modelled as a 48-hour storm event, through an emergency spillway. All discharge water from collection ponds must meet MDMER water quality requirements. All discharge water must meet CCME, Tier 1 NSE WQS or site-specific requirements within the 100 m mixing zone of the natural watercourse receiver (Killag River).
Pump Systems and Pipelines	Designed to convey stormwater runoff water from low-lying areas to settling ponds for up to the 1 in 2 year 24-hour, climate adjusted storm event (66 mm). Multiple back up pumps for larger storm events are to be located across the Site to be moved to different areas across the Site as needed.

mm = millimetres; TSS = Topsoil Stockpiles; MDMER = Metal and Diamond Mining Environmental Regulations; CCME = Canadian Council of Ministers of the Environment; m = metres.

The Site was modelled using PCSWMM (Version 7.3.3095) which is a hydrologic and hydraulic modelling software that uses the EPA SWMM (Version 5.1.015) engine. PCSWMM was used to develop the design storm hydrographs, estimate peak flow rates and runoff volumes for the design storm events.

To add contingency to the design, the impacts due to climate change were considered when developing the design storm hydrographs. To account for the project duration (operation life of less than 15 years) and nearest climate regions (Halifax Regional Municipality and Truro), a 3.3% increase in the total rainfall depth was applied to each design storm based on the requirements outlined in Climate Data Nova Scotia as the projected increase in annual precipitation for 2050 (https://climatechange.novascotia.ca/climate-data?tid=8#climate-data-map).

The estimated runoff volumes resulting from the 24-hour, 1 in 100-year climate change adjusted storm event were used to determine the storage capacity of the settling ponds. The 25 mm 4-hour, 10-year and 100-year climate change adjusted storm events were used to design the settling pond outlet structures such that a minimum 24-hour detention time was achieved in each settling pond to allow for settling of TSS. Hurricane Beth (as recorded by Halifax International Airport Climate Station (Climate ID: 8202251)) was used to size the emergency spillway of the settling ponds. The 100-year climate change adjusted storm event was used to size the swale, culverts and other conveyance pathways leading to the settling ponds. Additional design details for the various water management design elements are provided in the following sections.

2.7.2.9.4 Collection Ditches and Culverts

The Mine Water Management Plan (Appendix P.4) consists of a series of surface water ditches and culverts collecting all Site stormwater runoff. The surface water ditches include contact water ditches, which collect runoff from all mine infrastructure, and clean water ditches. The surface water ditches all include clean water diversion ditches, which collect water from adjacent undisturbed lands and direct it away from the Site. Culverts are dispersed throughout the Site to convey stormwater below mine infrastructure (i.e., haul roads). The contact water ditches drain to one of three settling ponds located across the Site.

Each ditch will be trapezoidal in section with 3H:1V side slopes and bottom widths and depths ranging from approximately 0.5 m to 2 m. Ditch slopes range between 0.3% and 7.5% depending on the location across the Site. Ditches will be excavated into the existing overburden and/or bedrock or formed by grading existing surface material to form the required channel cross-section. All excess material used to grade the channel to the required cross-section will be sloped to existing ground at a 3H:1V slope. The exposed slopes will be covered with a bio-degradable erosion control matting and seeded upon reaching finished grade to prevent erosion of these previously disturbed areas.

Contact water ditches will be lined with an HDPE liner followed by a layer of sand and a layer of riprap to prevent infiltration of stormwater into the surficial groundwater and protect the ditch from erosion. The riprap layer in the liner system will be sized appropriately to prevent erosion during the 1 in 100-year 24-hour climate change adjusted storm event. Detailed riprap requirements will be determined during later design stages. Rock check dams will be put in place on ditches that have a slope of greater than 3% in addition to the riprap layer to prevent erosion. Rock check dams reduce the overall slope of the water surface, reducing the potential for erosion. Rock check dams also allow time for suspended sediment to settle out prior to reaching the settling pond. The ditches leaving the settling ponds will contain clean water following TSS removal and any additional required water treatment via the WTS in the case of the north settling pond. The outlet of the effluent ditch into the receiving watercourse will be lined with riprap to prevent erosion. Detailed outlet design will be determined during later design stages.

Culverts are to be circular corrugated steel pipe (CSP) culverts with diameters ranging from 600 mm to 1600 mm and lengths between 30 m and 50 m. Culvert slopes range between 0.5% and 7% across the Site. Each culvert will include a riprap apron on the upstream and downstream sides of the culvert to prevent erosion around the inlet and outlet. The outlet riprap aprons are designed to include an energy dissipation basin. The energy dissipation reduces velocities in the downstream ditch, reducing the potential for erosion. The energy dissipation basin is to be lined with riprap specifically sized to withstand culvert exit velocities and reduce flow velocity downstream of the culvert.

The Site haul road crosses over top of WC-5, the watercourse leading from Crusher Lake to Mud Lake. In order to prevent disruption of the natural flow path, clean water ditches will collect surface water runoff on the south side of the haul road and drain this runoff back towards WC-5. WC-5 will be channelized in a culvert below the haul road for 50 m. The outlet of the WC-5 culvert will have an energy dissipation basin to reduce channel velocities and promote fish passage through the culvert. The contact water ditches

will pass overtop of the WC-5 culvert. As with all other sections of the ditch, the contact water ditch in this area will be lined with an HDPE liner to prevent infiltration of contact water into the adjacent watercourse.

2.7.2.9.5 Settling Ponds

Settling ponds will be constructed to collect and treat contact water prior to discharging to Cameron Flowage. Collection ponds are included for runoff from the NAG Waste Rock Stockpile, PAG Waste Rock Stockpile, Till Stockpile, Low Grade Ore Stockpile, Organics Stockpile and Crusher Pad/administrative building area. The ponds were designed to maintain a 0.3 m freeboard during the 1 in 100-year 24-hour climate change adjusted design storm event. All ponds were also designed with an emergency overflow spillway sized to convey Hurricane Beth sized storm event.

It is anticipated that the settling ponds will be excavated into the existing overburden. Due to the depth to bedrock in the areas of the settling ponds (approximately 4 m to 7 m deep depending on location) it is not anticipated that drilling or blasting into the bedrock will be required. The settling ponds will be lined with a similar liner to the contact water ditches including an HDPE liner and a sand and riprap layer. Due to the high groundwater elevation near the settling ponds (slightly above the bottom of pond invert in the east settling pond) the riprap layer will also act as a ballast to prevent the liner from being impact by buoyancy forces of the nearby groundwater. The ponds will be trapezoidal in cross-section with 3H:1V side slopes. The maximum depth in the ponds varies between 3.5 m and 5.5 m, depending on the location. Settling pond dimensions vary from 45 m to 60 m in width and between 200 m and 325 m in length. Two of the settling ponds (north settling pond and east settling pond) will be classified as dams due to the north embankment berm exceeding the 2.5 m threshold.

To assist with the removal of TSS from the stormwater runoff, each settling pond is to contain a gravel filter berm. The filter berm will consist of a gravel core with an outer riprap layer to provide erosion protection. Geotextile will be placed between the riprap layer and the gravel core to assist with TSS removal and separate the two material layers. In addition, the settling ponds have been designed to contain the 25 mm 4-hour storm event, 1 in 10 year 24-hour climate change adjusted design storm and 1 in 100-year 24-hour climate change adjusted design storm events for a minimum of 24 hours. A detention time of 24 hours allows for suspended particles to settle prior to discharge from the settling pond into the natural environment.

The settling ponds each consist of a concrete outlet structure and emergency overflow spillway. The concrete outlet structure will control storm events up to and including the 1 in 100-year, 24-hour climate change adjusted design storm event through a series of orifices and an overflow weir. The concrete outlet structures will be surrounded with a layer of riprap in order to recue exit velocities and further assist with TSS settling. The emergency overflow channel will convey flows resulting from storm events greater than the 1 in 100 year, 24-hour climate change adjusted design storm event, up to and including Hurricane Beth. The north settling pond will direct the emergency overflow spillway towards the open pit. Directing the overflow spillway towards the open pit will ensure no uncontrolled discharges occur from the Site. Effluent from the north settling pond will pass through the WTS prior to discharge into Cameron Flowage. All settling ponds will discharge effluent at concentrations below the federal MDMER regulations as per the *Fisheries Act*.

2.7.2.9.6 Pump Systems and Pipelines

A collection pond will be situated on the northeast side of the PAG stockpile. A pump and pipeline system will convey stormwater from the collection pond to the north settling pond. In addition to the PAG stockpile pump and pipeline system there will be portable back up pumps located across the site to deal with any potential pooling of water. The pumps will be moved around the Site as needed to dewater ponded water. The PAG stockpile pump system will consist of a single permanent pump, sized to convey the runoff generated from up to a 1 in 2-year 24-hour climate change adjusted storm event. In the event that a storm event greater than the 1 in 2-year climate change adjusted storm event occurs then back up pumps will be brought to the PAG stockpile collection pond to assist with pumping.

2.7.2.9.7 Erosion and Sediment Control Measures

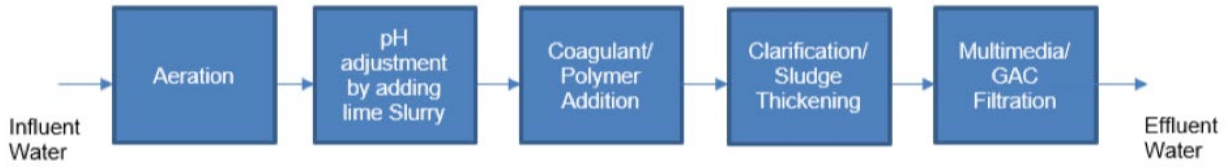
Erosion control measures in the contact water ditches and settling ponds are to be maintained during operations including replacement of riprap, restoration of check dams if damaged and general visual inspection of the ditches and settling ponds. Experience at the Touquoy Mine indicates that significant sediment build up could occur in the collection ditches. The contact water ditches should be inspected regularly and cleaned out as needed to ensure sediment does not build up within the ditches or travel directly into the settling pond, reducing the available storage volume of the settling pond itself.

Contact Water Treatment

During operations stormwater runoff will be directed towards three settling ponds prior to discharge to the natural environment. All potentially impacted water will be directed towards the north settling pond and the associated WTS. The east and south settling ponds are not anticipated to experience water quality concerns, however, regular monitoring will take place in these ponds as a part of federal MDMER regulations. If water quality exceedances occur in the east or south settling pond, a shut off valve on the pond outlet will be closed and the water will be pumped to the north settling pond and WTS for treatment.

During operations, the only constituent predicted to exceed CCME, Tier 1 EQS and Site-Specific guidelines is nitrite. In order to reduce the nitrite concentrations in effluent from the north settling pond, effluent will be routed through a nitrite oxidation unit (aeration treatment pond) to reduce the concentration of nitrite in the effluent. The effluent will pass through a final settling pond, to remove any further suspended solids which were re-suspended during aeration, prior to discharge.

The WTS which was present during construction will remain on Site in case of exceedances of constituents other than nitrite, consisting of aeration (oxidation), lime softening, coagulation/flocculation and multimedia and granular activated carbon (GAC) filtration.



2.7.2.9.8 Construction Water Treatment System Alternative

It is expected that metals such as aluminum, arsenic, cadmium, cobalt, copper, iron, manganese, mercury, lead, and zinc may be among the elements that potentially need treatment during the construction stage. Also, most of the COCs are likely attached to suspended solids, suggesting that a significant fraction of the COCs could be removed by physical filtration.

Aeration, lime softening, followed by coagulation, media and GAC filtration is proposed as the alternative WTS for the construction phase. This system includes an aeration phase at the beginning of the treatment train, which will help to oxidize metals and will reduce chemical demand in the downstream units.

A simplified block flow diagram of this alternative is shown in Figure 2.7-4.

Figure 2.7-4: Simplified Block Flow Diagram for Water Treatment

In the first step, collected contaminated water will be stored in a Frac tank sized to provide an approximate one-hour retention time for aeration purposes. The effluent will be monitored for pH, turbidity, and its flow recorded prior to discharge. There will be a sample port at the final effluent discharge line for sampling and monitoring purposes.

This proposed water treatment alternative will address higher concentration of COCs. The selected alternative technology will be tested in a bench-scale study before implementing the full-scale treatment system to identify optimum chemical conditioning parameters such as aeration rate and chemical dosing rates. This will inform the Standard Operating Procedures that will be developed before implementation.

2.7.2.9.9 Operation Water Treatment System Assessment

The water quality assessment also indicated that nitrite level will be the only exceeded CCME guideline parameter for the EOM scenario, and zinc and cobalt are the exceedances for the PC scenario at Killag River which will require treatment during the post closure stage of the Mine.

Reviewing the feasible alternatives, it was found that a nitrite oxidation unit such as aeration treatment pond could potentially reduce nitrite concentration and obtain the nitrite removal requirement of this project while also having the lowest capital and operation cost.

The proposed aeration treatment pond would consist of three ponds. The first Settling Pond will act as an equalization pond and capture the high influent water volumes during storm events. Furthermore, this pond will help to reduce total suspended particles by allowing settling. A coagulant injection point will be considered at the influent stream to the first pond to be used in case of high suspended solids concentrations or during large storm events to help accelerating precipitation of suspended solids. Water will then flow by gravity to an aeration pond, the air will be introduced by surface agitators to oxidize nitrite, as well as metals. Next, the water will flow by gravity to the third pond for resettling of suspended particles that are generated as the results of oxidation in the second pond.

It is expected that the concentration of nitrite and metals will be below discharge limits during large storm events. For that reason, a bypass ditch will be designed to directly discharge the water from the first pond after removal of suspended particles.

In addition, to address elevated arsenic concentration during operation phase, the water treatment system of construction phase will be used as contingency in case of higher metals concentrations during operation phase. If the aeration treatment pond's final effluent does not meet the discharge objectives, the water could be pumped into the water treatment train to address high metal concentrations.

The general chemistry of impacted water will determine if any nutrient or chemical addition would be required. These parameters could potentially drive the operation cost of the treatment system. It is highly recommended that the selected nitrite removal technology be tested in a bench-scale or even in a pilot-scale before designing the full-scale treatment system.

2.7.2.9.10 Post-Closure Water Treatment System

GHD has completed a predictive water quality assessment and developed a mass balance model which shows that zinc and cobalt are the only likely exceeded parameters during the PC phase. However, the exceedances are not significantly higher than the discharge limit and a passive water treatment system could reduce the concentration of these elements below discharge criteria. In mine-related settings, passive treatment systems are often designed to neutralize acidity and remove metals in drainage waters. Such systems do not require continuous chemical inputs because they are sustained by naturally occurring chemical and biological processes. Anoxic limestone drains (ALDs) have been selected as the passive alternatives for addressing high concentrations of metals in impacted water during the PC phase.

In this treatment approach, impacted water will initially pass through a settling pond for the removal of suspended solids. Then, water will pass through a trench ALDs. ALDs generate alkalinity and increase the pH of the impacted water. By increasing the pH, metals such as zinc and cobalt will precipitate in their hydroxide forms. The ALDs will be followed by an aeration cascade, pond, or aerobic wetland that oxidizes and removes the precipitated metals. A settling pond will then provide adequate hydraulic retention time to let those formed metal hydroxides precipitate. This treatment system is proposed due to its passive nature and the fact that utilities are not required for implementation. The success of an ALD depends on site-specific conditions, primarily on low dissolved oxygen, and minimal ferric iron and aluminum concentrations in the drainage.

The operation and maintenance of this alternative is minimal as no labour or power is required. The primary maintenance would be replacing depleted limestone which is dependent on-site condition and water chemistry. In suitable conditions, limestone could work efficiently for several years.

2.7.2.9.11 Surface Water Monitoring

Surface water quality assessment sites were selected to monitor baseline/construction, operation and post-closure water quality and water quantity at the Beaver Dam Mine. These include both surveillance locations and compliance locations.

During the construction phase, 16 water quality surveillance locations are proposed to be sampled monthly, along with two water quality surveillance locations to be sampled quarterly. At each surveillance monitoring stations, water quality grab samples are collected. Grab will be analyzed for the following list of parameters, in line with the baseline analysis:

- Total metals – (RCAp-MS);
- Total dissolved metals – (Dissolved RCAp-MS);
- Mercury (total, dissolved, methyl);
- Total Phosphorus;
- Cyanide (total, free);
- Tungsten (total, dissolved);
- Zirconium (total, dissolved);
- Dissolved Organic Carbon;
- Dissolved Fluoride;
- Total Chemical Oxygen Demand;
- Chlorophyll A;

- Salinity;
- Acidity;
- Total Suspended Solids;
- Total Dissolved solids; and
- Radium-226.

Three compliance locations are discharge monitoring locations required by the MDMER and are analyzed to this standard.

During the operation phase, the proposed surveillance and compliance locations do not change from the construction phase, although the proposed frequency changes for certain sample locations from monthly to quarterly.

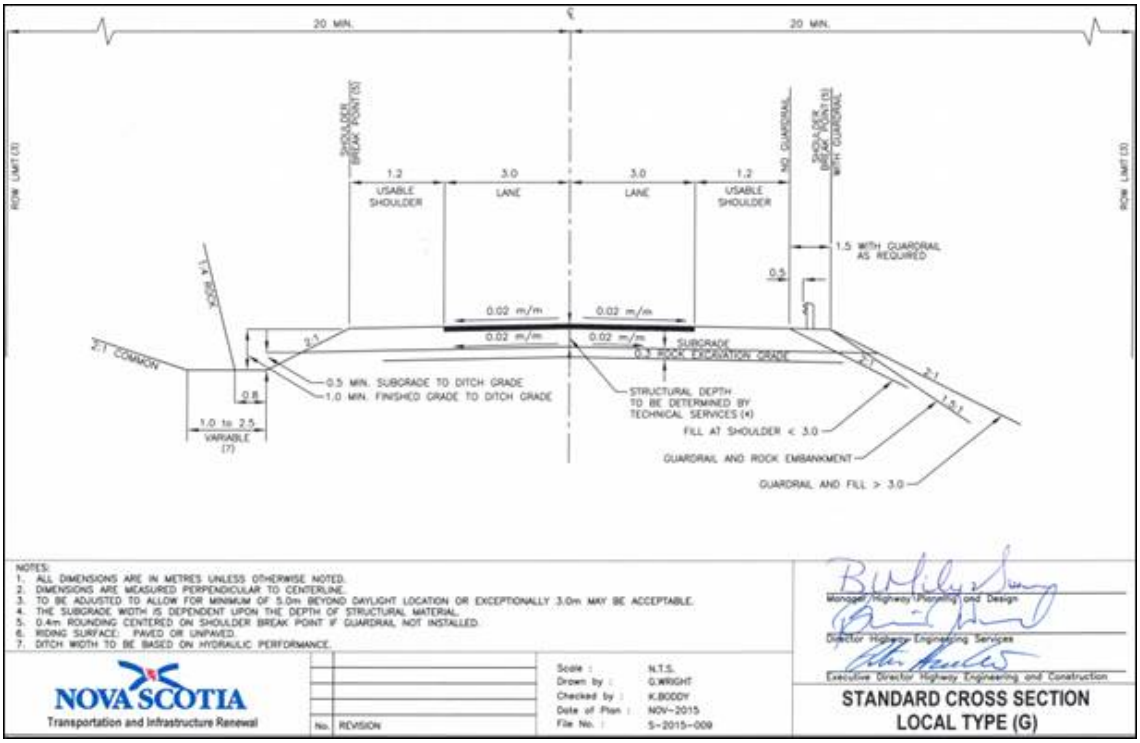
During the two years of active closure, the surveillance locations are proposed to be reduced to the ditches, three settling pond locations, and upstream and downstream of the Killag River. It is proposed that the sample frequency also be reduced, with samples collected quarterly during the first year and semi-annually for the second year. The three compliance locations discharging to the Killag River will continue to be monitored to MDMER standards.

After the completion of active closure, the proposed surveillance locations will further be reduced to three locations the Pit lake and upstream and downstream of the Killag River with a proposed sample frequency of semi-annually. The compliance locations discharging to the Killag River is proposed to be reduced to one location.

Continuous water levels (automated transducers) and manual flow data have been collected at seven water quantity surveillance locations historically by McCallum Environmental Limited (MEL) in 2019 and 2020. The collection of continuous water level and manual flow data at these seven surveillance locations is proposed to continue on a monthly frequency to support and improve the existing stage-discharge relationship/rating curves established by MEL and further help validate modelling completed for the Mine. This monitoring will continue until the completion of active closure.

2.7.3 Haul Roads

As Beaver Dam Mine Site will operate as a satellite surface mine, ore produced will require transport by road to the Touquoy Mine Site (Figures 2.3-3). Portions of the existing logging roads (Section 1 and Section 4A/B) between Beaver Dam Mine Site and the Touquoy Mine Site will require upgrading to a dual lane road to facilitate the safe passage of two-way truck traffic at 70 km/h. The total length of the Haul Road is approximately 31 km. It may be necessary to use the Public Roads during start-up (i.e., 6-8 months) depending on approval and permitting timelines and construction restrictions.



A new section of road (Section 3B; approximately 4.0 km in length) constructed to the same design standards connecting the Beaver Dam Mines Road/Highway 224 intersection with an existing woods road. The alignment displayed in Figure 2.3-2 is based on a preliminary engineering design. Final design will consider safety, social and environmental constraints to ensure the best-case scenario that will optimize worker safety and minimize potential environmental effects. The new 4.0 km section of road is being construction to avoid travel on Hwy 224, through the community at Beaver Lake IR 17.

The upgraded and newly constructed Haul Road will be designed to accommodate up to a 68t gross vehicle weights in either a B-Train or C-Train configuration year-round. Where upgrades will follow the course of the existing woods roads, the width will be increased from approximately 4 m to 10 m, with an additional width of 6 m, on average, to account for sloping and ditching on both sides of the road. Where new road construction is required, including deviations from the existing roads to ensure safe design

standards, the daylighted corridor for the Haul Road will be approximately 16 m wide (on average). Wider areas of disturbance will exist along the route where the natural topography exceeds design grades. In these areas, increased cut and fill will be required to reduce grade and maintain safe design standards. Where possible existing roads will be used in an effort to minimize disturbance of undeveloped areas.

Figure 2.7-5 below, Transportation and Active Transit standard cross-section for Type G gravel roads, represents the intended dimensional road cross section for the full length of Segments 1 through Segment 4. Thicknesses of Type 1 and Type 2 gravels for Segments 2-4 will be determined by road design contractor based on expected loadings. The road design contractor will recommend a road structure for the Mooseland Road upgrade, although NSTAT will perform the final detailed design in-house.

Figure 2.7-5: Transportation and Active Transit Standard Cross-section for Type G Gravel Road

Construction material will be sourced from either Touquoy Mine, Beaver Dam Mine, local quarries (< 4ha) or from a commercial operation. Before material is used it will be physically and chemically tested to ensure suitability for road construction. The lessons learned from Touquoy is select road construction material that is of a hardness that will not erode overtime, which will minimize siltation, which is discussed in Fish and Fish Habitat (Section 6.9).

Over 20 culverts are identified as fish bearing and these culverts will be constructed from concrete with specific details developed for each. The balance of simple drainage applications will be constructed of CSP culverts.

The Haul Road will be upgraded where required to enable the safe and economic transportation of ore. Relict portions of the Haul Road may be properly reclaimed at the end of the Project lifespan or returned to the original owner as per the lease arrangement. Re-vegetation may be undertaken on portions of the Haul Road to minimize stabilize slopes and minimize erosion.

For the purposes of this description, the Haul Road has been sectioned off as follows (Figure 2.3-3).

2.7.3.1 Beaver Dam Mines Road (Section 1)

- 7.2 km of unsealed two-lane private road historically used for logging known as Beaver Dam Mines Road and currently owned by Northern Timber with varying quality from the Beaver Dam Mine Site to Hwy 224.
- The intersection between the Beaver Dam Mines Road, Hwy 224, and the new construction will be designed to meet Nova Scotia Transportation and Infrastructure Renewal (NSTIR) standards.
- The extent of required Haul Road upgrades and new construction will encroach on land owned by Northern Timber and NSDL&F.
- Upgrades to this section of the Haul Road will also require replacement or new installation of up to 9 culverts, and upgrades to, or replacement of, single lane bridges with dual lane bridges across 2 watercourses. All upgrades will be made to government standards and permit requirements.

2.7.3.2 New Construction East of Hwy 224 Section 3B

- Approximately 4.0 km of new construction from the Beaver Dam Mines Road and Hwy 224 intersection to the Moose River Cross Road through a greenfield environment.
- The land required for new construction is currently owned by Northern Timber and NSDLF.
- Construction of the Haul Road will also require installation of one stream culvert. Others may be required to maintain flow in some wetlands. All installations will be made to NSE standards and permit requirements.

2.7.3.3 Haul Road to Mooseland Road Section 4A/B

- 8.2 km portion of the Moose River Cross Road that ends at the intersection with the Mooseland Road. This section is an unsealed single lane private road historically used for logging and currently owned by Northern Timber and others with varying road quality along its length.
- The intersection between the Moose River Cross Road and Mooseland Road will be designed to meet NSTIR standards.
- The extent of required Haul Road upgrades and new construction will encroach on land currently owned by Northern Timber, NSDL&F, Musquodoboit Lumber Limited, Deepwood Estates Limited, Prest Bros Limited, and private residences.
- Upgrades to this section of the Haul Road will also require replacement or new installation of up to 10 culverts and upgrades to, or replacement of, a single lane bridge with a dual lane bridge across one watercourse (WC-AD, Morgan River). All upgrades will be made to NSE standards and permit requirements.

2.7.3.4 Haul Road Mooseland Road to Touquoy Section 5A/B

- 10.7 km of sealed and unsealed dual lane provincial local road known as Mooseland Road and owned by NSTIR suitable for heavy traffic from the Moose River Cross Road to the Touquoy Mine processing facility.

Haul Road upgrades will utilize existing road centre lines where possible to minimize encroachment on adjacent lands. Where encroachment on Crown land is unavoidable, lease agreements through NSDL&F will be pursued. Similarly, where encroachment on private land is unavoidable, lease or purchase agreements will be pursued with the individual landowners. Leases will be in place prior to the beginning of any site work.

Mooseland Road is currently a Class G road with maximum Gross Vehicle Weight (GVW) of 41,500 kg. Most of the route is gravel surface although there is a short section of asphalt close to Touquoy mill. Based on a desktop study currently underway, cross

section is fairly consistent at 10 m (+/- 0.2 m) and indications are that this could be designed to a Type G road (8.4 m cross section) with a built-up gravel cap on the existing road without increasing the existing cross section width, dependent on the extent of additional Type 1/Type 2 gravels required to build up the road surface.

The intent is to upgrade the segment of Mooseland Road to a Schedule B all-season road with GVW capacity of 62,500 kg (C-train), which will maximize payload and eliminate spring weight restrictions. Classification will remain as a Type G road. It is anticipated that the upgrade to Mooseland Road will be designed and executed by Nova Scotia Transportation and Active Transit during 2022, under a cost sharing agreement with AMNS.

2.7.3.5 Bypass Roads

The bypass roads are intended to provide an alternate route for recreational users such as ATVs and pick-up trucks as well as Indigenous rightsholders. The existing logging road represents an integral part of the current ATV Association of Nova Scotia's trail network. It is anticipated that without a bypass road, recreational users will continue to use the haul road to access the trail network. Due to the high traffic volumes and large hauling trucks, it is not desirable to have uncontrolled vehicle conflicts between hauling trucks and ATV's. As a result, a adjacent and parallel bypass road is planned to be constructed adjacent to the haul road. The bypass road routing will improve the safety of the recreational users and haul truck operators by separating the traffic and reducing the number of crossings.

The preliminary haul road routing has been established as part of the 30% design submission. This alignment is not finalized and can be adapted to facilitate an optimized design for both roads simultaneously. As a starting point, the 30% haul road alignment was reviewed against the trail network to establish which side of the haul road the bypass road alignment should follow. To minimize trail crossings, the bypass road will be kept on one side of the haul road with connecting trails crossing the haul road as required.

Large sections of the existing logging road remain after the establishment of the 30% alignment. When possible, WSP has routed the bypass road along the existing logging road. This will reduce the amount of clearing and grubbing and overall construction to establish a bypass road.

There is one existing bridge structure along this portion of the alignment and is currently on the west side of the proposed haul road. The connections of the bypass road to the trail network at the start and end of the alignment are also along the west of the haul road. For this reason, the alignment through Segment 2 has been placed on the west side of the haul road. This will result in one primary intersection location at the mid point of the alignment for the ATVANS trail network. Additional intersections may be required during construction or during operation to facilitate local users.

There are also options under review for connecting the existing trail south of Mooseland Rd to the start of the bypass. The existing trail south of Mooseland, locally known as Scott Road, is approximately 300 m west of the start of the bypass road. The bypass road is currently planned to run on the north side of Mooseland Rd and cross perpendicular at Scott Rd. Consideration is being given to a gravel parking area be considered at the start of entrance from the Mooseland Road to the Haul Road to allow for recreational users to park and offload their ATVs – this parking area is intended for discussion with Nova Scotia Department of Transportation and Active Transit within the broader scope of Mooseland Road upgrades for summer 2022. The parking area is intended to keep the shoulders of Mooseland Road clear and minimize potential for interaction with vehicles and trailers at Mooseland/haul road intersection. This has been identified as part of Public Engagement (Section 3).

2.7.3.6 Haul Road Bridges

There are three bridges along the existing logging roads. These bridges are not sufficient to support the increased loading of the haul traffic. Rather than remove and replace these with new bridges, they will remain in place for use in establishing the bypass road network. The existing capacity of these bridges is under review to establish if any upgrades are required to support mine construction activities.

2.7.3.6.1 Bridge 1 (north of Highway 224)

The intended project use of Beaver Dam Mine Road Bridge 1 is for mobilization of construction and mine development activities, as well as continued use in the bypass road network. This bridge is located just north of Hwy 224 on Beaver Dam Mines Road. The structure is a single span timber superstructure supported on timber crib abutments. The timber girders were treated with creosote and generally appeared to be in fair to good condition. The girders are supported on timber cap beams that are spaced 11.2 m apart (clear span). The cap beams are supported on localized timber cribwork founded on loose rock.

The bridge was inspected by Harbourside Engineering Consultants (HEC) in October 2019 and HEC noted that the foundations are not considered to be adequate. The foundations are not considered to be adequate for the loadings proposed on the haul route. An upgrade to the east and west foundations will be necessary before commencing with construction mobilization to Beaver Dam mine site.

A structural assessment of the bridge superstructure itself is being assessed to determine whether it is suitable for the anticipated loads exerted during the construction period before the new bridge is constructed – the largest load anticipated is expected to be the 58T chassis of a Caterpillar 390 excavator (with 11 tonne boom removed).

2.7.3.6.2 Bridge 2 (Beaver Dam Mine Road)

The intended project use of Beaver Dam Mine Road Bridge 2 is for mobilization of construction and mine development activities, as well as continued use in the bypass road network.

This bridge is a single span timber superstructure supported on timber crib abutments. The runners are in poor condition with visible rot and deterioration. The deck members appeared to be pressure treated and in fair to good condition. The deck is attached to nine 8”x12” timber girders which appear to be pressure treated and are generally in good condition. The girders are supported on timber crib abutments that are spaced 3.4 to 3.5 m apart (clear span).

2.7.3.6.3 Bridge 3 (Moose River Cross Road)

The intended project use of Moose River Cross Road Bridge is for use in Segment 2 road construction activities, as well as continued use in the bypass road network. The bridge at the entrance to Moose River Cross Road is located just off Mooseland Road. The Moose River Cross Road Bridge is a single span timber superstructure supported on concrete abutments in overall good condition. The wearing surface included two timber runners in fair to good condition. The deck members appeared to be in fair condition with some visible wearing on the top of the deck between the runners. The deck is attached to nine 9”x18” timber girders which are treated with creosote and in fair condition. The girders are supported on concrete abutments that are spaced 8.6m apart (clear span). The width of the bridge deck is approximately 4.9 m. The wingwalls are concrete from the footings to the level of the bearing seat and are timber cribs above the bearing seat. The foundations appear in good condition with some cracking noted.

The prefabricated steel girder bridges from Algonquin Bridge (a subsidiary of AIL) is being considered. This bridge has a CL625 loading and offers a rapid construction schedule with minimal cranage requirements.

2.7.4 Touquoy Mine Site

The Beaver Dam Mine Project will utilize the existing permitted processing facility at the Touquoy Mine Site to process Beaver Dam ore. Processing of ore from the Beaver Dam gold deposit at the existing Touquoy processing plant will begin upon completion of mining ore from the Touquoy deposit. Beaver Dam tailings will not be stored in the Touquoy tailings management facility, but instead will be permanently stored in the exhausted Touquoy pit after that deposit has been mined. This allows the Touquoy Mine Site footprint to be maintained as originally permitted and no tailings management will be needed at the Beaver Dam mine site. All other aspects of the Touquoy Gold Project will remain as assessed and approved through the Nova Scotia EA process in 2008 and as approved and regulated under the Touquoy Industrial Approval (IA).

Changes to the Touquoy Mine Site as a result of the Beaver Dam Mine Project will include the following:

- an increase in the duration of ore processing (five years additional years);
- weigh scales, a pair of weigh scales will be installed within the existing footprint to quantify the tonnage haul (i.e., one for incoming load and one to weigh the empty trucks;
- minor alterations to the Touquoy processing facility to accommodate Beaver Dam ore; and
- disposal of tailings Beaver Dam ore processing in the exhausted Touquoy mine. Historic tailings collected during construction will be disposed in the pit as well.

The Touquoy Mine Site will be operational for an additional five years beyond the current lifespan anticipated for the Touquoy Project. There will be no increase in the Touquoy processing rate to accommodate Beaver Dam ore. This will result in four additional years of ore processing, water management, and tailings management (exhausted pit).

The Touquoy processing facility main building houses ball mill, gravity recovery, reagent make-up, elution, and refinery sections. The crushing, carbon in leach (CIL), and cyanide destruction sections are located outdoors. Tailings produced from processing Beaver Dam ore will be stored in the exhausted Touquoy open pit. Water from the deposited tailings will be recirculated through the processing facility in a closed loop. Make up water requirements will be sourced from Scraggy Lake or other sources as per existing approvals. Water withdrawal from Scraggy Lake for the processing of Beaver Dam Mine ore is only expected during start-up. A technical report that presents the technical water and tailings management plan (Appendix F.7) , including tailings deposition and the overall mine site water balance including the direction of flow between components, effluent discharge locations, mine component drainage areas, and locations of MDMER final discharge. The existing Effluent Treatment Plant will be used will be utilized during closure until such time regulatory discharge requirements are met and excess water from the pit discharges to the Moose River along a constructed discharge outline.

The additional operational life of the Touquoy Mine Site involves no new footprint disturbance to the existing Touquoy facility or property. The Beaver Dam tailings will be managed in the exhausted Touquoy open pit. As originally planned in the approved Touquoy Gold Project Reclamation Plan, the inflow of groundwater, surface flow and precipitation into the pit will naturally create a lake upon closure of the site. Air emissions generated from the Touquoy Mine Site associated with the processing of Beaver Dam ore will be limited to emissions from the existing permitted plant operation during processing. The primary potential effect of the continued use of the Touquoy Mine Site is on surface water and groundwater quality associated with processing the Beaver Dam ore through the use of the exhausted open pit for tailings storage. It should be noted that geochemical and water quantity/quality data collected during the operational phase of the current permitted Touquoy Mine Site has been utilized to model surface and

groundwater and to make predictions of future water quantity and quality. As the Touquoy operation progresses, these predictive models will continue to be refined and revised as warranted.

An amendment to the Touquoy IA will be sought as necessary to accommodate these changes. As well, the currently approved Reclamation Plan will be updated to reflect the above changes and re-submitted.

2.7.4.1 Currently Approved Operations at the Touquoy Mine Site

The Touquoy Gold Project was described in a Provincial EARD and planned as a surface operation using drilling and blasting, with processing on site. As described in Section 2.7.2.1, ore production from the pit will vary with a maximum of approximately 5,480 tonnes of ore per day with a total ore production estimate over the life of the mine of at least 9.2 million tonnes for recovery of 0.4 million ounces (oz.) of gold. The Touquoy Gold Project is currently in its fourth year of commercial production, the mine life is estimated to be five to seven years for processing of Touquoy ore, three to four years for processing of Beaver Dam ore based on favorable permitting, and two years for closure and decommissioning.

The open pit and associated infrastructure are centered on areas of previous (bulk sample in 1980's) and historic mining activity at Moose River Gold Mines. The Touquoy facilities include an open pit, processing plant, tailings storage facility, waste rock piles, power and water supply systems, offices, and a service support complex. The total area of the development at the Touquoy Mine Site is approximately 265 ha. The open pit and mine site roads will occupy approximately 40 ha, processing plant and service complex will occupy approximately 60 ha, the tailings management facilities will occupy approximately 130 ha, and the waste rock stockpile will occupy approximately 35 ha.

Ore is mined from the nearby Touquoy pit and delivered to the mill for processing. Processing involves size reduction of the ore by crushing and grinding and recovery of the contained gold by mechanical and chemical processes. Recovery entails gravity concentration, carbon-in-leach (CIL), elution and carbon regeneration, electro-winning and smelting, and cyanide destruction. Tailings from processing of the Touquoy ore are deposited in the permitted TMF. Water associated with the Touquoy tailings is recycled for use in processing. At closure, all facilities will be removed, disturbed lands rehabilitated, and the property returned to otherwise functional use.

As part of the conceptual reclamation plan for the Touquoy Mine Site identified in the Provincial EARD, all site facilities will be removed, and the pit will be allowed to fill with water forming a lake. The flooding of the pit will create a lake approximately 15 ha in size with edge habitat.

2.7.4.2 Touquoy Gold Mine Environmental Assessment

An Environmental Assessment Registration Document (EARD) was submitted for the Touquoy Gold Mine on March 15, 2007 As a result of the subsequent review, a Focus Report was requested by the Minister of Environment and Labour to provide additional details on certain specific aspects of the project. The nature of the Focus Report was detailed in the Terms of Reference (TOR) in a public letter to DDV Gold dated April 15, 2007. The Focus Report was submitted on November 19, 2007.

The EARD assessed the potential environmental effects of the Touquoy Project on biophysical and socio- economic Valued Environmental Components (VECs). This assessment was based on inputs from members of the public, the Mi'kmaq community, government regulators and the professional judgement of the study team. The VECs identified and evaluated for the Touquoy Gold Mine included:

- Air Quality;
- Noise;
- Surface Water Resources;
- Geology and Hydrogeology;
- Terrestrial Resources;
- Wetlands;
- Archaeological and Cultural Resources; and
- Population and Economy.

Species of special concern were also considered within each applicable VEC.

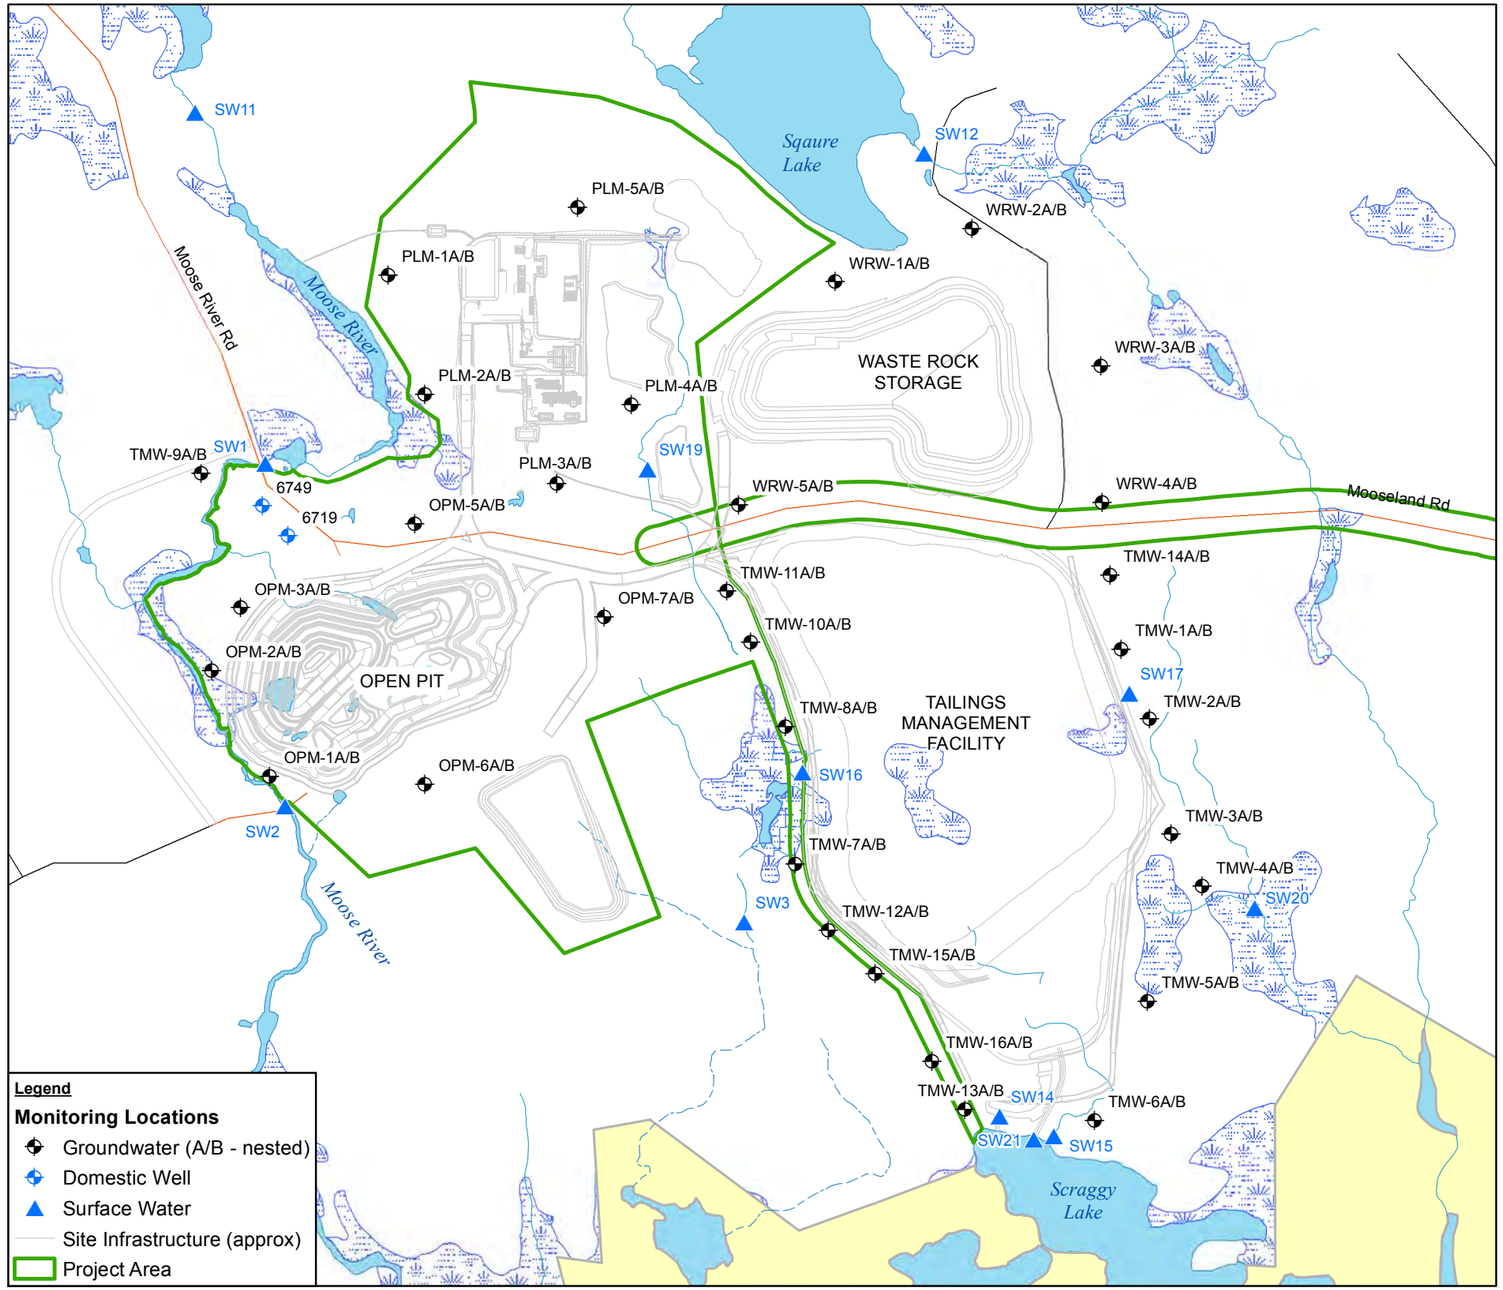
A review of the EARD and Focus Report identified that the following VECs were evaluated in terms of effects of the processing of ore during the Touquoy project: air quality, noise, surface water resources, and terrestrial resources. The remaining VECs were evaluated in terms of the effects of construction, mining operations, and use of the tailings management facility, and no additional effects were anticipated in the EARD or the Focus Report beyond the scope of these operations.

2.7.4.3 Existing Industrial Approval at the Touquoy Mine Site

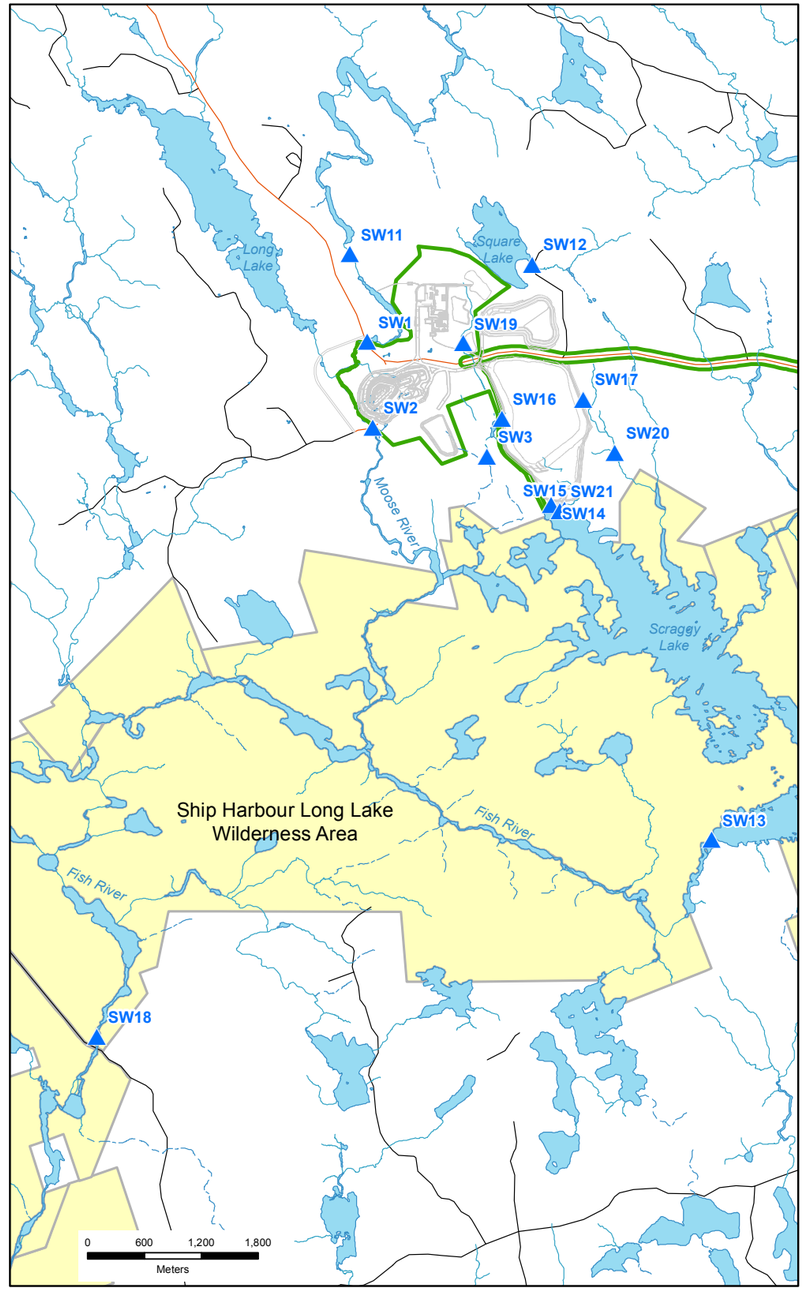
An Industrial Approval (IA) was developed by NSE to add specific conditions for environmental management and monitoring associated with the construction, operation and reclamation phases of the Touquoy Project. The IA contains over one hundred specific requirements in 25 sections which include but are not limited to the following:

- Particulate emissions (dust) and sound levels;
- Blasting management and monitoring;
- Air emissions from plant operations;
- Groundwater and surface water management and monitoring;
- Liquid effluent discharge management and monitoring;
- Tailings management and requirement for an engineer of record for the tailings management facility;
- Management and containment of historic tailings;
- Management of waste rock and sampling procedures;
- Handling, storage and management of reagents;
- Contingency / emergency response plan;
- Environmental impairment liability insurance requirements;
- Complaint response procedures;

- Community liaison committee (CLC) facilitation;
- Reporting requirements; and
- Reclamation planning and posting of bond to ensure completed.



The IA has specific requirements at various project stages of the Touquoy Project. This included installation of 32 nested pairs of groundwater monitoring wells prior to construction and completion of four quarterly monitoring events prior to operation. Subsequent to the start of operations, an additional 10 groundwater wells have been installed monitored: 8 shallow wells, and 1 nested pair. These groundwater monitoring data as well as surface water monitoring data are now being collected at the Touquoy Mine Site and are being used to periodically update the surface and groundwater modelling predictions for operations and post closure. The current compliance monitoring locations at the Touquoy Mine Site for groundwater and surface water are shown in Figure 2.7-6.



It is anticipated that many of the components of the Touquoy Project IA will be included in a future Beaver Dam Mine Project IA application reviewed by NSE prior to the Beaver Dam Mine Project commencing. As with other federal and provincial permits and approvals, these will be issued after the EA process is completed; typically, the conditions and framing of follow up programs as part of EA approval are reflected as appropriate at the permitting level.

2.7.4.4 Touquoy Mine Site and Benefits to the Beaver Dam Mine Project

Prior to the use of the Touquoy facility for the processing of Beaver Dam ore and storage of tailings in the exhausted Touquoy pit, approximately five years of operational data from the Touquoy operations will have been collected and modelling studies will be updated based on a review of these data. Monitoring of the current Touquoy Project includes air and noise monitoring, surface water monitoring of nearby water bodies, and groundwater monitoring of an extensive network of near and far groundwater monitoring wells. This ability to have actual data from an operational setting that is very similar to that proposed at Beaver Dam Mine Site is unique and important. The two sites have similar geology, ore, mining methods, wetlands and surface water bodies in close proximity to the extraction areas. AMNS will utilize the operational data to update models and provide greater refinement in the potential effect prediction for the Beaver Dam tailings deposition in the exhausted Touquoy pit.

Mining is complex and necessitates the proper use of personnel and equipment in creating an operation that is safe, benefits communities, and is executed in a manner that minimizes potential harm to the current and future natural settings. This operational expertise gained through the development and operation of the Touquoy Mine will be applied at the Beaver Dam Mine Site as proposed. The primarily local workforce will be able to be used at the Beaver Dam facility as it is in the same general area (within 30 km) and they will have over 5 years of additional operational experience beyond what they had prior to the Touquoy Project being opened.

2.8 Project Schedule

Site preparation and construction for the Beaver Dam Mine Project will begin in 2022 prior to exhaustion of the Touquoy pit so that the ore supply from the Beaver Dam Mine Site to the Touquoy Mine Site will follow shortly after the mining operations at Touquoy have ceased. Table 2.8-1 shows the Project Schedule.

Table 2.8-1: Beaver Dam Construction, Operation, and Reclamation Schedule

Event	Timeline
Beaver Dam Construction	Q4 2022
Beaver Dam Operation	Q1 2023 to Q2 2027
Touquoy Partial Reclamation (waste rock stockpile and tailings management facility) and Environmental Monitoring	2023-2026+
Beaver Dam Reclamation and Environmental Monitoring	2027-2029+
Touquoy Complete Reclamation (processing facility, surface mine/beaver dam tailings management facility) and Environmental Monitoring	2027-2029+

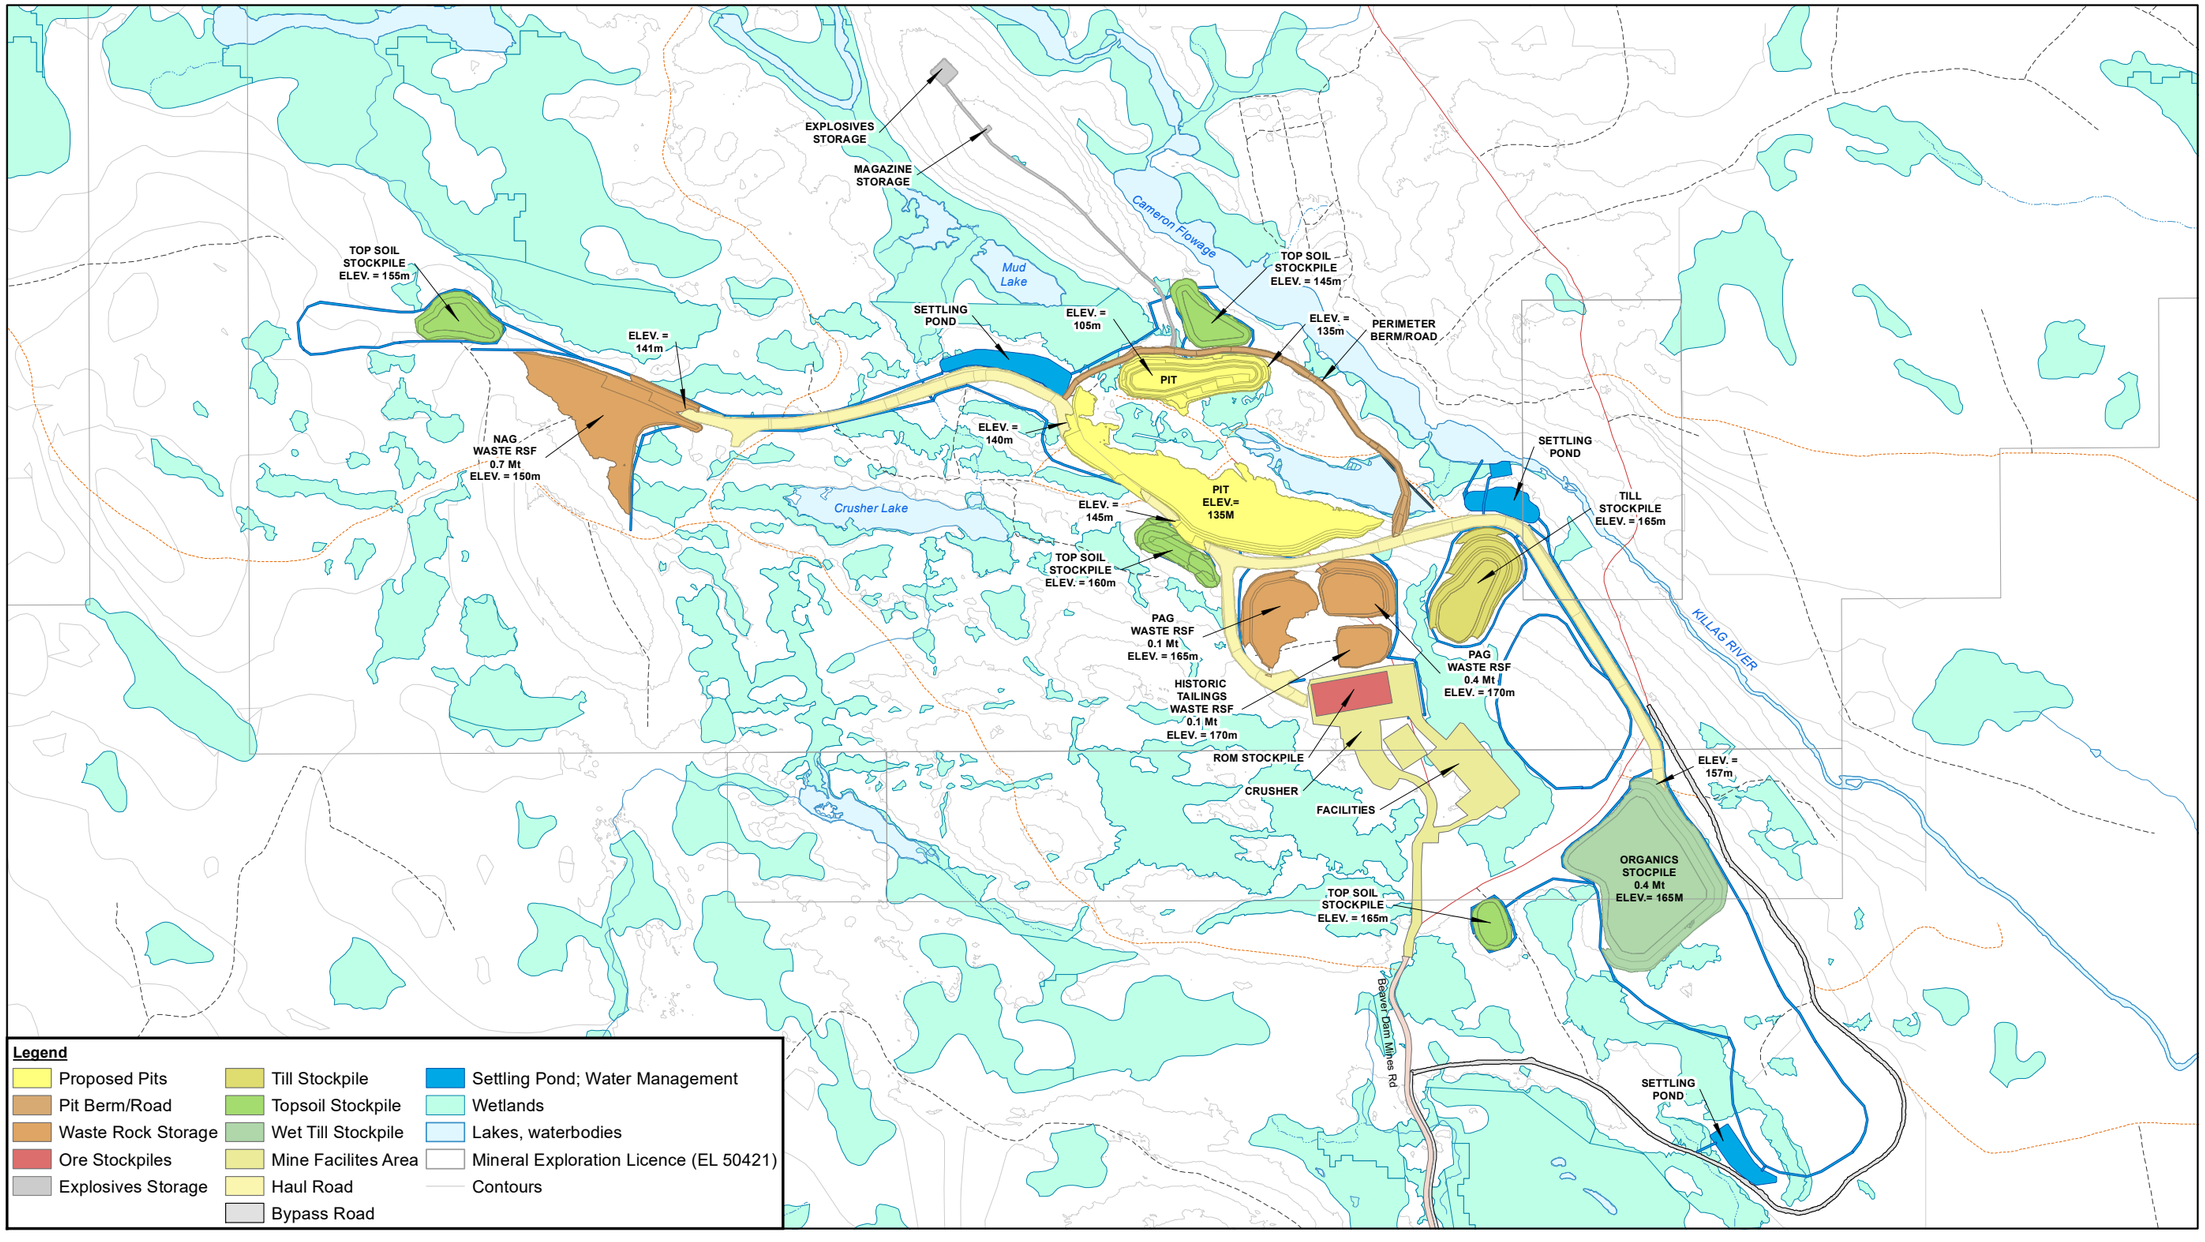
2.9 Project Activities

The Project consists four phases:

- one-year construction phase;
- five-years operations phase;
- two-year active closure and reclamation; and
- 10+ years post-closure monitoring and adaptive management.

2.9.1 Site Preparation and Construction (Year 1)

2.9.1.1 Beaver Dam Mine Site



Pre-production mine operations at Beaver Dam include the following tasks. These tasks are planned to take roughly eleven months of calendar time, from July 2022 to May 2023 so will be achievable within the year prior to opening the ore haul road to Touquoy.

Clearing and grubbing of planned disturbance footprints, including ex-pit haul roads, explosives storage access road and pads, topsoil stockpiles, till stockpiles, PAG rock stockpile, NAG rock stockpile, low grade waste stockpile, and open pit areas.

- Ditching around pit and stockpiles and development of north settling pond.
- Fish Out of the open pit area.
- Pump out of open pit area.
- Excavation and stockpiling of historic tailings along with potentially contaminated till materials.
- Removal and windrow/stockpiling of topsoil from haul road, till storage, PAG storage, NAG storage and open pit areas. Topsoil thickness of 30 centimetre (cm) is assumed in all areas.

- Removal and stockpiling of till from the open pits, starting with the construction pit areas in the northwest, then the upper elevations along the south side of the pit, and moving on to the remaining pit once the historic tailings are excavated.
- Grade control drilling on 10 m x 5 m pattern, 40 m depth, through estimated mineralized areas of the pit.
- Mining entire starter construction pit, P610.
- 1.7 Mt mined from 135 elevation down to the bottom on the 105 m bench.
- 0.6 Mt of topsoil/till material mined out and stockpiled.
- 0.7 Mt of rock used for haul road and pit perimeter berm construction.
- 0.3 Mt rock mined and stockpiled in the NAG pile.
- Mt rock mined and stockpiled in the PAG pile.
- Mining of benches 135 to 120 of the remaining pit.
- 8.0 Mt mined.
  - 4.7 Mt of topsoil/till material mined out and stockpiled.
  - 2.7 Mt of rock mined and stockpiled in the NAG pile.
  - 0.4 Mt rock mined and stockpiled in the PAG pile.
  - 0.2 Mt ore mined and stockpiled in the low-grade waste pile.
- Construction of haul roads as described in Section 2.7.3 above.
  - 0.7 Mt of waste rock from the pit used for construction, a portion of which will be crushed on site.

Mine construction to full operations is illustrated in Figures 2.9-1 to 2.9-3. Site access, truck shop, ROM pad area, site facilities, water diversions, and water management infrastructure will be constructed during the same time period.

2.9.1.1.1 Site Preparation

Clearing, grubbing, grading, and stockpiling of vegetation, topsoil, organics and till in the pit area will be conducted progressively prior to accessing host rock for mining purposes, to avoid erosion. All topsoil, organics, and till will be stored in stockpiles for use in reclamation and construction of berms, impoundments, mine site roads and/or general site grading. Vegetation clearing will be conducted in compliance with nesting bird directives from NSDL&F and Environment and Climate Change Canada. Once vegetation, topsoil, organics and till have been removed, drilling and blasting will be used to mine ore and non-ore bearing waste rock, as well as to establish benches along rock walls. Holes will be drilled into the host rock to receive explosives used for blasting. The open pit will be advanced from the surface at 130 to 155 masl down to 45 masl (i.e., pit depth will range from 175 to 200 m). A berm surrounding the pit will be constructed to act as an access road, noise attenuation and a flood berm.

Areas of waste material storage at the Beaver Dam Mine Site will include six topsoil stockpiles, four till stockpiles, and two non-ore bearing waste rock stockpiles (NAG and PAG). All these locations will be cleared and grubbed concurrently with the pit. The till and waste rock stockpile areas will also have topsoil removed and stored at the topsoil stockpile locations. The existing settling pond at the Beaver Dam Mine Site has been identified as a wetland during the baseline studies (Wetland 59). Inflow into the wetland will be removed and the wetland will be dewatered in preparation for the open pit development. As discussed in Section 6.9 (Fish and Fish Habitat), brook trout have been confirmed within this wetland and a fish rescue and relocation program is anticipated as an approval requirement prior to the pit development.

2.9.1.1.2 Site Construction

Mine site Haul Roads will be constructed to enable the mining fleet (loaders, dozers, haul trucks) to access various site locations including the open pit, waste rock areas, stockpiles and ROM pad area. A waste haulage road will be constructed connecting the pit exit with the topsoil, till, and non-ore bearing waste rock stockpiles. An ore haulage road will also be constructed connecting the pit exit and ROM stockpile. The roads will be dual lane and approximately 27 m wide, including berms and drainage, with a maximum speed limit of 40 kilometres per hour (km/h).

Where practical, mobile equipment and some support facilities will be transported from the Touquoy Mine Site to the Beaver Dam Mine Site for re-use. The mine plan currently is looking to using small blasts within the open pit to break up rock during construction and small crusher will be used for construction material that will be placed adjacent to the pit. Where practical, equipment will be relocated from Touquoy. In the event this is not possible new or used equipment will be sourced from contractors during construction. Fuel storage and distribution will be installed and managed by contractor similar to Touquoy.

Outdoor lighting for at the Beaver Dam Mine Site will be provided by 3 m pole-mounted high- pressure sodium weatherproof lights, while 8 m pole-mounted floodlights will be utilized for the ROM as well as operational facilities pad.

A temporary prefabricated facility equipped with office space, washroom facilities, a mine dry room, and a first aid facility will be provided. In addition, workshop facilities for general maintenance of the mining fleet and ore haulage fleet will be constructed.

A vehicle wash facility likely consisting of manually directed water jets and a high-pressure hot water and steam generator cleaner will be provided for the Beaver Dam Mine Site. The bulk of the mud will be washed off equipment within the pit area with surface water run-off captured within a sump. Final cleaning will occur in the truck wash where water will be circulated through an oil water separator before being directed to an evaporation pond located north of the facilities. Water from the pond will be ditched such that overflow will be directed towards the north settling pond. Water from the evaporation pond will be recycled for truck washing.

The north settling pond will be the first piece of site infrastructure early in construction to prevent discharge of sediment laden water from the Mine Site during construction. All site water will be directed towards the north settling pond (via an expanding network of surface water ditches or pumping) prior to discharge until the east settling pond and south settling pond have been constructed. The north settling pond is to be constructed prior to any clearing or grubbing in preparation for construction of other components of the Mine Site.

Historic tailings will be initially placed within the pit to allow dewatering and later to potentially the ROM pad for storage before being shipped to Touquoy Pit.

Runoff from the till stockpiles will be captured and directed into a collection pond located on the eastern side of the open pit. Water from both these ponds will be gradually decanted to Cameron Flowage by gravity via separate water discharge structures and engineered channels.

The discharge structures on all the settling ponds will be equipped with flow-control devices. The final design of the collection and settling ponds will be submitted as part of the IA application and process.

A berm will be constructed surrounding the pit to prevent shallow groundwater flow and/or surface water originating in Cameron Flowage from entering the pit. A water diversion ditch will be established around the perimeter of the open pit to intercept any surface water that infiltrates the berm and flows into the mine. This ditch will direct water to in-pit sumps where it will be directed to collection ponds located to the east and west of the open pit.

Development of the Beaver Dam Mine Site will cause direct and in-direct impacts to wetlands mostly within the construction phase of the Project. Direct impacts will be associated with clearing, grubbing, infilling and development of the mine and its associated infrastructure. Wetlands located within the Beaver Dam Mine Site are discussed further in Section 6.8 (Wetlands).

2.9.1.2 Haul Road

Site preparation for the Haul Road will begin one year prior to operations commencing, with construction of key infrastructure following shortly thereafter. Based on permitting timelines and environmental restrictions it may be necessary to transport ore along existing Public Roads until such time as Haul Road construction is complete.

The following activities will be undertaken to prepare the Haul Road for construction activities:

- clearing, grubbing, and grading; and
- topsoil, till, and waste rock management.

Once site preparation activities have been completed, construction will commence and involve the following activities:

- watercourse and wetland alteration;
- culvert and bridge upgrades and construction; and
- Haul Road construction and upgrades.

Clearing and grubbing will be conducted prior to upgrading or construction of the Haul Road. Saleable timber will be cut and stockpiled along the road length and the remaining vegetation mulched. Topsoil will be removed and stockpiled along the road length or used in berm construction, water diversion or reclamation of relict portions woods roads not required as part of the realignment.

Where upgrades follow existing woods roads, the width will be increased from approximately 4 m to 10 m, with an additional 3 m on either side to account for sloping and ditching on average. The portions of the Haul Road that require upgrading are anticipated to include approximately 17.8 ha of disturbance.

New road construction totaling approximately 4.0 km, built through a "greenfield" environment, will also be required to avoid travel on Hwy 224 and through Beaver Lake IR 17. The new road construction through the "greenfield" environment is anticipated to result in 6.4 ha of disturbance. The new construction will have a daylighted corridor of approximately 16 m width (on average) with wider areas of disturbance associated with cut and fill sections required to minimize grade and maintain safe design standards. Where possible existing roads will be used to minimize newly disturbed areas.

The upgraded and newly constructed Haul Road will be designed to accommodate up to a 68t gross vehicle weight in either a B-Train or C-Train configuration year-round. It is estimated for construction at total of approximately 275,000 m^3 of material will be excavated during the bulk earthworks phase of construction. The majority of this material will be utilized as fill to establish rough grading of the road. An additional 400,000 T of rock will be required for final grading comprising approximately 225,000 T rock fill for the road base and 175,000 T of gravel for the road surface. Construction material will be sourced from three quarries located along the length of the road with additional requirements for construction material, if required, sourced from either the Touquoy or Beaver Dam Mine Sites or local approved facilities. Road construction will allow for a clear porous subgrade or cross drainage culverts in order for wetland hydrology to be maintained post-construction. Sources of suitably tested clear stone may include the Haul Road corridor and/or the Beaver Dam Mine Site and Touquoy Mine Site or local approved facilities.

Three watercourses between 6 and 13 m wide are currently crossed via single lane timber bridges; these will be replaced by dual lane clear-span pre-engineered single arch modular bridges with an approximate lifespan of 30 years. Smaller watercourse crossings currently utilize culverts of varying sizes, makes, and conditions. Where the upgraded Haul Road follows the course of the existing Haul Road, culverts will be replaced by 600 mm corrugated steel culverts, each designed to extend 2 m beyond the edge of the Haul Road. Where deviations from the existing course are required, culverts of the same design will be installed beneath the new span and culverts beneath the old span will be removed where appropriate to facilitate the restoration of corresponding watercourses and to improve fish passage. Haul Road grades will be designed to maintain a minimum cover of 1 m over all culverts. Culverts will be installed in accordance with DFO and NSE guidance to reduce potential impacts to fish and fish habitat. Where appropriate, AMNS will work to install open bottom box culverts to reduce potential impact on the watercourses and associated fish habitat during road construction. Wetlands that are expected or confirmed to support fish habitat will be partially altered within the Haul Road to support road upgrades, widening and re-alignment as required.

The Haul Road will be upgraded where required to enable the safe and economic transportation of ore. Along the existing Haul Road at locations where the proposed road upgrade alignment will fall, it is anticipated that there could be up to 13 locations where there will be opportunity to improve fish habitat with new culvert installation and old culvert removed, up to 13 net zero scenarios where a new culvert could be installed, and 8 watercourses that will not be affected. Relict portions of the existing portions of the Haul Road that are not reclaimed during Haul Road construction will be properly reclaimed at the end of the Project lifespan or returned to the original owner as per any future lease arrangements.

Speed limit and right-of-way signage will be installed, and all haul truck operators will receive operator training to minimize the risk of collisions. All intersections will be designed to NSTIR Standards. Final design will consider safety and environmental constraints to ensure the best-case scenario for worker safety and environmental effects is developed.

Increased environmental disturbance is anticipated during initial site preparation, construction of new portions of the Haul Road, and during the replacement/upgrades that will be completed to over 20 culverts and 3 bridges.

Prior to construction it is anticipated that the following authorizations will be required:

- Nova Scotia Department of Transportation and Infrastructure Renewal (NSTIR)
  - Highway 224 crossing (preliminary discussions have occurred)
  - Haulage along Mooseland Road (preliminary discussions have occurred)
- Nova Scotia Department of Lands and Forestry (NSL&F)
  - Crown land access/lease (preliminary discussions have occurred)
- Nova Scotia Department of Environment (NSE)
  - Watercourse/Wetland alteration
- Department of Fisheries and Oceans
  - Fisheries Authorization

Authorizations will be sought during the Beaver Dam IA process.

2.9.1.3 Touquoy Mine Site

2.9.1.3.1 General

The Touquoy process plant is located east of Moose River, north east of the Touquoy open pit and north-west of the tailings storage facility. The approach by road to the plant will be from the east via the Mooseland Road.

The Touquoy plant, in particular the crushing circuit, has been designed for simple modification to handle the Beaver Dam feed ore once Touquoy pit is exhausted. The Ball Mill has been sized to accommodate the harder ore from Beaver Dam. Consequently, the Touquoy process flowsheets will remain fundamentally unchanged with the processing of Beaver Dam ore.

The main plant building houses the grinding, gravity recovery, reagent, elution, and refinery sections. The crushing, preleach thickener and CIL sections are located outdoors. The fine ore stockpile is covered for snow protection and dust control. The existing three stage crushing circuit is based on modular mobile crushing equipment to allow the modifications necessary to allow the introduction of Beaver Dam ore to Touquoy.

As noted in Section 2.7.4 weigh stations will be added.

No changes will be made to the remainder of the processing facility are anticipated.

2.9.1.3.2 Crushing Circuit

Ore from the Beaver Dam Mine Site will be transported to the Touquoy Mine Site and fed into the Touquoy ROM hopper by front end loader where it will be transferred by conveyor to the secondary crushing module. Both the secondary and tertiary crushers are similarly sized cone crushers and are designed to produce a fine ore product of P80 of 10 mm. This material is conveyed by a stockpile feed conveyor to the 12,000 t fine ore stockpile (FOS).

The FOS is protected with a cover to reduce moisture, prevent freezing, and minimize dust from the fine ore.

2.9.1.3.3 Grinding

The fine ore is transferred from the FOS via conveyor into the grinding circuit to be processed through one single pinion ball mill in closed circuit with hydrocyclones producing a final product of P80 150 micro metres (µm). The mill has a nominal solids throughput of 5,479 tonnes per day (t/d) and can process 250 tonnes per hour (t/h) at 91.3% availability. The overall ball mill circulating load is 250%. The mill has been sized to handle both the Touquoy and Beaver Dam ores without any mechanical adjustment required during the transition between mines. The Beaver Dam ore is expected to operate at a higher ball volume and steel ball consumption than Touquoy ore to compensate for the difference in hardness and abrasion characteristics.

Mill slurry discharge overflows onto a rubber lined trommel screen with trommel oversize discharging to a bunker for regular collection and disposal by a skid steer loader. The trommel undersize gravitates to the cyclone feed hopper where the slurry is diluted with process water and pumped with a duty/standby cyclone feed pump to the cyclone cluster. A density meter monitors and controls the amount of process water required to produce a target density to the cyclones. The cyclone underflow is split, with up to 30% feeding the gravity circuit and the remaining underflow stream gravitating back to the ball mill.

The cyclone produces a fine ground overflow product of P80 150 µm which is sampled and then gravitates to the vibrating trash screen. Oversize debris is removed and falls to a trash bin at ground level. The trash screen underflow flows by gravity to the pre-leach thickener.

2.9.1.3.4 Gravity and Intensive Cyanidation

A portion of the cyclone underflow (up to 30%) is split and fed into two 50% duty parallel gravity concentrator trains. The gold concentrate recovered is treated in an intensive batch leach system designed to handle 2.4 t/d of concentrate. The resulting concentrated gold solution is pumped to a dedicated eluate tank at the gold room.

The equipment is arranged to provide a gravity cascade under the cyclones. The gravity circuit splitter box provides the feed slurry to the two gravity concentrator trains. Each train consists of a scalping screen, gravity concentrator and gravity area electric chain hoist. The two gravity concentrators in parallel are sized for 188 t/h solids feed rate.

A controlled split of the cyclone underflow to each train is provided with orifice plates located in the underflow launder. The oversize from the scalping screen gravitates to the ball mill feed chute, while the undersize feeds the concentrator. The concentrate gravitates to the intensive cyanidation circuit at ground level.

The intensive cyanidation circuit receives the periodic gold concentrate for treatment in an intensive leach reactor. The gold containing pregnant solution pumps periodically to a dedicated eluate tank in the gold room.

The tailings from the concentrators are transferred back to the ball mill circuit for further processing.

2.9.1.3.5 Carbon-in-Leach (CIL)

The trash screen underflow is increased from 35 to 50% solids in the pre-leach thickener in preparation for the CIL step. The trash screen underflow enters the preleach feedwell after mixing with metered

flocculant. Thickener overflow gravitates to the process water standpipe and is recycled for plant use while the underflow slurry is pumped to the leach feed box for slurry conditioning prior to leaching.

The leach feed from the thickener underflow is pumped to a linear primary CIL feed sampler. The leach feed slurry is mixed with lime slurry in the leach feed box to raise the slurry pH for cyanide gold extraction. The feed box gravitates to the leach tank and optionally can feed directly to CIL Tank 1.

The circuit is a hybrid CIL type and consists of one leach tank and six adsorption tanks in series, each having a live volume of 1,169 m3. The design allows for a 250 t/h solids feed rate at 50% solids for an average 24-hour residence time. Each tank is interconnected with launders to allow slurry to flow sequentially by gravity to each tank in the train.

Barren carbon enters the adsorption circuit at CIL Tank 6. The carbon advances countercurrent to the main slurry flow during periodic transfers of slurry and carbon using air lift movement from a downstream to upstream tank. Carbon concentrations of 10 to 15 g/L are required in all tanks. Carbon will be retained in the upstream tank by an inter-tank screen. The countercurrent process is repeated until the carbon becomes loaded and reaches CIL Tank 1. Then a recessed impeller pump is used to transfer slurry and carbon to a loaded carbon recovery screen. The loaded carbon is washed with water and released to the acid wash column located inside the main plant, in the desorption area. The slurry will be returned to CIL Tank 1.

Following elution of the loaded carbon and thermal regeneration, the barren carbon is screened and reports to CIL Tank 6. Fine carbon is discarded to the CIL tailings hopper.

Tailings slurry from CIL Tank 6 flows by gravity to the vibrating carbon safety screen to recover any carbon in the event of damage, wear or other issues with the CIL Tank 6 inter-stage screen. Recovered carbon is collected in a bin that can be manually transferred for re-use or disposal. Tailings discharging from the safety screen gravitates to the cyanide detox Tank 1 in the cyanide detoxification circuit.

2.9.1.3.6 Desorption and Regeneration

The following operations are carried out in the desorption and regeneration areas:

- Acid washing of carbon.
- Stripping of gold from loaded carbon.
- Regeneration of carbon.

This circuit comprises a fibre reinforced plastic column located within the process building. A separate acid-proofed concrete bund is provided under the acid wash column area to ensure that all spillage is captured and kept separate from other process streams. Transfer and fill operations of the acid wash column are controlled manually. All other aspects of the acid wash and the pumping sequence are automated.

A pressure Zadra elution comprising an elution column, strip solution tank, strip solution pump and a strip solution heater package operates in a closed loop with the electro-winning cells located inside the Gold room.

The elution column is a pressure vessel with a live volume equivalent to 6 t of carbon. The elution column is constructed from carbon steel and includes insulation of all hot surfaces. The column is located next to the acid wash column and shares a bund and a sump pump with the strip solution and transfer water tanks.

The strip solution heater package is located inside the process building, near the elution column, but separately bunded. Within this package there is a recovery heat exchanger, trim heat exchanger, direct- fired heater, control panel, all interconnecting electrics and pipework. The heater is a direct-fired type with a propane fuel modulating burner. The heater is designed for a heat output to maintain the strip solution at 145°C during the stripping cycle. Both heat exchangers are plate and frame type and ensure that the nominal temperature of solution entering the electro-winning cells is less than 100°C.

After completion of the elution process barren carbon is transferred from the elution column to the kiln dewatering screen and into the carbon regeneration kiln feed hopper. In the kiln feed hopper, any residual and interstitial water is drained from the carbon before it enters the kiln. The kiln is a horizontal rotary unit sized for a feed rate of 330 kg/h at 75% utilization and is propane-fired.

The kiln operates at 650 to 750°C and has a nominal retention time of 15 minutes to allow reactivation to occur. Regenerated carbon discharges from the kiln to a quench tank and is then pumped using a recessed impeller pump to the carbon sizing screen. The screen oversize returns to CIL Tank 6, while the quench water and fine carbon report to the tailing's hopper via the carbon safety screen for disposal in the TMF. Fumes from the kiln pass through a wet scrubber to remove entrained minute carbon particles and then to atmosphere via an exhaust stack.

2.9.1.3.7 Gold Room

Three electrowinning sludging cells are used; one cell will be dedicated to the intensive cyanidation circuit and the other two to the elution circuit.

The electrowinning cell dedicated to the intensive cyanidation circuit is fed leach solution via a fixed speed centrifugal pump from the gravity leach liquor storage tank. Solution is pumped to the electrowinning cell and then gravitates back into the gravity leach solution storage tank in a closed loop until suitable gold recovery is achieved. The duration of this cycle varies with the quantity of gold recovered by gravity but is typically less than 24 hours.

The two electrowinning cells dedicated to the elution circuit operate in a closed loop with the elution column and associated equipment. Eluate flows directly from the top of the elution column to the electrowinning cells after cooling through heat exchangers. The eluate flows through the electrowinning cells and then gravitates back to the strip solution tank and then to the elution column in a continuous closed loop. The duration of this cycle is about 16 hours.

2.9.1.3.8 Cyanide Handling and Detoxification

Cyanide

Sodium cyanide (NaCN) is a key reagent used to leach gold from a sold matrix to form a gold cyanide complex that can be extracted from the slurry by adsorption onto activated carbon.

NaCN is delivered in the form of in dry briquettes from an approved supplier as per the International Cyanide Management Code (ICMC) standards. NaCN deliveries are made by truck in one tonne secured (strapped)wooden crates. Within the crates the NaCN is double and sealed close. At site the sodium cyanide is stored in a locked fenced area within the secure reagent building and kept under camera surveillance.

Prior to use, NaCN is mixed with water and sodium hydroxide (NaOH) for dilution and pH control within a mixing tank. Prior to mixing, operators will suit up in full personal protective equipment (PPE) including Tyvek suits and powdered air purifying respirators (PAPR). Water and NaOH are added to the cyanide mix tank. The wooden crates are opened, and a gantry crane lifts the bags out and transports them to the mix tank. The bags are lifted by crane into the bag cutter on top of the mix tank and the door is shut to enclose the bag. The bag is slowly lowered onto the bag cutter and the dry solids are emptied into the mix tank. The bag cutter has water sprays to clean the cyanide bags prior to removing from the enclosure. This process is repeated for 4 cyanide (NaCN) bags to achieve a mix concentration of -22%. Once the NaCN storage tank level is below 20% the mix tank is then transferred to the storage tank for distribution throughout the plant.

Cyanide is added into three areas; Leach tank #1, Intensive Leach Reactor (ILR) and Barren Eluate tank #12. Leach tank #1 is a continuous addition whenever the leach circuit is being fed with ore. It is controlled based on constant cyanide titrations throughout the leach/CIL circuit. The ILR and Barren Eluate tank are dosed based on a batch process. When a batch is ready, the dosage is controlled based on a flowmeter to a targeted concentration. All these addition points have pH control reagents (NaOH or Lime) with automated interlocks that will not permit NaCN addition until a suitable pH is achieved to avoid the formation of hydrogen cyanide (HCN) gas.

Cyanide target concentrations are as follows:

- Leach tank # 1 = 50 ppm (0.005%). By the end of the CIL circuit (CIL tank #6), the remaining cyanide is about 30 ppm (0.003%)
- ILR= 14,000 ppm (1.4%). Once the process is complete, this small volume (5.2 m^3) is transferred and diluted in the much larger Leach/CIL circuit (9,100 m^3) for consumption.
- Barren Eluate Tank #12= 1000 ppm (0.1%). Once the process is complete, the remaining cyanide stays in the tank to be re-used during the next batch. Each new batch, the cyanide is just topped up to the target concentration.

2.9.1.3.9 Cyanide Destruction

Cyanide destruction occurs within the cyanide destruction circuit. Slurry passing through the carbon safety screen gravitates to two 300 m^3 cyanide detoxification tanks which are designed on the conventional air- SO_2 process and can operate in series or parallel for operational flexibility. The average slurry residence time at 250 t/h is 1.5 hours.

The tanks utilize high shear agitators and air injection to enhance high oxygen dissolution in the slurry to meet the high oxygen demand of the cyanide destruction process. Sodium metabisulphite and copper sulphate solutions are dosed into either tank providing the oxidizing agent and catalyst respectively for the cyanide destruction. Acid generation is neutralized by the addition of lime slurry to the detox tanks via a ring main.

The detoxified slurry stream gravitates to the tailings hopper from where it is pumped through a single pipeline to the TMF by variable speed tailings pumps (1 duty/1 standby). The tailings slurry is then discharged at selected outlet points around the periphery of the facility. Pipe runs are designed to be self- draining to avoid dead legs.

Contingency measures for cyanide detoxification include primary linear and secondary rotary vezin tailings samplers taking representative tailings samples after the slurry has been detoxified and prior to entering the tailings hopper. The cyanide destruction and tailings hopper area has a dedicated bunded concrete area for collecting spillage. A local sump pump returns any spillage to the carbon safety screen. The area is enclosed for cold weather protection. A CNWAD analyzer automatically monitors slurry levels and an HCN detector provides monitoring for airborne gas.

Shutdown procedures are in place in the event of process upsets including cyanide detoxification.

2.9.1.3.10 Tailings Disposal

Prior to the completion of mining operations at Touquoy, a tailings line will be routed to the exhausted Touquoy pit in preparation to receive Beaver Dam tailings. Tailings will flow by gravity to the open pit. Initially, reclaim water will be withdrawn from the supernatant pond in the existing TMF to supply processing water needs for Beaver Dam ore. A reclaim water pump and barge, with a new pipeline to the process water tank, will be installed when process water accumulation from the tailings slurry deposited in the pit is adequate. The transition from the TMF to the open pit reclaim water system is expected to be smooth requiring minimal downtime and no extra fresh water requirements beyond what is currently permitted from Scraggy Lake under Touquoy water withdrawal approvals. It may be necessary to withdrawal water from Scraggy Lake at start-up but it is expected that water will be recycled from the pit for processing Beaver Dam mine ore.

Supernatant water collected in the open pit will be pumped to the process water tank located next to the pre-leach thickener. The sections of the tailings and reclaim pipelines between the plant site and open pit will be double-walled and run in HDPE lined trenches to an adequately sized lined collection ponds capable of containing the volume of the pipeline. Monitoring systems will be installed on the pipelines for leak detection and shutdown procedures.

The Touquoy Project currently employs an Operation, Maintenance and Surveillance (OMS) Manual for the existing TMF. This manual will be updated in advance of using the open pit for storage of Beaver Dam tailings in order to reflect changes in operating conditions and environmental factors. As well, Touquoy also currently employs an Emergency and Spill Response Plan which will also be updated, Environmental monitoring will continue as prescribed under the Touquoy IA which will be amended as necessary to reflect the changes in processing of Beaver Dam ore and storage of Beaver Dam tailings.

The minor works necessary to modify the Touquoy Mine Site for Beaver Dam ore, as described above, will begin before initiation of operation of the Beaver Dam Mine Site. This transition phase will likely not exceed two months.

No other changes will be made to the remainder of the processing facility and no additional land disturbances are anticipated to prepare the Touquoy Mine Site to receive Beaver Dam ore.

2.9.1.4 Construction Environmental Mitigations and Monitoring

The construction activities at Touquoy Mine Site required for the Beaver Dam Mine Project are minimal and within the existing Touquoy project footprint. The existing Touquoy IA well addresses construction activities, such as sediment and erosion control and spill protection and containment associated with construction equipment (e.g., fueling).

The existing environmental monitoring requirements at Touquoy include surface and groundwater monitoring as part of the IA. This will have occurred for about five years before construction activities associated with the Beaver Dam Mine Project commences. Also, existing approvals for wetland alteration include requirements for monitoring and compensation; these will be completed during the life of the Touquoy Gold Mine and no additional disturbance of wetlands is required as part of the Beaver Dam Mine Project activities at Touquoy.

2.9.1.4.1 Project Schedule

During the one-year construction phase, flexibility in the schedule may be employed to take advantage of seasonality. The upgrades to the Touquoy processing facility are not anticipated to exceed two months. This will likely be completed near the end of Year 1, after exhaustion of the Touquoy pit. Details regarding, he time of year when activities will begin will be determined at a later date and addressed during the IA process.

2.9.2 Operation and Maintenance (Years 2 to 6)

2.9.2.1 Beaver Dam Mine Site

During operation and maintenance of the Beaver Dam Mine Site the following activities will be undertaken:

- surface mine operation and maintenance:
  - drilling and rock blasting;
  - surface mine dewatering;
- ore management;
- waste rock management;
- surface water management;
- dust and noise management;
- petroleum products management; and,
- site maintenance and repairs.

2.9.2.1.1 Surface Mine Operation and Maintenance

Once accessible, in-situ rock will be drilled and blasted on 5 m bench heights. Diesel powered rotary drills will be used for production drilling and horizontal high wall depressurization drilling on the ultimate pit walls if required. Dedicated reverse circulation grade control drilling and sampling will be used to define ore and waste rock limits, while a fleet management system will track each load transported from the surface mine.

The open pit will remove approximately 56.6 million tonnes (Mt) of material (i.e., ore, non-ore bearing waste rock, till, and organic material) over the life of mine. The production schedule for the Beaver Dam Mine is shown in Table 2.7-1 and Figure 2.7-2. The pit will be mined in a west/east phases. Ultimate pit limits are split into phases or pushbacks to target higher economic margin material earlier in the mine life. The ultimate pit is subdivided into two phases, west and east, but for considerations of vertical advance the pit is mined as one phase from top to bottom. A small starter pit phase is also planned for the northwest corner of the pit to provide construction materials early in the mine life. The ore mined from the pit will range from 0.7 Mt to 2.1 Mt over the life of mine with approximately 0.5 Mt to a maximum of 14.9 Mt of waste being generated over life of mine. The open pit will be advanced from the surface at 130 to 155 masl down to 45 masl. At completion, the open pit will measure approximately 900 m along its east-west axis, approximately 500 m along its north-south axis, with a depth of ranging approximately 175 to 200 m based on the current ore delineation. The total area comprising the open pit will be approximately 31 ha.

A contract explosives supplier will provide the blasting materials for the mine. Emulsion will be the primary blasting agent as the majority of holes will be wet. It is anticipated that explosives and all accessories will be supplied on an as needed basis from the

contractor's base location off-site and delivered to the site explosive storage facilities or directly to the blast holes using the contractor's equipment. If required, magazines will be suitably located to conform with quantity and distance requirements as regulated by Natural Resources Canada (NRCAN). All on and off-site permitting requirements will be the responsibility of the contractor through NRCAN.

Diesel powered hydraulic excavators and a wheel loader will load both ore and waste rock into separate haul trucks. These loading units will also function to re-handle mine material, and load overburden and topsoil, as well as conduct mine clean up, road construction, and snow removal. The off-highway rigid frame haul trucks will have a 64-tonne capacity and haul ore to the ROM pad and ore stockpiles as required, while waste rock will be hauled to the waste rock stockpiles. If dust is generated from hauling during warmer months, it will be controlled by applying water to the Haul Roads utilizing a specialized water truck. At the ROM pad, off-highway haul trucks will dump ore material directly into the primary crusher or place it in an active stockpile on the pad to be re-handled as crusher feed later on. Active stockpiles will be constructed in lifts. Loading of stockpiled ore into the primary crusher will be accomplished via a diesel-powered wheel loader. At the waste rock stockpiles, haul trucks will dump waste rock and diesel-powered track dozers will spread it into lifts.

As all ore processing will be carried out at the existing Touquoy processing facility, no mill reagents, including cyanide, will be utilized at the Beaver Dam Mine Site. No changes will be made to the mill reagents used in the Touquoy gravity/CIL process as described in Section 2.7.4 due to the processing of Beaver Dam ore. All mill reagents used at the Touquoy will continue to be transported, stored, used, and disposed of, where necessary, in accordance with existing Touquoy standard operating procedures, permits, approvals and relevant regulations.

The only chemicals expected to be used at the Beaver Dam Mine Site, not including fuels, oils, lubricants, coolants, etc., are:

- flocculants, which will likely be used to meet suspended solids discharge limits at the discharge point; and,
- chemical dust suppressants, such as magnesium chloride, to supplement the use of water in controlling fugitive dust generation on roads and other trafficable areas. Chemical dust suppressants will be considered for use when conditions render water use alone inefficient in controlling fugitive dust from traffic.

In the event water treatment is required during the operational or post closure phases of mine development, reagents could include ferric sulphate (for arsenic and other metals removal), oxidizers such as hydrogen peroxide and potassium permanganate, lime for pH adjustment, and flocculants for final sludge removal.

The anticipated 246-person workforce at the Beaver Dam Mine Site will include approximately 105 mine personnel (working two or three shifts per day of 12 or 8 hours respectively, or approximately 26 persons per shift (includes 26 on leave at any time). The workforce also includes 60 haul truck drivers, 57 plant staff (at the Touquoy Mine Site), and 24 general and administrative staff (between the Beaver Dam mine site and the Touquoy Mine Site). An allowance of 12 days per year of no mine production has been assumed to allow for adverse weather conditions. No group transportation to the mine site or on-site lodging are anticipated at this time so long as the local labour pool can supply the necessary labour requirements.

A summary of the major mining equipment fleet requirements is provided in Table 2.9-1.

Table 2.9-1: Beaver Dam Primary Mining and Hauling Equipment Requirements

Activity and Equipment	Requirement				
	2022 (Partial year)	2023	2024	2025	2026 (Partial year)
Drilling					
Diesel DTH Tracked Drill, 110 mm holes	4	5	4	2	1
Diesel RC Tracked Drill, 135 mm holes	2	2	2	2	2
Loading					
Hydraulic Excavator - 4.55 m3 bucket	4	4	3	2	2
Wheel Loader - 7.0 m^3 bucket	2	2	2	1	1
Hauling					
Haul Truck - 64 tonne payload	13	13	11	5	4

To facilitate successful mining operations, the following in situ support services will be available:

- mine site road maintenance;
- mine floor and ramp maintenance;
- ditching;
- reclamation and environmental controls;
- surface mine dewatering;
- surface mine lighting;
- mine safety and rescue;
- transportation of personnel and operating supplies; and
- snow removal.

A summary of the equipment chosen to conduct these support services and their specific role is provided in Table 2.9-2.

Table 2.9-2: Beaver Dam Operational Equipment Requirements

Equipment	Function	Requirement
Motor Grader (4.3 m blade)	Mine site road maintenance	1
Water/Gravel Truck	Mine site road maintenance	1
Track Dozer (325 kW)	Waste rock stockpile maintenance	3
Water Pumps (150 m^3/h)	Mine sump dewatering	2
Track Dozer (237 kW)	Mine support and construction	1
Wheel Loader (5.5 m^3)	Mine support and construction	1
Hydraulic Excavator (2 m^3)	Utility excavator and rock breaker	2
On-highway Dump Truck	Utility material movement	2
Fuel and Lube Truck	Mobile fuel/lube service	2
Shuttle Bus (16 passenger)	Employee transportation	1

Table 2.9-2: Beaver Dam Operational Equipment Requirements (continued)

Equipment	Function	Requirement
Backhoe Loader (69 kW)	Utility loader and stemming loader	1
Pickup Trucks (1/4 tonne)	Staff transportation	7
Light Plants (20 kW)	Surface mine lighting	6
Skid Steer (54 kW)	Utility material movement	1
Track Dozer (149 kW)	Utility material movement	1
Maintenance Trucks	Mobile maintenance crew and tool transport	2
Mobile Crane (36 tonne capacity)	Mobile maintenance material handling	1
Float Trailer (55 tonne capacity)	Equipment transport	1
Forklift (3 tonne capacity)	Shop material and tire handling	1
Mobile steam cleaner	Mobile maintenance equipment cleaning	1

The majority of this equipment will be utilized during the site preparation and construction phase as well. Maintenance activities for the mobile mining, hauling, and operation equipment will be performed in the field and at the mine maintenance workshop facility located near the primary crusher. All field maintenance will be performed with dedicated maintenance equipment operated by qualified staff. A grader will be used to maintain the mine site roads. Snow clearing will be conducted regularly during the winter months. No salting of mine Haul Roads is anticipated during winter conditions for traction.

The maximum anticipated daily volume on the Highway #224 and Beaver Dam Mines Road associated with the Beaver Dam Mine Project is estimated to be 175 (passenger and service vehicles). In reality, based on use of the Haul Road, intermittent service vehicle schedules and car-pooling, the number on #224 could be reduced by 50% to around 85 to 90 per day over a 24-hour period or roughly 4 per hour on the #224. Traffic on Highway #224 is expected to remain within the traffic count ranges as provided by NSTIR (refer to Section 6.16 Socio-economic Conditions).

The Beaver Dam Mine Site will require a water source for fire protection and dust control. Raw water will be pumped either directly from Cameron Flowage or recycled from the site water collection ponds or ditches assuming the water quality meets regulatory requirements. Water will be distributed from the storage tank to various users including, but not limited to, the site facilities facility and primary crusher location if required. Dust control will occur as required and will consist primarily of wet suppression controls using only water on unpaved surfaces. However, in some high traffic areas including site facilities and internal access roads, a chemical suppressant (e.g., Magnesium Chloride) may be used to more effectively control dust. This will be applied during the summer/fall months (May to October) in liquid form using the mine water truck and in granular form during the colder months (November to April). There is no requirement for decant water and potable water will be delivered via specialized truck.

Daily domestic water usage is based on approximately 30 employees on the mine site at any time. It is anticipated that one drilled domestic water well will be required to provide water for sanitary usage as domestic wells in this area generally yield 5 to 10 L/min based on a literature review of several sources and the demand is estimated at less than 5 L/min. The use of a storage tank on-site and water demand equipment will keep extraction rates within the well capability.

A mobile vehicle wash down unit likely consisting of manually directed water jets and a high-pressure hot water and steam generator cleaner will be utilized at the Beaver Dam Mine Site.

Surface water runoff from truck washing will be contained and directed to the site collection pond. Sampling will determine whether this wastewater stream will require treatment prior to release to the receiving environment.

Sewage from the Beaver Dam Mine Site office facility will flow by gravity drain via a piped network buried below the frost line to septic tanks equipped with leach drains. No chemical waste will be disposed of through the septic system. The septic tanks will be pumped out as required by a contractor.

Hazardous wastes, such as used oil, lubricants, batteries and antifreeze will be collected by qualified hazardous waste contractors and taken off-site for re-cycling or disposal in accordance with relevant legislation. General non-mine waste will be collected by a contractor and transported off site for disposal.

2.9.2.1.2 Ore Management

Ore will be loaded into off-highway haul trucks for transport out of the open pit. From there, ore will be separated into low and ROM stockpiles prior, while non-ore bearing waste rock will be stockpiled for final disposal.

Waste Rock will either be directed to the Waste Rock Storage Area (NAG) or to the PAG Storage Area. The design capacities are described in Section 2.7.2.3.

The ROM stockpile will likely have up to a 30-day capacity for storing ore during plant shut-downs or short-term periods where ore extraction from the mine exceeds crusher or plant capacity. The ROM stockpile can also accommodate plant feed if ore hauling from the mine is reduced for weather or other reasons.

2.9.2.1.3 Waste Rock Management

Material storage at the mine site will include six topsoil stockpiles, two till stockpiles, and two non-ore bearing waste rock stockpile comprising a total of 98 ha.

2.9.2.1.4 Surface Water Management

Mine Water Management is described Appendix P.4 and is described in Section 2.7.2.9.

2.9.2.1.5 Petroleum Products Management

The site will be serviced by both propane and diesel. Diesel will be stored primarily at the mobile equipment fuelling station meant to serve both the mining fleet and the transport fleet. The fueling station consists of a 3,000 heated and insulated tank with a hybrid pump. The fueling system will supplied and owned by a third party vendor who will rent to the site as part of the fuel contract.

The generators will also be supplied with fuel tanks at 13,200 litres each and will be filled by the 3rd party vendor. Propane will be stored at site in two 7,500 L tanks which will be owned by the same vendor as the diesel fuel supplier. Propane will then be plumbed to the various buildings for heating.

The delivery of diesel fuel will be conducted by tanker trucks from suppliers who routinely transport and distribute petroleum products. Transfer of these products from the tanker truck to double-walled tanks with bollards will be constantly supervised by the delivery person to ensure constant observation and immediate response should a spill occur. Based on anticipated equipment, associated efficiency ratings, and hours of operation, diesel fuel consumption by operational equipment and haul trucks has been

estimated to be approximately 9.02 million litres of diesel fuel per year during full scale operations. During construction and decommissioning, diesel fuel consumption will be approximately 3.7 million litres per year.

2.9.2.2 Haul Road

During operation and maintenance of the Haul Road the following activities will be undertaken:

- ore transport; and
- Haul Road maintenance and repairs.

The only change in Haul Road is the removal of the Preferred Alternative Haul Road option, which has been noted in each the VC Sections (Section 6). It may be necessary to use the Public Roads during start-up (i.e., 6-8 months) depending on approval and permitting timelines and construction restrictions.

During operation and maintenance of the Haul Road the following activities will be undertaken:

- ore transport; and
- Haul Road maintenance and repairs.

2.9.2.2.1 Ore Transport

Crushed ore, either from either a primary crusher or small blasts in the pit, from the Beaver Dam Mine Site will be transported to the Touquoy Mine Site by truck travelling along the upgraded Haul Road. The route is Beaver Dam Mines Road to Hwy 224 to logging roads herein referred to as the Moose River Cross Road to Mooseland Road for a total distance of 31 km. It is anticipated that ore will be hauled under contract between the two sites, however, this is subject to further review and availability of suitable qualified contractors.

Approximately 20 highway trucks will be required to transport the ore from the Beaver Dam Mine Site to the Touquoy Mine Site. The exact number will depend on final payloads and the hauling schedules, which will likely be a single 12-hour shift, or two 8-hour shifts per day operating between the hours of 7:00 a.m. to 11:00 p.m. The number of return haul truck trips per day will be an annual average of approximately 190 round trips per year but will vary with production schedule (Table 2.7-1) for 353 days per year for the anticipated duration of the Project (5 years). Approximately 12 days a year the site will require shutdowns due to maintenance and/or weather events. This will result in an increase from the current average daily traffic on the Haul Road (when forestry operations are not occurring) which is estimated to be approximately 10 vehicles per day. Hours of operation during active hauling will likely occur between 7:00 a.m. to 11:00 p.m. The exact number trucks will depend on final payloads, production schedule and the hauling schedules. During construction and pre-production truck traffic will be reduced and will be associated with construction and upgrade of the Haul Road and transportation of equipment between the Touquoy Mine Site and the Beaver Dam Mine Site.

2.9.2.2.2 Haul Road Maintenance and Repairs

All grading, maintenance, snow clearing, gritting and dust suppression conducted on the Haul Road will be completed by a third-party contractor. With regards to Haul Road maintenance, it is anticipated that only minor surface repairs will be undertaken during the planned haulage schedule. Most of the road maintenance will occur outside of the planned hauling schedule so as not to impede the haul trucks and increase the safety risk on the road. Apart from road surface maintenance it is anticipated that major repairs will be localized in kept to a minimum with appropriate road design.

Snow clearing will be undertaken using an on-highway truck outfitted with a snow plough sand spreader. Clearing will occur on an as needed basis throughout the winter months and will require operations outside the planned haulage schedule depending upon the snowfall event. The sand spreader will be utilized during the winter months for traction control. In addition, localized salting during significant ice events will occur for safety reasons. Salting will be restricted to road sections with steeper grades and at least 30m from any watercourses.

Dust control will occur as required and will consist of a combination of chemical suppressant and/or water on unpaved surfaces. In order to provide longer term dust suppression, particularly throughout the winter months where water is not practical, an approved chemical dust suppressant will be applied to the road surface. Periodic application is anticipated depending upon road conditions and traffic. To support chemical dust suppression and provide short term suppression of dust throughout the warmer drier months, water will be applied. A water truck will spray the width of the Haul Road and operate during the haulage period.

Increased environmental disturbance is anticipated during peak transport times (7AM to 11 PM) and during maintenance activities along the Haul Road.

All grading, maintenance, snow clearing, gritting and dust suppression conducted on the Haul Road will be completed by a third-party contractor. With regards to Haul Road maintenance, it is anticipated that only minor surface repairs will be undertaken during the planned haulage schedule. Most of the road maintenance will occur outside of the planned hauling schedule so as not to impede the haul trucks and increase the safety risk on the road. Apart from road surface maintenance it is anticipated that major repairs will be localized and kept to a minimum with appropriate road design.

Snow clearing will be undertaken using an on-highway truck outfitted with a snow plough sand spreader. Clearing will occur on an as needed basis throughout the winter months and will require operations outside the planned haulage schedule depending upon the snowfall event. The sand spreader will be utilized during the winter months for traction control. In addition, localized salting during significant ice events will occur for safety reasons. Salting will be restricted to road sections with steeper grades and will only be applied at least 30m from any fish bearing watercourses.

Dust control will occur as required and will consist of a combination of chemical suppressant and/or water on unpaved surfaces. In order to provide longer term dust suppression, particularly throughout the winter months where water is not practical, an approved chemical dust suppressant will be applied to the road surface. Predictive modelling and evaluation of potential effects within this EIS has been completed based on 80-90% effective dust mitigation. Periodic application is anticipated depending upon road conditions and traffic. To support dust suppression and provide short term suppression of dust throughout the warmer drier months, water will be applied. A water truck will spray the width of the Haul Road and operate during the haulage period.

2.9.2.3 Touquoy Mine Site

During operation and maintenance of the Touquoy Mine Site the following activities will be undertaken:

- ore processing; and
- tailings management (exhausted pit).

2.9.2.3.1 Ore Processing

Other than the primary ore crushing, no mineral processing will be undertaken at the Beaver Dam Mine Site. All processing will be completed at the Touquoy Mine Site after mining from the Touquoy pit has been exhausted.

The Touquoy plant is designed to treat Beaver Dam ore with no modifications other than an increase in the total weight of grinding balls in the ball mill to accommodate the slightly harder ore from the Beaver Dam pit. This will not require any larger equipment.

Details regarding water and tailings management (exhausted pit) are provided in the Integrated Water and Tailings Management Plan presented in Appendix F.7. A summary is provided below for operational and closure phases of the project.

2.9.2.3.2 Tailings Management - Operations

There is no requirement for tailings management at the Beaver Dam Mine Site as all mineral processing will be undertaken at the Touquoy Mine Site. Tailings generated from this operation will be pumped to the mined-out Touquoy pit for storage and covered with water to create a lake during reclamation. The approved Touquoy Environmental Assessment stated that the pit would be allowed to fill naturally with water over a period of time through precipitation, surface flow and groundwater in-flow. No change to this method is planned to follow the deposition of Beaver Dam tails, except that the time frame for refilling will be shorter given the decrease in available volume taken by the tailings.

The processing of Beaver Dam ore at Touquoy involves the continued use of Touquoy water management facilities but flow patterns will be altered and rerouted as described, below. The Tailings Management Facility (TMF) will continue to receive surface runoff from the waste rock pile, seepage collection ditches, and direct precipitation and will continue to operate under the existing Industrial Approval (IA) which includes TMF effluent treatment plant operation and discharge to Scraggy Lake. Runoff from the mill site pond and run-of-mine (ROM) stockpile will continue to be collected and routed to the plant for use as make up water for the processing of Beaver Dam ore. Dewatering of the open pit to the TMF will cease at the end of Touquoy open pit mine life which will allow water inflows to accumulate in the open pit. At initial stages of Beaver Dam ore processing, reclaim water will be directed to the mill from the TMF through the existing decant tower or floating barge infrastructure for processing of Beaver Dam ore. Delay of water reclaim from the open pit will allow time for water inflows to collect in the pit as a start-up process water supply. When water is to be reclaimed from the open pit, the existing floating barge and associated infrastructure will be relocated from the TMF to the exhausted open pit. The barge will raise with the water and tailings elevation in the pit, decreasing pump head and associated pumping costs over time. If required, additional Beaver Dam ore processing start-up water supply will be sourced from Scraggy Lake, subject to NSE water withdrawal approval. Freshwater make-up for the process will continue to be sourced from Scraggy Lake as provided in existing water withdrawal approvals. Additional make-up process water required in a dry year will be sourced from effluent from the TMF treatment plant or Scraggy Lake, subject to NSE approval. Beaver dam tailings will be deposited in the open pit. The existing tailings slurry pipeline from the mill will be redirected from the TMF to the Touquoy open pit.

2.9.2.3.3 Tailings Management - Closure

During the closure phase, the objective is for water in the pit lake to meet the reclamation regulatory water quality requirements or site-specific criteria. Key water management features are described below.

The existing TMF effluent treatment plant and downstream discharge facilities will continue to be in operation to treat TMF water surplus. At the cessation of tailings deposition to the Touquoy open pit, the open pit will fill with water. During this period, there may be an opportunity to treat the pit lake as a batch reactor with the objective of adjusting the pH to precipitate metals thus improving discharge quality. Surplus water in the open pit will be pumped to the TMF for treatment, until such time as water quality

monitoring indicates that water quality is suitable for direct discharge to the environment. Until water quality meets discharge criteria, the water level in the pit lake will be maintained at or below elevation 104 masl (i.e., corresponding to the shallow permeable zone), thus reducing seepage to Moose River and normalizing treatment rates to the extent feasible. A minimum of 1 m water cover will be maintained above the deposited tailings to facilitate pumping. The water cover depth will vary over the tailings depositional period. The effluent treatment plant will operate intermittently during non-frozen periods (April - November, inclusive) to lower the pit lake to 103 masl seasonally by the end of November, thus providing storage over the period when the effluent treatment plan is shut down during the winter months. Assuming the existing effluent treatment rate of 400 m^3/hr, the effluent treatment plant would be in operation for an additional 4.4 months to pump and treat the annual climate normal surplus of the open pit watershed of 436,000 m^3. Operation of the existing effluent treatment plant will be modified to accommodate Beaver Dam water surplus or additional capacity will be added to effluent treatment plant to treat water over a shorter period simultaneously.

The effluent treatment plant and downstream discharge facilities are not required for the Project once effluent discharge meets regulatory discharge criteria and will not require treatment. Surplus water in the open pit will be discharged via a constructed spillway/conveyance channel to Moose River, subject to meeting regulatory discharge criteria. The spillway and conveyance channel will be sized to accommodate the inflow design flood in accordance with the Canadian Dam Association (CDA) guidelines. The spillway invert is set at elevation 108 m, approximately 2 m below the lowest open pit elevation to prevent overtopping.

2.9.2.4 Existing Environmental Mitigation Requirements Associated with Operations

There is an existing IA for the Touquoy Project which has specific environmental mitigation and monitoring requirements. This is relevant to the Beaver Dam Mine Project in two ways:

- Monitoring data is being collected since 2016 and will continue to be collected through to the start of the Beaver Dam Mine Project as part of requirements under the existing IA. This provides much background data to support the follow up programs anticipated at the Touquoy Mine Site for the Beaver Dam Mine Project.
- Mitigation measures required as part of the IA and other associated Touquoy Gold Mine environmental management plans will continue to be implemented as part of the Beaver Dam Mine Project.

Given the operational activities at the Touquoy Mine Site are limited to processing of ore and management of tailings (exhausted pit), existing mitigation and monitoring requirements applicable are directly related to atmospheric emissions, surface water and groundwater.

2.9.3 Active Reclamation (Years 5 to 7)

2.9.3.1 Reclamation Objectives and Goals

The objective of the Final Reclamation Plan is to return the site to a safe and stable condition, compatible with the surrounding landscape and anticipated final land use. The plan will employ recognized reclamation best practices, acknowledged principles of ecological restoration, and consultation with stakeholders and First Nations including the Millbrook First Nation and other Mi'kmaq communities. In the past, the site has hosted numerous mining/exploration activities (exploration declines, roads, camps, settling ponds, and small waste piles of rock and overburden), along with successive tree harvesting and silviculture operations. Evidence of recreational land use (hunting and off-road vehicles) and surface water use (fishing and boating) directly within the Beaver Dam Mine Site is limited and suggests these activities could be re-instated once the surface mine ceases operation and reclamation activities have been completed.

The goals of a successful Final Reclamation Plan include:

- remove all equipment and infrastructure not necessary for future use and care of the site;
- Create a physically, chemically and biologically stable site.
- stabilize the terrestrial environment and revegetate the site to encourage regrowth of native species;
- minimize disruption to the aquatic environment; and
- restore land and surface water use potential.

The reclamation goals are designed to enable eventual abandonment of the site in a safe and stable state. In order to achieve these goals, AMNS will undertake general decommissioning and reclamation activities as described below.

2.9.3.1.1 Beaver Dam Mine Site

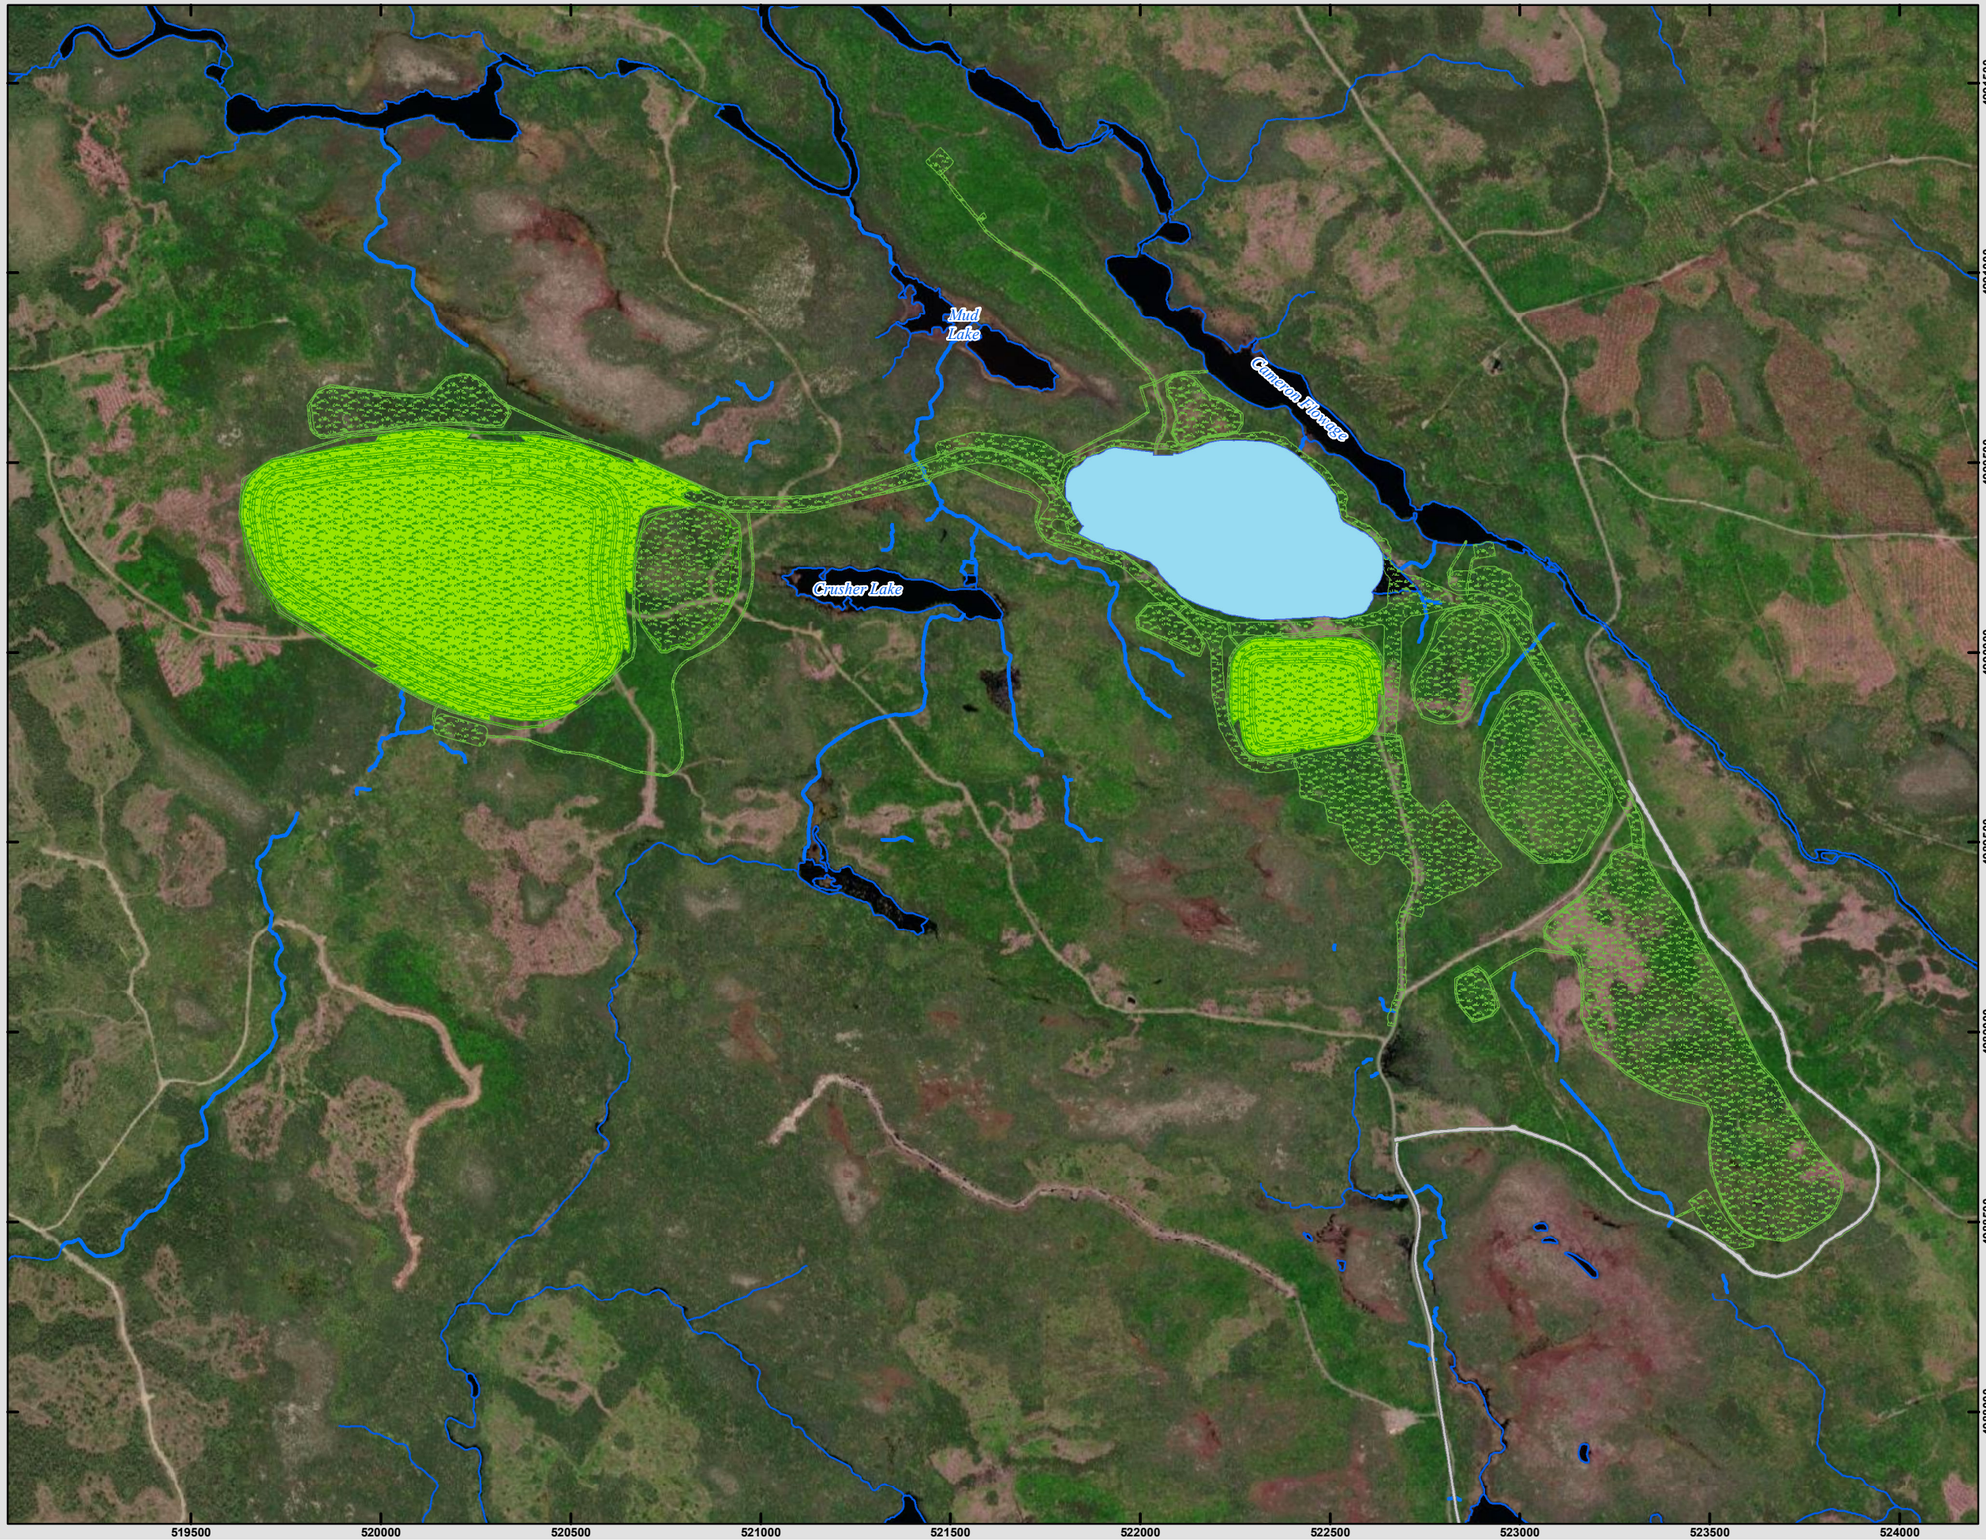
A draft Reclamation and Closure Plan has been developed for the Beaver Dam Mine Project and is provided in Appendix P.2. Figures 2.9-4 and 2.9-5 show closure landforms during active and post-closure.

2.9.3.1.2 Final Land Use

The goal of reclamation is to return the physical, chemical, and biological qualities of the land and water regimes disturbed by the Project to a state that is safe, stable, and compatible with the surrounding landscape and final land use.

The final land use of the Crown lands will require the landowner's (Nova Scotia Crown Lands) approval and the acceptance by Nova Scotia Department of Lands and Forestry (NSLF), Nova Scotia Environment and Climate Change (NSECC) and the Nova Scotia Department of Energy and Mines (NSDEM).

Specific objectives, criteria, planned reclamation activities and performance monitoring to achieve the closure goals are also outlined (Section 2.9.3.1).



2.9.3.1.3 Engagement

Initial land use activities identified by stakeholders for the post-mining landscape included outdoor recreation, commercial forestry and traditional land uses (AMNS 2021). Specific engagement is summarized below.

Continued engagement with the public and traditional land users regarding the mine's operational and closure planning will be undertaken through a combination of groups, as described in the Beaver Dam Mine Engagement Plan (AMNS 2021), including but not limited to:

- Millbrook First Nations;
- Mi'kmaq of Nova Scotia;
- Community Liaison Committee (CLC); and
- Reclamation and Closure working group that is anticipated to include representatives from members of the public, ATV association and other stakeholder groups.

It is anticipated, based on the results of this ongoing engagement, that the final land use concepts during post-closure will continue to evolve. It should be noted that future land use will need to comply with some restrictions related to minimizing disturbance and maintaining the structural, chemical and biological integrity of some of the closure measures. A brief description of the current closure vision for each major mine component is included in Table 2.9-3.

Table 2.9-3: Overview of Preliminary Closure Objectives/Criteria

Mine Component	Closure Vision	Closure Objective	Closure Criteria	Primary Reclamation Activity	Post-Closure Inspection/Monitoring	Notable Uncertainty/ Research
Administration and Ancillary Areas	The Mill Site will have all buildings, equipment, and related items removed, and the area will be revegetated. The area will be safe for the public to use for potentially outdoor recreation (e.g., hiking, trails, etc.).	Physical Stability	Buildings and equipment removed. Soil capping and revegetation treatments demonstrate early succession has been successful. No signs of significant erosion or sloughing prior to revegetation cover establishment.	Buildings demolished and removed from site. Equipment and other infrastructure removed from site. Surfaces graded and seeding/planting to allow drainage and prevent erosion.	Periodic inspections by a professional engineer will be completed.	No major uncertainties.
		Chemical Stability	Confirmatory soil sampling and ESA (as required) have been completed and results accepted by NSE. Runoff water quality is suitable for discharge to surrounding area.	Removal of impacted soils (if required) as recommended by the confirmatory soil sampling program and/or ESA.	Confirmatory soil sampling and ESA (as required) have been completed. Surface water quality monitoring completed in adjacent watercourses.	
		Ecological and Land Use	Wildlife and the public can travel across the area safely.	Following building removal, area is graded, soil cover placed and revegetated.	Vegetation and soil monitoring will be completed.	
Open Pit and Spillway	The Open Pit will flood, and overflow will discharge to Cameron Flowage/Killag River via an engineered spillway. The shoreline will be designed with shallow grading at the predicted water level to allow safe egress for wildlife, and a shallow water zone that can provide riparian and wetland habitat. The existing mine ramp at the northeast shoreline will be maintained to allow safe access to the pit lake. (e.g., boat launch site). The presence of self- sustaining fish populations is not intended and will be limited. The riparian zone and shallow water may provide habitat for avifauna, amphibians, and other species.	Physical Stability	Final conditions of the open pit walls, overburden slopes and spillway (once constructed) are confirmed to be within approved design constraints by a professional engineer. No visual indications of significant deformation and degradation is observed during a final inspection by a professional engineer.	Annual geotechnical inspections will be completed during the mine's operation to manage pit wall stability prior to final closure. The overburden bench and barrier berm materials will be re-sloped.	Periodic inspections by a professional engineer will be completed.	No major uncertainties.
		Chemical Stability	Water quality in the Pit Lake demonstrates a stable and/or decreasing trend and meets approved criteria. Decant elevation is suitable for discharge to Cameron Flowage/Killag River.	Dewatering will cease at the end of mining and the pit will be allowed to flood, eventually discharging via spillway to Cameron Flowage/Killag River. No treatment of this water is expected to be required prior to discharge.	Pit water quality and water levels will be monitored during flooding, and after discharge to Cameron Flowage/Killag River via spillway.	Pit flooding timelines and the Pit Lake water quality are uncertain. These processes will be assessed as part of ongoing monitoring and updated predictions completed prior to closure and during flooding.
		Ecological and Land Use	Safe access and egress options are available where practical to the Pit Lake once flooding is complete. Shallow water zones (< 5 m deep) are created along the Pit Lake perimeter where practical.to provide options for ecosystem restoration design.	Retreat blasting and benching and waste rock deposition is completed to allow construction of a shallow water zone where practical along the Pit perimeter. Final Pit slopes and shoreline are approved by a professional engineer.	Periodic inspections by a professional engineer will be completed.	The post-closure aquatic habitat quality and quantity is uncertain. As predictions for post-closure pit lake water quality are refined, options for riparian and littoral zone habitat enhancement will be considered for various flora and fauna.
Waste Rock Storage Area	The WRSA will consist of benched outer slopes and be revegetated, likely resembling a grass/shrub land and/or open meadow condition.	Physical Stability	Inspection and monitoring results indicate structures are stable and performing as intended. Soil cover is stabilized by means of a sustainable vegetative cover. Acceptable rates of erosion are observed, soil/vegetation cover is not adversely affecting the surrounding environment.	Design and construction of the WRSA within the approved design. Geotechnical stability analysis to be updated as required as part of the detailed design. Detailed design is signed by a professional engineer. The WRSA will be re-sloped progressively during mining, the final lift will be completed at closure. A soil cover is placed and revegetated to reduce erosion concerns to acceptable levels. Detailed design includes surface grading and drainage structures that will prevent erosion.	Periodic inspections by a professional engineer and vegetation specialist will be completed.	Desktop studies are planned to complete numerical simulations for runoff on the existing WRSA shape and identify any areas of erosion concern during construction and closure. Revegetation trials will be completed to confirm effective methods for establishing a vegetated cover.
		Chemical Stability	Water quality of runoff and seepage discharging from WRSA to perimeter ditches and WC-4 demonstrates a stable and/or decreasing trend and meets approved criteria.	Deposition of waste rock will occur as designed. Construction of a revegetated soil cover, properly graded, will reduce infiltration rates and water-rock interactions.	Surface water and groundwater monitoring will be completed through operations and following final sloping and soil cover placement.	Water quantity and quality of the runoff and seepage discharge from the WRSA are uncertain. These processes will be assessed as part of ongoing monitoring and updated predictions prior to closure.
		Ecological and Land Use	Wildlife travel and forage, and public use for safe outdoor recreation activities (e.g., hiking) that can be conducted across the WRSA.	Construction of a revegetated soil cover at the WRSA surface.	Periodic inspections by a professional engineer and vegetation specialist will be completed.	No major uncertainties.

Table 2.9-3: Overview of Preliminary Closure Objectives/Criteria (continued)

Mine Component	Closure Vision	Closure Objective	Closure Criteria	Primary Reclamation Activity	Post-Closure Inspection/Monitoring	Notable Uncertainty/ Research
Site Wide Revegetation	The various disturbed areas will have a soil cover placed and be revegetated to promote a mix of habitats suitable for the post-mining landscape (e.g., grassland/open meadow, shrubland, forest). The composition of habitats may be unique relative to surrounding area due to the changed landforms. Native seed mix will be used suitable to the area will be applied. Potentially traditional shrub species will be considered. Vegetation Trials at Touquoy and Beaver Dam will inform revegetation efforts.	Physical Stability/ Land Use[a]	Soil cover and revegetation treatments demonstrate early succession has been successful. Soil cover quality does not pose an elevated risk to humans and wildlife compared to surrounding areas.	Salvaged material stockpiling and management during operations. Revegetation trial plots will be completed to assess practical post-mining ecosystems possible and determine effective treatment applications prior to final closure. A soil cover and seeding/planting treatments will be applied to all disturbed sites as designed in the Final Plan.	Vegetation, soil and biodiversity monitoring.	Revegetation studies and field trials will be completed to assess practical post-mining ecosystems at each of the mine areas. An ad hoc committee will be established to confirm final land uses and provide input into final closure

Notes: [a] Additional land uses may be identified through ongoing engagement efforts with the Millbrook First Nations, the Mi'kmaq of Nova Scotia, CLC and Reclamation and Closure Working Group. Final approval of land uses requires the approval of NS Crown Lands, and acceptance by NSECC, DEM, and NSL.

2.9.3.1.4 Administration and Ancillary Areas

The reclamation of the Administration and Ancillary Areas consists of removal of buildings and other infrastructure, grading and revegetation. The final layout is shown on Figure 2.7-3.

The buildings will be removed during the first year of reclamation and either demolished, sold or re-used at other sites. Fuel, reagents, hazardous materials, chemicals etc. will be removed from structures prior to demolishing or removed from site. The wood-frame structures will be dismantled, with reusable parts being salvaged for recycling or re-use. The steel-frame and fabric-covered structures can be dismantled and removed from site. Trailer/mobile office units will be hauled from site. Crushing infrastructure, if used, will be dismantled, and removed from site. Septic tanks will be removed from site and disposed of at an approved facility.

Concrete foundation and slabs will be broken up into pieces with a maximum size of 0.5 m, any protruding reinforcing steel removed, and provided with a minimum of 0.5 m of cover using overburden soils.

The Stormwater/Evaporation Retention Pond will be drained, backfilled with overburden material, and re vegetated.

Following the removal of buildings and burial of foundations, the Administration and Ancillary area will be covered in salvaged overburden and topsoil, graded tore-establish drainage thereby prevent pooling, and revegetated.

2.9.3.1.5 Petroleum and Hazardous Waste

Petroleum products and waste will be removed from site at closure. Unused fuel will be returned to the supplier or disposed through a recognized waste management company. The contents of all fuel tanks will be pumped out by the fuel distributor or a waste management contractor. The petroleum and propane tanks owned by the suppliers will be removed form site by the supplier at the time of reclamation.

Reagents and other chemicals used in the mining/milling process remaining on site will be returned to the supplier or disposed of offsite at an approved facility.

2.9.3.1.6 Non-Hazardous Waste

Non-hazardous waste such as domestic waste will be removed from site. There is no landfilling on site.

2.9.3.1.7 Explosive Storage

Explosives onsite will be managed by contractors and will be removed from site once no longer required. Infrastructure associated with explosive storage will be removed following removal of explosives.

2.9.3.1.8 Touquoy Site

The Touquoy Mine Site will be reclaimed under a separate plan developed for the Touquoy Project and already approved by regulatory agencies. As mentioned previously, the currently approved Reclamation Plan will be updated to reflect the above changes associated with processing Beaver Dam ore and re-submitted. Water treatment at discharge location into the Moose River from the pit, as required, will occur, and monitoring programs will be on-going.

Ultimately the land will be returned to conditions similar to its original state as a natural woodland and wetland habitat used for recreation and forestry. The existing conditions at the site have been previously described as being in a disturbed state in many areas and therefore improvements at the site will be realized through the reclamation activities proposed.

2.9.4 Post-closure Monitoring (Year 7 to 10+ Years)

GHD has completed a predictive water quality assessment and developed a mass balance model which shows that zinc and cobalt are the only likely exceeded parameters during the PC phase. However, the exceedances are not significantly higher than the discharge limit and a passive water treatment system could reduce the concentration of these elements below discharge criteria. In mine-related settings, passive treatment systems are often designed to neutralize acidity and remove metals in drainage waters. Such systems do not require continuous chemical inputs because they are sustained by naturally occurring chemical and biological processes. Anoxic limestone drains (ALDs) have been selected as the passive alternatives for addressing high concentrations of metals in impacted water during the PC phase.

In this treatment approach, impacted water will initially pass through a settling pond for the removal of suspended solids. Then, water will pass through a trench ALDs. ALDs generate alkalinity and increase the pH of the impacted water. By increasing the pH, metals such as zinc and cobalt will precipitate in their hydroxide forms. The ALDs will be followed by an aeration cascade, pond, or aerobic wetland that oxidizes and removes the precipitated metals. A settling pond will then provide adequate hydraulic retention time to let those formed metal hydroxides precipitate. This treatment system is proposed due to its passive nature and the fact that utilities are not required for implementation. The success of an ALD depends on site-specific conditions, primarily on low dissolved oxygen, and minimal ferric iron and aluminum concentrations in the drainage.

The operation and maintenance of this alternative is minimal as no labour or power is required. The primary maintenance would be replacing depleted limestone which is dependent on-site condition and water chemistry. In suitable conditions, limestone could work efficiently for several years.

2.9.4.1 Beaver Dam Mine

During decommissioning, the pit will be filled with water, creating a lake, with the re-establishment of a connection between the newly formed lake and Cameron Flowage. Figure 2.9-4 and 2.9-5 show landforms during active and post-closure.

GHD has completed a predictive water quality assessment and developed a mass balance model which shows that zinc and cobalt are the only likely exceeded parameters during the PC phase. However, the exceedances are not significantly higher than the discharge limit and a passive water treatment system could reduce the concentration of these elements below discharge criteria. In mine-related settings, passive treatment systems are often designed to neutralize acidity and remove metals in drainage waters. Such systems do not require continuous chemical inputs because they are sustained by naturally occurring chemical and biological processes. Anoxic limestone drains (ALDs) have been selected as the passive alternatives for addressing high concentrations of metals in impacted water during the PC phase.

In this treatment approach, impacted water will initially pass through a settling pond for the removal of suspended solids. Then, water will pass through a trench ALDs. ALDs generate alkalinity and increase the pH of the impacted water. By increasing the pH, metals such as zinc and cobalt will precipitate in their hydroxide forms. The ALDs will be followed by an aeration cascade, pond, or aerobic wetland that oxidizes and removes the precipitated metals. A settling pond will then provide adequate hydraulic retention time to let those formed metal hydroxides precipitate. This treatment system is proposed due to its passive nature and the fact that utilities are not required for implementation. The success of an ALD depends on site-specific conditions, primarily on low dissolved oxygen, and minimal ferric iron and aluminum concentrations in the drainage.

The operation and maintenance of this alternative is minimal as no labour or power is required. The primary maintenance would be replacing depleted limestone which is dependent on-site condition and water chemistry. In suitable conditions, limestone could work efficiently for several years.

Water treatment will continue as described above and in Appendix P.4 monitoring programs will be on-going until such time that discharge water quality meets appropriate confirmed criteria at the point of discharge. This post closure phase is estimated to be 10+ years in length and is subject to revision with expected refinements to model predictions.

2.9.4.2 Touquoy Mine

During decommissioning, the tailings will be covered with water and the pit will fill, creating a lake, with the re-establishment of a connection between the newly formed lake and Moose River. Water treatment will continue, as required, at this discharge location and monitoring programs will be on-going until such time that discharge water quality meets appropriate confirmed criteria at the point of discharge. This post closure phase is estimated to be 15 to 20 years in length and is subject to revision with expected refinements to model predictions.

During decommissioning, the tailings will be covered with water and the pit will fill, creating a lake, with the re-establishment of a connection between the newly formed lake and Moose River. Water treatment will continue, as required, at this discharge location and monitoring programs will be on-going until such time that discharge water quality meets appropriate confirmed criteria at the point of discharge. This post closure phase is estimated to be 15 to 20 years in length and is subject to revision with expected refinements to model predictions.

2.9.4.3 Reclamation Schedule

The estimated timeline for decommissioning reclamation for the Beaver Dam Mine Site is presented in Table 2.9-4.

Table 2.9-4: Beaver Dam Reclamation Schedule

Reclamation Activity	No. of Years	Start Date[(a)]	End Date
Construction	1	2022	2023
Operations	5	2023	2028
Active Closure	0.5	2028	2030
Post Closure (Monitoring)	10+	2029	2032+

(a) Schedule is preliminary based on permitting and current model predictions that are subject to refinement.

2.9.5 Greenhouse Gas Emissions

A significant adverse environmental effect for Greenhouse Gases (GHG) has not been predicted for the Project for the following reasons, with consideration of the ecological and social context of the LAA surrounding the Project:

- **During Construction:** GHG will be elevated above baseline but not a significant contributor with a low magnitude (above 1% NS 2018 levels) that will be intermittent and short-term in duration and reversible.
- **During Operations:** GHG will be elevated above baseline during this period but not a significant contributor with a low magnitude (i.e., combined 21.69 kt CO_2e 21.69 kt CO_2e - approximately 0.128% above NS 2018 levels) that will be continuous but mid-term in duration and reversible.

- **During Active closure:** GHG will be elevated above baseline but expected to be negligible in magnitude (i.e., less that 0.1% above NS 2018 Levels) intermittent to allow for earthworks and reclamation activities and medium-term duration (i.e., 2 years in duration) and reversible.

Mitigations presented in Section 6.4 (Greenhouse Gases), Table 6.4-8 will be established to reduce the impact to GHGs from Project activities.

2.10 Alternative Means of Carrying out the Project

In accordance with Section 19(1)(g) of CEAA 2012, environmental assessments for designated projects must consider alternative means of carrying out the Project that are technically and economically feasible, as well as the environmental effects of any such alternatives.

The process for consideration of alternative means is outlined in the CEAA Operational Policy Statement entitled "*Addressing "Purpose of" and "Alternative Means" under the Canadian Environmental Assessment Act, 2012*" and includes the following steps:

- Step 1 - identify technically and economically feasible alternative means.
- Step 2 - list their potential effects on valued components.
- Step 3 - select the approach for the analysis of alternative means.
- Step 4 - assess the environmental effects of alternative means.

The evaluated alternative means of carrying out the Project are discussed following identification of alternative means.

2.10.1 Identification of Alternative Means

Alternative means of carrying out the Project are defined as means of similar technical character or methods that are functionally the same. Alternative means differ from alternatives in that they represent the various technical and economically-feasible ways that a project can be carried out, and which are within AMNS's scope and control.

As a minimum, the EIS Guidelines require AMNS to conduct an alternative means analysis for the following Project components:

- mine type;
- ore extraction methods;
- ore processing methods;
- ore processing locations;
- ore transportation;
- energy source;
- project component locations;
- water supply and management; and
- mine waste management facilities.

A qualitative approach primarily utilizing the professional knowledge and judgement of the Consultant Contributors has been employed for the assessment of alternative means in Section 1 (Introduction) of this EIS.

2.10.2 Mine Type

The potential alternatives to mining the Beaver Dam ore are through open pit (ramp access) and underground (shaft access) methods.

2.10.2.1.1 Open Pit Mining

Open pit mining requires the removal of overburden (topsoil, till) and non-ore bearing waste rock, followed by the stepped development of concentric levels into the deposit with an inclined roadway connecting subsequent levels. Open pit mining methods are best suited to:

- shallow ore deposits at or near surface that are covered by shallow overburden;
- large deposits with a uniformly distributed ore body or scattered randomly distrusted pockets; and
- high tonnage, low grade deposits which are not economical using underground mining methods.

2.10.2.1.2 Underground Mining

Underground mining typically requires the construction of a vertical, underground shaft from surface to a targeted depth into the ore body. Horizontal tunnels are then driven from the shaft at strategic intervals to access the ore body. Underground mining methods are best suited for:

- smaller ore bodies which are higher in grade; and
- disseminated ore bodies that easily traceable underground.

2.10.2.1.3 VCs Potentially Affected

The environmental effects of underground mining would be similar to those of open pit mining at the Beaver Dam Mine Site with the need for the infrastructure noted for the surface operation with a smaller disturbed footprint but likely a longer duration for ore extraction and overall project activities.

2.10.2.1.4 Preferred Approach

In this particular instance the gold at the Beaver Dam Mine Site is relatively uniformly distributed, and at relatively low grades, throughout the local rock mass to the extent that large scale, high volume throughput from an open pit is commercially viable. Concentrations of gold of sufficient grade, continuity or predictability in quartz veins, or other specific sites at the Beaver Dam Mine Site to support a commercially viable underground operation have not been identified through exploration and feasibility studies completed to date. An underground mine configuration for the Beaver Dam gold deposit is not currently a viable option.

Mining can theoretically be undertaken by either underground or open pit methods, but underground mining as a primary extraction method does not make practical or economic sense in this situation. In this particular case, the resource is near surface. The proximity to surface and lower grade make it amenable to open pit methods. A continuation of the surface mining into an underground operation may be viable depending on the final depth of the deposit but this is currently not under consideration and would not be economic unless there was a dramatic increase in gold price.

2.10.3 Ore Extraction Methods

2.10.3.1.1 Drilling and Blasting

Drilling and blasting is proposed to extract ore at the Beaver Dam Mine Site. Drilling and blasting is generally accepted as the most efficient method of breaking large volumes of rock. Drilling and blasting will generate noise; however, the noise from drilling would be significantly less than that generated by rock breaking. Blasting will generate short duration noise less frequently.

2.10.3.1.2 Rock Breaking (Ripping)

Rock breaking, or ripping, involves the use of heavy equipment that breaks the rock by inserting hardened metal teeth or prongs into fractures or planes of weak within the rock. Rock breaking creates continuous significant noise. Due to the extremely hard nature of the ore in the vicinity of the Beaver Dam Mine Site, rock breaking is not considered to be economically, technically, or environmentally feasible.

2.10.3.1.3 VCs Potentially Affected

The atmospheric environment is the key VC that would be affected by both drilling and blasting, and rock breaking (ripping); however, ripping would create significantly more noise over a continuous time period whereas drilling and blasting creates noise at lower levels and blasting occurs less frequently.

2.10.3.1.4 Preferred Approach

Drilling and blasting is the preferred approach for ore extraction from the Beaver Dam Mine Site. Alternative methods of extracting ore, such as rock breaking (ripping), are not technically or economically feasible due to the extremely hard nature of the ore in the vicinity of the mine site. There are no feasible alternatives to ore extraction at the Beaver Dam Mine Site.

2.10.4 Ore Processing Methods

2.10.4.1.1 Gravity/CIL Processing

The gravity/CIL processing methodology described in Section 2.9.2.3 of this EIS represents the most conventional processing option. It is the preferred processing option in Canada and is used worldwide in almost all major gold mining/processing operations. Two independent experienced consultant gold metallurgists have determined that gravity/CIL processing is extremely well suited to this particular ore in that gold recoveries are very high (about 95%) resulting in maximum use of the resource, and the cyanide destruction process is highly efficient (Ausenco 2015). Furthermore, gold ore is produced at the Touquoy facility, with minimal off-site value-adding.

2.10.4.1.2 Gravity/Flotation

Regardless of the above, a second processing option, gravity/flotation with either intense cyanidation or smelting of the flotation concentrate, has been explored. Gravity/flotation recoveries are also very high (about 95%), with the flotation concentrate comprising 4 to 5% of the total throughput. On the basis of expected daily throughput, about 200 tonnes of concentrate would be produced per day. The gold in the flotation concentrate may be recovered either by high intensity cyanidation or by off-site smelting.

High intensity cyanidation of the float concentrate will require at least the same quantity of sodium cyanide as conventional CIL (since the same amount of gold is available for dissolution) or possibly more. This multi-stage process is unorthodox, inherently more complex than conventional CIL processing and commercially unattractive with no perceived advantage.

This multi-stage process could potentially be undertaken off site with the concentrate transported to an existing CIL plant for contract treatment, the closest plants being in Quebec and Ontario. Enquiries have been made to eleven such operations with no availability offered. Indicative costs, including freight, determined from this exercise show this option to be commercially unattractive, with the added disadvantage of substantial off-site value-adding and reduced benefits to Nova Scotia.

The flotation concentrate could also potentially be transported elsewhere for smelting to recover the gold. Indicative costs for freight and contract treatment of the concentrate at Falconbridge's Horne smelter in Rouyn-Noranda have been obtained and these confirm this option to be commercially unviable, and again with substantial resultant off-site value-adding and reduced benefits to Nova Scotia.

2.10.4.1.3 VCs Potentially Affected

Environmental effects are generally similar in both alternatives. The same quantity of sodium cyanide is required in both alternatives, if not more for gravity/flotation. Smelting required during the flotation process would require transport to an off-site facility, thereby generating additional GHG emissions. The key VCs affected by the use of gravity/flotation processing would include the atmospheric environment.

2.10.4.1.4 Preferred Approach

Having carefully examined the above processing options AMNS has selected conventional gravity/CIL as its preferred processing methodology. The required equipment is in place at the Touquoy Mine Site prior to the Beaver Dam operation beginning thus reducing infrastructure needs at the Beaver Dam Mine Site.

2.10.5 Ore Processing Locations

2.10.5.1.1 Touquoy Mine Site

No new processing or tailings facility is planned for this site - ore will be trucked to Touquoy for milling and tailings will be deposited in the exhausted Touquoy pit. The Touquoy plant is designed to treat Beaver Dam ore with no modifications other than an increase in the total weight of grinding balls in the ball mill to accommodate the slightly harder ore from the Beaver Dam pit.

2.10.5.1.2 Beaver Dam Mine Site

If the economics of the Project change significantly such that this Project could be developed without Touquoy then a mill and a tailings storage plan for the Beaver Dam Mine Site would be required, which would involve a significant increase in the Project footprint. Alternatives to processing ore at the Touquoy Mine Site are cost prohibitive and environmentally inferior.

2.10.5.1.3 VCs Potentially Affected

Construction of an additional processing and tailings management facility would affect all VCs being considered in this EIS.

2.10.5.1.4 Preferred Approach

The preferred approach for ore processing locations is to utilize the Touquoy Mine Site for the milling of Beaver Dam ore, and depositing tailings in the exhausted Touquoy pit.

2.10.6 Ore Transportation

Off-site processing at the Touquoy Mine Site involves the transport of material via local roadways. This haul is an increase in the cost of production and will generate additional greenhouse gases from the highway truck fleet as compared to on-site processing. This will be at least partially offset by the significant environmental benefits of processing Beaver Dam ore at the Touquoy mill and the storage of tailings in the exhausted Touquoy pit. No other gold processing facilities exist within the economic trucking limit that can handle the planned volume of material. In addition, no new construction or expansion of the approved processing or tailings storage facilities at Touquoy to process Beaver Dam ore is required.

2.10.6.1.1 Alterative Haul Road Routes

Alternative Haul Road routes were considered to transport the Beaver Dam ore to Touquoy for processing. The original Haul Road route considered included approximately 5.1 km of travel along Hwy 224 (Alternate Section 2; Figure 2.3-3) and 3.9 km along Moose River Cross Road (Alternate Section 3A). The current Haul Road configuration includes a more direct route on the Moose River Cross Road. Specifically, the travel along Hwy 224 itself has been replaced with a direct route of 4.0 km of new construction which allows direct crossing of Hwy 224 (Section 3B; Figure 2.3-3). This increases the travel along private logging roads and eliminates the travel along Hwy 224 completely as only a direct crossing is required. The total Haul Road is then reduced by 5 km (from 35.1 km to 30.1 km).

Included as part of this revised EIS is a Preferred Alternative Haul Road section of road, approximately 5.75 km in length, which if adopted would avoid residences and private land. This alternative section of road would replace approximately 4.3 km of the proposed Mooseland Cross Road (Section 4B) and approximately 4.0 km of Mooseland Road (Section 5A). The total haul distance would be reduced from 30.1 km to 27.5 km. This Preferred Alternative Haul Road has been proposed as a secondary option in order to address potential landowners and residential locations with the proposed updated alignment and is fully evaluated in this EIS.

It is intended to use sized waste rock from the local borrow pits or Beaver Dam waste rock as the surge rock base material to reduce the cost and disturbance of the road upgrading and new construction activity.

2.10.6.1.2 VCs Potentially Affected

The key VCs affected by the Alternative Haul Road locations are the atmospheric environment, Indigenous Peoples populations, and socio-economic conditions due to additional noise and dust being generated along Hwy 224, near Beaver Lake IR 17. Air, noise and light considerations are also evaluated for the Preferred Alternative Haul Road, as this route is farther away from residences and private land considerations.

2.10.6.1.3 Preferred Approach

The Haul Road as currently planned is the preferred approach. The current Haul Road route for the Project reduces the total length and eliminates travel along Hwy 224, including the passing of Beaver Lake IR 17 which is a satellite community of Millbrook First Nation.

2.10.7 Energy Source

2.10.7.1.1 Diesel-Powered Generators

Two (duty and standby) self-contained, skid mounted, 500-kilowatt (kW) diesel powered generators will provide 600 volt (V) electrical power to all Beaver Dam surface consumers via 60 hertz (HZ), three phase, four wire overhead power lines. The generator fuel tank will receive diesel fuel from the dedicated refueling truck and has a one-day capacity at maximum power demand.

2.10.7.1.2 Alternative Energy Sources

The power demand required for the Beaver Dam Mine Site is insufficient to justify construction of a permanent grid tie-in to the existing electrical distribution lines.

Renewable energy sources are considered technically feasible but would also not be economically feasible or practicable due to the short duration of the Project.

2.10.7.1.3 VCs Potentially Affected

The key VCs affected by the use of diesel-powered generators on the mine site include the atmospheric environment, surface water, wetlands, fish and fish habitat, and habitat and flora.

The key VCs affected by a permanent grid tie-in include the atmospheric environment, wetlands, habitat and flora, and terrestrial fauna due to disturbances caused by constructing a right-of-way for the power lines.

The environmental effects associated with a renewable energy source would depend on the renewable energy technology used; however, air emissions would likely be reduced.

2.10.7.1.4 Preferred Approach

The preferred approach based on economic and environmental feasibility is to provide electrical power to the Beaver Dam mine site through the use of diesel-powered generators.

2.10.8 Project Component Locations

There are no alternatives for the positioning of the open pit - the gold deposit is fixed and the open pit has been designed to envelope the existing settling pond (wetland 59). The settling pond that had been previously established on the Beaver Dam Mine Site will largely become part of the proposed open pit

and thereby reclaimed. The Project components have also been placed to generally avoid heritage resources that have been identified during field investigations.

The waste rock stockpiles have been re-positioned to be located down-gradient of nearby watercourses and waterbodies and removed from the Boreal Felt Lichen Critical Function Zone. The site configuration, including other Project components, has been specifically designed to avoid interference with aquatic habitat, and hence it is the preferred option to minimize environmental effects. Wetlands were avoided to the greatest extent possible for the placement of site infrastructure and the use of existing roads has been maximized in site layout planning as well.

2.10.8.1.1 VCs Potentially Affected

The key VCs affected by altering the Project component locations include wetlands, surface water, fish and fish habitat, and physical and cultural heritage resources.

2.10.8.1.2 Preferred Approach

The preferred approach is to maintain project component locations as shown on Figure 2.3-2. This limits the impacts to watercourses, avoids wetlands to the greatest extent possible, and avoids the Critical Function Zone for the Boreal Felt Lichen.

2.10.9 Water Supply and Management

2.10.9.1.1 On-Site Water Supply and Management

Water use on the Beaver Dam Mine Site will be limited to water required for dust control, the vehicle wash down facility, fire protection, and domestic water usage. Sources of raw water include water collected during mine dewatering, surface water runoff from waste rock piles and constructed areas and, if needed, raw water pumped from Cameron Flowage. Raw water drawn from Cameron Flowage, if needed, would be pumped by a single duty submersible water pump to a combination raw water and firewater reserve storage tank. Two (duty and standby) centrifugal pumps will supply various users including, but not limited to, the vehicle wash down facility and the de-dusting crusher area locations. Potable water will be delivered via specialized truck to the site for use in facilities at the crusher area for personnel. It is anticipated that one drilled domestic water well will be required to provide water for sanitary usage as domestic wells in this area generally yield 5 to 10 L/min and the demand is estimated at less than 5 L/min. Dust control will occur as required and will consist of wet suppression controls on unpaved surfaces using water, or chemical dust suppressants, as required.

2.10.9.1.2 Off-Site Water Supply

Alternatives for water supply, such as transporting all required water to the Beaver Dam Mine Site were considered but the availability of adequate water for site operations (for site staff only and dust control) is a more reasonable approach, is economically sound and is technically feasible. One domestic water well will be required based on the demand anticipated and regional water resources studies confirm the low amount (less than 10 litres per minute) is easily available.

2.10.9.1.3 Surface Water Management

Surface water run-off from the Beaver Dam Mine Site crusher pad will flow by gravity, with the aid of berms and channels, to a collection pond located to the south of the crusher pad. A culvert located beneath the mine entrance road will facilitate decant overflow from the collection pond to a discharge channel that will run down gradient to the south and ultimately discharges into wetland area (Wetland 64) located to the south of the Beaver Dam Mine Site. Surface water run-off from the eastern and western waste rock stockpiles, low grade ore stockpiles, Beaver Dam Mine Site roads, and some natural area will flow by gravity, with the aid of berms and channels, to the north settling pond, located west of the pit. This settling pond will also receive water from the pit dewatering program. Overflow from the north settling pond is directed to the Killag River outfall (Cameron Flowage). On-site control of water with batch discharges when water quality meets applicable standards is typical for this type of operation and the most technically and economically feasible.

Runoff from the till stockpiles located to the southeast of the open pit and east of the mine facilities area will be captured with the aid of channels around the stockpile perimeter and diverted north to Cameron Flowage by gravity via separate water discharge

structures and engineered channels. At this time, it is not anticipated that a collection pond would be required, however such a pond can be constructed should settling of solids prior to discharge be required.

No alternatives for water supply management were considered to be technically or environmentally feasible. Cameron Flowage is a valuable local and regional watercourse and direct discharge without settling and back-up ability for other treatment is not acceptable to AMNS.

2.10.9.1.4 VCs Potentially Affected

The key VCs affected by the transportation of potable water to the Beaver Dam Mine Site include the atmospheric environment. If all required water were transported to the Project, a greater volume of emissions would be generated during the transport of water.

2.10.9.1.5 Preferred Approach

On-site water collected from surface water run-off and pit dewatering will be used for dust control, the vehicle wash down, and fire protection. Domestic water requirements will be fulfilled by potable water delivery, and an on-site drilled well for sanitary usage.

2.10.10 Mine Waste Management Facilities

2.10.10.1 Waste Rock Storage

2.10.10.1.1 Stockpile

The two waste rock stockpiles will have capacities of 20.7 Mt and 14.8 Mt of material and final peak grade elevations of 210 masl and 190 masl respectively. Waste rock will be stored in multiple lifts of 15 m with each lift having an active slope of 1.5:1. This approach will minimize the amount of exposed waste rock at any given time and reduce the potential for erosion and acid rock drainage (ARD). A safety berm will separate each lift resulting in overall slope angle of 2.6:1. A 20 m wide dual lane Haul Road running up the side of each stockpile will provide progressive access to all lifts. At reclamation, the waste rock stockpile will be reclaimed with topsoil and growing medium to a depth matching the native surroundings. After final shaping and vegetating, the piles will mirror current local topography and landscapes.

2.10.10.1.2 Backfill

Backfilling of the open pit with waste rock would eliminate the permanent storage stockpile as described above. However, the same stockpile would still be required to be constructed over the life of the mine and then re-handled to place back in the pit at closure and the footprint would require reclamation. Such re- handling would result in additional emissions due to equipment use and would be cost prohibitive for the overall Project viability. As well, backfilling with broken rock would overfill the open pit due to the swell factor, requiring reclamation of the open pit area as well as the remaining excess waste rock.

2.10.10.1.3 VCs Potentially Affected

Environmental effects are generally similar in both alternatives as the stockpile is required in both cases and either the stockpile itself or the footprint would be reclaimed at closure. Additional atmospheric effects are associated with the backfill alternative due to the extensive equipment use requirements associated with re-handling the waste rock.

2.10.10.1.4 Preferred Approach

The preferred approach for mine waste rock management includes the on-site management of using the waste rock stockpile.

2.10.10.2 Tailings Storage

2.10.10.2.1 Touquoy Open Pit

As processing of Beaver Dam ore at the Touquoy Mine Site is not scheduled to commence until mining at Touquoy is complete, the mined out open pit at Touquoy will be available for storage of tailings. The mined out Touquoy open pit will provide a very stable natural containment structure for tailings and will have the capacity to store all projected Beaver Dam tailings. Hydrogeological assessments of the Touquoy open pit indicate that it will eventually fill with water from rainfall, runoff and groundwater infiltration creating an in-pit lake which is in accordance with the approved closure plan. Tailings storage in the pit will therefore be sub-aqueous and will require no additional disturbance.

2.10.10.2.2 Touquoy TMF

The existing TMF at Touquoy was designed to accommodate projected tailings volumes generated from processing of Touquoy ore and does not have the capacity to store all the projected Beaver Dam tailings under the approved design. The tailings dams were constructed using a downstream construction technique. As a result, expansion of the Touquoy TMF to accommodate Beaver Dam tailings would require continued raising of the dams by downstream construction. This would result in substantially higher dams and a much larger footprint. Such expansion would also impact other existing infrastructure such as the polishing pond which would have to be decommissioned and re-established further away. For these reasons, this alternative is not considered to be favorable economically, technically, or environmentally.

2.10.10.2.3 Beaver Dam TMF

There is no requirement for tailings management at the Beaver Dam Mine Site as all mineral processing is proposed be done at the Touquoy Mine Site as per Section 2.7.2. It is not considered economically or environmentally feasible for tailings to be transported back to the Beaver Dam Mine Site following processing at Touquoy.

Processing of ore at the Beaver Dam Mine Site would require construction of a new gravity/CIL cyanide processing facility as described in Section 2.9.2.3, duplicating the existing facility at the Touquoy Mine Site. As well, storage of tailings on-site at the Beaver Dam Mine Site would require construction of a new Tailings Management Facility along with all of the associated raw water requirements and water management structures, including pumphouse, raw water line, tailings line, reclaim water line and water storage tanks. All of this additional infrastructure would substantially increase the disturbance footprint at the Beaver Dam Mine Site and potential environmental effects. For these reasons, this alternative is not considered to be favorable economically, technically, or environmentally.

2.10.10.2.4 VCs Potentially Affected

The key VCs potentially affected by the use of the exhausted Touquoy open pit for tailings storage are surface water and groundwater quality as described in more detail in Sections 6.7 (Surface Water Quantity and Quality) and 6.6 (Groundwater Quality and Quantity). It should be noted however that an existing monitoring program is already in place under the Touquoy Industrial Approval and that groundwater and surface water quality and quantity will continue to be monitored over the life of the Touquoy Mine Site as part of existing approvals for approved life span of the facility and for the proposed extended life of the Touquoy Mine

Site associated with processing of Beaver Dam ore. As well, there will be over 7 years of data available prior to the Beaver Dam tailings being introduced to the exhausted Touquoy pit, which will enhance water quality modeling and predictions.

The key VCs potentially affected by the expansion and use of the Touquoy TMF are the same as for using the open pit, surface and groundwater quality, plus additional VCs associated with the increased disturbance area.

Construction of an additional processing and tailings management facility at the Beaver Dam Mine Site would affect all VCs being considered in this EIS.

2.10.10.2.5 Preferred Approach

The preferred approach for tailings management is to manage Beaver Dam tailings at the Touquoy Mine Site by storage in the mined out open pit.

2.10.11 The Preferred Approach

Based on the consideration of technical and economic feasibility, environmental effects, and socioeconomic effects, the preferred approach for the Project consists of:

- an open pit gold mine located at the Beaver Dam Mine Site;
- ore extraction methods that employ drilling and blasting;
- ore processing methods that employ gravity/CIL processing methodology which represents the most conventional processing option and is the preferred processing option in Canada;
- processing Beaver Dam ore at the Touquoy Mine Site once reserves at Touquoy have been exhausted;
- transportation of ore from the Beaver Dam Mine Site to the Touquoy Mine Site for processing via a 30.1 km Haul Road, which will include upgrades to approximately 15.4 km of existing road and approximately 4.0 km of new road construction through a greenfield environment;
- the use of two (duty and standby) self-contained, skid mounted, 500-kilowatt (kW) diesel powered generators to provide) electrical power to the Beaver Dam Mine Site;
- Project component locations as shown on Figure 2.3-2;
- on-site water supply and management, with delivery of potable water;
- waste rock management stockpiles located on the Beaver Dam Mine Site; and
- tailings management by storage of tailings from Beaver Dam ore processed at the Touquoy facility in the mined out Touquoy open pit.

A summary of the review of alternative means to carry out the Project is presented in Table 2.10-1 for each Project component of activity. This provides justification on the preferred approach for the Project relative to technical feasibility, economic feasibility and environmental and social effects. The VCs considered are noted as applicable under the environmental and social effects.

Table 2.10-1: Summary of Alternative Means of Undertaking the Project

Project Component or Activity	Alternative Means	Technical Feasibility	Economic Feasibility	Environmental Effects	Preferred Option
Mine Type	Surface Mine	Technically Feasible	Economically Feasible	Environmental effects are associated with the surface mine construction and operation; however, no significant residual environmental effects are anticipated for the Beaver Dam Mine Site.	Yes
	Underground Mine	Not Technically Feasible considering the configuration of the gold deposit.	Not Economically Feasible	Not assessed	No
Ore Extraction Methods	Blasting	Technically Feasible	Economically Feasible	Environmental effects include noise and dust impacts; however, blasting will be conducted in shorter duration and will be controlled.	Yes
	Rock Breaking	Not Technically Feasible considering the hardness of the ore deposit	Not Economically Feasible based on the hardness of the ore deposit	Environmental effects include continual noise and dust impacts.	No
Ore Processing Methods	Gravity/CIL	Technically Feasible considering it is the preferred processing option in Canada and is used worldwide in almost all major gold mining/processing operations. Well suited to this particular ore	Economically Feasible	Environmental effects are generally similar in both alternatives: the same quantity of sodium cyanide is required in both alternatives, if not more for gravity/flotation.	Yes
	Gravity/Flotation	Not Technically Feasible based on an unorthodox complex multi-stage process for cyanidation or off-site smelting.	Not Economically Feasible as it requires a complex multi-stage process or additional off-site smelting.	Environmental effects are generally similar in both alternatives: the same quantity of sodium cyanide is required in both alternatives, if not more for gravity/flotation. Smelting would require transport to an off-site facility.	No

Table 2.10-1: Summary of Alternative Means of Undertaking the Project (continued)

Project Component or Activity	Alternative Means	Technical Feasibility	Economic Feasibility	Environmental Effects	Preferred Option
Ore Processing Locations	Touquoy	Technically Feasible as the Touquoy facility is already designed to treat Beaver Dam ore with minimal modifications.	Economically Feasible as the infrastructure for processing Beaver Dam ore is already in place. Haul Road upgrades will need to be completed but are off-set by the benefits or using the existing processing facility.	Environmental effects for the Touquoy facility have previously been identified. Processing Beaver Dam ore at the Touquoy facility will result in an additional four years of processing beyond the current lifespan of the Touquoy Project and will result in an increase in the cost of production and greenhouse gas emissions due to transporting ore to Touquoy.	Yes
	Beaver Dam	Technically Feasible	Not Economically Feasible as the infrastructure for processing Beaver Dam ore is already in place at the Touquoy facility.	Environmental effects of processing ore at the Beaver Dam Mine Site are greater in this scenario as a second processing facility and tailings management facility would be required to be constructed and operated. Construction of an additional processing and tailings management facility would affect all VCs being considered in this EIS.	No
Ore Transportation	Haul Road avoiding Hwy 224 via new construction	Technically Feasible	Economically Feasible	Environmental effects are similar for both alternatives. Construction of 4.0 km of new Haul Road will cause additional environmental effects than simply upgrading the Haul Road; however, the new road eliminates travel along Hwy 224 and the passing of Beaver Lake IR 17, which reduces potential effects on those residents. The Preferred Alternative Haul Road reduces interaction with residence and private landowners.	Yes
	Haul Road along Hwy 224	Technically Feasible	Economically Feasible	Environmental effects are similar for both alternatives. Travel along Hwy 224 through the Beaver Lake IR will cause noise and dust issues for residents due to the increased truck traffic.	No
Energy Source	On-site Generators	Technically Feasible	Economically Feasible	Environmental effects will include emissions associated with two diesel fuel-powered generators.	Yes
	Provincial Grid Tie-in	Technically Feasible	Not Economically Feasible as the current power demand is insufficient to justify the construction of a permanent grid tie-in.	Environmental effects would include construction of a right- of-way for electrical lines, including noise and emissions generated during construction and habitat and vegetation loss in the right-of-way.	No
	Renewable Energy Sources	Technically Feasible	Not Economically Feasible due to short duration of Project	Environmental effects would depend on renewable energy technology used; however, air emissions would be reduced	No

Table 2.10-1: Summary of Alternative Means of Undertaking the Project (continued)

Project Component or Activity	Alternative Means	Technical Feasibility	Economic Feasibility	Environmental Effects	Preferred Option
Project Component Locations	As shown in Figure 2.3-2	Technically Feasible	Economically Feasible	Environmental effects will include loss of habitat; however, this configuration avoids interference with aquatic habitats and Critical Function Zone for Boreal Felt Lichen.	Yes
	Alternative Locations	Technically Feasible	Not Economically Feasible as this would require the reconfiguration of the components	Environmental effects would be similar in both scenarios; however, the alternative location of the waste rock stockpile could interfere with nearby aquatic habitat and Boreal Felt Lichen. Project components have also been positioned to generally avoid identified heritage resources.	No
Water Supply and Management	On-site water supply and management, with delivery of potable water	Technically Feasible	Economically Feasible	Environmental effects will include emissions associated with the transport of potable water to the mine site.	Yes
	Alternative sources of water	Technically Feasible	Not Economically Feasible to transport all water requirements to the mine site.	Environmental effects would include a greater volume of emissions generated during the transport of all water to the mine site.	No
	Waste rock stockpiles	Technically Feasible	Economically Feasible	Stockpiles to be rehabilitated at closure	Yes
Mine Waste Management Facilities	Waste rock backfill in open pit	Technically Feasible	Not Economically Feasible	Stockpile disturbed area footprint backfilled open pit and excess waste rock require reclamation after backfill	No
	Beaver Dam tailings stored in Touquoy open pit	Technically Feasible	Economically Feasible	Potential environmental effects on surface and groundwater	Yes
	Beaver Dam tailings stored in expanded Touquoy TMF	Technically Feasible	Not Economically Feasible	Potential environmental effects on surface and groundwater; Increased disturbed footprint area; higher TMF dams increasing failure risk.	No
	Beaver Dam tailings stored in new TMF at Beaver Dam Mine site	Technically Feasible	Not Economically Feasible to transport tailings back to Beaver Dam; Not Economically Feasible to construct new processing facility at Beaver Dam; Not Economically Feasible to construct new TMF at Beaver Dam	Potential effects on all VCs. Substantially larger disturbed area at Beaver Dam and potential environmental effects associated with significant additional infrastructure development.	No

2.11 Conclusions

The environmental benefits of the Project to Nova Scotia are numerous to correct past practices with respect to the environment. Given the area has been subjected to extensive exploration, mining, and logging activity over several decades, baseline conditions show obvious effects from these historic activities (Section 6.5 Geology, Soil, and Sediment Quality). The current condition at the Beaver Dam Mine Site is disturbed, and fragmented habitat based on significant timber harvesting, associated road building and yarding areas and historic exploration/mining activity. The PA contains a diversity of habitat types and landscape features but has experienced a considerable amount of disturbance and habitat fragmentation as a result of these activities. The level of disturbance within the Beaver Dam mine site disproportionately affects uplands, over wetlands. The level of new fragmentation associated with the Project is anticipated to be moderate, given the existing disturbance. Historic tailings and waste rock will be removed from the site and encapsulated in the Touquoy exhausted pit. Water will be treated during construction to remove metals associated with historic tailings.

The poor condition of the majority of existing Haul Road culvert crossings directly contributes to poor surface water quality and fish passage in watercourses and wetlands along the Beaver Dam Mines Road and the Moose River Cross Road (Figure 2.3-3) Upgrades to this existing Haul Road will include culvert replacements at over 20 locations and 3 new bridges, where determined to be necessary (Section 2.7.3 and Section 6.9 Fish and Fish Habitat). It is expected that correctly installed culverts will increase fish passage and positively affect fish habitat through improved surface water quality.

All environmental baseline investigations for the Project have added to the scientific understanding of the area and improved background data held by the province. Background data helps increase the knowledge base of its users and increases public ecological awareness and promotes conservation of natural ecosystems.

At closure, reclamation will occur at the Project Site and Touquoy Mine Site. The reclamation plan will be secured with a bond held by the Province of Nova Scotia to ensure there are sufficient funds to reclaim the site at any point during the Project. The plan for reclamation requires approval of the Nova Scotia Department of Lands and Forests.

KPMG International completed an Economic Impact Assessment of the Moose River Consolidated (MRC) Project to evaluate the economic benefits stemming from the Proponent's mining projects in Nova Scotia (KPMG 2015). This assessment considered the Touquoy and Beaver Dam Mine Projects together and found that socio-economic benefits will stem primarily from the construction and operation phases of the Project.

Construction activities will involve preparing the Project Site, setting up infrastructure and facilities, and purchasing mining processing equipment to enable the MRC Project to reach full production. Much of the spending associated with these activities will be incurred in Nova Scotia and Canada. As per the KPMG report, it was projected that construction costs will be approximately $146 million, with approximately $97.6 million, or 67%, being spent in Nova Scotia, and approximately $111.9 million, or 77%, being spent in Canada. As a result of this spending, it is anticipated that 391 full time equivalent jobs will be created in Nova Scotia per year during construction. For Canada as a whole, the construction phase will create 437 full time equivalent jobs per year. Tax revenues stemming from the construction phase are expected to be $4.1 million for the Government of Nova Scotia and $5.5 million for the Government of Canada. This is a conservative estimate as corporate income taxes paid by contractors and suppliers cannot be estimated.

Operational mining and processing activities will involve the deployment and operation of new mining production capacity. Similar to the construction phase, much of the spending associated with operation of the MRC Project will be incurred in Nova Scotia and Canada. As per the KPMG report, it was projected that annual operating costs will be approximately $52.3 million, with

approximately $38.1 million, or 73%, being spent in Nova Scotia, and approximately $39.4 million, or 75%, being spent in Canada. The costs include several spending components, the most important being:

- salaries and benefits for 27% of total annual operating costs;
- cyanide, lime, and reagents for 24% of total annual operating costs;
- diesel for 22% of total annual operating costs;
- wear parts and spare parts for 15% of total annual operating costs; and
- electricity (Touquoy only) for 7% of total annual operating costs.

As a result of this spending, it was anticipated in the KPMG report that 228 yearly and recurrent full-time equivalent jobs will be created in Nova Scotia during operation. For Canada as a whole, the operation phase will create 278 yearly and recurrent full-time equivalent jobs during operation. Tax revenues stemming from the operation phase are expected to be $10.2 million annually for the Government of Nova Scotia and $8.1 million annually for the Government of Canada. These represent conservative estimates as corporate income taxes paid by suppliers cannot be estimated.

The Province of Nova Scotia's unemployment rate is higher than the national average (8.8%>6.9%) and its gross domestic product (GDP) growth was the slowest of all Canadian provinces the last few years. In addition, the GDP per capita is the second lowest in Canada. The MRC Project would greatly benefit the Province of Nova Scotia due to substantial upfront investments and significant annual operation costs contributing to job creation and government tax revenue.

AMNS is committed to working with local communities and the Mi'kmaq of Nova Scotia to maximize socio-economic benefits as the Company developments its projects in the Province, including the Beaver Dam Mine Project.

3 PUBLIC ENGAGEMENT

3.1 Introduction

AMNS believes that engagement is a critical component of an Environmental Assessment (EA) and has dedicated significant efforts and resources to develop meaningful, two-way relationships with stakeholders and rightsholders. Engagement is important to resolve problems, create a shared understanding with local stakeholders and rightsholders, and build trust around projects that may be controversial. Engagement can also help communities and stakeholders seize and build upon opportunities that the mine project may present. Atlantic Mining NS Inc. (AMNS) is committed to working with stakeholders and rightsholders throughout the EA process and mine life.

This section outlines the public engagement activities, tools, and commitments related to the Beaver Dam Mine Project (the Project). The section establishes the objectives for community engagement, the specific tools used in the engagement strategy, the public engagement activities that have occurred to date, the concerns that have arisen resulting from engagement activities and any mitigation measures.

3.1.1 Summary of Public Engagement Before the Updates

AMNS began engagement specifically for the Project in 2015, which provided input into the identification of valued components, and identified key concerns for stakeholders and rightsholders. This engagement was summarized in the original 2017 Environmental Impact Statement (EIS) submission (AGC 2017).

In 2018, AMNS established a variety of engagement tools to improve stakeholder communication and engagement. These included a Community Liaison Committee (CLC; the mandate of the Touquoy Mine CLC was expanded to include Beaver Dam in 2018 [Appendix A.3]), community relations email and dedicated phone line, a community newsletter and a website. AMNS conducted engagements with stakeholder organizations that included the Nova Scotia Salmon Association (NSSA), the Sheet Harbour Chamber of Commerce, the Eastern Shore Forestry Watch Association (ESFWA).

3.1.2 Summary of Updates to Public Engagement

This update includes activities, initiatives and concerns that occurred after the submission of the Revised 2019 EIS (AMNS 2019) and in response to Round 2, Information Requests (IR2s). AMNS conducted a supplementary engagement program in 2020, which identified additional areas of concern for some members of the public not identified through the previous engagement activities described in Section 3.1.1 and provided updates on technical conclusions. This engagement included:

- Meeting and discussions with ATV and snowmobiling groups: ATV Association of Nova Scotia, Pleasant Valley Upper Musquodoboit (PUMA) ATV Club, Sheet Harbour ATV Snowmobile and ATV Club and the Lake Charlotte ATV Club. Engagements including initial meetings to identify concerns, a validation meeting where the input of the Clubs was reviewed, and various emails and calls to discuss potential bypass route options.
- Mooseland and Area Community Association meetings. There were three in-person meetings held with representatives of the Association, including a validation meeting where the input of MACA was reviewed for accuracy. There also has been regular email and phone communication.
- Rocky Brook Lake resident online meeting to discuss the Beaver Dam Mine Project, review proposed bypass roads and to identify recreational usage.

- Individual stakeholder meetings – Although AMNS attempted to hold a community meeting in Mooseland, this was not possible due to COVID-19 public health restrictions. AMNS went door to door within the community of Mooseland.

An up-to-date public engagement database is provided as Appendix A.4a.

AMNS recent discussions with Nova Scotia Salmon Association (NSSA) in 2019 and 2020 to engage their input on the proposed BDM Project Description and how best AMNS accommodate their ongoing important mitigation and research on the Killag River and adjacent watersheds. Recent engagements include a meeting on September 9, 2020 to provide an infrastructure update, introduce EEM monitoring and data collection. Notes where shared from this meeting and follow up phone call occurred on November 30, 2020, AMNS send a follow up letter on March 2, 2021 seeking clarification on the NSSA's Current and Future Programs (Appendix A.4b) , AMNS reached out to confirm our understanding of cumulative effects and potential interactions with NSSA existing and future plans in the area (Appendix A.4b). The NSSA communicated in December 2020 that they do not want to engagement with AMNS at this time. AMNS values a cooperative relationship with NSSA and look for opportunities where we can support their work and also share information and data. AMNS will continue to reach out to the NSSA regarding the Project.

AMNS has reached out to the Eastern Shore Forestry Watch Association (ESFWA) President Barb Markowitz to communicate that AMNS will address their IRs and are open to a follow-up meeting to discuss the Project. AMNS plans to reach out to ESFWA to review responses and answer follow-up questions.

AMNS prepared a draft Public Engagement Plan (Appendix A.6) in 2021 which will guide engagement over the life of the mine. AMNS would like to review the draft Public Engagement Plan before finalizing. A summary of updates to the public engagement are presented in Table 3.1-1.

Table 3.1-1: Updated Subsections from the 2019 Revised Environmental Impact Statement for Public Engagement

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
-	-	3.1 Introduction	• new
3.1 Objective	Yes	3.2 Objectives	• included list of objectives for the Public Engagement Plan
-	-	3.3 Spatial Boundary	• new included as indicated in IR2s from ESFWA (ESFWA 2-22)
3.2 Engagement Strategy	Yes	3.4 Engagement Strategy	• Included additional detail regarding AMNS public engagement strategy (ESFWA 2-14b, ESFWA 2-20 and ESFWA 2-22) • Included description and reference to AMNS Public Engagement Plan (Appendix A.6) included description regarding Complaint Resolution Plan and Form
3.3 Regulatory Consultation	No	3.5 Regulatory Consultation	-
3.4 Public Engagement Activities	Yes	3.6 Public Engagement Activities	• Updates on CLC as indicated in IR2s from ESFWA (ESFWA 2-14b, ESFWA 2-20 and ESFWA 2-22) • Updated to include additional detail regarding commitments from previous community stakeholder engagement meetings • Added information on 2020 Beaver Dam Mine Project supplemental engagement and stakeholder meetings
3.5 Key Issues Raised and Proponent Responses	Yes	3.7 Key Concerns Raised and Proponent Responses	• Included additional detail regarding key concerns from public engagement from 2015 to 2019 • Added information, key concerns and AMNS responses from the 2020 supplemental engagement
3.6 Ongoing Community Engagement	Yes	3.8 Ongoing Community Engagement	• Updated to include public engagement commitments table

Notes: AMNS = Atlantic Mining NS Inc.; CLC = Community Liaison Committee; ESFWA = Eastern Shore Forestry Watch Association; IR2 = Round 2, Information Requests; - = no update.

3.2 Objectives

AMNS is committed to stakeholder and rightsholders engagement as part of its Beaver Dam Mine Project. Using key values of openness, transparency, collaboration, and respect, AMNS has continued to work with the local community, non-governmental organizations (NGOs), regulatory agencies, and interested members of the public for over a decade. As part of the planning and permitting of the Touquoy Gold Mine, AMNS developed relationships with members of the local community and NGOs, such as the Moose River Gold Mine Museum Society. A CLC has been in place since 2011 (Appendix A.3).

Both federal and provincial EA legislation requires engagement with the public to recognize concerns about adverse effects of the environment and identification of steps taken by AMNS to address these concerns; therefore, these are specifically identified in the EIS related to the Project. Beyond the regulatory requirements, AMNS strongly believes that meaningful engagement is crucial to the success of any development. AMNS is committed to maintaining stakeholder engagement throughout the life of the Project; these activities extend well beyond the EA process.

The objectives of AMNS's draft Public Engagement Plan are:

- to listen and incorporate into the EIS the community knowledge gathered from stakeholders and rightsholders;
- to determine opportunities to include participation of stakeholders during the development and implementation of the follow up program and future management plans;
- to seek input and feedback on the spatial and temporal boundaries used by this EIS;
- to provide information to stakeholders, particularly those most potentially impacted by the Project;
- to build meaningful, two-way relationships with communities most impacted to address any current or potential future land use conflicts; and
- to gather and consider local and regional knowledge and expertise during construction, operations and post-closure.

3.3 Spatial Boundary

The draft Public Engagement Plan for AMNS's Beaver Dam Mine Project (Appendix A.6) recognizes the local communities, and the people who live in them which are located near the mine. The communities of Mooseland, River Lake, Jacket Lake, Pleasant Valley, Marinette, and Sheet Harbour are the primary areas for focused engagement. The Public Engagement Study Area was developed based on engagement efforts in 2020 with local community members who live, own seasonal dwellings or are affiliated with these communities (Figure 3.3-1). These communities use the lands in and around the mine site and the Haul Road extensively for recreational purposes, such as ATV usage, hunting, fishing, and snowmobiling (Figure 3.3-2).

3.4 Engagement Strategy

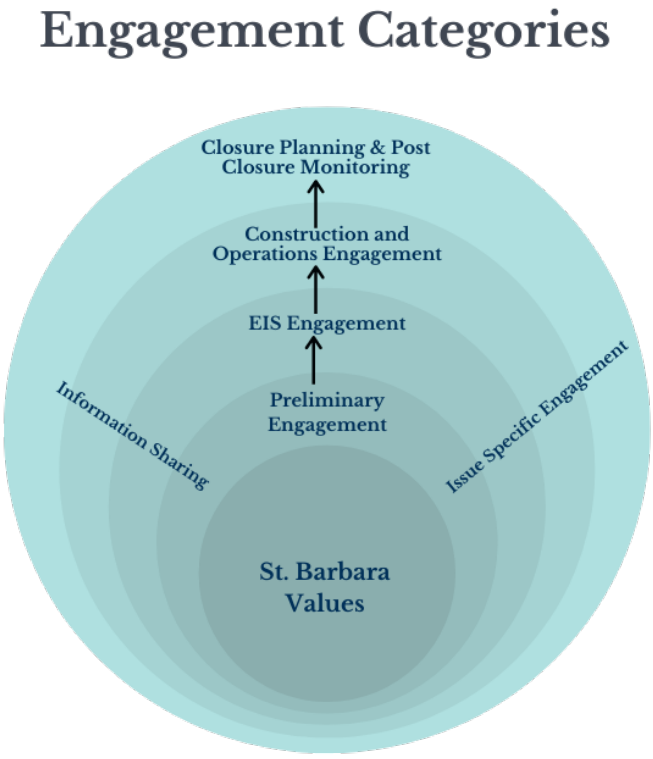
A community engagement strategy was developed by AMNS for the Project to guide engagement during preparation of the Project Description and the original 2017 EIS (AGC 2017). It set out the formal engagement activities that AMNS will undertake throughout all phases of its exploration activities and mining operations in Nova Scotia. This includes the development, operation and reclamation of the Project, which includes the permitted Touquoy Mine Site and the proposed Beaver Dam Mine Site. AMNS is also active in efforts to provide broader awareness relative to advanced exploration activities at Fifteen Mile Stream Gold Project and Cochrane Hill Gold Project.

A successful community engagement strategy provides flexibility to allow adaptation to the needs of the community. In 2016, AMNS developed its strategy for community engagement to coincide with the start of construction of the permitted Touquoy Mine and the development of the EA for the Project. AMNS drafted a Public Engagement Plan to reflect changes in the Beaver Dam Mine Project since the initial engagement occurred in 2015 to 2016. This draft Public Engagement Plan is included in Appendix A.6.

The draft Public Engagement Plan (Appendix A.6) uses the values of St Barbara as its foundations to create meaningful, two-way conversations throughout the life of the mine. AMNS Corporate Values are:

Figure 3.4-1: Atlantic Mining NS Inc. Corporate Values

Note: AMNS Corporate Values are adopted from St Barbara Limited.
AMNS is a wholly owned subsidiary of St Barbara Limited.



Engagement will occur according to a familiar process that includes several elements. The engagement elements are centred on an adaptive management approach for managing ongoing concerns and emerging issues. Adaptive management is a term that arose from the environmental field but also has applicability for general management principles. Essentially, it is the process of working with stakeholders to identify outcomes, implementing a particular course of action to meet that outcome, measuring the outcome and then making changes in an iterative way (adapting) as needed based on data and input received from stakeholders and other sources to reach the desired outcome.

Using adaptive management principals, the Project will update and adjust its management plans to reflect what is being heard from stakeholders.

The draft Public Engagement Plan (Appendix A.6) outlines various engagement categories that generally, but not necessarily, link to the different phases of the mine (Figure 3.4-2). Information sharing and specific key concerns engagement occur throughout the mine life. This Public Engagement Plan will be reviewed and updated yearly, or as required, using the adaptive management approach.

The draft Public Engagement Plan identifies and groups stakeholders, outlines the reasons why each stakeholder group needs to be engaged, the frequency of the engagement and the engagement tools. AMNS has also identified indicators of success for engagement activities which link to the engagement objectives. The indicators of success will enable regular reporting, tracking, and evaluation of effectiveness of the draft Public Engagement Plan (Appendix A.6).

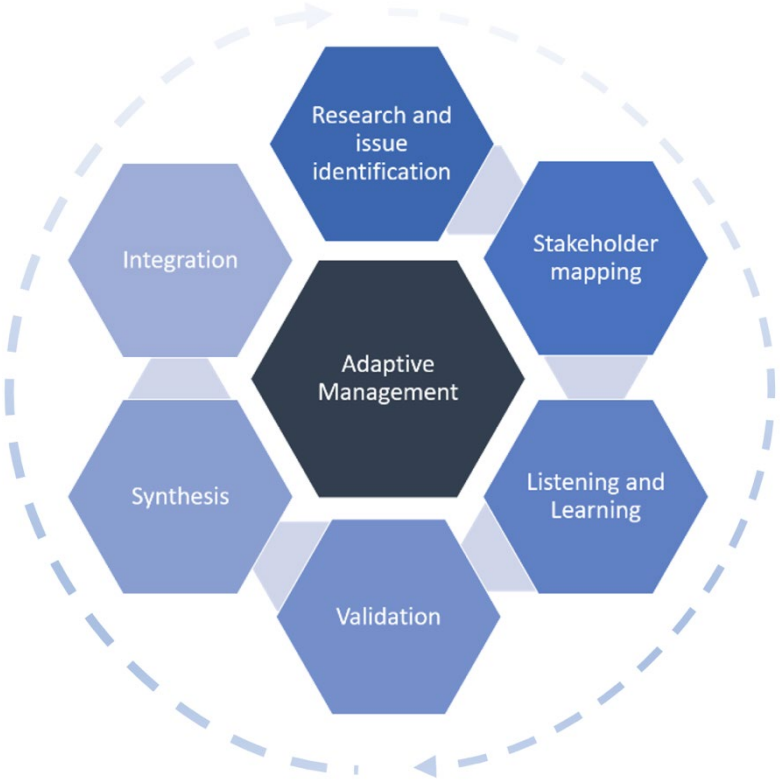


Figure 3.4-2: Engagement Categories

3.4.1 Adaptive Management

Adaptive management is the process of working with stakeholders to identify outcomes, implementing a particular course of action to meet that outcome, measuring the outcome and then making changes in an iterative way (adapting) as needed based on data and input received from stakeholders and other sources to reach the desired outcome.

Figure 3.4-3: Adaptive Management Cycle

AMNS plans to integrate the adaptive management approach into their other mine projects, including Fifteen Mile Stream Gold and Cochrane Hill Gold projects as part of ongoing updates throughout the regulatory process. Environmental Assessments are intended to be iterative and updates to engagement plan for the Fifteen Mile Stream Gold and Cochrane Hill Gold projects are anticipated

AMNS has created its own adaptive management process, which includes the following steps:

- **Research and preliminary concern identification** – This basic information gathering includes understanding the history, context of the project, key sensitivities, and community and regional perspectives so that preliminary concerns can be identified for further discussion and exploration with the stakeholders.
- **Stakeholder mapping and identification** – At this stage, the "who needs to be contacted or communicated with" is determined. This allows for a fuller understanding of the stakeholder ecosystem.
- **Listening and Learning** – Through focused efforts to engage the initial list of stakeholders and identifying other stakeholders who were missed in the previous step, the project team will listen and learn. Key questions are asked, such as:
  - What is important to you about this project?

  - Tell us about your community, organization or group? What is critical for you over the next few years? What do you value about your community?
  - What are your concerns about the project?
  - What additional information do you need to better understand the project? What information can you share to help us better understand your point of view?
  - How do you want to be involved? What is the best way to communicate with you?
  - How can Atlantic Gold support the work you are already doing? Are you active in the area of the proposed mine site?
  - What benefits, if any, do you hope your community, organization or group realizes from this project?
  - Are you interested in partnering around a potential key concern or project?
  - Who else should we talk to?
  - What does AMNS need to understand?
- **Validation** – Throughout and after the listening and learning, we will validate our understanding of what we heard through follow up communications, summary documents, and other validation tools.
- **Synthesis** – The engagement perspectives and key concerns will be synthesized to identify themes, trends, areas of concerns and opportunities.
- **Integration** – The engagement data will be integrated into the appropriate project category. This could include the EIS, construction, operation or post closure phase of the mine. It is through the integration step that changes and adaptations to plans, operations and activities will occur.

Engagement will occur to support adaptive management and will feed into planning and operational processes throughout the life of the mine.

3.4.2 Community Liaison Committee

Community engagement is important to AMNS and the CLC is one of its foundations. The CLC is diverse with representation from the surrounding communities; it was expanded to a nine-member CLC. The volunteer membership acts as an advisory board to AMNS. The CLC provides a mechanism for information exchange between communities and the company, as well as a forum to share questions, concerns, and input regarding the Touquoy Mine Site and the Beaver Dam Mine Site (Appendix A.3). The CLC meet quarterly with the potential for additional meetings depending on interest and Project developments.

The current members are: Charles Brown (Musquodoboit Harbour), Rick Deale (Middle Musquodoboit), Gilbert Fahie (Mooseland), Robin Webber (Oyster Pond) Gary Leslie (Upper Musquodoboit), Brice Kennedy (Tangier) and Barry Prest (Mooseland). The CLC is currently recruiting for members to bring the membership back to full.

A draft Terms of Reference for the CLC was developed and approved by the CLC on June 24, 2017 (Appendix A.3). The Terms of Reference sets out the governance for the CLC and defines its objective as an advisory body to AMNS with volunteer members representing local communities. On October 13, 2018 the CLC made a formal motion to include the Project in the Terms of Reference and will provide advice to AMNS on concerns related to this Project in addition to the Touquoy Mine. Fifteen Mile Stream Gold Project and Cochrane Hill Gold Project will have their own separate CLCs.

As defined in the Terms of Reference, guests, such as technical consultants or community groups, may be invited to the CLC meetings where topics of interest are planned. To date, the CLC has received presentations from Intrinsik Corp. on Metal and Dimond Mining Effluent Regulations (MDMER), Cyanco on Cyanide, and from a local community group (Eastern Shore Forestry Watch Association).

3.4.3 Open Houses and Town Hall Meetings

Open houses allow a proponent to inform the general public about a proposed project, and conversely, interested members of the public have the opportunity to view information and speak directly with representatives of AMNS. This allows one-on-one discussions to answer questions of the visitor. For many members of the public, this can be a more comfortable form of communicating with AMNS than town hall type meetings.

The meetings can take many forms but usually involve information boards and displays showing the location of the proposed project in relation to nearby communities, fact and figures pertaining to the development, and an update of the general public on the status and progress of development activities, such as the EA and anticipated construction schedule.

Many open houses have been held as part of the Touquoy Gold Project over the past decade. In spring 2016, four meetings were held to update the local communities on the construction start of the Touquoy Gold Project and provide specific details on the proposed Project. In response to concerns on traffic potentially associated with the work at the Touquoy Gold Project, a town hall meeting was held in Mooseland in late 2016. AMNS attempted to organize an in-person open house in the community of Mooseland for the Beaver Dam Mine Project; however, with an outbreak of COVID in the fall of 2020 in the Halifax region that meeting was moved to an online forum. Additional details regarding the open house is provided in Section 3.6.1.

3.4.4 Presentations and Meetings with Local Community Groups

AMNS has made presentations to many organizations, community groups and educational institutions on its exploration and mine development activities in Nova Scotia. To date, these organizations include but are not limited to, Sheet Harbour Chamber of Commerce, Council of the Municipality of the District of St. Mary's, and engineering students at Dalhousie University. Depending on interest of community groups, AMNS will continue to make presentations to share information about its operations in Nova Scotia.

In 2020, AMNS undertook extensive engagement activities with local and provincial ATV groups, the Mooseland and Area Community Association, the Icelandic Heritage Society, a group from the Rocky Brook Lake area and individual landowners. The learnings from this most recent engagement are outlined in Sections 3.6, 3.7, and Appendix A.4a.

AMNS has and will continue to meet with local community groups in a smaller venue, including the ESFWA, Moose River Gold Mines Museum Society, and NSSA. Depending on interest of community groups as the Project develops, AMNS will continue to meet with community groups to provide information and respond to any concerns. This may include local ATV clubs, environmental groups, business development organizations and other interested community groups.

3.4.5 Community Bulletins (Newsletter)

May 2018 AMNS launched a quarterly community bulletin (Appendix A.4c). The purpose of the bulletin is to keep the community informed about the AMNS activities, update the public on the status of all Project EAs, provide information on AMNS's activities in the local community and provide basic technical information on AMNS's projects. The bulletin will continue indefinitely so that community members are kept informed throughout all stages of the Project.

As of January 7, 2021 had 369 email addresses on its distribution list. AMNS has issued eight Community Bulletins, and seven Special Bulletins to announce things such as the public comments periods for the Fifteen Mile Stream and Cochrane Hill Gold Projects or special meetings. The September 11, 2020 bulletin was delivered to 346 people and had an open rate of 46.9. The open rate demonstrates interest in the bulletin and that people are opening the email. The bulletin has also been forwarded by the initial recipients meaning the distribution network is wider than the initial recipients (Appendix A.4c).

3.4.6 Signage

AMNS posts, and will post, signs at their Project sites with contact details and other general information. For example, in the instance of the Touquoy Mine, the blasting schedule is posted for public information. Working with local groups, such as the Moose River Gold Mine Museum Society, interpretative panels on AMNS Projects may be integrated into the Moose River Gold Mine Provincial Park.

AMNS will also work with the local community and ATV clubs to post signage along the Haul Road. A signage plan will be included in the Operational and Safety Management Plan for the Haul Road.

3.4.7 Website, Email, Phone Line and other Digital Media

AMNS has a website (atlanticgold.ca) where information on the Beaver Dam Mine Project can be found. The website continues to be populated with new information and AMNS intends for the website to be a hub of information for reference by the community.

The purpose of this website is to:

- inform and update the public about the Project;
- address community questions gathered from other communication channels; and
- provide information for further engagement.

The website provides a sign-up location for the quarterly community bulletin (newsletter) and provides access to meeting notes for the CLC.

AMNS has established a regularly monitored email address - communityrelations@atlanticgold.ca- specifically as a point of contact for the public.

AMNS will continue to monitor various social media channels for posts and comments regarding the Project. The purpose of this monitoring will be to check for information being shared regarding the Project, to better understand public questions and concerns, and to identify opportunities to engage. AMNS is evaluating opportunities to include social media platforms as well.

AMNS established a community phone line (902-391-4653) in March 2018 where the public can call/text when there are questions or concerns, or to request a meeting with a representative. This phone line is answered during business hours. This phone line has been advertised on the website, in all newsletters and on a business card given out to those who have expressed interest in further communicating with AMNS.

3.4.8 Media and Press Releases

AMNS posts news releases to promote accurate information about the Project. Most news releases to date are associated with AMNS's business interests; however, this has been expanded to include Nova Scotia media outlets to better communicate the benefits of the mine developments with the broader community, address public questions and concerns, and encourage engagement.

AMNS is also considering regular advertising and content in the Guysborough Journal to assist in sharing information on the Project.

3.4.9 Meetings with Local Residents and Landowners

Meetings with residents, landowners and community organizations are vital to understanding concerns, potential impacts and proposed mitigation strategies. Until early 2018, meetings with local residents and landowners have occurred opportunistically where specific interests are expressed.

In the spring of 2018, AMNS initiated a more active engagement process with adjacent landowners by sending letters and offering to meet with property owners potentially impacted by the Haul Road and the Beaver Dam Mine Site. AMNS has also reached out to landowners whose land may be required for mine infrastructure. AMNS will continue to communicate directly with potentially impacted landowners to resolve land issues.

In 2020, engagement efforts with residents and landowners used the steps of adaptive management to reinvigorate and guide engagement activities. This involved undertaking additional research, updating stakeholder mapping, listening and learning, validation, synthesis, and finally integration (Appendix A.4a).

3.4.10 Complaints Response Procedure

Associated with the ongoing work for the Touquoy Mine, a Complaint Resolution Plan and Form is being developed and will be used by AMNS when a complaint is received from the public. This Plan is intended to standardize the formal response procedure to complaints from members of the public. AMNS is committed to addressing complaints in a timely and respectful manner. Information gathered under the Complaint Resolution Plan is shared with the CLC and Nova Scotia Environment on a quarterly basis, including any corrective actions.

AMNS keeps a complaints log that tracks all engagements and communications associated with the complaint. The Complaints Resolution Plan is a component of the adaptive management approach adopted by AMNS.

3.5 Regulatory Consultation

Regulatory engagement on the Project has been ongoing since October 2014 with a Provincial "One Window Process: Mineral Development in Nova Scotia" meeting. This initial meeting was intended to present the planned Project and to receive feedback on the regulatory regime and regional expertise.

Departments from federal and provincial governments have been consulted on the Project, including:

- IAAC Impact Assessment Agency of Canada (formerly the Canadian Environmental Effects Agency [CEAA]) ;
- Fisheries and Oceans Canada (DFO);

- Environment and Climate Change Canada (ECCC);
- Canadian Wildlife Service (CWS);
- Health Canada;
- Transport Canada;
- Natural Resources Canada (NRC);
- Nova Scotia Environment (NSE);
- Nova Scotia Transportation and Infrastructure Renewal;
- Nova Scotia Lands and Forestry (formerly Nova Scotia Department of Natural Resources);
- Nova Scotia Energy and Mines (formerly Nova Scotia Department of Natural Resources); and
- Nova Scotia Office of Aboriginal Affairs.

Engagement includes one-on-one meetings or correspondence, larger meetings or workshops and site visits. A one-day workshop was held on May 13, 2016 for interested provincial and federal regulators. On November 29, 2016 a site visit and tour was held for interested provincial and federal regulators and representatives of the two closest Mi'kmaq communities, Sipekne'katik and Millbrook, and staff of the Kwilmu'kw Maw-klusuaqn Negotiation Office (KMKNO). A description of recent engagement activities with the First Nations is provided in Section 4.

3.6 Public Engagement Activities

While broader engagement on the Project has occurred for over a decade and will continue as per the draft Public Engagement Plan (Appendix A.6), specific public engagement activities have occurred to support the environmental assessment process for the Project since the federal process was commenced in December 2015. A summary of engagement activities conducted with stakeholders is included (Appendix A.4a).

3.6.1 Community Open Houses

Four open houses were held in May 2016; two of these were open to the public while the other two were open to First Nations community members as described under Indigenous Peoples engagement. Two more open houses were held in 2018 with Millbrook First Nation and are outlined in the Indigenous Peoples Engagement section (Section 4).

The two public open houses were advertised in the local papers, including the Eastern Shore Cooperator (monthly print issued on May 5), Guysborough Journal (weekly print issued on May 16) and the Town Cryer (monthly print issued on May 2). The members of the CLC also circulated information. Flyers were also posted in local communities. The dates and locations were as follows:

- May 18, 2016 at Natural Resources Education Centre, 12014 Hwy 224, Middle Musquodoboit.
- May 19, 2016 at Sheet Harbour Lions Club, 183 Pool Road, Sheet Harbour.

The format and layout were the same for all open houses. Each open house was hosted from 3:00 pm to 8:00 pm with refreshments provided. Upon entry, attendees were asked to sign in and were provided a comment form to complete at end of their stay. Maps were also available for viewing and a 3D model of the Beaver Dam Mine Site was used to demonstrate the existing conditions, proposed full mine development (including pit and waste rock pile) and reclamation of the site.

A total of fifteen of large informational poster boards (panels) were placed on easels with AMNS and its consultants hosting the panels. After a welcome and introduction to AMNS and the Project background (three panels), an overview of open pit mining, process of gold recovery, and economic benefits of the Project was provided (three panels). The next three panels provided an update on the Touquoy Gold Project which was soon to begin construction (June 2016). Before the one closing panel, the remaining five panels focused on the Project and the engagement opportunities, specifically:

- presentation of the site location, the gold deposit and the existing site features;
- map of the proposed Beaver Dam Mine site plan;
- information on the transportation of ore, including both options considered for the route and the trucking rate;
- overview of the EA process for the Project including the ongoing baseline studies for the VCs and the regulatory process with opportunities for public participation; and
- opportunities for community and Mi'kmaq engagement, including an overview of the CLC and an invitation for expressions of interest from residents who are interested in joining the CLC.

A total of 94 interested community members attended these two open houses (i.e., Middle Musquodoboit had a total of 61 attendees with 49 providing contact information; Sheet Harbour had a total of 33 attendees with 32 providing name and/or contact information). In total, nine comment forms were completed, two expressed interest in joining the CLC, and many resumes were provided to AMNS.

In 2020, AMNS attempted to hold an Open House on November 27 and 28 in the community of Mooseland. This Open House was organized in response to a request from the local community to provide information on concerns relating to the proposed Haul Road and the Beaver Dam Mine Site. AMNS recognized that additional engagement was required with the community as the last open house was in 2016. Due to the COVID-19 pandemic, the Open House format had to be modified to small information sessions to meet Nova Scotia Public Health directives. AMNS created an internal plan to guide the delivery of information sessions in Mooseland to address concerns identified, in part, by the Mooseland and Area Community Association.

Invitations to the Information Sessions were delivered by hand, email or phone to most property owners in Mooseland and several residences in Jacket Lake. MACA also placed a notification of the meeting on the community sign located in front of the community hall in Mooseland. At least one property owner in Ferry Lake was notified of the meeting. Individuals were asked to pre-register to meet with an AMNS representative to discuss concerns or learn more about the Project.

Due to an increase in COVID-19 cases in HRM, the Office of Public Health issued an order on November 26, 2020[1] that restricted non-essential travel of people within most of HRM. AMNS cancelled the Information Session on November 26, 2020 in the interest of public safety and notified the local community through both formal means (phone calls and emails) and informal means (informing key community leaders about the cancellation and asking them to spread the word). AMNS will hold an Open House in Mooseland after the Updated 2021 EIS is submitted.

As the Information Sessions could not occur on November 27 and 28, 2020, AMNS provided copies of the Plain Language Summary (Appendix A.1) to the 36 mailboxes in Mooseland along with a covering letter with the community relations phone line and email address, to which questions or concerns could be sent.

[1] https://novascotia.ca/coronavirus/restriction-updates/

3.6.2 Community Liaison Committee

The Touquoy CLC was activated in 2016. Due to the operational links between the Touquoy operation and the proposed Beaver Dam Mine, and the fact that the community of Mooseland is geographic link between the operating mine and the proposed mine from a, the mandate of the Touquoy CLC was expanded to include the Project in 2018.

Six CLC meetings were held in 2016. Of these, the last two meetings held on October 29, 2016 and December 3, 2016 included the expanded membership of nine. In 2016, the CLC membership represented different communities, including: Middle Musquodoboit, Millbrook First Nation, Mooseland, Musquodoboit Harbour, Sheet Harbour, Sipekne'katik First Nation, Pleasant Harbour, and Upper Musquodoboit.

Due to the ongoing preparation of the EIS for the Project, a special meeting on December 3, 2016 was held to focus on the Project. As per the Terms of Reference, the CLC may invite guests who may be interested in topics in forthcoming meetings. The CLC invited representatives from the Eastern Shore Forestry Watch (Barbara Markovits and two guests) and the NSSA (Eddie Halfyard and guest).

The meeting was about 2.5 hours in duration. Presentations were made by staff of AMNS and the EA Study Team, maps were provided and a 3D model of the Beaver Dam Mine Site was used to demonstrate the existing conditions, proposed full mine development (including pit and waste rock pile), and reclamation of the site. Questions and answers were facilitated. The agenda included:

- introduction and special purpose of the meeting;
- overview of the Project;
- review of participation opportunities in the federal and provincial EA processes;
- presentation of summary assessment for each VC; and
- description of timelines of the Project.

Offers to meet with specific members of the CLC and/or NGOs present to provide additional information on the Project were made by AMNS.

The CLC has continued to meet regularly:

- in 2017, the CLC met two times;
- in 2018, the CLC has met three times;
- in 2019, the CLC met four times; and
- in 2020, the CLC met three times. Due to the COVID-19 Pandemic, meetings did not occur between January 2020 and November 2020.

The CLC membership continues to fluctuate as members resign and new ones are recruited. The most significant membership change is the agreed upon withdrawal of Millbrook First Nation and Sipekne'katik First Nation on the CLC in 2017. Both First Nation Communities have elected to not participate in the CLC and have decided to directly engage with AMNS. AMNS has made it clear to both Millbrook and Sipekne'katik First Nations that they are welcome to rejoin the CLC or attend as guests. Information regarding specific Indigenous Peoples engagement is provided in Section 4.

In an effort to promote transparency and understanding of the role of the CLC, AMNS publishes meeting notes for the Touquoy/Beaver Dam CLC, which can be found at https://stbarbara.com.au/community/nova-scotia/

3.6.3 Stakeholder Meetings

AMNS regularly reviews the stakeholder mapping associated with the Project. This is done by continuously scanning the stakeholder ecosystem for individuals, communities and groups who may be impacted or interested in this Project. AMNS keeps a database of stakeholders, along with contact information, to ensure communication occurs as required. As the Project develops, AMNS will continue to review and update the stakeholder mapping to ensure stakeholders and rightsholder are consulted and engaged. For example, if a property sells near the Project Area, then AMNS update the stakeholder mapping.

A complete list of the stakeholder meetings is shown in (Appendix A.4a).

Through the preliminary engagement, four main organizations arose where a closer relationship is required. Although the draft Public Engagement Plan identifies many important stakeholders, two of these organizations, the NSSA and the ATV clubs, are particularly impacted by the proposed Beaver Dam Mine Project due to the significant infrastructure investments each have made. The other two organizations, MACA and the Sheet Harbour Chamber of Commerce, are links to community groups that represent community perspectives near the mine site. When AMNS works with a community organization or other non-governmental organization, information will be provided with a request that it be shared through the NGO's membership and broader network.

3.6.3.1 Nova Scotia Salmon Association

AMNS acknowledges the significant and important activities of the Nova Scotia Salmon Association. The Acid Rain Mitigation (ARM) Project on the West River is of particular importance as it is a multi-year, science-based project active in the watershed in which the proposed Beaver Dam mine is located. The West River Acid Mitigation Project started in 2005 and is.., " being developed as a model for the restoration of acid-stressed rivers in the region."[2] In 2016, the NSSA installed and operates a lime doser on the Killag River near the proposed mine site.

In recent years, the NSSA has received funding from the federal government, "to improve the water quality of fish habitat using aquatic, in-stream liming."[3] The Acid Rain Mitigation Project is just one of the many initiatives that support the overarching goal of the NSSA to "maximize the likelihood of survival and sustainability of our fish, rivers and recreation." (NSSA 2020).

AMNS has been meeting regularly with the NSSA to share information, learn more about its activities along the West River and provide information on the Project as it develops. AMNS will continue to meet with the NSSA to share its future activities, share information and look for collaborations to benefit the fish and fish habitat of the watershed.

Over the course of several meetings, emails and phone calls with AMNS over the last several years, the NSSA has shared information regarding the scope and importance of the ARM Project on the West River. The ARM project is focused on addressing acidification by conducting in-stream liming. The NSSA has expressed concerns about the potential impact of AMNS mine rocks piles, potentially acid generating (PAG) mine rock and organic stockpiles. NSSA also has concerns regarding river drawdown

[2] https://www.salmonconservation.ca/projects/the-west-river-acid-mitigation-project/

[3] https://www.nssalmon.ca/acid-rain-mitigation (web reference December 2020)

resulting from pit development, loss of catchment area and water loss during and until the pit is refilled. On September 9, 2020, AMNS presented updates on the Project (Appendix A.4b).

AMNS supports the NSSA's efforts on the Killag River and is actively seeking opportunities to work with the NSSA. Offsetting opportunities, data sharing and ongoing communication throughout the Project are currently being explored. In addition, AMNS, through its adaptive management process, will seek NSSA input into the Project to ensure all management plans developed for the Project are updated and improved through the life of the Project.

3.6.3.2 Mooseland and Area Community Association

The Mooseland and Area Community Association (MACA) is active in the community of Mooseland and includes the smaller communities of Jacket Lake and River Lake. This community organization manages the Mooseland Community Centre and hosts occasional community activities. MACA has established a working committee that has met with AMNS representatives to discuss potential community investments and to provide input and feedback on the proposed Beaver Dam Mine. The northern boundary of Mooseland is located approximately 850 m from the entrance to the proposed Haul Road (known locally as the "old dump road"). The community is comprised of a mixture of full-time and seasonal residents. The seasonal residents often have historical family connections in the area and treasure the lifestyle and access to the wilderness that Mooseland provides. The proposed Haul Road is a major recreational corridor for Mooselanders.

Given the small population of the Mooseland community, AMNS has worked with this organization and will continue to do so, as many of the permanent and seasonal residents of the area are affiliated with it. AMNS is committed to working with this community on potential mitigation options, adaptive management inputs and to identify community development opportunities.

The MACA members have identified the following as concerns:

- access by residents and user groups of the ATV trails and recreation lands in and around the proposed Haul Road;
- truck traffic and truck noise; and
- impacts on residents' lifestyle.

Many residents have also acknowledged the importance of local employment and the opportunities a mine project can bring.

Detailed technical results related to truck traffic and noise are detailed in Section 6.1 and Appendix B.2 (Updated Noise Impact Assessment). To mitigate impacts of perceived or actual impacts on recreational land use on or around the proposed Haul Road, AMNS is committing to the construction of bypass roads that will allow recreational vehicles, light trucks, and active transportation users to access the desired recreational areas. In addition to the bypass roads, AMNS will identify crossings for the Haul Road for recreational users and include specific protocols in the Access and Safety Management Plan for road usage. Using the adaptive management process, AMNS will work with recreational users to monitor the effectiveness of the mitigation strategy.

3.6.3.3 Sheet Harbour and Area Chamber of Commerce

The Sheet Harbour Chamber of Commerce is a business organization located in Sheet Harbour, but also hosts a website promoting the Sheet Harbour area. Under the Atlantic Gold banner, AMNS is a member of this organization. This membership will be maintained over the life of the Project.

Although Sheet Harbour is approximately 25 minutes from the Beaver Dam Mine Site, it is the largest community in the vicinity. Direct impacts from construction and operations on Sheet Harbour will be related to socio-economic impacts and generally will be

positive; however, AMNS needs to establish a feedback loop with the community to monitor this assumption which is included as part of the draft Public Engagement Plan (Appendix A.6). Housing availability, the local hospital and businesses could experience changes if the mine begins operation. AMNS also sees community and economic development opportunities that can align with the provincial economic development priorities of improved social wellbeing, increased population and economic growth (Section 6.16 Socio-Economic Conditions).

3.6.3.4 All Terrain Vehicle Groups

AMNS has clearly heard that the areas in and around the Beaver Dam Mine Site and Haul Road are used extensively for recreational land uses, such as ATV riding, hiking, hunting, fishing and snowmobiling. Local ATV clubs (PUMA, Sheet Harbour and Lake Charlotte) (Figure 3.3-1), along with the All-Terrain Vehicle Association of Nova Scotia (ATVANS) have made considerable investments in the construction and maintenance of trails and related infrastructure for its members use. These same trails are used also by non-members, and it is believed many of these are local residents. The local clubs are run by groups of committed, passionate volunteers who build and manage their own trails systems (Figure 3.3-2).

The Haul Road and mine site intersect with the ATV and snowmobile trails managed by the ATV clubs, some of which provide provincial and regional connections. These trails are well travelled throughout the year. The proposed Haul Road will include both crossings for recreational land users and bypass routes for continued connectivity. The safety of all parties – recreational land users, AMNS staff and contractors, and the public – is critical and AMNS will work closely with the ATV clubs on the concerns of safety and accessibility.

AMNS is also interested in having discussions with the ATV clubs on potential community investment opportunities and partnerships that further shared interests. These could include:

- trail construction;
- trail maintenance; and
- safety and education programs.

3.6.4 Summary of Supplementary Engagement - 2020

In 2020, AMNS implemented a supplementary engagement program. The supplementary engagement program included contacting environmental groups, community associations, ATV Clubs and landowners with an offer to meet. In 2020 alone, AMNS had over 322 communications with stakeholders regarding the Project EIS. The supplementary engagement program also includes contacting property owners near the Project Area. All property owners were contacted by phone, letter or email and provided updated information and offered a meeting to answer questions or discuss concerns.

AMNS, in July 2020, began meeting regularly with the MACA where concerns regarding the Haul Road, recreational land use, potential community investment projects and other concerns were raised by the Association. At the request of MACA, AMNS organized and planned a series of community information sessions with the local community (Section 3.6.1).

A property owner from the Ferry Lake area contacted AMNS in 2020 expressing concerns regarding the Project. AMNS has attempted to meet with the property owner several times. AMNS continues to welcome the opportunity to answer questions, address concerns and develop a relationship with the property owners along Ferry Lake.

Also in 2020, AMNS met with property owners near Rocky Brook Lake, which is located in Pleasantville approximately 8 km from the intersection of the Beaver Dam Mines Road and Hwy 224. These residents expressed concern about their ability to continue

to access the lands in and around the Beaver Dam Mine Site, for recreational uses. Specific recreational uses included fishing, hunting, ATV riding, hiking, accessing camps and snowmobiling. AMNS held a video call with five property owners in the area on December 14, 2020 to answer questions, validate information gathered about recreational land usage in the area, and review proposed mitigation measures. The main mitigation proposed to address recreational land access concerns is to construct alternative access routes or bypass roads to the desired recreational locations. A map showing proposed new bypass routes was reviewed with attendees and there was general agreement that the proposed bypass roads were acceptable (Figure 3.3-2).

Through the supplementary engagement program, new stakeholders were identified that have camps or land that are accessed from the proposed Haul Road. All known landowners were contacted and provided information on the Haul Road. Further contact and communication will occur as the Project progresses. Landowners and camps owners include:

- Marilyn Prest and family;
- Deepwood Estates;
- Harry Casey;
- Darren Lasaga;
- Jeff Bevis;
- Deborah Marlborough;
- Musquodoboit Lumber Company;
- Prest Brothers Ltd.; and
- Northern Pulp.

AMNS will continue to identify other potentially impacted property owners and camp owners as the Project progresses.

Through the public engagement in 2020, the stakeholders identified the follow community sites presented in Table 3.6-1 and described in Section 6.16.5 Socio-economic Conditions.

Table 3.6-1: Community Sites

Community Site	Location	Discussion
Date Rock	Along the Haul Road between Mooseland Road and Highway 224	Request by community members to maintain the rock. Rock will be maintained or, if required, moved to a site acceptable to the community.
Otter Lake	Otter Lake is a popular recreational area located to the north of the Haul Road, along Trail #320	This area is a destination for family and outdoor recreational pursuits. The cabin, located on the shore of Otter Lake, is a known stopping location. Access to Otter Lake will not be restricted and the Haul Road bypass will include a crossing to access Trail #320. Otter Lake can also be directly accessed from Hwy 224.
Lake Alma	Lake Alma is located to the south of the Haul Road	Lake Alma is a fishing and boating, and there are a l camps located near it on or on its shores. During engagement, at least one person indicated that he left his boat moored during the summer in Lake Alma. Lake Alma can be accessed from Highway 224 and via Trails #394 and 106. Access to Lake Alma from Mooseland will be maintained via the Haul Road bypass.

Table 3.6-1: Community Sites (continued)

Community Site	Location	Discussion
10 Mile Lake	Located west of the Mine Site and Cameron Flowage	There are camps located on 10 Mile Lake and this area is also identified for recreational uses. This area is accessed via Trail #394. Trail #106 and #320 both connect to Trail #394. Trail #320 will be dead-ended at the Project Area boundary. A new connector trail between Trail #320 and the BDMR Bypass will be created, as will a Mine Site Bypass that will allow ATV and light vehicles to access Trail #394 and the 10 Mile Lake area.
Otter Lake Demonstration Forest (OLDF)	To the southeast of the community of Mooseland	The OLDF is, "…a place for all Nova Scotians to learn about forest ecology and the sustainable management of our nature.
Mooseland and Area Community Hall	4032 Mooseland Road	This is a community centre that is used for local residents. AMNS is in talks with the Mooseland and Area Community Association (MACA) to develop a partnership. MACA is identified in the Public Engagement Mitigation Plan as a key stakeholder and includes several commitments regarding ongoing information sharing and relationship development.
Ferry Lake	Located approximately 4 km southwest from the Haul Road	Seasonal dwellings are located on the southern shore of Ferry Lake. No impact to residents are predicted based on the impact assessment. A technical memorandum assessing possible linkages is provided in Appendix F.9. The technical memorandum concludes that there are no impacts from dust, noise or surface and groundwater quality to Ferry Lake residents.,

Notes: AMNS = Atlantic Mining NS Inc.; ATV = All-terrain vehicle; BDMR = Beaver Dam Mines Road.

3.7 Key Concerns Raised and Proponent Responses

AMNS began stakeholder engagement in 2015, in advance of the June 12, 2017 submission of the EIS to CEAA, now referred to as IAAC for the Project. In previous submissions of the EIS, these engagements were documented and detailed. This section breaks the historical engagement into two distinct historical periods: engagement between 2015 and 2019 and engagement that occurred in 2020 under the draft Public Engagement Plan (Appendix A.6).

3.7.1 Public Engagement 2015 to 2019

The main concerns, along with AMNS responses are outlined in Table 3.7-1. The table includes key concerns identified by stakeholders, the response from AMNS to these concerns and the section of the EIS where the concern is dealt with in detail.

3.7.2 2020 Supplementary Engagement Strategy

In the spring of 2020, AMNS submitted a Supplementary Engagement Strategy (Appendix A.4a) that focused on contacting local property owners, seasonal residents and recreational users regarding the proposed Beaver Dam Mine. This additional engagement was requested by IAAC and agreed to by AMNS due to the length of time the Project has been under review by IAAC, the more refined technical analysis and conclusions and to ensure that new and existing stakeholders were engaged.

The objectives of the 2020 Supplementary Engagement Strategy were:

- To notify potential receptor locations of summary conclusions from the updated modeling for air, noise, light and water.
- To notify property owners near the Haul Road of summary conclusions from the updated modeling for air, noise, light and water.
- To provide information to the local community on the status of the Beaver Dam Mine Project Environmental Assessment.
- To ensure local residents, landowners and local community groups are aware of AMNS engagement tools, which include a newsletter, dedicated phone line, email address and website.
- To meet with any local resident or property owner who may have questions about the Beaver Dam Mine Project.
- To offer to meet with any community group active in the area to review summary conclusions related to updated modeling for air, noise, light and water, or any other information that is of interest.

Additional key concerns were raised during the 2020 supplementary public engagement. AMNS continued engagement beyond the original scope to ensure a fuller understanding of the concern and to, if appropriate, identify mitigations strategies. This included identifying any stakeholders missed during the 2015 to 2019 engagement period, identifying any additional impacted landowners in and around the Project Area, the identification of new concerns or questions, researching and exploring each concern, validating what was heard, synthesizing the information and adapting plans or processes to mitigate concerns, where appropriate. AMNS developed a draft Public Engagement Plan (Appendix A.6) based on the historical engagement activities and the results of the 2020 Engagement to inform the Project. Adaptive management is the foundation of the 2021 draft Public Engagement Plan for Project.

AMNS made significant efforts to reach out to and listen to the public in 2020 to 2021. AMNS tracks each contact with stakeholders and assessed the atmosphere of each communication. Positive reflects a productive conversation where topics are discussed and explored in a spirit of cooperation. It does not reflect endorsement of the Project or that concerns are resolved but rather that the tone of the meeting was positive and productive. Neutral reflects engagements where information is simply provided and data share. Negative reflects engagements where there is dissatisfaction or a breakdown in discussions. Similarly, negative atmosphere does not necessarily indicate opposition but rather that the engagement itself was unsatisfactory to the stakeholder (Figure 3.7-1).

Table 3.7-1: Summary of Key Concerns Raised During Stakeholder Engagement 2015 to 2020

Key Concerns	Summary of Proponent Response	Corresponding Updated 2021 EIS Section Reference[(a)]	Follow-up/ Commitment
2015 to 2019 Engagement			
Concern about metals leaching from waste rock pile, including arsenic, and acid rock drainage.	Leaching of metals is not expected, e.g., arsenic is expected to be within baseline conditions. PAG will be covered using an engineered cover that reduces infiltration rate and thereby limiting potential acid drainage. If necessary, water treatment will be put in place. Runoff from NAG and PAG will be monitoring during construction, operation, closure, and post closure to determine if adaptive management should be applied.	Section 6.5.4 Bedrock Geology; Section 6.7 Surface Water Quality and Quantity, including Surface Water Quality and Quantity Mitigation (Section 6.7.9) and Groundwater Mitigations (Section 6.6.8)	Monitoring, Mitigations and Adaptive Management of waste rock throughout life of mine

Table 3.7-1: Summary of Key Concerns Raised During Stakeholder Engagement 2015 to 2020 (continued)

Key Concerns	Summary of Proponent Response	Corresponding Updated 2021 EIS Section Reference[(a)]	Follow-up/ Commitment
Concern about effect on water quantity in Cameron Flowage from pit development.	Local hydrogeological conditions ensure that groundwater will be maintained to recharge Cameron Flowage. Baseline and ongoing monitoring of surface water and groundwater levels will be in place to identify trends.	Section 6.6.7 Project Activities/Interaction with Groundwater Quality and Quantity	Implement Aquatic Effects Monitoring Program and Groundwater Monitoring Program.
Questions about contingency planning for accidents and malfunctions.	Hazards have been identified and assessed based on risk with mitigations and contingency planning in place. Future detailed planning and implementation of the Project will further address potential accidents and malfunctions.	Section 6.18 Accidents and Malfunctions	Establish Emergency Response Plan and Operational Procedures to manage planned and unplanned events.
Concern about wetlands being impacted at Beaver Dam Mine Site and future compensation.	Where possible, wetlands have been avoided; otherwise minimization of effects was incorporated into Project planning. Any wetlands altered must have NSE approval and will require compensation.	Section 6.8 Wetlands, including Wetlands Mitigation (Section 6.8.8)	Limit mine footprint and compensate for wetlands that cannot be avoided
Questions about addressing species at risk if identified in Project area.	Species of conservation interest (SOCI) and species at risk (SAR) have been assessed. Effect is minimal and where a potential Project interaction, mitigation and monitoring plans are identified for priority species, including fish, vascular flora and lichens, terrestrial fauna and birds.	Section 6.13.8 Mitigation for SOCI and SAR	Monitoring, Mitigation and Adaptive Management of SOCI and SAR
Concern about effect on habitat from Haul Road construction.	Effects of road construction will be minimized by using existing corridors where possible and improving drainage where damaged culverts exist. Effects and mitigation measures are specifically identified for ecological VCs, including habitat and flora.	Section 2.8.2 Haul Roads for Transporting Ore, and key sections for each VC in Section 6 Environmental Effects Assessment	Limit the size of Haul t the extent possible. Replace culverts and
Concern about volumes of truck traffic in context of safety on public roadways and recreational vehicles.	Potential interaction exists with operation of the Haul Road and the public; the risk of a mobile equipment accident has been assessed as low with mitigations in place including design of Hwy 224 crossing, appropriate signage, and haul truck driver training.	Section 2.8.2 Haul Road; Section 6.16.10 Project Activities and Socio-economic Interactions and Effects; and Section 6.18.5.4 Mobile Equipment Accident	Implement Haul Road Operations and Safety Management Plan will be developed by an ad hoc advisory committee
Request to prefer Haul Road option that does not travel along Hwy 224.	Based comments received on two options during the stakeholder and Mi'kmaq engagement, AMNS completed a feasibility review of the second option which does not pass by any residences. This was selected and is carried forward in the EA.	Section 2.8.2 Haul Roads for Transporting Ore;	Re-Routing of Haul Road to avoid permanent residents and Beaver Lake IR 17

Table 3.7-1: Summary of Key Concerns Raised During Stakeholder Engagement 2015 to 2020 (continued)

Key Concerns	Summary of Proponent Response	Corresponding Updated 2021 EIS Section Reference[(a)]	Follow-up/ Commitment
Concern on cyanide use at plant for gold processing.	The approved Touquoy Gold Project includes a gravity/CIL processing of the ore using a highly efficient cyanide destruction process. This use of this existing plant will be extended for the processing of ore from the Beaver Dam Mine Site. Mitigations for transportation, handling storage and processing will be incorporated into the extended use of the plant.	Section 2.8.3 Operations and Maintenance associated with the processing plant: Section 2.8.3 and AppendixF10 Tailings and Water Management	Maintain Operation and Maintenance Plan for Cyanide Use
Concern on effect of tailings disposal in mined-out Touquoy pit.	Use of the approved pit as part of the Touquoy Gold Project allows the existing footprint to be used and eliminates the need to process the tailings at the Beaver Dam Mine Site. Geological conditions predict minimal effect on the receiving environment; conditions will be monitored and compared with the developing baseline data set for the Touquoy Gold Project.	Section 2.8.3 Operations and Maintenance associated with tailings management (exhausted pit), and key sections for surface water and groundwater in Section 6 Environmental Effects Assessment	Establish operational plan for deposit of tailings into the mined-out pit and ongoing monitoring of surface and groundwater water will determine if adaptive management should be applied
Request to be informed on the Project activities.	AMNS is committed to maintaining its CLC for the life of the Project. Other aspects of community engagement will continue as per Engagement Plan.	Section 3.6 Public Engagement; Section 6.16.11 Mitigation for Socio-economic Conditions	Implement Engagement Plan
2020 Engagement			
Concerns about access to ATV and snowmobile trails.	Restrictions on usage are required for safety reasons. Alternative access for ATVs, snowmobiles and light vehicles are being considered.	Section 6.16.5.4 Land Use, Recreational and Indigenous, Section 6.16.11 Mitigation and Appendix A.4a Summary of Public Engagement as Completed for the Beaver Dam Mine Project	Construct bypass roads to maintain access during operations
Concerns about access to camps, hunting and fishing locations.	Access to camps, hunting areas and fishing areas will be maintained. Camps, hunting and fishing areas have been identified by stakeholders and AMNS will work with stakeholders to allow continued access.	Section 6.16.5.4 Land Use, Recreational and Indigenous, Section 6.16.5.5 Parks and Open Space, Tourism, Section 6.16.11 Mitigation and Appendix A.4a Summary of Public Engagement as Completed for the Beaver Dam Mine Project To-date	Construct bypass roads to maintain access during operations
Concerns about traffic through Mooseland.	Traffic is not expected to impact Mooseland. As AMNS is developing routes for ATVs, snowmobiles and light vehicles, no traffic increases are expected in Mooseland.	Section 6.16.5.4 Land Use, Recreational and Indigenous, Section 6.16.5.6 Roads and Traffic, Section 6.16.11 Mitigation and Appendix A.4a Summary of Public Engagement as Completed for the Beaver Dam Mine Project To-date	Construct bypass roads to maintain access during operations Implement engagement plan to address public concerned during life of Mine

Table 3.7-1: Summary of Key Concerns Raised During Stakeholder Engagement 2015 to 2020 (continued)

Key Concerns	Summary of Proponent Response	Corresponding Updated 2021 EIS Section Reference[(a)]	Follow-up/ Commitment
Concerns about noise in Mooseland.	Noise modeling shows that all residences and receptors in Mooselands meet guidelines.	Section 6.1 Noise, Section 6.16.5.4 Land Use, Recreational and Indigenous, Section 6.16.11 Mitigation, Appendix A.4a Summary of Public Engagement as Completed for the Beaver Dam Mine Project To-date and Appendices B.1 Beaver Dam Mine Construction Noise Assessment and B.2 Updated Noise Impact Assessment Technical Report	Implement a Noise Complaint Protocol and Engagement Plan
Concerns about safety of the road network and trail network on Haul Road.	AMNS Haul Road Operations and Safety Management Plan will be developed by an ad hoc advisory committee.	Section 6.16.5.4 Land Use, Recreational and Indigenous, Section 6.16.5.6 Roads and Traffic, Section 6.16.11 Mitigation and Appendix A.4a Summary of Public Engagement as Completed for the Beaver Dam Mine Project To-date	Implement Haul Road Operations and Safety Management Plan will be developed by an ad hoc advisory committee
Questions and concerns regarding receiving communications and information during the life of the Project.	Draft Public Engagement Plan has been drafted and will be circulated to stakeholders for feedback and comment. Community relations telephone line, email, website and news releases will continue. AMNS is evaluating opportunities to include social media platforms as well.	Sections 3.2 Objectives, Section 3.4 Engagement Strategy, and Appendix A.6 draft Public Engagement Plan	Implement Engagement Plan
Identification of potential mainland moose in the area.	The information provided by a stakeholder is being reviewed as of the updated 2021 EIS.	Section 6.11.4.1.1 Mainland Moose and Appendix A.4a Summary of Public Engagement as Completed for the Beaver Dam Mine Project To-date	Implement Engagement Plan
Concerns regarding slurry and dust from the Mooseland Road related to the Touquoy operations.	AMNS has a skid steer with a broom dedicated to cleaning the crossing. AMNS commits improving visibility and removing debris at the Mooseland Road crossing.	Sections 2.11.11 The Preferred Approach	Implement Operational Procedure to Manage Haul Roads
Concerns that the original EIS incorrect statements regarding the distances between residents and the Mooseland entrance to the Haul Road (known as the “old dump road”).	Updated 2012 EIS will be corrected as appropriate.	Section 2.3 Project Location and 2.5Project History, Section 6.16.4.12 Land and Resource Use, Section 6.16.5.6 Roads and Traffic	Corrected in EIS
Requested signage be placed on the “old dump road” to notify non-local residents that AMNS is considering construction of a Haul Road.	It is premature to place signage until project is approved. Also signage would require landowner approval. Business cards are being provided to local residents for them to distribute so that anyone with questions can contact community relations.	Section 6.16.5.6 Roads and Traffic, Section 6.16.10 Project Activities and Socio-economic Integrations and Effects, and Section 6.16.11 Mitigation	Implement Haul Road Operations and Safety Management Plan will be developed by an ad hoc advisory committee

Table 3.7-1: Summary of Key Concerns Raised During Stakeholder Engagement 2015 to 2020 (continued)

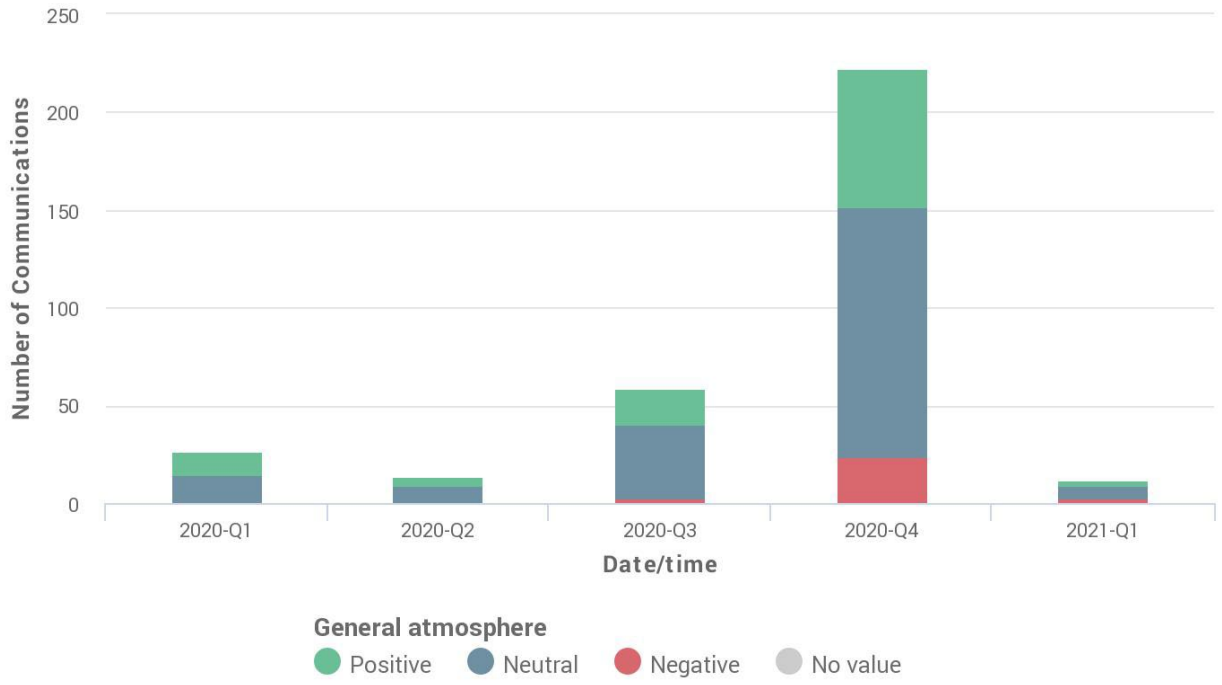
Key Concerns	Summary of Proponent Response	Corresponding Updated 2021 EIS Section Reference[(a)]	Follow-up/ Commitment
Concerns that the life of the Beaver Dam project use of the Haul Road will extend beyond 5 years.	The life of mine for the Project is 5 years but Fifteen Mile Stream Gold Project and Cochrane Hill Gold Project will also use the Haul Road.	Section 1.2 Atlantic Mining NS Inc. Information and Section 8 Cumulative Effects Assessment	Implement Engagement Plan
Request to have truck and ATV access between the Mooseland Road and Hwy 224.	truck and ATV access between the Mooseland Road and Hwy 224 is accommodated via bypass roads.	Section 6.16.5.6 Roads and Traffic and Appendix A.4a	Implement Haul Road Operations and Safety Management Plan will be developed by an ad hoc advisory committee
Request to have the Mooseland Road entirely paved between Touquoy and the entrance to the Hwy 224.	The Mooseland Road is a provincially owned road and decisions regarding paving at made at the provincial level. This concern has been forwarded to the CLC to assess next steps and possibly providing letter of support for paving.	Section 6.16.5.6 Roads and Traffic and Section 6.16.8 Consideration of Engagement Results	CLC Follow-up
Questions regarding the safety monitoring of the Mooseland road.	AMNS has a close working relationship with NS Department of Transportation and Active Transportation and will work collaboratively with an ad hoc advisory committee.	Section 6.16.5.6 Roads and Traffic, Section 6.16.11 Mitigation, and Appendix A.4a	Implement Haul Road Operations and Safety Management Plan will be developed by an ad hoc advisory committee
Question regarding if the Haul Road can have blended traffic	AMNS explored this option and determined that for safety and operational reasons, that blended traffic is not the best option and instead is pursuing a dedicated bypass option for ATVs, snowmobiles and light vehicles.	Section 6.16.5.6 Roads and Traffic	Commitment to reconsider blended traffic after Beaver Dam Mine operations is completed
Request for a public meeting in Mooseland.	AMNS organized an open house for Mooseland residents on November 27 and 28, 2020. Public Health restrictions issued by the province required that this meeting be cancelled. An open house potentially will occur in Q2/Q3, determined on health restrictions due to COVID-19.	Sections 3.6 Public Engagement and Section 3.8 and Appendix A.6 Ongoing Engagement	Implement Engagement Plan
Request for input into the operational and safety plan for the Haul Road.	AMNS will seek input in the operations and safety plan for the Haul Road. AMNS may established an ad hoc advisory committee to solicit advice.	Section 6.16.5.6 Roads and Traffic, Section 6.16.11 Mitigation, and Appendix A.4a and A.6	Implement Haul Road Operations and Safety Management Plan will be developed by an ad hoc advisory committee
Concerns about impacts on hunting near the Haul Road.	Hunting will be governed by provincial hunting requirements, which will restrict hunting near the Haul Road.	Section 6.14.7.1 Project Interactions with Traditional Use/Rights	Implement Engagement Plan
Concerns about providing access to Marilyn Prest's land.	Access will be provided to this particular landowner.	Section 6.16.5.4 Land Use, Recreational and Indigenous	Construct by-pass roads and provide landowner access
Concerns about AMNS is communicating its plan for the Haul Road to the general population outside of the immediate area.	Communication and engagement with this stakeholder will occur as per the draft Public Engagement Plan.	Appendix A.6 draft Public Engagement Plan	Implement Engagement Plan

Table 3.7-1: Summary of Key Concerns Raised During Stakeholder Engagement 2015 to 2020 (continued)

Key Concerns	Summary of Proponent Response	Corresponding Updated 2021 EIS Section Reference[a]	Follow-up/ Commitment
Concerns about Impacts on Ferry Lake.	Ferry Lake is not modeled to be impacted by the Beaver Dam Mine Project. Ferry Lake property owners who have expressed interest in the project have been contacted.	Section 3.6 and Appendix F.9 (Response to IR2s. CEAA 2-36, CEAA 2-37, and NSE 2-130 Evaluation of Potential Impacts from Metals COCs to Groundwater and Surface Water from Dust Deposition along the Haul Road)	Implement Engagement Plan
Impacts on NSSA West River Project and fish habitat.	Fish and fish habitat assessment, mitigation and monitoring plans to address ongoing concerns. Develop an aquatic Effects Monitoring Program.	Section 6.9.8 Mitigation (Fish), Section 6.16.11 Mitigation (Socio-economic) and Section 8 Cumulative Effects Assessment	Implement Aquatic Effects Monitoring Program
Speeding by AMNS vehicles on the Mooseland Road.	Complaints from residents will be investigated. All AMNS vehicles include a GPS so that vehicle speeds can be tracked. AMNS committed to installing digital speed sign as a pilot project.	Section 6.16.8 Consideration of Engagement Results	Implement Haul Road Operations and Safety Management Plan will be developed by an ad hoc advisory committee
Concerns about the widening of the Haul Road on private landowners.	The width of the Haul Road right of way is approximately 100 m. The Haul Road and bypass road will remain within this right of way and no additional land is required for the bypass roads.	Section 2.8.2 Haul Road for Transporting Ore, Section 2.8.2 Project Activities	Implement Haul Road Operations and Safety Management Plan will be developed by an ad hoc advisory committee

Notes: NSE = Nova Scotia Environment; SOCI = Species of Conservation Interest; SAR = Species at Risk; VC = Valued Component; EA = Effects Assessment; CLC = Community Liaison Committee; AMNS = Atlantic Mining NS Inc.; CIL = Carbon in Leach.

Figure 3.7-1: Number of Communication in 2020 by Quarter



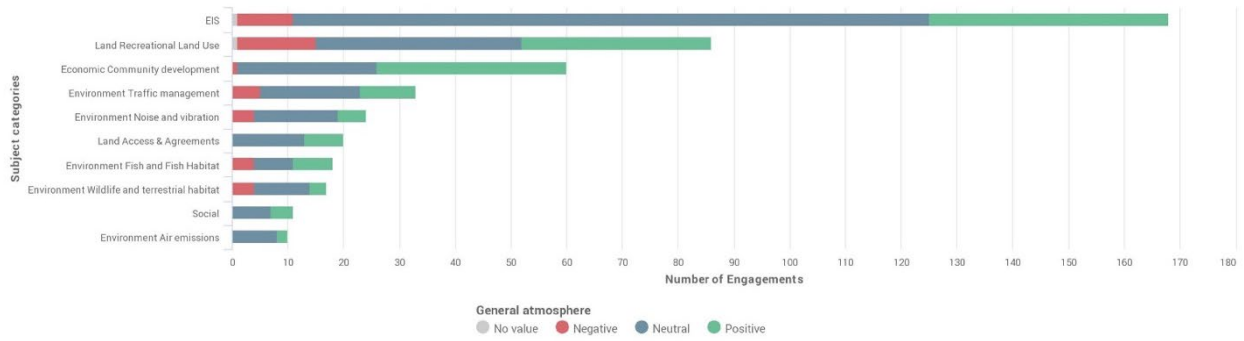


Figure 3.7-2: Key Subject Categories in 2020 to 2021

The key subject categories (Figure 3.7-2) show the topics of discussion during 2020 and the atmosphere related to each concern. This kind of tracking helps AMNS identify topics and concerns where additional focus is required. Please note that each engagement may have more than one subject category associated with it (Figure 3.7-2).

In total, AMNS had approximately 322 communications with over 147 individuals or organizations in 2020. Key concerns which arose from the 2020 engagements are shown in Table 3.7-2. Although many of the concerns were previously identified and mitigations proposed in the pre-2020 engagement summary, additional concerns did arise which required additional mitigation and/or analysis. Table 3.7-2 outlines the key concerns heard during this engagement period.

The concerns raised during all the public engagement activities since 2015 were incorporated into the design of the Project and the development of the EIS. Improvements to planning and design as a result of feedback from this engagement includes, but is not limited to, minimizing Project footprint, including limiting direct effects to watercourses and wetlands, and changing the Haul Road to cross Hwy 224 rather than travel along Hwy 224 to avoid passing by residences and to minimize travel on Hwy 224. AMNS commitments and mitigations regarding the construction of bypass roads, using adaptive management principles and identifying crossing of the Haul Road for recreational users are detailed in the Socio-economic Conditions Sections 6.16.5, 6.16.8, 6.16.10 and 6.16.11. The proposed bypass roads are also shown on Figure 3.3-2.

The meetings, site visits, telephone calls, emails, and other correspondence that formed the Public stakeholder and the Mi'kmaq of Nova Scotia engagement activities are included in Appendices A.4a and A.5, respectively.

Table 3.7-2: Key Concerns Raised during 2020 Public Engagement Meetings

Key Concerns	Summary of Proponent Response	Corresponding EIS Reference/Appendix
Concerns about access to ATV and snowmobile trails.	Restrictions on usage are required for safety reasons. Alternative access for ATVs, snowmobiles and light vehicles are being considered.	Section 6.16.5.4 Land Use, Recreational and Indigenous, Section 6.16.11 Mitigation and Appendix A.4a Summary of Public Engagement as Completed for the Beaver Dam Mine Project To-date
Concerns about access to camps, hunting and fishing locations.	Access to camps, hunting areas and fishing areas will be maintained. Camps, hunting and fishing areas have been identified by stakeholders and AMNS will work with stakeholders to allow continued access.	Section 6.16.5.4 Land Use, Recreational and Indigenous, Section 6.16.5.5 Parks and Open Space, Tourism, Section 6.16.11 Mitigation and Appendix A.4a Summary of Public Engagement as Completed for the Beaver Dam Mine Project To-date
Concerns about traffic through Mooseland.	Traffic is not expected to impact Mooseland. As AMNS is developing routes for ATVs, snowmobiles and light vehicles, no traffic increases are expected in Mooseland.	Section 6.16.5.4 Land Use, Recreational and Indigenous, Section 6.16.5.6 Roads and Traffic, Section 6.16.11 Mitigation and Appendix A.4a Summary of Public Engagement as Completed for the Beaver Dam Mine Project To-date
Concerns about noise in Mooseland.	Noise modeling shows that all residences and receptors in Mooselands meet guidelines.	Section 6.1 Noise, Section 6.16.5.4 Land Use, Recreational and Indigenous, Section 6.16.11 Mitigation, Appendix A.4a Summary of Public Engagement as Completed for the Beaver Dam Mine Project To-date and Appendices B.1 Beaver Dam Mine Construction Noise Assessment and B.2 Updated Noise Impact Assessment Technical Report
Concerns about safety of the road network and trail network on Haul Road.	AMNS Haul Road Operations and Safety Management Plan will be developed by an ad hoc advisory committee.	Section 6.16.5.4 Land Use, Recreational and Indigenous, Section 6.16.5.6 Roads and Traffic, Section 6.16.11 Mitigation and Appendix A.4a Summary of Public Engagement as Completed for the Beaver Dam Mine Project To-date
Questions and concerns regarding receiving communications and information during the life of the Project.	Draft Public Engagement Plan has been drafted and will be circulated to stakeholders for feedback and comment. Community relations telephone line, email, website and news releases will continue. AMNS is evaluating opportunities to include social media platforms as well.	Sections 3.2 Objectives, Section 3.4 Engagement Strategy, and Appendix A.6 draft Public Engagement Plan
Identification of potential mainland moose in the area.	The information provided by a stakeholder is being reviewed as of the updated 2021 EIS.	Section 6.11.4.1.2 Mainland Moose and Appendix A.4a Summary of Public Engagement as Completed for the Beaver Dam Mine Project To-date

Table 3.7-2: Key Concerns Raised during 2020 Public Engagement Meetings (continued)

Key Concerns	Summary of Proponent Response	Corresponding EIS Reference/Appendix
Concerns regarding slurry and dust from the Mooseland Road related to the Touquoy operations.	AMNS has a skid steer with a broom dedicated to cleaning the crossing. AMNS commits improving visibility and removing debris at the Mooseland Road crossing.	Sections 2.11.11 The Preferred Approach
Concerns that the original EIS incorrect statements regarding the distances between residents and the Mooseland entrance to the Haul Road (known as the "old dump road").	Updated 2012 EIS will be corrected as appropriate.	Project Location and History (Section 2.3 and 2,5), Land and Resource Use Section 6.16.4.12, Section 6.16.5.6 Roads and Traffic
Requested signage be placed on the "old dump road" to notify non-local residents that AMNS is considering construction of a Haul Road.	It is premature to place signage until project is approved. Also signage would require landowner approval. Business cards are being provided to local residents for them to distribute so that anyone with questions can contact community relations.	Section 6.16.5.6 Roads and Traffic, Section 6.16.10 Project Activities and Socio-economic Integrations and Effects, and Section 6.16.11 Mitigation
Concerns that the life of the Beaver Dam project use of the Haul Road will extend beyond 5 years.	The life of mine for the Project is 5 years but Fifteen Mile Stream Gold Project and Cochrane Hill Gold Project will also use the Haul Road.	Section 1 Proponent Information and Section 8 Cumulative Effects Assessment
Request to have truck and ATV access between the Mooseland Road and Hwy 224.	truck and ATV access between the Mooseland Road and Hwy 224 is accommodated via bypass roads.	Section 6.16.5.6 Roads and Traffic and Appendix A.4a
Request to have the Mooseland Road entirely paved between Touquoy and the entrance to the Hwy 224.	The Mooseland Road is a provincially owned road and decisions regarding paving at made at the provincial level. This concern has been forwarded to the CLC to assess next steps and possibly providing letter of support for paving.	Section 6.16.5.6 Roads and Traffic and Section 6.16.8 Consideration of Engagement Results
Questions regarding the safety monitoring of the Mooseland road.	AMNS has a close working relationship with NS Department of Transportation and Active Transportation and will work collaboratively with an ad hoc advisory committee.	Section 6.16.5.6 Roads and Traffic, Section 6.16.11 Mitigation, and Appendix A.4a
Question regarding if the Haul Road can have blended traffic	AMNS explored this option and determined that for safety and operational reasons, that blended traffic is not the best option and instead is pursuing a dedicated bypass option for ATVs, snowmobiles and light vehicles.	Section 6.16.5.6 Roads and Traffic
Request for a public meeting in Mooseland.	AMNS organized an open house for Mooseland residents on November 27 and 28, 2020. Public Health restrictions issued by the province required that this meeting be cancelled. An open house potentially will occur in Q2/Q3, determined on health restrictions due to COVID-19.	Sections 3.6 Public Engagement and Section 3.8 Appendix A.6 Ongoing Engagement
Request for input into the operational and safety plan for the Haul Road.	AMNS will seek input in the operations and safety plan for the Haul Road. AMNS may established an ad hoc advisory committee to solicit advice.	Section 6.16.5.6 Roads and Traffic, Section 6.16.11 Mitigation, and Appendix A.4a

Table 3.7-2: Key Concerns Raised during 2020 Public Engagement Meetings (continued)

Key Concerns	Summary of Proponent Response	Corresponding EIS Reference/Appendix
Concerns about impacts on hunting near the Haul Road.	Hunting will be governed by provincial hunting requirements, which will restrict hunting near the Haul Road.	Section 6.14.7.1 Project Interactions with Traditional Use/Rights
Concerns about providing access to Marilyn Prest's land.	Access will be provided to this particular landowner.	Section 6.16.5.4 Land Use, Recreational and Indigenous
Concerns about AMNS is communicating its plan for the Haul Road to the general population outside of the immediate area.	Communication and engagement with this stakeholder will occur as per the draft Public Engagement Plan.	Appendix A.6 draft Public Engagement Plan
Concerns about Impacts on Ferry Lake.	Ferry Lake is not modeled to be impacted by the Beaver Dam Mine Project. Ferry Lake property owners who have expressed interest in the project have been contacted.	Section 3.6 and Appendix F.9 (Response to Information Request Nos. CEAA 2-36, CEAA 2-37, and NSE 2-130 Evaluation of Potential Impacts from Metals COCs to Groundwater and Surface Water from Dust Deposition along the Haul Road)
Impacts on NSSA West River Project and fish habitat.	Fish and fish habitat assessment, mitigation and monitoring plans to address ongoing concerns.	Section 6.9.8 Mitigation (Fish), Section 6.16.11 Mitigation (Socio-economic) and Section 8 Cumulative Effects Assessment
Speeding by AMNS vehicles on the Mooseland Road.	Complaints from residents will be investigated. All AMNS vehicles include a GPS so that vehicle speeds can be tracked. AMNS committed to installing digital speed sign as a pilot project.	Section 6.16.8 Consideration of Engagement Results
Concerns about the widening of the Haul Road on private landowners.	The width of the Haul Road right of way is approximately 100 m. The Haul Road and bypass road will remain within this right of way and no additional land is required for the bypass roads.	Section 2.8.2 Haul Road for Transporting Ore

Notes: ATV = all-terrain vehicle; AMNS = Atlantic Mining NS Inc.; EIS = Environmental Impact Statement; GPS = Global Positioning System; CLC = Community Liaison Committee; m = metre; NSSA = Nova Scotia Salmon Association.

3.8 Ongoing Public Engagement

As per the draft Public Engagement Plan, there are many tools to engage stakeholders, including members of the local community, government regulators, NGOs, landowners, and members of the public. AMNS has a broad objective to continue to engage the community and will continue to implement its strategy.

Within the draft Public Engagement Plan specific commitments are made by AMNS to engage during the next steps in the EA processes and beyond, including:

- sharing key aspects of the EIS with interested NGOs and/or CLC members;
- holding meetings with interested NGOs, including ESFWA and NSSA;
- aligning in data collection and mitigation measures with local organizations, specifically with the ongoing field work of NSSA; and
- answering specific questions posed directly to the company by providing additional information where feasible.

As part of the understanding that engagement plans need to be flexible, AMNS will address and respond to additional stakeholders identified or concerns noted as the Project moves forward and into construction, operation and active closure.

The Public Engagement Plan (Appendix A.6) is a long-term plan which makes a series of commitments that will be delivered over the life of the Project.

4 INDIGENOUS PEOPLES ENGAGEMENT PROGRAM

4.1 Introduction

4.1.1 Summary of Indigenous Peoples Engagement Before the Updates

AMNS is committed to developing a long-term, positive and productive relationship with the Mi'kmaq of Nova Scotia based on principles of mutual respect, transparency, honesty and integrity, and a partnership approach to engagement. Meaningful engagement is a key component of the Project and began as part of planning and environmental assessment of the Touquoy Gold Project over a decade ago. The engagement has focused on building relationships with the Assembly of Nova Scotia Mi'kmaq Chiefs and the Kwilmu'kw Maw-klusuaqn Negotiation Office (KMKNO), as well as the community members, staff and Chief and Council of nearby Mi'kmaq communities, specifically Millbrook First Nation, and Sipekne'katik First Nation. AMNS has, and will continue to, exchange important Project information and answer questions; discuss the concerns and interests of the Mi'kmaq, including traditional and current use and the importance of the area; discuss potential impacts on the Mi'kmaq and develop avoidance and mitigations strategies together to address their concerns; and, to develop opportunities for involvement in environmental monitoring, and other aspects of the Project.

The focus of engagement has, and will continue to be, with the Assembly, the KMKNO, and the communities of Millbrook and Sipekne'katik. Focused engagement has and will continue with Millbrook due to their proximity to the Project. Aligning mutual interests, such as environmental protection specifically related to current use of land and resources for traditional purposes, is a core part of the engagement.

4.1.2 Summary of Updates to Indigenous Peoples Engagement

Participation of the Mi'kmaq of Nova Scotia has been ongoing to identify impacts to the Mi'kmaq, in consideration of traditional knowledge as part mine planning and development of the EIS. AMNS respects the consultation, decision-making and governance structures that the Mi'kmaq of Nova Scotia have put in place within their organizations and communities. The focus of engagement has, and will continue to be, with the Assembly, the KMKNO, and the communities of Millbrook and Sipekne'katik. Egagement has and will continue with Millbrook due to their proximity to the Project. Aligning mutual interests, such as environmental protection specifically related to current use of land and resources for traditional purposes, is a core part of the engagement.

With the receipt of Information Requests from the Agency after AMNS submitted the EIS in 2017 and revised 2019 EIS (AMNS 2017 and 2019), AMNS has continued to engage with the Mi'kmaq of Nova Scotia on a regular basis to better understand existing land uses. Millbrook initiated a Traditional Land and Resource Use Study (TLRUS) in 2018 and delivered the results in 2019 just prior to the revised 2019 EIS (i.e., response Round 1 Information Requests submission [AMNS 2019]). AMNS has been working with Millbrook to review TLRUS results and continue ongoing and regular engagement throughout the Round 2, Information Requests (IR2) process.

The two closest Mi'kmaq communities of Millbrook and Sipekne'katik First Nations have registered total populations of 1,995 and 2,771, respectively (CBU 2020). As stated above, the two communities have chosen to represent themselves directly in consultation with the Crown. There are two communities near the Beaver Dam Mine Project: Beaver Lake IR 17 (49.4 ha) is located approximately 5km southwest from the Beaver Dam Mine Site, and Sheet Harbour IR 36 (32.7 ha) is located 20 km south of the Project. Both these reserves belong to the Millbrook First Nation which is located in Truro, Nova Scotia, 54 km northwest of the Beaver Dam Mine Site. Beaver Lake Indian Reserve (IR) I7 with an on-reserve population of about 21 and Sheet Harbour IR 36 with an on-reserve population of about 25 (Statistics Canada 2017).

Updates have been focused on engagement as well as information that has become available since the submission of the 2019 Revised EIS. This includes but not limited to responses to IR2.

Table 4.1-1: Updated Subsections from the 2019 Revised Environmental Impact Statement – Indigenous Peoples

Section 4 from the 2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Reason for Update
4.1 Objectives	Yes	Ongoing and continued engagement
4.2 Indigenous People in Nova Scotia	Yes	Ongoing and continued engagement
4.3 Engagement Strategy	Yes	Ongoing and continued engagement
4.4 Indigenous Peoples Engagement Activities	Yes	Ongoing and continued engagement
4.5 Key Issues Raised and Proponent Responses	Yes	Ongoing and continued engagement
4.6 Ongoing Indigenous Peoples Engagement	Yes	Ongoing and continued engagement

4.2 Objectives

AMNS is committed to developing a long-term, positive and productive relationship with the Mi'kmaq of Nova Scotia based on principles of mutual respect, transparency, honesty and integrity, and a partnership approach to engagement. Meaningful engagement is a key component of the Project and began as part of planning and environmental assessment of the Touquoy Gold Project over a decade ago. The engagement has focused on building relationships with the Assembly of Nova Scotia Mi'kmaq Chiefs and the Kwilmu'kw Maw-klusuaqn Negotiation Office (KMKNO), as well as the community members, staff and Chief and Council of nearby Mi'kmaq communities, specifically Millbrook First Nation, and Sipekne'katik First Nation. AMNS has, and will continue to, exchange important Project information and answer questions; discuss the concerns and interests of the Mi'kmaq, including traditional and current use and the importance of the area; discuss potential impacts on the Mi'kmaq and develop avoidance and mitigations strategies together to address their concerns; and, to develop opportunities for involvement in environmental monitoring, and other aspects of the Project.

The Beaver Dam Mine Project EIS Guidelines prepared by the Impact Assessment Agency of Canada (IAAC; formerly the Canadian Environmental Assessment Agency [CEAA 2016]) provides guidance on specific aspects of Mi'kmaq engagement. For Mi'kmaq groups with potential to be most affected by the Project, it was expected that AMNS would strive toward developing a productive and constructive relationship based on ongoing dialogue with the groups to support information gathering and effects assessment. Further, the *Province of Nova Scotia's Proponent's Guide: The Role of Proponents in Crown Consultation with the Mi'kmaq of Nova Scotia, 2011* provides guidance on engaging with Indigenous groups. AMNS continues to follow the guidance from the federal and provincial governments and intends to build on and strengthen the relationship developed with the Mi'kmaq of Nova Scotia during the past decade.

As per Supreme Court of Canada instruction and subsequent guidance from governments, such as the Updated Guidelines for Federal Officials to Fulfill the Duty to Consult (Government of Canada, 2011) and AMNS's Guide: Engagement with the Mi'kmaq of Nova Scotia (Province of Nova Scotia, 2012), the Crown may delegate procedural aspects of consultation to proponents. However, the duty to consult, and constitutional obligation remains with the Crown. As noted in the EIS Guidelines (CEAA 2016) the results of the AMNS's Mi'kmaq of Nova Scotia engagement program *"helps to contribute to the Crown's understanding of any potential adverse impacts of the project on potential or established Aboriginal or treaty rights, title and related interests, and the effectiveness of measures proposed to avoid or minimise those impacts"*.

The Made-in-Nova Scotia Process is the forum for the Mi'kmaq, Nova Scotia, and Canada to resolve issues related to Mi'kmaq treaty rights, Aboriginal rights, including Aboriginal title, and Mi'kmaq governance. The process involves the Mi'kmaq of Nova Scotia as represented by the Assembly of Nova Scotia Mi'kmaq Chiefs and the provincial and federal governments. Both the federal and provincial governments have requirements for consultation under the *Updated Guidelines for Federal Officials to Fulfill the Duty to Consult: 2011*, and the *Mi'kmaq-Nova Scotia-Canada Consultation Terms of Reference. Further, the Nova Scotia Environmental Assessment Regulations* include a requirement to identify concerns of Indigenous People about potential adverse effects and steps taken, or proposed to be taken, by AMNS to address concerns, as well as the steps taken to identify these concerns.

Participation of the Mi'kmaq of Nova Scotia has been ongoing to identify impacts to the Mi'kmaq, in consideration of traditional knowledge as part mine planning and development of the EIS. AMNS respects the consultation, decision-making and governance structures that the Mi'kmaq of Nova Scotia have put in place within their organizations and communities. The focus of engagement has, and will continue to be, with the Assembly, the KMKNO, and the communities of Millbrook and Sipekne'katik. Focused engagement has and will continue with Millbrook due to their proximity to the Project. Aligning mutual interests, such as environmental protection specifically related to current use of land and resources for traditional purposes, is a core part of the engagement.

With the receipt of Information Requests from the Agency after AMNS submitted the EIS in 2017 and revised 2019 EIS (AGC 2017 and AMNS 2019), AMNS has continued to engage with the Mi'kmaq of Nova Scotia on a regular basis to better understand existing land uses. Millbrook initiated a Traditional Land and Resource Use Study (TLRUS) in 2018 and delivered the results in 2019 just prior to the revised 2019 EIS (i.e., responses Round 1 Information Requests [AMNS 2019]). AMNS has been working with Millbrook to review TLRUS results and continue ongoing and regular engagement throughout the IR2 process.

4.3 Indigenous People in Nova Scotia

The Mi'kmaq are the original people of Nova Scotia and remain the predominant Indigenous Peoples within the Province. The courts have confirmed that the Mi'kmaq of Nova Scotia have both Aboriginal and Treaty rights protected under Section 35 of the *Constitution Act*. The nature and extent of those rights, as well as the responsibilities and authorities of governments with respect to those rights, are the subject of negotiation between the federal and provincial governments and the Mi'kmaq of Nova Scotia, as described above.

The Mi'kmaq Nation of Nova Scotia has a general interest in all lands and resources as the Mi'kmaq Nation maintain that they did not give up their land rights through treaty, voluntary cessation, or otherwise. The Mi'kmaq of Nova Scotia maintains a claim of Aboriginal title to the lands and waters of Nova Scotia and adjacent areas of the offshore.

As part of the Umbrella and Framework Agreements developed for the Made-in-Nova Scotia Process, a draft Consultation Terms of Reference (TOR) was adopted in 2007. After a three-year pilot period the thirteen Mi'kmaq communities, through the Assembly of Nova Scotia Mi'kmaq Chiefs, signed the Mi'kmaq-Nova Scotia-Canada Consultation TOR in 2010 with the Governments of Canada and Nova Scotia. The TOR lays out a process for the parties to follow when governments wish to consult with the Mi'kmaq of Nova Scotia. The Made-in-Nova Scotia Negotiation Process and the historic development of the Consultation TOR are based on the principle of the Mi'kmaq of Nova Scotia as one Mi'kmaq Nation.

Nova Scotia has thirteen Mi'kmaq First Nations with a total registered population of 16,760 as of 2017, including both on- and off-reserve populations (AANDC 2019). The Assembly of Nova Scotia Mi'kmaq Chiefs (ANSMC) represents all thirteen communities in dealings with the Crown. The Kwilmu'kw Maw-klusuaqn Negotiation Office (KMKNO) is the administrative group that represents the ANSMC in the consultation and negotiations with the Province of Nova Scotia and the Government of Canada. Millbrook and Sipekne'katik First Nations have chosen to consult through their own community Chief and Councils, rather than the KMKNO.

As part of engagement of the Mi'kmaq of Nova Scotia, the following are groups who were listed in the EIS Guidelines (CEAA 2016) as being possibly affected by the Project. These include the thirteen Mi'kmaq First Nations in Nova Scotia, the Assembly of Nova Scotia Mi'kmaq Chiefs, and the KMKNO:

- Acadia First Nation;
- Annapolis Valley First Nation;
- Bear River First Nation;
- Potlotek First Nation;
- Eskasoni First Nation;
- Glooscap First Nation;
- Membertou First Nation;
- Millbrook First Nation;
- Paq'tnkek (Afton) First Nation;
- Pictou Landing First Nation;
- Sipekne'katik First Nation;
- Wagmatcook First Nation;
- We'koqma'q First Nation; and
- Assembly of Nova Scotia Mi'kmaq Chiefs and the KMKNO.

In addition, the Native Council of Nova Scotia (NCNS) is a self-governing authority for the community of Mi'kmaq or other Indigenous Peoples residing off-reserve in Nova Scotia. The Native Council has established thirteen geographic zones encompassing the Province of Nova Scotia and has an elected Office of Chief and President.

The two closest Mi'kmaq communities of Millbrook and Sipekne'katik First Nations have registered total populations of 1,995 and 2,771, respectively (CBU 2020). As stated above, the two communities have chosen to represent themselves directly in consultation with the Crown. There are two communities near the Beaver Dam Mine Project: Beaver Lake IR 17 (49.4 ha) is located approximately 5 km southwest from the Beaver Dam Mine Site, and Sheet Harbour IR 36 (32.7 ha) is located 20 km south of the Project. Both these reserves belong to the Millbrook First Nation which is located in Truro, Nova Scotia, 54 km northwest of the Beaver Dam Mine Site. Beaver Lake IR I7 with an on-reserve population of about 21 and Sheet Harbour IR 36 with an on-reserve population of about 25 (Statistics Canada 2017).

AMNS's approach to Mi'kmaq engagement and development of the EIS has respected the current framework for engaging the Mi'kmaq of Nova Scotia – providing Project information, summaries of Project conclusions, descriptions of mitigation measures and monitoring programs through a variety of methods (direct face to face meetings, written correspondence, virtual meetings and phone calls) to the KMKNO, Millbrook and Sipekne'katik First Nations.

AMNS has used a similar approach to the discussion of potential benefits and opportunities related to the Project – focusing on discussions with the ANSMC/KMKNO, Millbrook and Sipekne'katik First Nation communities. Focused engagement has and will continue with Millbrook due to their proximity to the Project.

4.4 Key Engagement Activities

As part of an overall Indigenous Peoples Plan, AMNS's approach to Mi'kmaq engagement allows for flexibility to permit adaptation based on discussions and feedback from the Mi'kmaq and ongoing development of AMNS's projects.

AMNS uses the following methods, depending on the need, to engage with the Mi'kmaq of Nova Scotia:

- one-window regulatory meetings;
- face-to-face meetings with Mi'kmaq organizations, Chiefs and Councils and communities;
- one point of contact for the Mi'kmaq of Nova Scotia;
- phone calls;
- emails;
- dropbox and FTP sites for document sharing;
- Mi'kmaq community open houses;
- public open houses and town hall meetings;
- site visits and tours;
- newsletters and regular Project Updates; and
- website and other digital and social media;

In addition to AMNS's engagement program related to the EIS the following elements are being discussed to further develop the company's decade-long relationship with the Mi'kmaq of Nova Scotia – one that has been built on mutual understanding and transparency, maintaining flexibility and open lines of communication to adjust implementation as the relationship and Project develops:

- Providing opportunities and benefits to all Mi'kmaq in Nova Scotia. Benefits can take the form of, but are not limited to, opportunities for training and capacity building, contracting and procurement, support for education and employment. Supporting cultural and traditional activities of the Mi'kmaq of Nova Scotia; and, providing cultural learning exchange opportunities for mining staff.
- Engagement to date has been positive and productive; the relationship was formalized in a Memorandum of Understanding (MOU) with the ANSMC through the KMKNO from 2014-2016 with a renewed MOU proposed in 2018 and pending approval by ANSMC as of January 2021. AMNS initiated the engagement program for the Beaver Dam Mine Project in early 2016 with Mi'kmaq community open houses and Public open houses to provide general information on the proposed Project to all interested community members. The public open houses were followed by a series of face-to-face meetings with Millbrook and Sipekne'katik First Nations, and the KMKNO through to the end of 2020. Information regarding the EIS and the EA process was shared and discussed during these meetings, including archaeological reports, summaries of potential impacts and mitigations, and other key details of the Project. AMNS also arranged a tour of the area and invited both Millbrook and Sipekne'katik First Nations to participate in the Community Liaison Committee (CLC).

In 2016, AMNS developed its strategy for Mi'kmaq engagement to coincide with the start of construction of the permitted Touquoy Gold Mine and the development of the EA for the Beaver Dam Mine Project. These elements listed below are specific to Mi'kmaq engagement and are often supported by community engagement activities listed above. These elements of the Mi'kmaq engagement strategy will be built upon over time as the Project develops.

In 2018, AMNS continued to exchange information with the KMKNO, and Millbrook and Sipekne'katik First Nations, and attempted to organize meetings to discuss Project information, traditional and current use of the area by the Mi'kmaq of Nova Scotia, and potential impacts and mitigations. Millbrook undertook a TLRUS in 2018 and delivered the results to AMNS in early 2019, just prior to submission of the Round 1 IR responses to the CEA Agency. Meetings were held to discuss further IR requests, the integration of TLRUS and land use date into the EIS, and the ongoing engagement process through 2019 and 2020.

AMNS met with the ANSMC/KMKNO in early 2020, prior to the global pandemic that was declared on March 11, 2020. Since that time, AMNS continued internal work to further understand any potential impacts of the proposed project on Mi'kmaq rights, such as ensuring all Indigenous perspectives that have already been shared with AMNS were considered, and any additional opportunities to understand specific impacts on current and traditional practices and perspectives identified. It is anticipated that these discussions will continue during the EIS review process.

AMNS suspended all Project-related engagement activities in early March 2020 as everyone began to contend with protection and prevention in communities, and the associated uncertainties and risks. AMNS kept in contact with communities during Nova Scotia's "lockdown" period from March to June 2020, through 2020, and again in 2021 and moved all engagement activity online. Specifically, AMNS has recently completed the following engagement activities:

- An online/virtual meeting was held with Millbrook First Nation's Chief and Council in early May 2020 to provide an overview of the Beaver Dam Mine Project and other Proponent projects to new council members.
- A Plain Language Summary (PLS) was prepared and shared with Millbrook First Nation on September 1, 2020, with the KMKNO on November 2, 2020 and with the Sipekne'katik First Nation on May 7, 2021.
- As part of on-going engagement and Project discussions specifically with the Millbrook First Nation, a draft Summary of Effects document outlining preliminary Project summaries, mitigation measures and cumulative effects was shared with the community in September 2020.
- On February 16, 2021, a draft response to Round 2 Information Requests CEAA-48/49 was shared with the Millbrook First Nation to support pending Millbrook community meetings. This draft response and associated mapping were also reviewed in a virtual meeting with Gerald Gloade on February 3, 2021.
- On April 1, 2021, the Mi'kmaq of Nova Scotia draft section of the EIS was shared with the Millbrook First Nation for review and feedback. The purpose of this review was twofold:
  - a request to validate and provide feedback of impact conclusions and proposed mitigation; and
  - to provide feedback on the level of specificity regarding the referencing of data in the TLRUS and to ensure the presentation is acceptable in consideration that the TLRUS is considered restricted and confidential.
- At the time of submission of this updated EIS, no specific feedback has been received from the Millbrook First Nation. AMNS understands that community meetings have taken place and that a report summarizing these meetings is drafted. Regular and consistent communications to receive this feedback has been ongoing with Millbrook First Nation through April and May 2021. Although the feedback has not been received, AMNS will continue to reach out and find opportunities to address feedback in the Projects development plans.

It is anticipated that engagement will continue throughout and beyond the current environmental assessment process. This will require ongoing dialogue regarding potential impacts on Mi'kmaq communities, and AMNS is committed to continuing those discussions. AMNS looks forward to receiving feedback and commits to discussing with Millbrook First Nation how best to address their feed back into Project design, mitigation and monitoring measures and potentially additional monitoring and mitigation measures.

A record of all engagement activities conducted between 2016 and the current date is provided in the Summary of Mi'kmaq of Nova Scotia Engagement Activities in Appendix A.5.

4.5 Mi'kmaq of Nova Scotia Engagement Activities

The objective of Mi'kmaq engagement relative to the development of the EIS for the Project is to gather views from Mi'kmaq groups with respect to both potential environmental effects of the Project and the potential adverse impacts of the Project on potential or established Aboriginal or treaty rights, title and related interests.

While broader engagement on the Touquoy Project has occurred for over a decade and will continue as per the Mi'kmaq engagement strategy, specific public engagement activities have occurred to support the EA for the Project since the federal process was commenced in December 2015.

These include aspects specific to the Project including:

- CLC, where two members were appointed by their Chief and Council as representatives of Millbrook First Nation and Sipekne'katik First Nation. Although Millbrook First Nation and Sipekne'katik First Nation have both withdrawn from the CLC, AMNS will continue to invite them to the CLC as guests.
- Open houses, specifically two community open houses occurred in May 2016 on lands of Millbrook and Sipekne'katik First Nations prior to the two public open houses.
- Presentations to Chief and Council of Millbrook First Nation and of Sipekne'katik First Nation, as well as the Benefits Committee Chiefs of the Assembly.
- Meetings, information sharing and correspondence with the KMKNO and thirteen Mi'kmaq First Nations of Nova Scotia, as well as the Nova Scotia Native Council for the purpose of good governance.
- Mini employment fairs set up in collaboration with staff of Millbrook and Sipekne'katik First Nations, as well as sharing of employment opportunities with Millbrook and Sipekne'katik First Nations and the KMKNO, with Mi'kmaq employment during the construction of the Touquoy Gold Project exceeding ten percent.
- Ongoing dialogue on formal agreements in terms of participation and benefits sharing with Millbrook First Nation, Sipekne'katik First Nation and the Assembly of Nova Scotia Mi'kmaq Chiefs.
- Participation of staff of KMKNO and Millbrook and Sipekne'katik First Nations in a site visit and tour of the proposed Beaver Dam Mine Project with provincial and federal regulators on November 29, 2016.
- Use of many tools for Mi'kmaq engagement that are used for the general community engagement, such as newsletters, signage, website, email and other digital media, media and press releases, meetings with local residents, and a complaints response procedure.
- Two Open Houses in January 2018 with Millbrook First Nation (one in Millbrook and one in Sheet Harbour) to address specific technical questions.
- Review of Project mitigation and monitoring with Sipekne'katik and KMKNO on September 12 and September 18, 2018, respectively.
- An online/virtual meeting was held with Millbrook First Nation's Chief and Council in early May 2020 to provide an overview of the Beaver Dam Mine Project and other Proponent projects to new council members.

- A Plain Language Summary (PLS) was prepared and shared with Millbrook First Nation on September 1, 2020, with the KMKNO on November 2, 2020 and with the Sipekne'katik First Nation on May 7, 2021.
- As part of on-going engagement and Project discussions specifically with the Millbrook First Nation, a draft Summary of Effects document outlining preliminary Project summaries, mitigation measures and cumulative effects was shared with the community in September 2020.
- On February 16, 2021, a draft response to Round 2 Information Requests CEAA-48/49 were shared with the Millbrook First Nation to support pending Millbrook community meetings that were being planned. This draft response and associated mapping were also reviewed in a virtual meeting with Gerald Gloade on February 3, 2021.
- On April 1, 2021, the Mi'kmaq of Nova Scotia section of the EIS was shared with the Millbrook First Nation for review and feedback.

These meetings, calls, site visits and correspondence are included in the summary of engagement activities conducted with the Mi'kmaq of Nova Scotia since EA commencement in December 2015 and are provided in Appendix A.5.

4.5.1 Community Open Houses

As discussed in Section 3.4.1 of this EIS, four open houses were held in May 2016; two of these were open to the public while the other two were specific to community members of Millbrook First Nation and Sipekne'katik First Nation.

The two Mi'kmaq community open houses were advertised by staff of each community. In addition, community members were invited to attend the two public open houses if convenient (held on May 18, 2016 in Middle Musquodoboit and on May 19, 2016 in Sheet Harbour). The dates and locations for the two Mi'kmaq community open houses were:

- May 16, 2016 at Millbrook Community Hall, 72 Church Rd, Truro; and,
- May 17, 2016 at Saint Kateri Tekakwitha (Church Basement), Indian Brook.

The format and layout were the same for all community open houses. Each open house was hosted from 3pm to 8pm with refreshments provided. Upon entry, attendees were asked to sign in and were provided a comment form to complete at end of their visit. Maps were also available for viewing on table and a 3D model of the Beaver Dam Mine Site was used to demonstrate the existing conditions, proposed full mine development (including pit and waste rock pile) and reclamation of the site.

A total of fifteen panels were placed on easels with AMNS and its consultants hosting the panels. After a welcome and introduction to AMNS and their Projects' background (three panels), an overview of open pit mining, process of gold recovery, and economic benefits of the projects was provided (three panels). The next three panels provided an update on the Touquoy Gold Project which was soon to begin construction (June 2016). Before the one closing panel, the five panels focused on the Beaver Dam Mine Project and the engagement opportunities, specifically:

- presentation of the site location, the gold deposit and the existing site features;
- map of the proposed site plan at the Beaver Dam Mine Site;
- information on the transportation of ore, including both options considered for the route and the trucking rate;
- overview of the EA process for the Project including the ongoing baseline studies for the VCs and the regulatory process with opportunities for public participation; and

- opportunities for community and Mi'kmaq engagement, including an overview of the CLC and an invitation for expressions of interest from residents who are interested in joining the CLC.

A total of 32 interested community members attended these two open houses. Millbrook First Nation had a total of 16 attendees with 9 providing name and/or contact information. Sipekne'katik First Nation had a total of 16 attendees with 14 providing name and/or contact information. In total, four comment forms were completed; many attendees expressed an interest in employment and some provided resumes to AMNS.

To address specific technical questions posed by Millbrook First Nation, AMNS held two information sessions at Millbrook First Nation in Truro and Sheet Harbour IR #36 in Sheet Harbour in January 2018 that provided information on:

- Cyanide;
- Reclamation and Contingency Planning;
- Ore Processing and Mine Processes; and
- Haul Road information.

Both information sessions included 17 poster boards which provided detailed information on each topic area. The poster boards showed, among other things, a map of the proposed location of mine infrastructure, an infographic that detailed ore processing, specific information on cyanide handling, shipping and use, a map of the Haul Road, and a list of Contingency and Management Plans that will be developed.

On January 23, 2018 at the Millbrook Community Hall at 72 Church Road, Truro 14 members of the public, including the two consultants undertaking the IRTLUS for Millbrook First Nation and two representatives from the Agency attended the 2-hour session. AMNS provided a PowerPoint presentation and hosted a question and answer session with attendees. The event ended with an Open House session where people were able to have one-on-one discussions with AMNS's technical experts.

On January 24th at the Albert Noel Howe Multi-Purpose Community Center, 83 Church Point Rd, Sheet Harbour 16 members of the public, including the two consultants undertaking the IRTLUS for Millbrook First Nation, attended the 1-hour session. AMNS also received requests from 7 people for additional information on the Project. This session took an open house format, where the poster boards were placed in the room and attendees reviewed them and had the opportunity to engage with AMNS representatives to discuss specific issues or ask questions.

4.5.2 Community Liaison Committee

As discussed in Section 3.6.2 of this EIS, in 2016 the CLC was expanded to a nine-member committee including representation of the two closest Mi'kmaq communities, Millbrook First Nation and Sipekne'katik First Nation. In the Spring of 2018, representatives of Millbrook First Nation and Sipekne'katik First Nation decided to cease participating in the CLC and prefer direct engagement with AMNS. AMNS continues to welcome Mi'kmaq participation on the CLC either as guests or with full membership.

4.6 Key Concerns Raised by the Mi'kmaq of Nova Scotia and Proponent Responses

As part of submitting the EIS and EARD to respective government authorities, the Mi'kmaq engagement to date associated with the Beaver Dam Mine Project was documented, including a summary of key issues raised, Proponent responses and associated adjustments to Project design. This summary also includes general and specific feedback received from the Mi'kmaq of Nova Scotia. Note that Project adaptation will continue, as needed and practicable, through engagement with the Mi'kmaq.

For each key concern identified in the following table, a summary of proponent response is provided along with reference(s) to sections in this EIS which address the issue.

Table 4.6-1: Summary of Key Concerns Raised During Mi'kmaq Engagement

Key Concern	Summary of Proponent Response	Updated 2021 EIS Reference
Concern about air emissions and noise associated with mining operations and trucking.	Air emissions and noise will be minimized with mitigation measures. Monitoring for air quality, including total suspended particulates, will be completed. Dust suppression (water and/or chemical treatment); 80% for the BD Haul Road. Additional Human Health Risk Assessments to assure the communities that plants and animals are safe to eat and that water is safe for swimming.	Section 6.2.8 Mitigation - Air
Concern about how elevated noise and light levels may impact hunting near the mines.	Engagement with communities to understand where they hunt and whether elevated light and noise levels in close proximity to the mines is a concern, based on hunting patterns. Minimize impact by reducing noise and light from trucks and mine operations. Modelling to show dust, noise and light meet guidelines at the Property Boundary.	Section 6.1 Noise Section 6.2 Air
Concern about quality and quantity of water in streams, rivers and lakes & potential effect on fish and other aquatic species.	Manage site water to a single point of discharge, where possible. Treat water prior to discharge, when needed. Robust monitoring program to confirm water quality; opportunity for Indigenous participation in monitoring programs including Environmental Effects Monitoring in receiving waters.	Section 6.7 Surface Water; Section 6.9.6 Project Activities/Interactions with Fish and Fish Habitat
Concern about impacts to fish and fish habitat.	Reduce impact by moving infrastructure to avoid fish habitat. Predictive modelling to understand how the mine operations may indirectly impact fish habitat; and, monitoring to confirm predictions and adapt as required. Offsetting Plans – Indigenous participation in plan development and implementation.	Section 6.9.6 Project Activities/Interactions with Fish and Fish Habitat
Concern about effect on groundwater, specifically related to domestic wells at Beaver Lake, from development of pit at Beaver Dam.	As the nearest domestic well is over 5 km from the Beaver Dam Mine Site, no effect is expected on groundwater quality or quantity at Beaver Lake. A network of monitoring wells will be used to monitor groundwater quality and quantity at the Beaver Dam Mine Site.	Section 6.6.6 Project Activities/ Interactions with Groundwater Quality and Quantity
Questions about plans for reclamation at the Beaver Dam Mine Site	The Beaver Dam Mine Site facilities will be removed, the pit will naturally fill with water and disturbed surfaces covered with stockpiled topsoil and re-vegetated. The site will be returned to landowner for forestry and recreational use.	Section 2.9.3 Decommissioning and Reclamation
Questions about contingency planning for accidents and malfunctions	Hazards have been identified and assessed based on risk. Mitigation measures and contingency planning will be in place to address potential accidents and malfunctions.	Section 6.18 Accidents and Malfunctions

Table 4.6-1: Summary of Key Concern Raised During Mi'kmaq Engagement (continued)

Key Concern	Summary of Proponent Response	Updated 2021 EIS Reference
Concern on habitat loss from Project development, including forest, wetlands, flora and fauna.	Disturbance exists on the Beaver Dam Mine Site which will be reclaimed at end of operation. The existing alignment of Haul Road was used where feasible and practical to minimize footprint. Existing facilities will be used for processing and tailings management (exhausted pit). Effect on habitat is minimal. Reduce mine site footprints. Wetland and fish habitat restoration will be completed to compensate for lost wetland and fish habitat. Commitment to reclamation providing an opportunity for Indigenous participation in reclamation planning and implementation. Re-vegetate impacted areas with a native mix of plants determined in consultation with Millbrook and other Indigenous communities.	Section 2.3 Project Location and Section 2.5 Project History, as well as the Valued Components effects assessments in Section 6
Concern about effect of haul truck traffic on birds.	There is potential effect on birds due to noise and dust from haul truck traffic as well as potential bird strikes. This effect is limited to operational phase and was assessed to not be significant.	Section 6.12.7 Project Activities/Interactions with Avifauna
Concern about effect on traditional uses of the Mi'kmaq of Nova Scotia.	Working with Millbrook First Nation to understand their use through data sharing of the TLRUS findings and project mapping. Multi-use bypass roads to maintain access to areas around the mine and haul road. Commitment to reclamation with the opportunity for Mi'kmaq participation in planning and implementation to restore habitats and allow traditional practices to resume within the Beaver Dam Mine Site. Re-vegetation with a native mix of plants determined in consultation with Mi'kmaq communities.	Section 6.14.6 Project Activities/Interactions with the Mi'kmaq of Nova Scotia; Appendix M.1 Mi'kmaq Ecological Knowledge Study, and Section 2.3.2 Haul Road (multiuse bypass road)
Changing landscape within Eskikewa'kik. Cumulative loss of access to the area for traditional purposes.	Reduced waste and mine footprint at Beaver Dam due to Project design. Use of existing transportation routes, wherever possible Evaluation of Crown land loss in Eskikewa'kik from all known and planned projects.	
Request to prefer Haul Road option that does not travel along Hwy 224.	Based on comments received on two option during the stakeholder and Mi'kmaq engagement, AMNS completed a feasibility review of the second option which does not pass by residences, including Beaver Lake IR17. This was selected and is carried forward in the EA.	Section 2.2.1.7 Haul Roads for Transporting Ore; Section 2.3.5 Summary of Changes to Project Activities; Section 2.6.6 Ore Transportation
Questions about cumulative effects of multiple projects in the region.	A cumulative effects assessment was completed for each VC including current use of lands and resources for traditional purposes. Ongoing engagement specific to AMNS existing and any future projects will also occur with the Mi'kmaq of Nova Scotia.	Section 8.6 Cumulative Effects Summary; Section 4.7 Ongoing Indigenous Peoples Engagement
Request ongoing engagement of the Mi'kmaq of Nova Scotia.	AMNS is committed to ongoing Mi'kmaq engagement for the life of the MRC Project, including Beaver Dam Mine Project. Other aspects of Mi'kmaq engagement will continue as per the Mi'kmaq engagement strategy with focus on issues identified as part of the EA and additional issues that may arise as the Project develops.	Section 4.6 Ongoing Indigenous Peoples Engagement; Section 6.14.8 Mitigation and Monitoring associated with Indigenous Peoples

The issues raised during Mi'kmaq engagement activities were incorporated into the design of the Project and the development of the EIS. The fundamental change to the Project as a result of Mi'kmaq engagement was the change to the Haul Road to cross Hwy 224 which eliminated the haul trucks passing by the Mi'kmaq community of Beaver Lake. This addressed many concerns with safety, noise, air, and light emissions and other issues related to health and socio-economic aspects. In 2020, a multiuse bypass road was added to further reduce project impacts to traditional use and allow for continued access to areas around the Beaver Dam Mine Site and Haul Road during operations. It is the understanding of AMNS based on engagement with the Mi'kmaq that the changed Haul Road and addition of the multi-use bypass road were seen as positive change as effects on the community of Beaver Lake were greatly reduced through these project design changes.

In terms of the development of the EIS, there were no additional VCs included in addition to those identified in the CEA Agency Guidelines associated with the input from the Mi'kmaq of Nova Scotia. The VCs listed in the CEA Agency Guidelines addressed the issues brought forward during engagement. However, specific attention was paid to effects assessment of specific VCs, in particular groundwater and its potential effect on the potable water supply of Beaver Lake and the effect on local surface and groundwater quantity from pit development. In addition, focused questions from the Mi'kmaq of Nova Scotia on potential effects of accidents and malfunctions enhanced the development of this portion of the EIS, including the commitments to contingency planning.

As part of AMNS's engagement of the Mi'kmaq completed to date on the Beaver Dam Mine Project, the potential effects and the proposed mitigation measures and monitoring programs were presented and discussed directly with interested Mi'kmaq communities and organizations. The objective was to provide information on the Project to the Mi'kmaq and for AMNS to better understand the views of the Mi'kmaq on the potential effects and proposed mitigation measures and monitoring programs; this supported the development of the EIS. Specifically, alongside on-going meetings with the KMKNO and Mi'kmaq communities, documents have been shared, with requests for feedback and input from the Mi'kmaq communities, to support communication of EIS conclusions, summary of technical VC impacts, summary of Mi'kmaq impacts, mitigation measures and proposed monitoring plans. Exchange has also taken place to support Proponent knowledge and learning relating to specificity of traditional use of the land in the area surrounding the Project, and also to support broader understanding of potential effects of the Project on the economic, social and mental well-being of the Mi'kmaq of Nova Scotia.

In response to the interest of the Mi'kmaq, AMNS has made strong commitments to ongoing Mi'kmaq engagement, including specific activities to further support the participation of the Mi'kmaq in this EA process for the Beaver Dam Mine Project. The ongoing engagement ensures that the potential effects of the Project and the proposed mitigation measures and monitoring programs are understood by the Mi'kmaq of Nova Scotia in order to evaluate the effects on their communities and potential or established Aboriginal or treaty rights, title and related interests.

It is anticipated that engagement will continue throughout and beyond the current environmental assessment process. This will require ongoing dialogue regarding potential impacts on Mi'kmaq communities, and AMNS is committed to continuing those discussions. AMNS looks forward to receiving feedback and commits to discussing with Millbrook First Nation how best to address their feed back into Project design, mitigation and monitoring measures and potentially additional monitoring and mitigation measures.

The key meetings, site visits, telephone calls, emails, and other correspondence with Mi'kmaq groups engaged are included in Appendix A.5.

4.7 Ongoing Mi'kmaq of Nova Scotia Engagement

As mentioned above, Atlantic Mining is committed to ongoing engagement with the Mi'kmaq of Nova Scotia throughout the lifecycle of all of its projects. As part of submitting the EIS and EARD to respective government authorities, the engagement to date associated with the Beaver Dam Mine Project was documented, including a summary of issues raised and proponent responses and adjustments to the project. AMNS has a broad objective to continue to meet with KMKNO, Millbrook and Sipekne'katik First Nations to continue dialogue on the Project, review AMNS conclusions, proposed mitigation measures, and opportunities for Mi'kmaq participation in the EIS.

Relative to the Beaver Dam Mine Project, specific commitments are made by AMNS in terms of Mi'kmaq engagement during the next steps in the EA processes, including:

- Offering to share key aspects of the EIS with staff of Millbrook and Sipekne'katik First Nations and the Assembly, including the MEKS.
- Holding meetings with key staff of KMKNO and Millbrook and Sipekne'katik First Nations.
- Offering opportunities for presentations and site visits to Chief and Councils, specifically Millbrook and Sipekne'katik First Nations.
- Having additional community open houses or site visits as deemed appropriate in consultation with staff and/or leadership of Mi'kmaq communities.
- Answering specific questions posed directly by the Mi'kmaq to AMNS by providing additional information and/or holding meetings where feasible.
- Request for feedback on EIS and information response conclusions. AMNS looks forward to receiving feedback and commits to discussing with Millbrook First Nation how best to address their feed back into Project design, mitigation and monitoring measures and potentially additional monitoring and mitigation measures.

Develop an opportunity for potential partnerships with Mi'kmaq environmental groups on specific ecological monitoring and restoration projects. Engagement planning needs to be flexible. AMNS will continue to address and respond to additional questions or concerns identified or issues noted as the EA moves forward into Project development, operation and closure. AMNS is strongly committed to continue its engagement with the Mi'kmaq of Nova Scotia in the ongoing spirit of cooperation and with mutual benefit and respect.

5 ENVIRONMENTAL EFFECTS ASSESSMENT METHODOLOGY

5.1 Introduction

5.1.1 Summary of Environmental Effects Assessment Methodology Before the Updates

The Project being assessed through this EIS is a proposed surface gold mine consisting of the construction, operation, and decommissioning of a surface mine, Haul Road, and processing facility, known as the Beaver Dam Mine Project. The project will encompass three primary locations spanning from Marinette to Moose River Gold Mines, Halifax County, Nova Scotia.

The scope of the Project to be assessed in accordance with CEAA 2012 and the Environmental Assessment Regulations made under the *Nova Scotia Environment Act* includes Project components and activities outlined in Section 5.2.1. The methodology used to conduct this EA is based on the identification and assessment of potential environmental effects of the Project on Valued Components (VC), as defined in Section 5.4.

An effects assessment was conducted for each to determine the potential direct and indirect interactions between Project activities and VCs. The results of the effects assessments, in consideration of mitigation measures, were used to assess residual effects and determine the significance of Project effects on each VC. Follow-up management and monitoring programs area proposed as required

5.1.2 Summary of Updates to Environment Effects Assessment Methodology

The EIS has been updated due to changes in Project Description since the Revise 2019 EIS submission (AMNS 2019). While the general methods presented in this section by which the EA was conducted have not changed, VC specific baseline and effects assessments have been updated in consideration of revised baseline conditions and Project interactions. Additional analysis as defined in Section 5.11, Table 5.11-1 is also identified and supports the characterization and significance determination for residual effects. In response to Round 2, Information Request (IR2) from the Impact Assessment Agency of Canada (IAAC; formerly the Canadian Environmental Assessment Agency [CEAA 2019]) CEAA 2-02 criteria to assess significance thresholds, particularly magnitude have been defined quantitively to the extent possible. Detailed VC information and updates are presented in the corresponding subsection within Section 6 of this EIS update.

Table 5.1-1: Updated Subsections from the Revised 2019 Environmental Impact Assessment – Environmental Effects Assessment Methodology

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
-	-	5.1 Introduction	• New
5.1 Scope of Environmental Assessment	No	5.2 Scope of Environmental Assessment	• N/A
5.2 Overview of Approach	No	5.3 Overview of Approach	• N/A

55 Standards or Thresholds for Characterization and Determining Significance	Yes	5.6 Standards or Thresholds for Characterization and Determining Significance	• Minor updates
5. 6 Baseline Condition	No	5.7 Baseline Conditions	• N/A
5.7 Anticipated Project Environment Interactions	No	5.8 Anticipated Project Environment Interactions -	• N/A
5.8 Effects Prediction	No	5.9 Effects Predicted	• N/A
5.9 Mitigation	No	5.10 Mitigation	• N/A
5.10 Residual Effects and Determination of Significance	Yes	5.11 Residual Effects and Determination of Significance	• Reference to updates to the characterization of effects as requested in CEAA 02-2
5.11 Follow-up and Effects Monitoring	No	5.12 Follow-up and Effects Monitoring	• N/A
5.12 Effects of Environment on the Project	Yes	5.13 Proposed Compliance and Effects Monitoring Program	• Minor updates to reference CEAA 2-03

PA = Project Area; LAA = Local Assessment Area; RAA = Regional Assessment Area; - = no update; IR2 = Round 2, Information Requests; CEAA = Canadian Environmental Assessment Agency; EIS = environmental impact statement N/A = Not Applicable

5.2 Scope of the Environmental Assessment

5.2.1 Designated Project

The Project being assessed through this EIS is a proposed surface gold mine consisting of the construction, operation, and decommissioning of a surface mine, Haul Road, and processing facility, known as the Beaver Dam Mine Project. The project will encompass three primary locations spanning from Marinette to Moose River Gold Mines, Halifax County, Nova Scotia.

The scope of the Project to be assessed in accordance with CEAA 2012 and the Environmental Assessment Regulations made under the *Nova Scotia Environment Act* include the following components and activities:

Physical Components

- surface mine for extracting ore and waste rock;
- Mine Site roads;
- waste material storage piles for waste rock, till, and topsoil;
- run-of-mine (ROM), high grade, and low-grade ore stockpiles;
- crusher and operational facilities;
- water management;
- haul road for transporting ore; and
- Touquoy Mine Site (processing and tailings management using the exhausted Touquoy pit).

Physical Activities

- clearing, grubbing, and grading;
- drilling and rock blasting;
- topsoil, till, and waste rock management;
- existing settling pond dewatering;
- watercourse and wetland alteration;
- Mine Site road construction;
- surface infrastructure installation and construction;
- collection and settling pond construction;
- culvert and bridge upgrades and construction;
- Haul Road construction and upgrades;
- ore processing equipment upgrades;
- tailings line alteration;
- surface mine dewatering;
- ore management;
- waste rock management;
- surface water management;
- petroleum products management;
- site maintenance and repairs;
- ore transport;
- Haul Road maintenance and repairs;
- tailings management (exhausted pit);
- infrastructure demolition;

- site reclamation;
- environmental monitoring; and
- general waste management.

These components and activities reflect the scope of the Project outlined in Section 3.1 of the EIS Guidelines (CEAA 2016) and reflect the components and activities that would occur throughout the duration of the Project. The effects assessment outlined in Section 6 of this EIS is formed based on these components and activities.

Additional details regarding Project components and activities can be found in Section 2.7 and Section 2.9. A review of the potential interactions between valued components (VCs) and the Project components/activities outlined above can be found in Section 5.8, Tables 5.8-1, 5.8-2, and 5.8-3.

5.2.2 Factors to be Considered

This EIS considers all factors outlined in Section 19(1) of CEAA 2012 and Section 3.2 of the EIS Guidelines (CEAA 2016). Specifically, this includes the following:

- environmental effects of the Project, including the environmental effects of malfunctions or accidents that may occur in connection with the Project and any cumulative environmental effects that are likely to result from the Project in combination with other physical activities that have been or will be carried out;
- the significance of effects;
- comments from the public;
- mitigation measures that are technically and economically feasible and that would mitigate any significant adverse environmental effects of the Project;
- the requirements of the follow-up program in respect of the Project;
- the purpose of the Project;
- alternative means of carrying out the Project that are technically and economically feasible and the environmental effects of any such alternatives (Project Description Sections 2.10);
- any change to the Project that may be caused by the environment; and
- the results of any relevant regional study pursuant to CEAA 2012.

5.2.3 Scope of Factors to be Considered

The scope of the factors to be considered focuses this EIS on relevant issues and concerns. As indicated in Section 5(1) of CEAA 2012, the environmental effects that are to be considered regarding an act or thing, a physical activity, a designated project, or a project are:

(a) a change that may be caused to the following components of the environment that are within the legislative authority of Parliament:

(i) fish and fish habitat as defined in subsection 2(1) of the Fisheries Act,

(ii) aquatic species as defined in subsection 2(1) of the Species at Risk Act,

(iii) migratory birds as defined in subsection 2(1) of the Migratory Birds Convection Act, 1994, and

(iv) any other component of the environment that is set out in Schedule 2;

(b) a change that may be caused to the environment that would occur

(i) on federal lands,

(ii) in a province other than the one in which the act or thing is done or where the physical activity, the designated project or the project is being carried out, or

(iii) outside Canada; and

(c) with respect to aboriginal peoples, an effect occurring in Canada of any change that may be caused to the environment on

(i) health and socio-economic conditions,

(ii) physical and cultural heritage,

(iii) the current use of lands and resources for traditional purposes, or

(iv) any structure, site, or thing that is of historical, archaeological, paleontological, or architectural significance.

Certain additional environmental effects must be considered under Section 5(2) of CEAA 2012 where the carrying out of the physical activity, the designated project, or the Project requires a federal authority to exercise a power or perform a duty or function conferred on it under any Act of Parliament other than CEAA 2012. As the Project may require an authorization from DFO, the following environmental effects have also been considered:

(a) a change that may be caused to the environment and that is directly linked or necessarily incidental to a federal authority's exercise of a power or performance of a duty or function that would permit the carrying out, in whole or in part, of the physical activity, the designated project or the Project; and

(b) an effect, other than those referred to in paragraph 1(c), of any change referred to in paragraph (a) on

(i) health and socio-economic conditions,

(ii) physical and cultural heritage, or

Any structure, site or thing that is of historical, archaeological, paleontological, or architectural significance.

These categories of direct and indirect environmental effects have been considered in defining the scope of the assessment, including the selection of VCs and identification of spatial and temporal boundaries.

5.3 Overview of Approach

The methodology used to conduct the EA and predict the effects of the Project was developed to meet the requirements of the EIS Guidelines issued by CEAA on January 19, 2016. The EIS Guidelines include requirements for EA's under CEAA 2012 and the Nova Scotia Environmental Assessment Regulations made under the Nova Scotia Environment Act. In addition to these requirements, the EA methodology was developed to incorporate:

- input from Indigenous Peoples and the public throughout the duration of the Project;
- environmental and social points of interest to the scientific and regulatory communities; and
- other federal, provincial, and municipal legislative and regulatory requirements that may apply to the Project.

The following sections will describe the methodology used to derive:

- the general rationale in VC selection;
- the spatial, temporal, administrative, and technical boundaries for assessing effects on VCs;
- the standard and/or threshold for characterizing and determining significance of residual effects;
- the programs developed to assess the baseline condition of those VCs;
- the anticipated Project and environment interactions for the duration of the Project;
- the prediction of effects that Project activities may have on VCs;
- the mitigation measures that will be used to eliminate, reduce, or control the potential effects of Project activities;
- the residual effects that may remain after mitigation measures are applied and the significance of those residual effects;
- the cumulative effects of the Project may have in combination with the residual effects of other projects within temporal and spatial confines of the Project;
- the follow-up and monitoring programs proposed to verify the accuracy of predicted impacts; and
- the effects of the environment on the Project.

The defined methodology described herein has allowed the Consultants to carefully examine Project activities to ensure they will not cause serious or irreversible harm to the environment.

5.4 Valued Components Selection

The methodology used to conduct this EA is based on the identification and assessment of potential environmental effects of the Project on VCs. VCs refer to environmental, biophysical, or human features that may be affected by the Project that are of value or interest because they have been identified to be of concern to Indigenous Peoples, regulators, the Consultants, and/or the general public. Their value not only relates to its role in the ecosystem, but also the value humans place on it.

The selection of VCs was based on consideration of the following:

- regulatory guidance and requirements, specifically those outlined in Section 6.2 of the EIS Guidelines provided by CEAA on January 19, 2016 and Section 5 of CEAA 2012. For a discussion of CEAA 2012 Section 5 requirements refer to Section 5.4 of this EIS;

- a review of federal, provincial, and municipal legislation, including an appraisal of species of conservation interest (SOCI) and SAR. Guidelines specifically requires consideration of the factors listed in Section 79 of SARA are provided in Section 6.13 and 6.17 of the EIS;
- workshops and discussions with representatives of CEAA, DFO, Environment and Climate Change Canada (ECCC), TC, NSE, and NSL&F;
- concerns raised by the public through open house meetings hosted by the Proponent;
- concerns raised by Indigenous Peoples, including traditional ecological knowledge obtained through completion of a Mi'kmaq Ecological Knowledge Study (MEKS);
- technical aspects of the Project, including the nature and extent of Project activities;
- the existing physical, biophysical, and socio-economic conditions and characteristics of the Project area;
- a review of publicly available information and reports submitted in support to nearby and similar environmental assessments; and
- the professional experience of the Consultants.

Based on these considerations, the following VCs were selected to facilitate a focused and effective EA:

Physical VCs

- noise, light, greenhouse gases, and air;
- geology, soil, and sediment quality;
- surface water quality and quantity; and
- groundwater quality and quantity.

Biophysical VCs

- wetlands;
- fish and fish habitat;
- habitat and flora;
- terrestrial fauna;
- avifauna; and
- species of conservation interest and species at risk.

Socio-economic VCs

- Mi'kmaq of Nova Scotia;
- physical and cultural heritage; and
- socio-economic conditions

A summary of the rationale for the selection of each VC can be found in Table 5.4-1, detailed selection information is presented in the VCs corresponding subsection within Section 6 of this EIS update.

Table 5.4-1: Rationale for Selection of Valued Components

Environment	Valued Component	Relevance to Environmental Impact Statement										Valued Component Selection Rationale
		Project – Environment Interaction (Direct/Indirect [D/I])	Legal Requirement	Scientific Interest	Biophysical Context	Socio-economic Context	Human Health	Human Quality of Life	Cultural	IAAC or Public Concern	Requirement of EIS Guidelines	
Physical Environment	Noise	D, I	X		X		X	X		X		• Potential for increases in noise
	Light	D, I	X		X		X	X		X		• Potential for increases in ambient light levels
	Air	D, I	X		X		X	X		X		• Potential for direct adverse effects to air quality
	Greenhouse Cases	D, I	X		X		X	X		X		• Potential for direct contributions to climate change
	Geology, Soil and Sediment	D, I			X		X			X		• Potential for direct adverse effects to soil and sediment • Potential for ARD from Halifax Formation bedrock • Pathway for potential adverse effects to surface water quality, wetlands, fish and fish habitat, habitat and flora, birds, fauna, SOCI/SAR, and human health
	Surface Water Quality and Quantity	D, I	X	X	X		X	X		X		• Potential for direct adverse effects to surface water quality • Potential for direct adverse effects to surface water quantity • Pathway for potential adverse effects to wetlands, fish and fish habitat, birds, fauna, SOCI/SAR, and human health
	Groundwater Quality and Quantity	D	X	X						X		• Potential for direct adverse effects to groundwater quality • Potential for direct adverse effects to ground water quantity
Biophysical Environment	Wetlands	D, I	X	X	X					X		• Potential for direct loss and/or adverse effects to wetlands and their function • Pathway for potential adverse effects to surface water quality and quantity, fish and fish habitat, habitat and flora, birds, fauna, and SOCI/SAR
	Fish and Fish Habitat	D, I	X	X	X	X	X	X		X	X	• Potential for direct adverse effects to fish and fish habitat • Pathway for potential adverse effects to birds, fauna, SOCI/SAR and human health
	Habitat and Flora	D, I	X	X	X	X	X	X		X		• Potential for direct loss of habitat • Potential for direct adverse effects to flora • Pathway for potential adverse effects to the atmospheric environment, surface water quality and quantity, wetlands, fish and fish habitat, birds, fauna, SOCI/SAR, Indigenous Peoples, and human health
	Avifauna	D, I	X	X	X	X	X	X		X	X	• Potential for direct adverse effects to birds • Pathway for potential adverse effects to fauna, Indigenous Peoples, and human health
	Terrestrial Fauna	D, I	X	X	X	X	X	X		X		• Potential for direct adverse effects to fauna • Pathway for potential adverse effects to birds, Indigenous Peoples, and human health
	Species of Conservation Interest/Species at Risk	D, I	X	X	X					X	X	• Potential for direct adverse effects to SOCI/SAR • Pathway for potential adverse effects to birds and fauna
Socio-economic Environment	Mi'kmaq of Nova Scotia	D	X			X	X	X	X	X	X	• Potential for direct adverse effects to the current use of land and resources for traditional purposes
	Physical and Cultural Heritage	D	X			X			X			• Potential for direct adverse effects to archaeological sites
	Socio-economic Conditions	D				X						• Employment opportunities • Economic spin-off • Contribution to government revenue through taxation

Note: Refer to Section 5.8 Anticipated Project-Environment Interaction definitions and examples relating to direct and/or indirect interactions. D = Direct; I = Indirect; CEAA = Canadian Environmental Assessment Agency; SOCI/SAR = Species of Conservation Interest/Species at Risk

5.5 Project Boundaries

5.5.1 Temporal Boundaries

The temporal boundaries represent the duration over which Project activities interact with each valued component VC. Generally, the temporal boundary encompasses all Project phases (construction, operation, active closure, and post-closure); however, the temporal boundary can vary depending on the valued component VC being considered.

The construction phase will be completed in one year, while the operation phase will last approximately five years. Active closure (i.e., decommissioning and reclamation) activities will commence after operation has ceased and likely occur over approximately two years. Post closure involves the required monitoring period once active reclamation and decommissioning is completed and is estimated to be 10+ years in length (timeline for this phase will be refined through on-going geochemical testing and water quality modelling and will documented in updated closure plans).

Temporal boundaries for each VC are described in their corresponding subsection within Section 6 of this EIS.

5.5.2 Spatial Boundaries

The spatial boundaries represent anticipated geographic limits that will aid in defining the scale and range of interactions between Project activities and VCs. The following spatial boundaries will be used for this EIS.

5.5.2.1 Project Area (PA)

The PA encompasses the immediate area in which Project activities may occur and are likely to cause direct and indirect effects to VCs. This area has also been identified as the study area for the purposes of baseline investigations. The PA includes three primary components from Marinette to Moose River Gold Mines, Halifax County, NS. The Beaver Dam Mine Site will be located at the north end of the Beaver Dam Mines Road and the Haul Road will span from the Beaver Dam Mine Site west to Moose River Gold Mines, where the Touquoy Mine Site (processing and exhausted pit [to be used to dispose Beaver Dam tailings]) is located. The three PA's (i.e., study areas) are outlined in Figure 5.5-1.

5.5.2.2 Local Assessment Area (LAA)

The LAA encompasses adjacent areas outside of the PA where Project related effects to VCs are reasonably expected to occur. Generally, the LAA is limited to the area in which Project activities are likely to have indirect effects on VCs; however, the size of the LAA can vary depending on the VC being considered, and the biological and physical variables present.

5.5.2.3 Regional Assessment Area (RAA)

The RAA encompasses all Project and VC interactions including diffuse or longer-range effects such as those from Project activities are presented in Table 5.5-1. The RAAs may vary in size depending on the VC being considered, and the biological and physical variables present.

Spatial boundaries will vary for each VC and are described in Table 5.5-1, as well as the corresponding subsections within Section 6 of this EIS.

Table 5.5-1: Spatial Boundary Assessment by Valued Component

Environment	Valued Component	Project Area	Local Assessment Area	Regional Assessment Area	Spatial Boundary Selection Rationale
Physical Environment	Noise	X	X	X	Effects from the Project on noise may potentially occur within and immediately adjacent to the Project area, therefore, the Project Area, Local Assessment Area and Regional Assessment Areas are considered.
	Light	X	X	X	Effects from the Project on ambient light may potentially occur within and immediately adjacent to the Project Area, therefore, the Project area, Local Assessment Area and Regional Assessment Areas are considered.
	Air	X	X	X	Effects from the Project on air may potentially occur within and immediately adjacent to the Project Area, therefore, the Project area, Local Assessment Area and Regional Assessment Areas are considered.
	Greenhouse Gases	X	X	X	Effects from the Project on greenhouses gasses may potentially occur over a diffuse area and are related to provincial initiatives, therefore, the Project Area, Local Assessment Area, and Regional Assessment Area are considered.
	Geology, Soil, and Sediment Quality	X	X		Effects from the Project on geology, soil, and sediment may potentially occur within and immediately adjacent to the Project Area, therefore, the Project Area and Local Assessment Area are considered.
	Surface Water Quality and Quantity	X	X	X	Effects from the Project on surface water quality and quantity may potentially occur within and immediately adjacent to the Project Area, therefore, the Project area, Local Assessment Area and Regional Assessment Areas are considered. are considered
	Groundwater Quality and Quantity	X	X	X	Effects from the Project on groundwater quality and quantity may potentially occur within and immediately adjacent to the Project Area, therefore, the Project Area and Local Assessment Area are considered.
Biophysical Environment	Wetlands	X	X	X	Effects from the Project on wetlands may potentially occur within and immediately adjacent to the Project Area, therefore, the Project Area, Local Assessment Area and Regional Assessment Areas are considered. are considered.
	Fish and Fish Habitat	X	X	X	Effects from the Project on fish and fish habitat may potentially occur within and immediately adjacent to the Project Area, therefore, the Project Area Local Assessment Area, and Regional Assessment Areas are considered. are considered are considered.
	Habitat and Flora	X	X	X	Effects from the Project on habitat and flora may potentially occur within and immediately adjacent to the Project Area, therefore, the Project Area Local Assessment Area and Regional Assessment Areas are considered. are considered are considered.
	Avifauna	X	X	X	Effects from the Project on birds may potentially occur within and immediately adjacent to the Project Area, therefore, the Project Area, Local Assessment Area and Regional Assessment Areas are considered.

Table 5.5-1: Spatial Boundary Assessment by Valued Component (continued)

Environment	Valued Component	Project Area	Local Assessment Area	Regional Assessment Area	Spatial Boundary Selection Rationale
	Terrestrial Fauna	X	X	X	Effects from the Project on fauna may potentially occur within and immediately adjacent to the Project Area, therefore, the Project Area, Local Assessment Area and Regional Study Area, and Regional Assessment Areas are considered.
	Species of Conservation Interest/Species at Risk	X	X	X	Effects from the Project on species of conservation interest and species at risk may potentially occur within and immediately adjacent to the Project Area, therefore, the Project Area, Local Assessment Area and Regional Assessment Areas are considered.
Socio-economic Environment	Mi'kmaq of Nova Scotia	X	X	X	Effects from the Project on Indigenous Peoples may potentially occur within and immediately adjacent to the Project Area, therefore, the Project Area, Local Assessment Area and Regional Assessment Areas are considered.
	Physical and Cultural Heritage	X			Effects from the Project on physical and cultural heritage are likely limited to the Project area, therefore, only the Project Area is considered.
	Socio-economic Conditions	X	X	X	Effects from the Project on socio-economic considerations of the area may potentially occur over a diffuse area, therefore, the Project Area, Local Assessment Area, and Regional Assessment Area are considered.

5.5.3 Administrative Boundaries

The administrative boundaries represent the regulatory, public policy, and/or economic limitations placed on the execution of the Project. Administrative boundaries for each VC are described in their corresponding subsection within Section 6 of this EIS.

5.5.4 Technical Boundaries

The technical boundaries represent the limits of the Consultant team's ability to assess a VC. The limitations to measure, assess, and/or monitor the effects of the Project on VCs may be theoretical or physical. These technical boundaries may create gaps in knowledge and understanding related to key conclusions, therefore, limiting the Consultant's ability to predict potential effects of the Project on a VC. Technical boundaries for each VC are described in their corresponding subsection within Section 6 of this EIS.

5.6 Standards or Thresholds for Characterizing and Determining Significance of Effects

Criteria or established thresholds for determining the significance of residual effects from Project activities are described for each VC in their corresponding subsection within Section 6 of this EIS. These criteria or threshold were developed through the following avenues:

- consultation with appropriate regulatory agency responsible for each VC;
- using information obtained in stakeholder and right holder consultation;
- using available information on the status and characteristic of each VC;
- using applicable regulatory documents, environmental standards, guidelines, and/or objectives, and
- using professional judgement of the Consultant Team.

These criteria or thresholds establish a level beyond which a residual effect would be considered significant. Thresholds may be based on regulations, standards, resource management objectives, scientific literature, and/or ecological processes. Significance criteria has been defined quantitatively where possible, and qualitatively with supporting justifications where no standards exist.

Additional analysis as defined in Section 5.11 and Table 5.11-1 also identifies and shows the characterization and significance determination for residual effects with cross-referencing to respective sections where this information has been updated from the Revised 2019 EIS (AMNS 2019).

5.7 Baseline Conditions

Baseline conditions for each physical, biophysical, and socio-economic VC are described in their corresponding subsection within Section 6 of this EIS in order to characterize the existing environment for which the Project is being undertaken, to establish an understanding of the receiving environment, and to provide sufficient context to enable an understanding of how the Project may affect existing environmental conditions. Inclusion of existing conditions is limited to that which is necessary to assess the effects of the Project and support the development of mitigation measures, monitoring and follow-up programs. Existing conditions consider the effects of past and current projects occurring within and outside of the PA.

Various methodologies were employed to obtain baseline conditions for each VC. Methodologies are outlined for each VC in their corresponding subsection within Section 6 of this EIS.

5.8 Anticipated Project-Environment Interaction

Interactions between Project activities, and the VCs outlined in Section 5.4 of this EIS will either be direct or indirect.

Direct interactions between the Project and VCs are typically more obvious and can be logically expected based on a good understanding of Project activities, and existing physical, biophysical, and socio- economic conditions and characteristics of the Project Area. Indirect interactions are less obvious and typically require an active pathway between Project activities and the VCs they are affecting. A pathway provides a link between a Project component or activity and VC and facilitates the interaction and potential effect.

As an example, a direct effect may be the potential loss of a wetland through clearing, grubbing, and grading in preparation of surface mine construction. Clearing, grubbing, and grading may also decrease infiltration and therefore increase runoff from the site; resulting in a potential indirect effect on surface water quality and quantity. Poor surface water quality and quantity may then affect fish and fish habitat; this is an example of a VC acting as both the receptor of an effect and the pathway for an effect.

In order to determine the potential direct and indirect interactions between Project activities, and VCs the Consultants conducted the following:

- reviewed the anticipated components and activities required to construct, operate, and decommission the Project;
- selected VCs that may have the potential to be directly or indirectly affected by Project activities;
- assessed the direct effects that Project activities may have on VCs;
- identified anticipated pathways between Project activities and any receiving VCs; and
- assessed the indirect effect that Project activities may have on VCs.

Once the direct or indirect interaction between Project activities and VCs is established, assessing the magnitude, duration, and other criteria for significance determination of the effects of those interactions becomes much easier. Subsequently, evaluating mitigation measures to eliminate, reduce, or control the effects of those interactions becomes easier as well.

Accidents and malfunctions have been considered for every phase of the Project; however, they are separated in the Project-VC interaction table to present the actual accidents and malfunctions that may occur during these phases.

The anticipated Project component and activities, and VCs interaction for the Beaver Dam Mine Site, Haul Road, and Touquoy Mine Site is presented in Tables 5.8-1, 5.8-2, and 5.8-3.

Interactions noted in Table 5.8-3 are specific to those that relate to new interactions as a result of the Project and not those that pre-exist at Touquoy Mine Site as part of that site's development, operation and reclamation.

Table 5.8-1: Potential Valued Components Interactions with Project Activities at Beaver Dam Mine Site

5.9 Effects Prediction

Potential Project-related effects are changes to the physical, biophysical, and/or human environment that are caused by Project activities. Interactions between VCs and Project activities are described in corresponding subsections within EIS Section 6 and form the basis for effects prediction. Establishment of interaction relationships between VCs and Project activities is described in EIS Section 5.8. Once these interaction relationships are established, determination of changes to VCs, defined as effects, as a result of Project activities is accomplished through:

- predicting adverse effects from Project activities, and evaluating the scope and scale of those effects;
- detailing mitigation measures triggered through regulatory requirements and/or best management practices to eliminate, reduce, or control the effect Project activities have on VCs;
- predicting cumulative effects from other projects occurring in the same spatial and temporal boundaries; and
- determining residual effects remaining after mitigation measures are considered and cumulative effects are identified, to assess the significance of those effects in the context of each VC.

5.10 Mitigation Measures

A variety of mitigation measures are typically available to eliminate, reduce, or control the effect Project activities have on the environment. These measures range from procedures within standard industry best management practices for construction and operation, policies and practices communicated through training programs and management plans, and/or engineering controls incorporated into the final design. Given the Proponents' experience with gold mining in the region, specifically the Touquoy Project, as well as past experience outlined in EIS Section 1.4, a number of mitigation measures were proactively incorporated into the Project design in order to eliminate, reduce, and/or control the effect of Project activities on the environment. Mitigation measures for each VC are described in the corresponding subsections within Section 6. A summary of all mitigation measures is provided in Section 9 and 10 of this EIS update, as per Information request CEAA 2-03 (AMNS 2021).

5.11 Residual Effects and the Determination of Significance

Residual effects are effects to VCs that are predicted to remain even after the implementation of mitigation measures. The process by which they are identified is as follows:

- Determine the potential interactions between VCs and Project activities and the effects those interactions will have.
- Assess effect of each mitigation strategy applied to the interactions.
- Characterize the extent and nature of the remaining, residual effects after mitigation measures have been applied for the Project.
- Evaluation of the Project including Haul Road.

In order to identify if residual effects are significant or not, consideration of the magnitude, geographical extent, duration, frequency, and reversibility is required. A description of these effects characteristics and the varying degrees in which they can contribute to the significance of an effect is presented in Table 5.11-1. Where possible, criteria will be described quantitatively. When residual effects cannot be characterized quantitatively, they will be characterized qualitatively.

Table 5.11-1: Characterization Criteria for Residual Environmental Effects

Characterization	Description	Quantitative Measure or Definition of Qualitative Categories	Valued Component Specific Definitions
Significance Threshold	The definition of a significant adverse effect based on Project interactions with each Valued Component.	Determinations of Significance based on characterization criteria as defined for each VC..	Noise – 6.1.6.2 Air – 6.2.6.2 Light – 6.3.6.3 Greenhouse Gases – 6.4.6.2 Geology, Soils and Sediment – 6.5.6.2 Groundwater Quality and Quantity-6.6.6.4 Surface Water Quality and Quantity 6.7.7.2 Wetlands – 6.8.6.3 Fish and Fish Habitat – 6.9.6.2 Habitat and Flora – 6.10.6.2 Terrestrial Fauna – 6.11.6.2 Avifauna – 6.12.7.2 SAR and SOCI – 6.13.6.2 Mi'kmaq of Nova Scotia – 6.14.6.2 Physical and Cultural Heritage – 6.15.6.2 Socioeconomic Conditions - 6.16.12 Assessment of VC within Federal Jurisdiction NA Accidents and Malfunctions 6.18.7 and 6.18.8 Effects of the Environment 7.

Table 5.11-1: Characterization Criteria for Residual Environmental Effects (continued)

Characterization	Description	Quantitative Measure or Definition of Qualitative Categories	Valued Component Specific Definitions
Magnitude	The size or degree of the effects compared against baseline conditions or reference levels, and other applicable measurement parameters (i.e., standards, guidelines, objectives)	Negligible (N) – Differing from the average value for the existing environment/baseline conditions to a small degree, but within the range of natural variation and below a threshold value Low (L) – Differing from the average value for the existing environment/baseline conditions, outside the range of natural variation, and less than or equal to appropriate guideline or threshold value Moderate (M) – Differing from the existing environment/ baseline conditions and natural variation, and marginally exceeding a guideline or threshold value High (H) – Differing from the existing environment/ baseline conditions and natural variation, and exceeding a guideline or threshold value	Noise-6.1.6.2 Air – 6.2.6.2 Light – 6.3.6.3 Greenhouse Gases 6.4.6.2 Geology, Soils and Sediment -6.5.6.2 Groundwater Quality and Quantity-6.6.6.4 Surface Water Quality and Quantity 6.7.7.2 Wetlands – 6.8.6.3 Fish and Fish Habitat – 6.9.6.2 Habitat and Flora – 6.10.6.2 Terrestrial Fauna – 6.11.6.2 Avifauna – 6.12.7.2 SAR and SOCI – 6.13.6.2 Mi'kmaq of Nova Scotia – 6.14.6.2 Physical and Cultural Heritage – 6.15.6.2 Socioeconomic Conditions - 6.16.12 Assessment of VC within Federal Jurisdiction NA Accidents and Malfunctions – 6.18.7

Table 5.11-1: Characterization Criteria for Residual Environmental Effects (continued)

Characterization	Description	Quantitative Measure or Definition of Qualitative Categories	Valued Component Specific Definitions
Geographic Extent	The geographic area over or throughout which the effects are likely to be measurable	Project Area (PA) – the residual environmental direct and indirect Local Assessment Area (LAA) – Occurs beyond the PA and LAA and within the RAA Regional Assessment Area (RAA) – Occurs beyond the PA and LAA and within the RAA	Noise – 6.1.6.1 Air – 6.2.6.1 Light – 6.3.6.1.1 Greenhouse Gases – 6.4.6.1 Geology, Soils and Sediment – 6.5.6.1 Groundwater Quality and Quantity – 6.6.6.1 Surface Water Quality and Quantity – 6.7.7.1 Wetlands – 6.8.6.1.1 Fish and Fish Habitat – 6.9. 6.1.1/6.9.6.2 Habitat and Flora – 6.10.6.1.1 Terrestrial Fauna – 6.11.6.1.1 Avifauna – 6.12.7.1.1 SAR and SOCI – 6.13.6.1.1 Mi'kmaq of Nova Scotia – 6.14.6.1.1 Physical and Cultural Heritage – 6.15.6.1.1 Socioeconomic Conditions - 6.16.9.1 Assessment of VC within Federal Jurisdiction NA Accidents and Malfunctions – 6.18.7 and 6.18.8
Timing	Considers when the residual environmental effect is expected to occur. Timing considerations are noted in the evaluation of the residual environmental effect, where applicable or relevant.	Not Applicable (N/A) — seasonal aspects are unlikely to affect VC's (i.e., fisheries productivity). Applicable — seasonal aspects may affect VC's (i.e., fisheries productivity)	Light – 6.3.6.3 Groundwater Quality and Quantity-6.6.6.4 Surface Water Quality and Quantity 6.7.7.2 Fish and Fish Habitat – 6.9.6.2 No specific definitions for other VCs
Duration	The time period over which the effects are likely to last	Short-term (ST) – effects are limited to occur from as little as 1 day to 24 months Medium-term (ML) – effects can occur beyond 24 months and up to 4 years Long-term (LM) – effects extend beyond 4 years Permanent (P) – valued component unlikely to recover to baseline conditions	Groundwater Quality and Quantity-6.6.6.4 Surface Water Quality and Quantity 6.7.7.2 Fish and Fish Habitat – 6.9.6.2 No specific definitions for other VCs

Table 5.11-1: Characterization Criteria for Residual Environmental Effects (continued)

Characterization	Description	Quantitative Measure or Definition of Qualitative Categories	Valued Component Specific Definitions
Frequency	The rate of recurrence of the effects (or conditions causing the effect)	Once (O) – effects occur once Sporadic (S) – effects occur at irregular intervals throughout the Project Regular (R) – effects occur at regular intervals throughout the Project Continuous (C) – effects occur continuously throughout the Project	No specific definitions for other VCs
Reversibility	The degree to which the effects can or will be reversed (typically measured by the time it will take to restore the environmental attribute or feature)	Reversible (R) – VCs will recover to baseline conditions before or after Project activities have been completed. Partially Reversible (PR) – mitigation cannot guarantee a return to baseline conditions Irreversible (IR) – effects to VCs are permanent and will not recover to baseline conditions	No specific definitions for other VCs

It should be noted that each of the criteria will also incorporate the social and ecological context, reflecting the importance of the environmental attribute or feature to ecosystem health and function as well as the influence of past and current human activity and the disturbance associated with that activity. Further, timing considerations will be noted in the evaluation of the residual environmental effect for each VC, where applicable or relevant. For example, if the VC has a period of time for sensitive life stages (i.e., breeding/spawning), the VC will provide a description of the timing considerations as part of the evaluation.

In conjunction with the effects characteristics outlined in Table 5.11-1, each VC assigns a standard or threshold as described in Section 5.6 of this EIS to determine the significance of an effect caused by the Project.

5.12 Follow-up and Effects Monitoring

Follow-up and monitoring recommendations for each VC are described in the corresponding subsections within Section 6. A summary of all monitoring recommendations is provided in Sections 9 and 10 of this EIS as per Information request CEAA 2-03 (AMNS 2021a).

The Proponent will also evaluate the need for effects monitoring to ensure regulatory compliance. To supplement the effects monitoring, the Proponent will also develop and implement environmental management and contingency plans to prevent or address accidents or malfunctions that have the potential to occur and produce unexpected effects throughout the life of the Project.

5.13 Effects of the Environment on the Project

Effects of the environment on the Project consider potential changes to the Project that may result from interactions with the environment. Project components and activities were reviewed for interaction with the natural environment and effects caused by variations in meteorological conditions from wind, ice, and extreme precipitation events, as well natural hazards like seismic activity. A significant effect on the Project from the environment would include, but not be limited to, the following:

- environmental conditions cause harm to Project personnel and/or the public;
- environmental conditions cause extended delays in construction or a shutdown of operations;
- environmental conditions damages infrastructure and compromises safety; and
- environmental conditions damages infrastructure to the point repair is not feasible.

The assessment of effects of the environment on the Project includes discussion regarding potential interactions, as well as details regarding planning, design, and construction strategies for reducing the likelihood of potential effects on the Project, thereby reducing the likelihood of accidents and malfunctions caused by the environment.

Project components and activities have been designed to consider the hazards and limitations imposed by the natural environment on the Project. The effects of the environment on the Project are discussed further in Section 7.

6 ENVIRONMENTAL EFFECTS ASSESSMENT

6.1 Noise

6.1.1 Introduction

6.1.1.1 Summary of Noise Before the Updates

This section describes the methods and results of baseline characterization as well as predictive studies that were undertaken to support characterization of potential Project effects on the Noise Valued Component (VC). Noise is a physical aspect of the environment that may be altered by the Beaver Dam Mine Project (the Project) that can, in turn, affect related biophysical and socioeconomic VCs (Sections 6.10 to 6.12 and Section 6.16).

6.1.1.2 Summary of Updates to Noise

The Noise Environmental Impact study for the Project has been updated to reflect updates of the Project Description (Section 2) and to address Round 2, Information Requests (IR2) issued by the Impact Assessment Agency of Canada (IAAC, formerly the Canadian Environmental Assessment Agency [CEAA 2019]) and Nova Scotia Environment (NSE 2019). The following key changes to the Project Description (Section 2) and approach for predictive modelling include the following:

- Duration of Construction Phase reduced to less than 1 year (previously 1 to 2 years);
- Duration of Operation Phase extended to 5 years (previously 3 to 4 years);
- Maximum daily volume of Project truck traffic on the haul road reduced to 95 trips per day (previously 190 trips per day);
- Two options for raw material processing considered at the Beaver Dam Mine Site (Option A: jaw crusher at crusher pad; and Option B: secondary blasting and rock breaking in the pit); and
- Truck traffic used in the noise assessment and related modelling has been adjusted to a 16-hour shift, including the nighttime hour of 6:00 AM to 7:00 AM.

Direct responses to IR2s are provided in Appendix B.1 and Appendix B.2 and in the combined AMNS IR2 response submission (AMNS 2021). An outline of updates to the Noise Environmental Effects Assessment are summarized in Table 6.1-1.

Table 6.1-1: Updated Subsections from the Revised 2019 Environmental Impact Statement - Noise

Notes: PA = Project Area; LAA = Local Assessment Area; RAA = Regional Assessment Area; - = no update; IR2 = Round 2, Information Requests; CEAA = Canadian Environmental Assessment Agency; EIS = environmental impact statement.

6.1.2 Rationale for Valued Component Selection

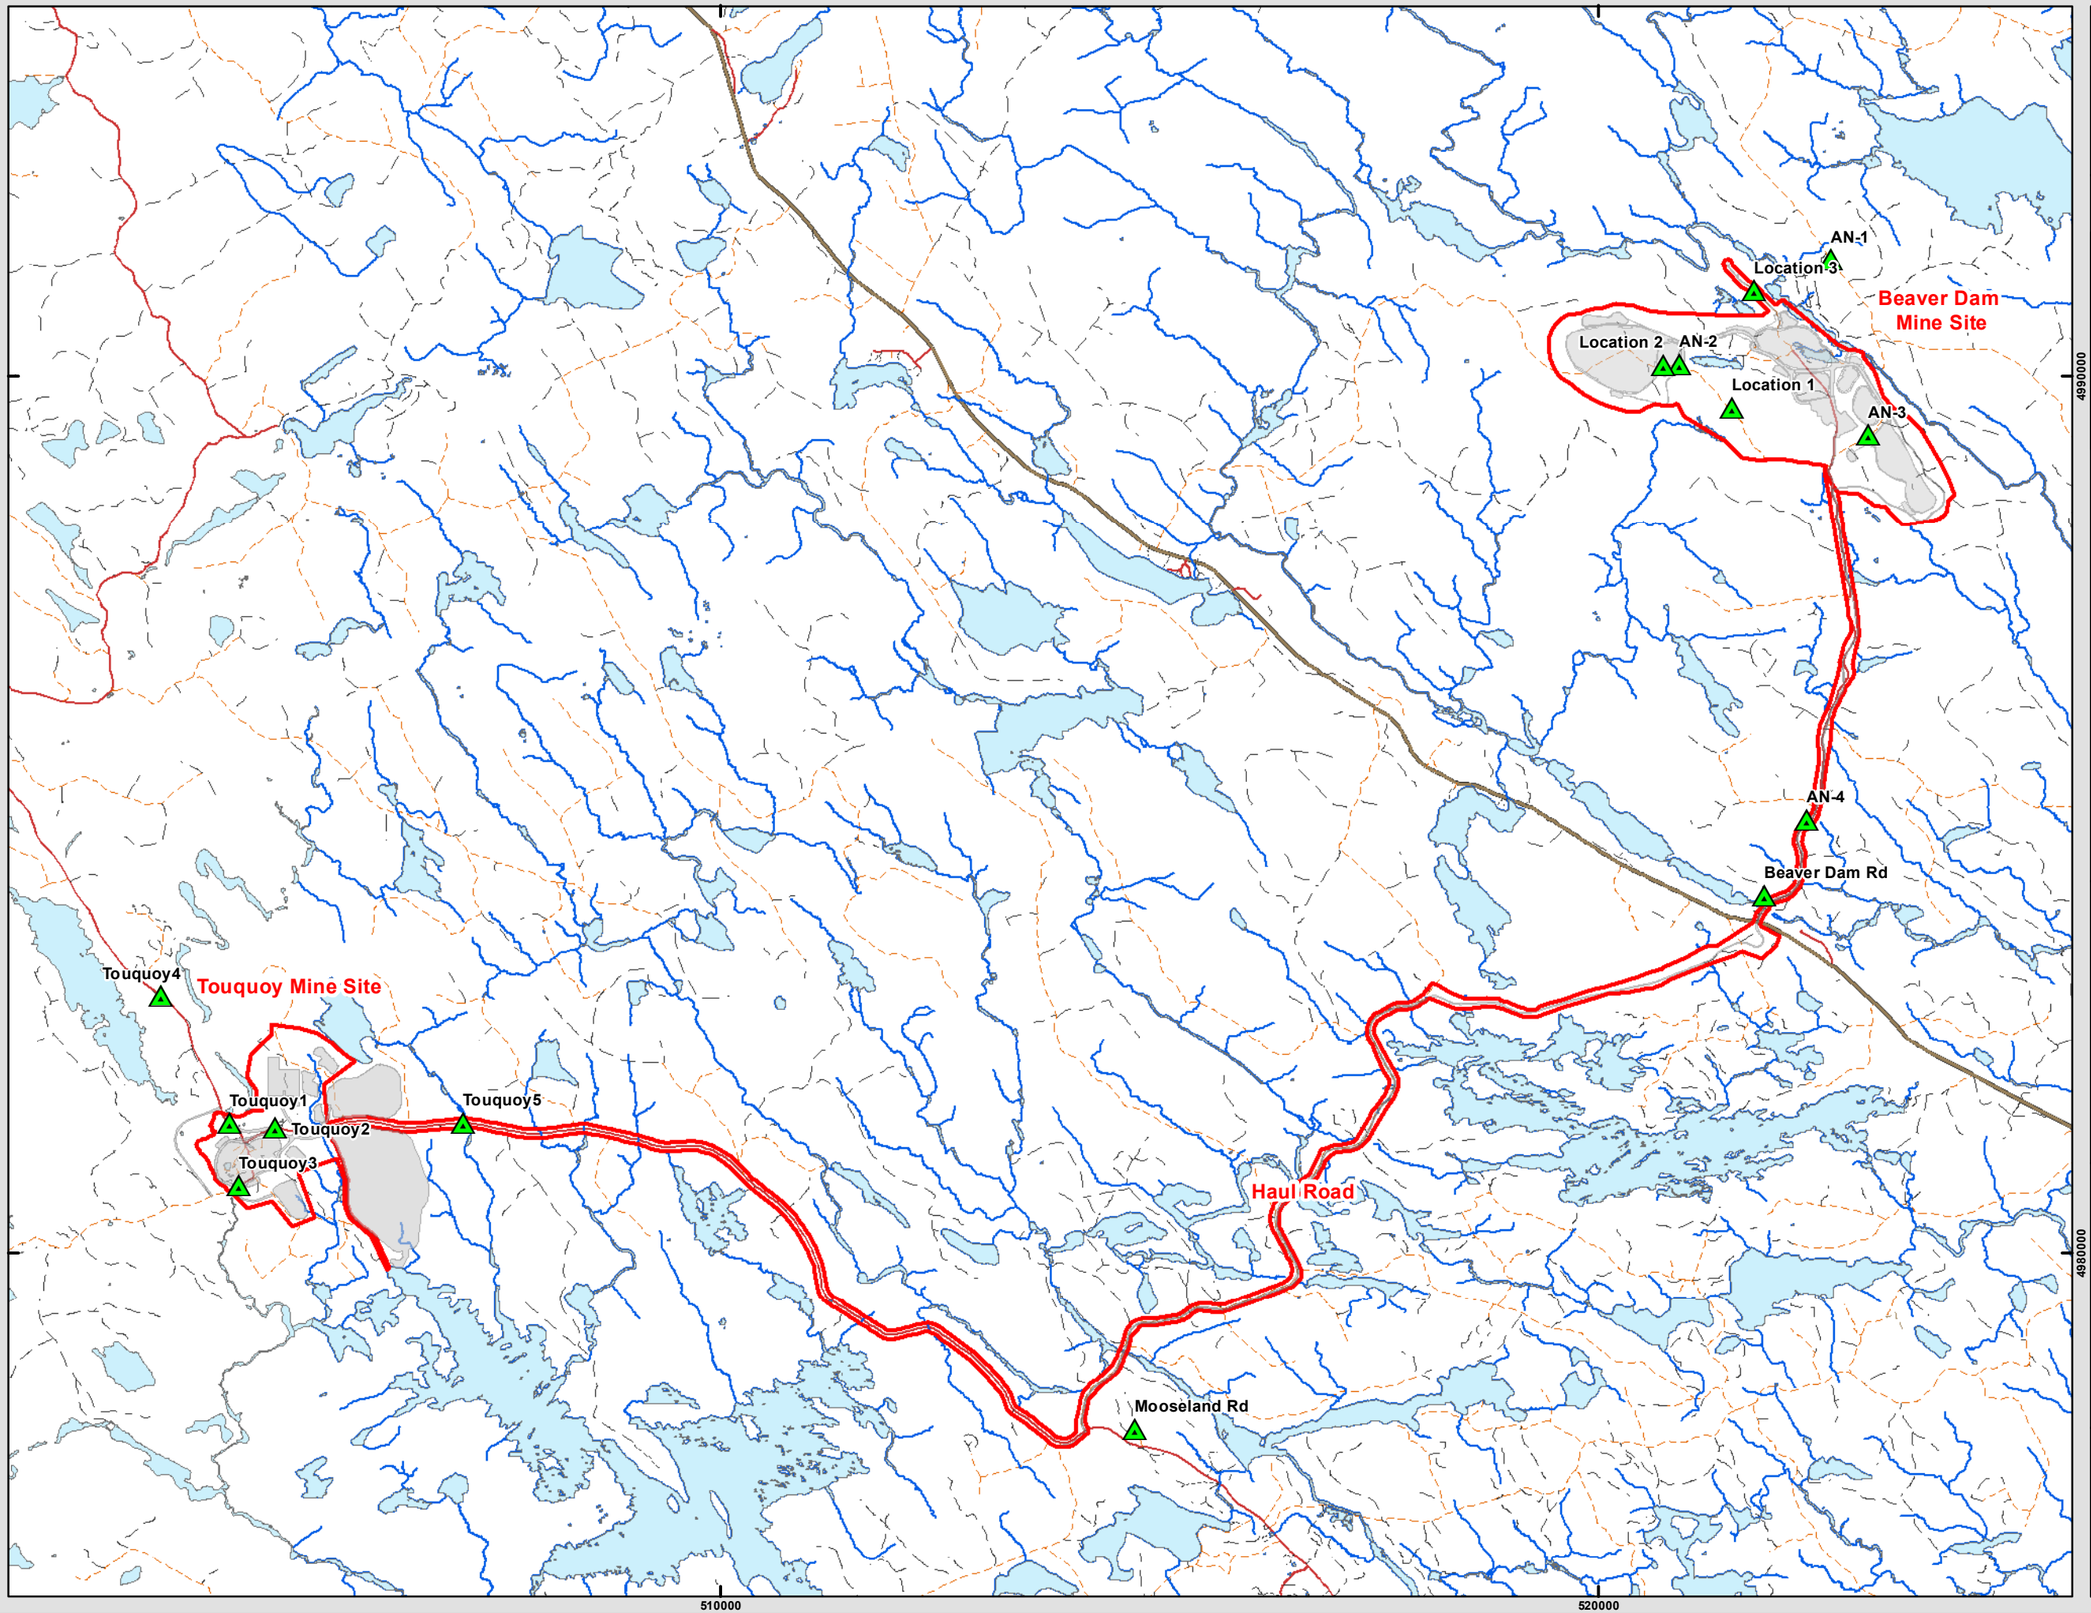
Noise is a physical aspect of the environment, that can affect local wildlife, traditional land use and human health. Activities associated with the proposed Project will introduce Noise to the surrounding environment, potentially creating adverse noise effects to receptors located within the vicinity of the Project. Project-related noise levels are therefore assessed to allow for comparison to relevant benchmarks and guidance levels for the protection of wildlife and human health (Sections 6.10 to 6.12 and Section 6.16).

Noise will be generated throughout the life of the Project at the Beaver Dam Mine Site, Haul Road, and Touquoy Mine Site. Sources of Project-related noise will include heavy machinery during the construction phase and heavy truck traffic during the construction and operational phases. The majority of mining operations will occur in the pit well below current ground surface, which will

attenuate the effects of noise. During the construction and operation phase of the Beaver Dam Mine Site, rock blasting using explosives is a source noise and vibration that would be generated.

Noise and Vibration is provincially regulated via the Workplace Health and Safety Regulations and the Pit and Quarry Guidelines (1999), which protects the health of site workers and the general public at Project area boundaries, respectively.

6.1.3 Baseline Program Methodology



The objective of the noise baseline study was to collect information on baseline noise conditions before commencement of the proposed Project.

Baseline ambient noise levels were evaluated using a Quest Sound Pro-DL Class 1 Precision Integrating sound level metre (serial number BGG040024). Data collected was evaluated against the provincial Pit and Quarry Guidelines as a reference. Sound level measurements were collected at several sample locations near the Beaver Dam Mine Site boundary and along the Haul Road, and one location at the Touquoy Mine Site, taking into consideration the nearest receptors and proposed mining equipment operational locations. Sound level measurements were not undertaken at any additional locations (such as at the nearest residence to the Beaver Dam Mine Site). Ambient noise levels in the vicinity of the Beaver Dam Mine Site and the Haul Road provide a more conservative baseline for comparative purposes.

Table 6.1-2 summarizes the baseline noise monitoring locations these locations are shown on Figure 6.1-1.

Table 6.1-2: Baseline Noise Monitoring Locations

Sample Location	General Area	Sample Location Rationale
Location #1 (2008)	Approx. 450 m south of Crusher Lake	On site boundary, near Waste Rock Storage area
Location #2 (2008)	West end of Crusher Lake	500 m west of site boundary, northwest of Waste Rock Storage
Location #3 (2008)	Near northwest end of Cameron Flowage, east of Mud Lake	North edge of site boundary, at pit and water diversion channel
AN#1	North of Cameron Flowage	North of Pit
AN#2	West end of Crusher Lake	400 m west of site boundary, northwest of Waste Rock Storage; in close proximity to Location #2 (2008)
AN#3	East southeast of proposed stockpile area and ROM Pad	400 m east of site boundary, in Stockpile and ROM Pad area.
AN#4	Near junction of Beaver Dam Mines Road and Hwy 224, approx. 1.35 km NNW of Hwy 224	Proposed crusher location
Beaver Dam Road	Near junction of Beaver Dam Mines Road and Hwy 224, approx. 300 m NNW of Hwy 224.	East end of Haul Road
Mooseland Road	130 m north of Mooseland Road, 560 m east of Haul Road	West end of Haul Road
Location 1 (Touquoy)	North of the proposed open pit	Proposed open pit location

6.1.4 Baseline Conditions

6.1.4.1 Overview

Baseline ambient sound level monitoring was conducted at several locations in the Project Area between January 2007 and September 2016 (Appendix B.1 and Figure 6.1-1). Based on the data obtained from these sound level monitors, ambient sound levels are generally low, as expected for a characteristically rural environment. Specific non-residential locations of traditional land use and recreation have not been identified for inclusion in the analysis; however, it is understood that traditional uses such as hunting may occur in areas close to the Project Area.

6.1.4.2 Ambient Noise

Ambient noise has been sampled at several representative locations (Table 6.1-3). The key sensitive receptor in the area is the Beaver Lake IR 17; a satellite community of the Millbrook First Nation located approximately 5 km south of the Beaver Dam Mine Site. At its nearest point, the Haul Road is approximately 3 km east of Beaver Lake IR 17. Other receptors in the area include a permanent residence, and seasonal camps/cottages near the Beaver Dam Mines Road at Highway 224, seasonal camps/cottages on the Cross Road near Mooseland Road, and residences along Mooseland Road (Figure Section . Receptors are located further along Highway 224 and Mooseland Road up to 18 km over considerable changes in topography and are generally forested. Activities in these areas are ongoing and include recreational use (hunting, ATVs, etc).

Camp Kidston, which operates only in the summer months, is located 3.5 km northeast of the Touquoy Mine Site. The nearest permanent full-time occupied residences from the Touquoy Mine Site are located approximately 5.8 km to the north of the open pit along Caribou Road. The next closest permanent residences to the Touquoy Mine Site are approximately 7.4 km to the northwest and 11.7 km to the southeast. Sampling locations are shown in Figure 6.1-1.

Noise data was recorded in A-weighted decibels (dBA) and presented as equivalent continuous noise level (Leq) averaged over a time period and compared to Nova Scotia Environment criteria by time of day.

Sound level measurements for all sample locations, except for Location #1 at the Beaver Dam Mine Site, met NSE Pit and Quarry criteria for all time intervals. Sample Location #1 was approximately 10 feet from a hauling road that was in use during the monitoring period contributing to elevated noise level readings. Typical sound sources would include recreational vehicles, traffic on local roadways and contribution from existing forestry operations. The degree to which these sources would influence the existing noise levels would vary depending on the time of day and season.

The noise monitoring locations were chosen to be representative receptors and also to understand the ambient noise at the Beaver Dam Mine Site, along the Haul Road, and at the Touquoy Mine Site. Location #1, 2 and 3 and AN #1, 2, and 3 were placed so to understand the noise levels directly around the Beaver Dam Mine Site. The Beaver Dam Mines Road site was chosen as the closest receptor to a permanent resident to the Beaver Dam Mine Site and the Haul Road. It is a surrogate for the Beaver Dam IR 17 location because the monitoring site would be more greatly affected by noise than the IR but would also record the same vehicle traffic from Highway 224 as would pass by the Beaver Dam IR. The IR is located approximately 3 km north of this monitoring location. The Mooseland Road monitoring location was chosen as a mid-point between the nearest dwelling on the Mooseland Road and the Haul Road. Location #1 at Touquoy was chosen to understand the noise levels directly around the Touquoy Mine Site and proposed open pit.

	January 10, 2007	15:00 - 23:59	40.9	1900-2300 <60 dBA
	January 11, 2007	0:00 - 06:59	40.2	2300-0700 <55 dBA
	January 11, 2007	07:00 - 18:59	42.9	0700-1900 <65 dBA
	January 11, 2007	19:00 - 22:59	41.4	1900-2300 <60 dBA
	January 11-12, 2007	23:00 - 06:59	40.7	2300-0700 <55 dBA

At the measurement locations around the Beaver Dam Mine Site, based on the 2014 values (AN# 1,2,3) the average value is 33 dBA ±. The dominant noise sources noted are natural, including birds, the movement of leaves, and possibly the odd vehicle on a logging road. The measurement locations at Beaver Dam Mines Road and Mooseland Road would be mostly from natural sources. Mooseland Road measurements are comparable to the Beaver Dam Mine Site. It is located on a little used gravel road. The Beaver Dam Mines Road is elevated and is near a paved highway with regular traffic. This road also passes through Beaver Dam IR and ambient sound will be the same as at the measured location.

Based on the measured ambient sound levels discussed above, the estimated lowest baseline ambient sound levels throughout the Study Area are as follows:

- 7:00 AM to 7:00 PM 33 dBA;
- 7:00 PM to 11:00 PM 31 dBA; and
- 11:00 PM to 7:00 AM 27 dBA.

At the Touquoy Mine Site, noise monitoring will be undertaken throughout the operation of the facility if any complaints or concerns are received. To date, no noise complaints have been received or are anticipated.

6.1.5 Consideration of Engagement Results

Key concerns raised during public and Mi'kmaq engagement relating to atmospheric environment include noise from mining operations at the Beaver Dam Mine Site and trucking along the Haul Road. The change to the Haul Road alleviated these concerns with respect to passing by existing residences, especially concerns of Millbrook First Nation regarding its residents in Beaver Lake. Concerns about greenhouse gas emissions and noise specifically associated with the trucking were also noted.

The results of the public and Mi'kmaq engagement have been considered in the environmental effects assessment, including the Proponent's commitments on mitigation and monitoring measures and proposed compliance and effects monitoring programs, as well as the Proponent's broader commitment to ongoing public and Mi'kmaq engagement. Specific to evaluating the effect on atmospheric environment, these are found within the following environmental effects assessment.

Engagement undertaken since the 2019 Revised EIS that included public, stakeholders and Mi'Kmaq of Nova Scotia, including Millbrook First Nation are documented in updates to Sections 3 and 4 and Appendices A.4 and A.5.

6.1.6 Effects Assessment Methodology and Modelling

The scope of this assessment is to quantify Construction and Operations noise at property lines and at identified sensitive receptors within the spatial boundaries defined for the Noise VC. Effects assessment boundaries, modelling methodologies and assumptions for the Noise VC are provided in this section.

As described in Section 6.1.1.2, the effects assessment has been updated to address IR2 issued by Canadian Environmental Assessment Agency and Nova Scotia Environment as well as updated estimates of truck traffic on the Haul Road; technical studies informing the effects assessment presented in the underlying sections are provided in Appendix B.1 and Appendix B.2.

6.1.6.1 Boundaries

6.1.6.1.1 Spatial Boundaries

The spatial boundary used for the assessment of effects of noise are described below and presented in Figure 6.1-2.

The Project Area (PA) encompasses three primary components from Marinette to Moose River Gold Mines, Halifax County, NS. The Beaver Dam Mine Site will be located at the end of the Beaver Dam Mines Road and the Haul Road will span from the Beaver Dam Mine Site to Moose River Gold Mines, where the Touquoy Mine Site (processing and exhausted pit [to be used to dispose Beaver Dam tailings]) is located.

The Local Assessment Area (LAA) encompasses adjacent areas outside of the PA where Project related effects to Noise are reasonably expected to occur. The LAA constitutes the noise modelling domain based on the location of the Project noise emission sources and predicted noise levels for Project Constriction and Operations phases, as well as the location of potential sensitive receptors. The Noise modelling domain was established so that it would be inclusive of, at minimum, any predicted noise contours above 35 dBA, a threshold value criteria for baseline nighttime noise levels adopted from the Alberta Energy and Utilities Board (Alberta ERCB 2007).

4990000 4980000

The Regional Assessment Area (RAA) extends beyond the LAA as to encompass potential indirect effects of Noise with other related VCs, such as human health and wildlife. Direct effects on the Noise VC from the Project are not expected to occur in the RAA.

6.1.6.1.2 Temporal Boundaries

The temporal boundaries used for the assessment of effects to ambient noise are the Construction phase, Operational phase, and Active Closure.

Construction Phase (1 Year)

In the updated Project Description, the timeline for construction is now planned to be less than 1 year; and was previously anticipated to be up to 2 years. For construction activities lasting less than one year, Health Canada's "Guideline for Evaluating Human Health Impacts in Environmental Assessment: Noise" (Health Canada 2017) categorizes the noise effects as 'short-term construction noise exposure'.

Operations Phase (5 Years)

Crushed ore from the Project will be transported by truck via the Haul Road to the existing and fully permitted Touquoy Mine. Processing of ore from the Beaver Dam gold deposit at the existing the Beaver Dam Mine Site is anticipated to begin construction in 2022, come into production in 2023, cease operations in 2027 and then be reclaimed.

Active Closure (2 Years)

Decommissioning phase will involve infrastructure demolition, site reclamation and environmental monitoring activities. Anthropogenic noise during Active Closure (and Post-Closure) periods will be substantially lower than noise generated during Construction and Operations phases. Therefore, predictive modelling and subsequent assessment of potential effects focus on the Construction and Operations phases, which are the temporal boundaries associated with the greatest amount of anthropogenic noise. Active Closure and post-closure phases will not be considered further in this assessment.

6.1.6.1.3 Technical Boundaries

No technical boundaries were identified for the effects assessment of noise.

6.1.6.1.4 Administrative Boundaries

Noise within the Project site is regulated by the province through the Workplace Health and Safety Regulations, which establishes the noise environment needed to maintain worker health. The Nova Scotia Pit and Quarry Guidelines (NSE 1999) indicate that noise levels at the boundaries of the Beaver Dam Mine Site and Touquoy Mine Site are not to exceed the following levels:

- Leq $\leq$ 65 dBA between 0700 to 1900 hours (daytime);
- Leq $\leq$ 60 dBA between 1900 to 2300 hours (evening); and
- Leq $\leq$ 55 dBA between 2300 to 0700 hours (night-time, Sunday and statutory holidays).

The *Guidelines for Environmental Noise Measurement and Assessment* (NSE 2005) also require these noise levels to be met at locations where people normally live, work, or take part in recreation.

6.1.6.2 Thresholds for Determination of Significance

Residual effects are effects to VCs that are predicted to occur even after the implementation of mitigation measures (Section 5.10). Significant residual effects for the Noise VC would be defined as having high magnitude (i.e., an **exceedance** of the maximum noise or vibration limits), occur beyond the PA and LAA, be of long-term to permeant duration, occur at regular intervals or be continuous throughout the Project, and be only partially reversible to irreversible (Table 6.1-4). The screening of project effects, and mitigation measures, are assessed in aggregate to determine whether the residual impacts are "Not Significant" or "Significant" according to the following definitions.

Table 6.1-4: Noise Quality Characterization Criteria

Criteria	Groundwater Quality Impact Description
Magnitude	• **Negligible**: predicted change to noise is less than 35 dBA, a threshold value criteria for baseline nighttime noise levels adopted from the Alberta Energy and Utilities Board (Alberta ERCB 2007) and less than 45 dBA, which has been used to assess effects to Wildlife . • **Low**: Exceeds 35 dBA, a threshold value criteria for baseline nighttime noise levels adopted from the Alberta Energy and Utilities Board (Alberta ERCB 2007) but does not exceed 45 dBA, which has been used to assess effects to Wildlife . • **Medium**: Exceeds not exceed 45 dBA, which has been used to assess effects to Wildlife. • **High**: Predicted Noise Levels exceeds NSE (1999) Guidelines that include: • Leq $\leq$ 65 dBA between 0700 to 1900 hours (daytime); • Leq $\leq$ 60 dBA between 1900 to 2300 hours (evening); and • Leq $\leq$ 55 dBA between 2300 to 0700 hours (night-time, Sunday and statutory holidays).
Geographical Extent	• **Discrete**: effect is limited to the immediate footprint or Project Area (PA). • **Local**: effect is limited to the near-field Local Assessment Area. • **Potential Regional**: effect persists to the far-field Local Assessment Area and Regional Assessment Area.
Timing	• Timing represents seasonal occurrence of the effect. Nice propagation in winter months may be higher than spring summer when deciduous attenuate noise.
Duration	• **Short term**: effect is restricted to Construction and/or Operations Phases. • **Medium term**: effect occurs in Construction Phase and Operations. • **Long term**: Effect persists in PC.
Frequency	• **Intermittent**: VC interaction or effect will occur at irregular intervals throughout any Project Phase. • **Regular**: effect occurs on a regular basis but not continuous basis. • **Continuous**: effect occurs constantly.
Reversibility	• **Reversible**: effect can be reversed. • **Partially reversible**: effect can be partially reversed. • **Irreversible**: effect cannot be reversed, is of permanent duration.

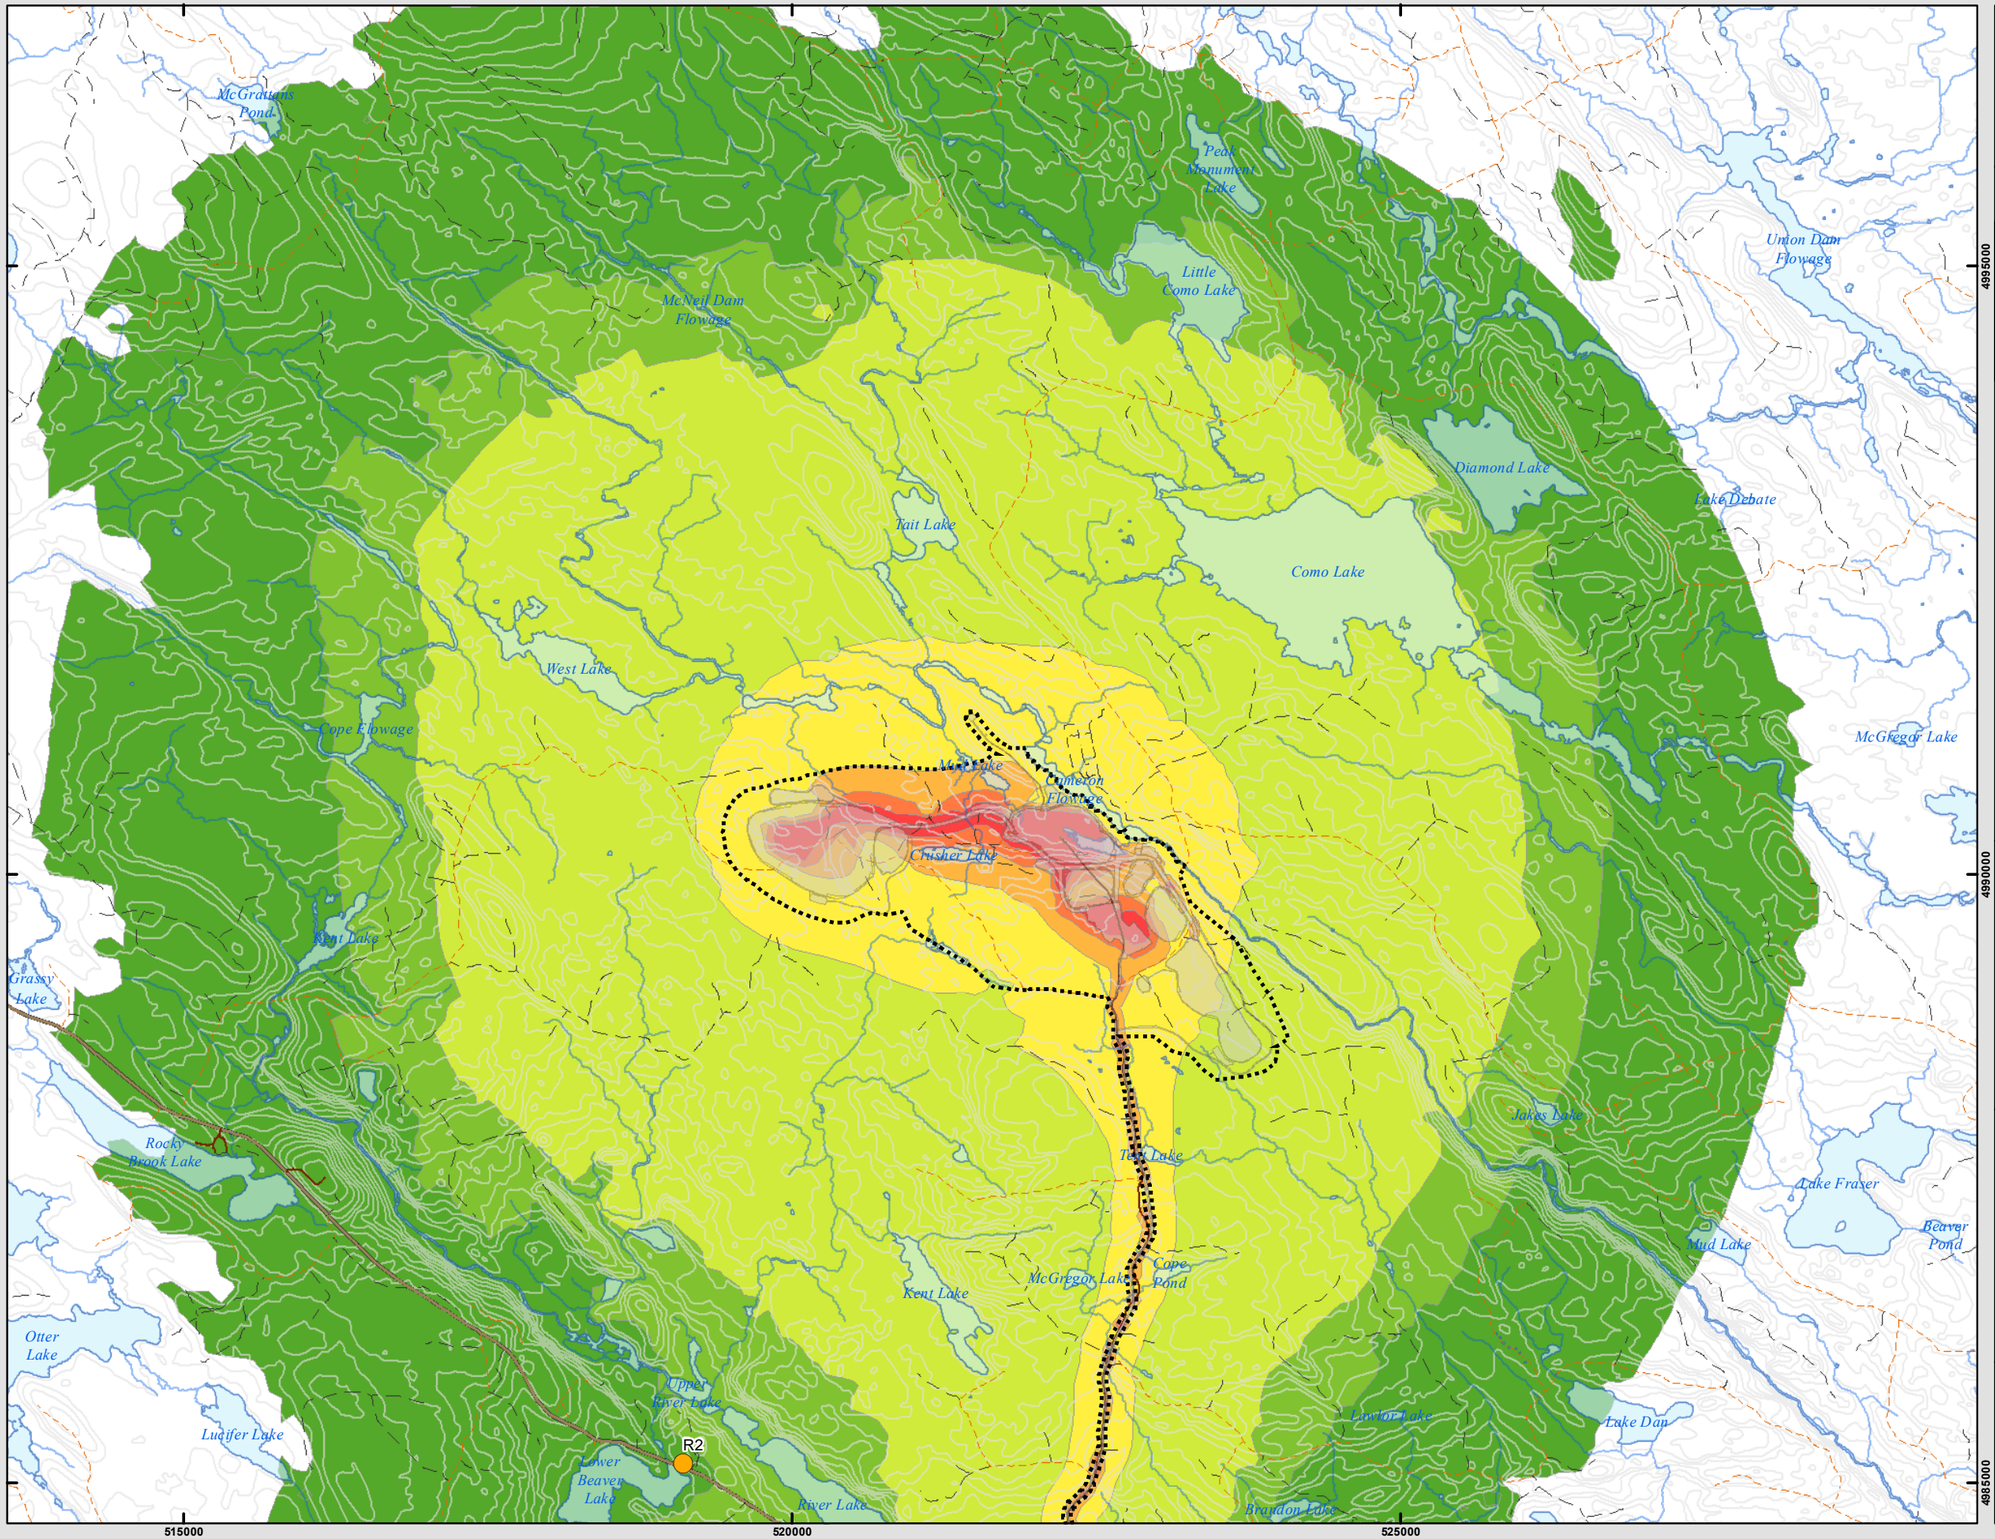
6.1.6.3 Noise Modelling Methodology

Potential Noise interactions and effects for Construction and Operations are quantitatively assessed by acoustic modelling. The technical reports documenting the updated approach and inputs for Noise modelling (Construction, Operations) are provided in Appendix B.1 and Appendix B.2, and are summarized in this section.

The updated noise analysis results presented herein include all identified worst-case human receptor locations (R1 to R9, Figure 6.1-3). Specific non-residential locations of traditional land use and recreation have not been identified for inclusion in the analysis; however, it is understood that traditional and recreational uses such as hunting may occur in areas close to the Project Area.

In summary, an updated acoustical model was undertaken to provide an order of magnitude estimation of the estimated noise from the crushing operations at the Beaver Dam Mine Site and haul truck travel along the Haul Road. The noise sources and topography were input into an industry standard acoustic model. Computer Aided Noise Abatement Acoustical Modeling Software (Cadna A), version 4.6, is based on the ISO 9613-2 standard "Acoustics - Attenuation of Sound During Propagation Outdoors - Part 2: General Method of Calculation." The Cadna A model is the industry standard for environmental noise modeling in Canada.

To predict the future worst-case noise impacts from the Project activities, representative octave band noise data was used, measured from processing equipment similar to what is noted to be required for the Project. This data was obtained from the Department of Environment Food and Rural Affairs (DEFRA) "Update of Noise Database for Prediction of Noise on Construction and Open Sites, 2005 and 2006". The United States Department of Transportation, Federal Highway Administration (FHWA) document "FHWA Roadway Construction Noise Model User's Guide, 2006" was used as a supplemental document to obtain sound level data for equipment not listed by DEFRA.



For the Touquoy Mine Site An acoustic assessment was conducted as part of the 2007 Focus Report, focusing on sound emissions from noise sources identified at the facility and determining effects on sensitive receptors including; Camp Kidston (3 km north of the Touquoy mine), the nearest permanent resident (5 km north of the proposed open pit) and the Scraggy Lake area. Sound level impacts were compared to the Nova Scotia Guidelines for Environmental Noise Measurement and Assessment. An estimated worst case facility sound level measurement for a 1-hour period was estimated for each receptor near Touquoy Mine Site.

6.1.7 Project Activities, Noise Interactions, and Predicted Effects

6.1.7.1 Overview

The Project will operate as a satellite open pit mine. Crushed ore from the Project will be transported by truck via the Haul Road to the existing and fully permitted Touquoy Mine. Noise will be generated at the Beaver Dam Mine Site, the Haul Road, and the Touquoy Mine Site. Sources of Project-related noise include heavy machinery and trucking during the Construction phase and haul truck and mining machinery traffic during Operations. The majority of mining operations will occur in the pit well below current ground elevation, which will attenuate the effects of noise. During the Construction and Operation phase of the Project, rock blasting using explosives was also considered as noise and vibration that would be generated.

Table 6.1-5 and Table 6.1-6 present specific potential Noise interactions with Project activities for Construction and Operation phases.

Potential Noise interactions and effects for Construction and Operations were subsequently quantitatively assessed by acoustic modelling (Section 6.1.6.3). The Noise contour plots and overall study area are provided in Figures 6.1-3 and 6.1-4 and indicate the predicted noise levels produced by the Project. These noise contours are used to assess effects on wildlife, birds, traditional uses and socioeconomic conditions (Section 6.11 to 6.12 and 6.16); details for all isopleths are provided in Appendix B.1 and B.2.

Table 6.1-5: Potential Noise Interactions with Project Activities at Beaver Dam Mine Project Area during the Construction

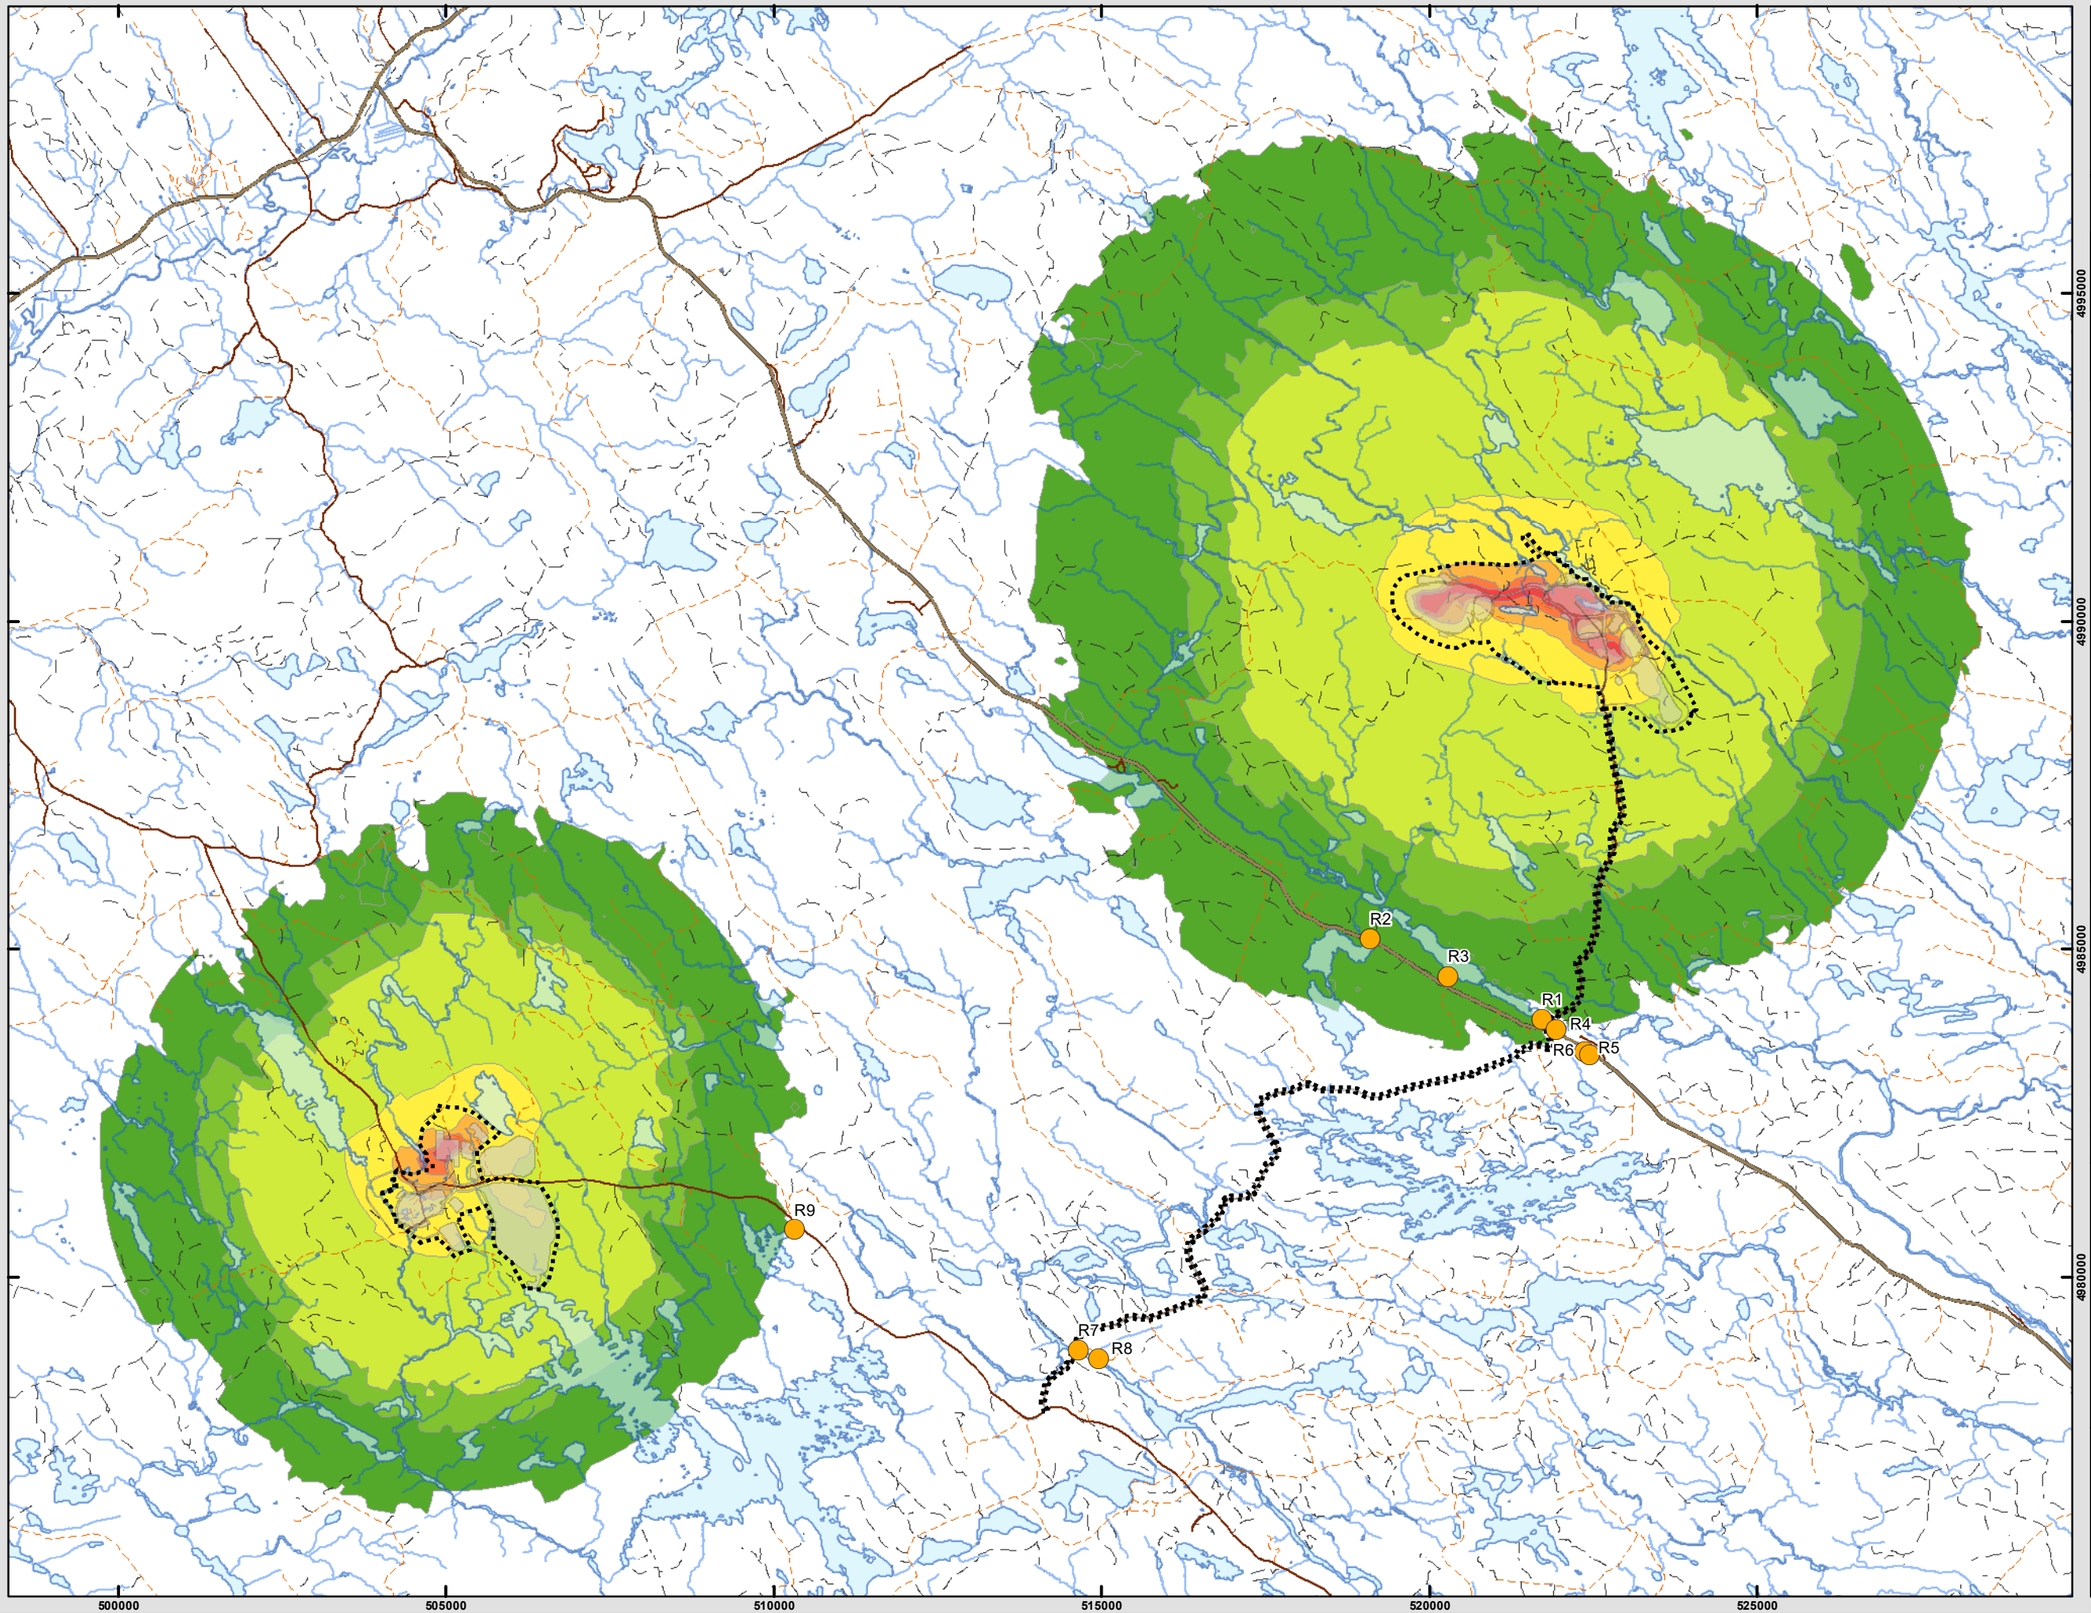
Project Area Location	Duration	Relevant Project Activity
Beaver Dam Mine Site	<1 Year	• Clearing, grubbing, and grading in preparation of construction • Drilling and rock blasting in preparation of construction • Till and waste rock removal from site preparation transport and storage • Existing settling pond dewatering in preparation of for construction • Watercourse and wetland alteration in preparation of construction • Mine Site road construction • Equipment to power lighting at Mine Sites and along roads • Surface infrastructure installation and construction • Collection and settling ponds construction • General management of wastes derived from site • General Construction activities
Along Haul Road	<1 Year	• Clearing, grubbing, and grading in preparation of construction • Till and waste rock from site preparation transport and storage • Watercourse and wetland alteration in preparation of construction • Haul road construction and upgrades
Touquoy Mine Site	<1 Year	• Tailings pipeline, make-up water pipeline alteration, and relocation of reclaim infrastructure

Table 6.1-6: Potential Noise Interactions with Project Activities at Beaver Dam Mine Site During the Operation Phase

Project Area Location	Duration	Project Interaction
Beaver Dam Mine Site	5 Years	• Rock blasting to access and extract ore • Management of waste rock produced from crushing and/or blasting and preparing ore for transport • Petroleum products management • Site maintenance and repairs • Equipment to power lighting at Mine and along roads • General management of wastes derived from operation activities
Along Haul Road	5 Years	• Ore transport • Road lighting • Equipment to power lighting at Mine Sites and along road • Haul road maintenance and repairs
Touquoy Mine Site	5 Years	• Ore management and processing • Lighting equipment for on-site facilities and Mine roads

The key sensitive receptor in the area is the Beaver Lake IR 17; a satellite community of the Millbrook First Nation located approximately 5 km south of the Beaver Dam Mine Site. A permanent resident is located along the Beaver Dam Mines Road near Highway 224. A seasonal dwelling is located on the Cross Road near Mooseland Road.

Camp Kidston, which operates only in the summer months, is located 3.5 km northeast of the Touquoy Mine Site. According to the Proponent, the nearest permanent full-time occupied residences are located approximately 5.8 km to the north of the open pit along Caribou Road.



The Touquoy Mine Site is in production. The primary effect of the continued use of the Touquoy Mine Site is the continued generation of noise due to haul truck traffic on the site, processing of Beaver Dam ore. There are no new or additional effects from noise anticipated to be caused by the processing of ore and the management of tailings (exhausted pit) from the Project, as no new construction or disturbance is required at the Touquoy Mine Site related to the processing of Beaver Dam ore. The effects of noise previously described for the Touquoy Mine Site in the EARD and Focus Report are presented in the sections below.

Document Name: BD_EIS_Figure6-1-3 Noise_Night

6.1.7.2 Model Results: Prediction of Noise Effects, Construction

The acoustic modelling has been updated to reflect the current infrastructure layouts for the Project and estimates of construction activities (Appendix B.1). An assessment of predicted construction noise has been included in accordance with Health Canada's "Guideline for Evaluating Human Health Impacts in Environmental Assessment: Noise" (Health Canada 2017). Site specific topography and mine layout was used for the model, as well as all mobile sources, and equipment.

Construction activities at the Project have a planned duration of less than one year (Table 6.1-5). The Health Canada guideline for noise suggests that noise from construction activities lasting less than one year (i.e., short-term construction) be assessed using the United States Environmental Protection Agency (US EPA 1974) methodology. This methodology provides mitigation noise levels (MNLs) as criteria with various correction factors to evaluate whether adverse effects are likely, and if mitigation should be considered.

To support the Noise Assessment for Construction, the suggested base MNL is 47 dBA, which is specified in terms of the day-night sound level (Ldn), and assumes that the dominant sources of noise are tonal/impulsive. Ldn is an equivalent continuous sound level taken over 24 hours, with the night-time (10:00 PM to 7:00 AM) sound levels adjusted by +10 dB to account for increased noise sensitivity at night (Health Canada 2017). The Health Canada guideline also specifies correction factors that should be applied to the base MNL dependent on the type of community in which the construction activities occur, as well as some other additional corrections. These correction factors are summarized in Table 6.1-7.

Table 6.1-7: Corrections to Determine Appropriate Mitigation Noise Levels for Short-Term Construction

Community Description	Applied Correction Factors	Suggested MNL
Quiet suburban or rural	-	7 dBA Ldn
Norman suburban	+5 dB	52 dBA Ldn
Urban residential	+10 dB	57 dBA Ldn
Noisy urban	+15 dB	62 dBA Ldn
Very noisy urban	+20 dB	67 dBA Ldn
Other Additional Correction Factors		
Construction duration less than 2 months	+10 dB	-
Winter (or windows always closed)	+5 dB	-
Negligible tonal or impulsive noise	+5 dB	-

Source: Health Canada 2017.

Notes: bB = decibels; Ldn = day-night sound level; MNL = mitigation noise levels; - = not applicable.

The Project is located in an area best described as rural, where the corresponding suggested MNL is 47 dBA Ldn. Other additional correction factors, where applicable. Nine worst-case human receptor locations have been identified for assessment (R1 to R9; Figure 6.1-3).

At the worst-case residential receptors, noise emissions from construction activities at the Beaver Dam Mine Site are negligible in comparison to noise emissions from road construction and material transport on the roads. It is predicted that construction of Section 3B of the Haul Road (Section 2, Figure 2.3-3) will produce the most significant noise levels at residential receptors. At the beginning of construction of this section of the Haul Road, construction activities will occur approximately 120 m from R4 and 170 m from R1. However, as construction of Section 3B of the Haul Road progresses (Section 2, Figure 2.3-3), construction equipment will move farther from these receptors and noise impacts will decrease.

Construction noise was evaluated using the following two model scenarios to represent worst-case noise emissions during the Construction Phase:

- **Scenario A:** Road construction near R1 and R4 (less than 2 months of construction of Section 3B of the Haul Road).
- **Scenario B**: Road construction minimum 500 metres from R1 and R4 (after approximately 2 months of construction of Section 3B of the Haul Road).

For Scenario A, the dominant sources of noise are heavy road construction equipment, which are conservatively assumed to include one dozer, one wheeled loader, and one excavator conducting excavation/earthworks continuously for the entire daytime period, as well as one dump truck unloading for 2.5 hours per day at each road construction location (i.e., at each end of Section 3B and 4C of the Haul Road [Section 2, Figure 2.3-3].). Since this scenario represents construction activities that are estimated to have a duration of less than 2 months (i.e., correction of +10 dB applies), the corrected MNL for this scenario is 57 dBA Ldn.

For Scenario B, the dominant sources of noise are trucks carrying raw materials along the haul road and other roadways to deposit material for construction of Section 3B of the haul road. It is assumed that truck traffic will include 95 one-way trips per day on the haul road, and up to 60 one-way trips per day on Highway 224 through Beaver Lake IR 17. This assumption is conservative, as road construction material will be sourced primarily from three quarries along the length of Section 3B, with additional construction materials, if required, sourced from either the Touquoy or Beaver Dam Mine Sites or other local approved facilities (Section 8). Truck traffic is not considered a tonal/impulsive source of noise (i.e., correction of +5 dB applies), therefore the corrected MNL for this scenario is 52 dBA Ldn.

Based on the model scenarios, assuming concurrent construction of the Haul Road and Beaver Dam Mine Site facilities, predicted construction noise effects at each of the identified receptors are summarized in Table 6.1-8 and Figure 6.1-4; complete details are provided in Appendix B.1.

Table 6.1-8: Predicted Noise Effects during the Construction Phase of the Project

Receptor ID	Receptor Description	Scenario A: Road Construction Near R1 and R4 (<2 months)		Scenario B: Remainder of Construction (>2 months)		Compliance
		Predicted Noise Level (Ldn)	MNL[a] (Ldn)	Predicted Noise Level (Ldn)	MNL[a] (Ldn)	
R1	9 Beaver Dam Mine Road (Marlborough Property)	53	57	49	52	Yes
R2	4112 Highway 224 (Beaver Lake IR 17)	52	57	52	52	Yes
R3	4115 Highway 224 (Cottage on Crown Land)	43	57	43	52	Yes
R4	3492 Highway 224 (Hobbs Property)	56	57	49	52	Yes
R5	3379 Highway 224 (McLeod Property)	41	57	40	52	Yes
R6	3373 Highway 224 (Smith Property)	38	57	39	52	Yes
R7	Tangier River (Deepwood Estates Property)	52	57	52	52	Yes
R8	Tanger River (Musqudoboit Lumber Co. Ltd. Property/John Dickson Lease)	41	57	41	52	Yes
R9	5579 Mooseland Road (Lloy Property)	49	57	49	52	Yes

The prediction results for Construction (Table 6.1-8; Figure 6.1-4) represent the typical expected construction activities and equipment from the Beaver Dam Mine Site and Haul Road, at the predictable worst-case locations, assuming Construction activities will be limited to the day and evening time periods only (7:00 AM to 11:00 PM). Noise level contributions at each receiver due to each noise source are provided in Appendix B.1.

During the worst-case scenario, noise effects from the Construction Phase activities are within the suggested MNL criteria. For Scenario A, these worst-case effects are predicted at the start of construction of Section 3B of the Haul Road, and will diminish significantly as construction progresses due to the increased distance from the receptors. Based on these results, adverse effects are expected to be unlikely, and mitigation is not required.

6.1.7.3 Model Results: Predicted of Noise Effects, Operations

The methodologies used and assumptions made for the Noise Impact Study are provided in Appendix B.2. The assessment considered residential points of reception (POR) and property boundary (PBR) assessments. Site specific topography and mine layout was used for the model, as well as all mobile sources, equipment, and open pit operations were included.

The calculated noise impacts at each POR are presented below. For the processing of raw materials at the Beaver Dam Mine Site during the Operation Phase, a jaw crusher (noise model source ID: S120) will be used at the crusher pad of the Beaver Dam Mine and is considered in the Noise Effects modelling. Truck traffic used in the noise assessment and related modelling has been adjusted to a 16-hour shift, 7:00 AM to 11:00 PM.

Figure 6.1-4 presents Noise contour plots for the overall study area, for day and night, respectively.

6.1.7.3.1 Residential Receptors

Nine worst-case human receptor locations have been identified for assessment (R1 to R9; Figure 6.1-3). During the Operation Phase, predicted noise levels at each of the identified residential receptors, inclusive planned and required noise mitigation measures, are summarized in Section 6.1.8. The predicted noise levels include equipment and activities at the Beaver Dam Mine Site, the Haul Road, and the Touquoy Mine Site.

Predicted noise effects during the Operation Phase of the Project are within the applicable sound level limits at all the identified receptors (Table 6.1-9). Most notably, predicted noise levels during the nighttime period are at least 27 dBA below the applicable nighttime sound level limit at all identified receptors.

Table 6.1-9: Predicted noise effects during the Operation Phase of the Project

Receptor ID	Receptor Description	Noise Level (dBA) (Day/Evening/Night)	Sound Level Limit [a] (dBA) (Day/Evening/Night)	Compliance
R1	9 Beaver Dam Mine Road (Marlborough Property)	48 / 48 / 27	65 / 60 / 55	Yes
R2	4112 Highway 224 (Beaver Lake IR 17)	30 / 30 / 28	65 / 60 / 55	Yes
R3	4115 Highway 224 (Cottage on Crown Land)	32 / 32 / 28	65 / 60 / 55	Yes

R9	5579 Mooseland Road (Lloy Property)	50 / 50 / 27	65 / 60 / 55	Yes

Source: NSEL 1999.

6.1.7.3.2 Property Lines

Noise levels were evaluated at the property boundaries of the Beaver Dam Mine, Haul Road, and Touquoy Mine Site (Appendix B.2). All of the noise sources from the Operations at the Beaver Dam Mine, Haul Road, and Touquoy Mine Site were used in the property line noise level predictions (Appendix B.2). Predicted noise levels were also evaluated at the property lines for the Operation Phase. The NSEL regulates noise levels at the property lines of mines using noise level limits contained in the "Pit and Quarry Guidelines" (NSEL 1999). The noise level criteria contained in this guideline are as follows:

- Leq ≤ 65 dBA between 7:00 AM and 7:00 PM;
- Leq ≤ 60 dBA between 7:00 PM and 11:00 PM; and
- Leq ≤ 55 dBA between 11:00 PM and 7:00 AM.

Operations, infrastructure, and property boundaries for the Beaver Dam Mine have been updated to mitigate predicted noise levels at the property line; Figure 6.1-5 and Figure 6.1-6 presents Noise contour plot results for the overall study area. The following noise mitigation measures are incorporated into the current design of the Beaver Dam Mine:

- The pit entrance/exit has been relocated to the west side of the pit, farther from the northeast property boundary.
- No more than four drills will operate concurrently during any day, evening, or nighttime hour.
- Increase the height of the safety berm along the north boundary of the pit.

The maximum predicted noise levels at the property boundaries for each of the Beaver Dam Mine Site and Touquoy Mine Site, inclusive of planned mitigation measures for Noise, are presented in Table 6.1-10.

Predicted noise levels at the property line of the Beaver Dam Mine, along the length of the Haul Road, and the Touquoy Mine Site are within the sound level limits specified in the NSEL Pit and Quarry Guidelines (NSEL 1999) provided that the recommended mitigation measures for Option A or Option B are applied at Beaver Dam Mine Site (Table 6.1-10). Appendix B.2 provides the applicable noise level isopleths in areas of residential receptors, and at the Beaver Dam Mine Site, Touquoy Mine Site, and Haul Road.

Table 6.1-10: Maximum (Worst-case) Predicted Noise Levels at Property Boundaries

Property Line Description	Maximum Noise Level (dBA) (Day/Evening/Night)	Sound Level Limit [(a)] (dBA) (Day/Evening/Night)	Compliance
Beaver Dam Mine Site Property, Option A	55/55/55	65 / 60 / 55	Yes
Beaver Dam Mine Site Property, Option B	55 /55 /55	65 /60 /55	Yes
Haul Road[(a)] (30 m from centerline of road)	59 /59 /-	65 / 60 / 55	Yes
Touquoy Mine Site Property	54 /54 /54	65 / 60 / 55	Yes

Notes: [(a)] Truck traffic used in the noise assessment and related modelling has been adjusted to a 16-hour shift, including the nighttime hour of 6:00 AM to 7:00 AM.

(a) NSEL 1999.

6.1.7.4 Noise Effects Summary

6.1.7.4.1 Beaver Dam Mine Site and Haul Road

The nearest permanent residential dwelling from the Beaver Dam Mine Site is located in the Beaver Lake IR 17. This is located approximately 5 km south of the Beaver Dam Mine Site and is separated from the Beaver Dam Mine Site by forest and two topographic ridges. These ridges block direct views from the houses to all work areas. The pit is located in a topographic depression and the crusher is in a more elevated position; however, distance to any sensitive receptors would mitigate any effects. The modelling (Section 6.1.7.2, Section 6.1.7.3) supports a conclusion that the likelihood of any dwellings in this rural area being occasionally impacted by noise from the Beaver Dam Mine Site is very low. The majority of mining operations will occur in the pit well below ground surface thereby provide excellent noise shielding. The modelling used a conservative pit depth of 10 m, therefore, as the pit depth increases mining noise (blasting etc.) will diminish.

Sources of Project related noise on the Haul Road will include heavy machinery and truck traffic during the construction and operational phases. The nearest point of the Haul Road to the Beaver Lake IR 17 is approximately 3 km. The Haul Road is currently in use for forestry activities and occasional construction activities for road upgrades. The activities on the Haul Road related to the Beaver Dam Mine Site will be similar in nature but larger in scale. The predicted sounds levels at the IR are equivalent to the lowest average (30 dBA) ambient values measured during sampling. The likelihood of Beaver Lake IR 17 being impacted by sound from the Haul Road is also very low (Appendix B.2).

Further assessment of baseline monitoring before construction, during construction, and during mining operations will be conducted to ensure impacts are below the NSE guidelines and the Health Canada noise guidance which allows for an incremental increase in the percentage of highly annoyed population in the community to remain below 6.5% at sensitive receptors. At 500 m from the Beaver Dam Mine Site, the sound levels are predicted to be below the noise goals, with sound levels dropping towards the ambient levels with distance. Blasting events may provide a slight spike in the sound levels at distance for a brief period of time at the same time of day (daytime) once or twice a week. This assessment was conducted prior to the change in the waste rock stockpile (WRSP) configuration and the introduction of the western waste rock stockpile. Given the distance from receptors, the topography, and proposed operational scenarios for waste rock stockpile construction, the assessment conclusions for the revised site are anticipated to be the same.

Predicted noise impacts were estimated using an acoustical model for provincial guidelines. The model was undertaken to predict noise from during the Construction phase, mining and crushing operation, and haul truck travel along the Haul Road (Section 6.1.7.2, Section 6.1.7.3). The results are cumulative for the equipment that was evaluated. Additional monitoring could be undertaken in the future if required as part of the Industrial Approval process.

The mine operations are at times expected to increase the ambient sound levels for certain distances from the Beaver Dam Mine Site and Haul Road. Based on the baseline ambient sound level monitoring, ambient sound levels in the LAA are as low as 33 dBA during the day, 31 dBA in the evening, and 27 dBA at night. Predicted noise levels from the proposed mine operations attenuate over large distances to these low ambient conditions. For instance, sound levels at Beaver Lake IR are expected to be 33 dBA at night, so above baseline but well below the 55 dBA regulated threshold for the overnight period.

6.1.7.4.2 Effects Summary Touquoy Mine Site

At the Touquoy Mine Site, the primary source of noise during the processing of Beaver Dam ore will be the crushing circuit, CIL circuit, and service vehicles. All other processing equipment is located within the processing building. As indicated in the EARD, the maximum sound generated at the processing plant is 80 dBA, which attenuates to the background of 40 dBA over a distance

of 500 m. Based on an additional acoustic assessment conducted as part of the Focus Report, predicted values at the sensitive receptors ranged from 34.6 to 42.3 dBA. All estimated values are below the NSEL daytime sound level criteria on the dBA scale. Predicted noise levels at Scraggy Lake and Camp Kidston were approximately 2 dBA greater than daytime values measured in the baseline study. The predicted sound level at the farthest sensitive receptor from the proposed site was 34.6 dBA, which is below the baseline value measured. The Noise Impact Study (Appendix B.2) shows that the predicted levels for sound propagation from the Touquoy Mine Site for the Project will be below the noise thresholds (day/evening/night) at the property boundaries.

6.1.8 Mitigation

Table 6.1-11 summarizes mitigations measures being considered in the Explosive Management Plan will be developed during the permitting process to reduce noise and vibration impacts.

Table 6.1-11: Mitigation for Noise

Project Phase	Mitigation Measure
C, O	Restrict blasting to a specific and regular daytime schedule during weekdays. Specifically, blasting will not be undertaken on Sundays, or statutory holidays (NSEL 1999)
C	Haul road construction will be restricted to the day and evening periods
O	If necessary, construct a large safety berm along the entire north boundary of the pit, dependent on how raw materials are processed at the Beaver Dam Mine Site.
O	Operating hours for trucking on the Haul Road will be restricted to the day and evening periods only (7AM to 11PM)
O	Maximum 4 drills will operate at the Beaver Dam Mine Site pit at any time during the Operation Phase of the Project
C, O, CL	Implement preventative maintenance plans for all mobile and stationary equipment
C	Noise-reduction as criteria in equipment selection
C, O	Communicate general blasting schedule to the local community
C	Consider placement of stockpiles and infrastructure to mitigate noise migration from processing equipment
C	Consider the use of natural landforms when available as noise barriers when designing final site details and when placing fixed equipment
O	Operating hours for processing plants and trucking on the Haul Road will be limited to reduce nighttime noise levels
O	Regular check by site manager for excessive noise on site and in relation to sensitive receptors so that resolution can be timely
C, O, CL	Implement preventative maintenance plans for all mobile and stationary equipment
C	Noise-reduction as criteria in equipment selection
C, O	Speed reduction
C, O	Use equipment that meets appropriate noise emission standards for off- road diesel equipment
C, O	Subcontractor agreements will include an obligation to comply with environmental protection including noise reduction
C, O	Site design to reduce need for reversing and vehicle reversing alarms
C, O	A procedure, including a response plan, will be available for public to be able to register complaints regarding noise concerns

Noise from the equipment and lack of effective mufflers is a source of noise. Procurement of equipment that meets best practices in terms of noise emissions, and regular maintenance of the equipment will reduce noise levels. Site workers will be trained to ensure equipment is used in ways that minimize noise and are maintained regularly. As part of the workplace health and safety program, noise monitors may be attached to workers from time to time to measure and monitor noise exposure over a shift.

Haul Road construction activities will generally be restricted to the day and evening periods, which will minimize noise along the Haul Road during nighttime hours. The dense forest surrounding the Beaver Dam Mine Site and the Haul Road will also provide noise attenuation, which is not accounted for in the Construction Noise Model to be conservative. Topography and distance from receptors also contribute to a reduction of Project-generated sound at greater distances, and topographical elevation data has been included in the model to account for this effect.

During the Operations phase, the majority of mining will occur in the pit well below ground surface thereby provide excellent noise shielding and blasting will be restricted to daytime hours, per the NSE Pit and Quarry Guidelines (NSEL 1999). Additionally, traffic on the Haul Road will generally be restricted to 12 to 16 hours per day during the operational phase. This will minimize noise along the Haul Road during nighttime hours. The dense forest surrounding the Beaver Dam Mine Site and the Haul Road will also provide a dampening effect to any noise generated; i.e., noise attenuation. Note, this additional nose attenuation was not accounted for in the noise model and thus predictions can be considered conservative in this regard.. Topography and distance from receptors will also provide contribute to a reduction of Project-generated sound at a greater distances, and topographic elevation has been included in the model to account for this effect.

This combination of measures will adequately mitigate potential noise impacts. The mitigation procedures may vary as long as noise levels are in accordance with the regulatory approval.

Additionally, noise monitoring would be completed during each blasting event, as required as required by the NSEL Pit and Quarry Guidelines (NSEL 1999). Blast monitoring generally involves noise and vibration monitoring during each blasting event and includes monitoring at the nearest residence to the Beaver Dam Mine Site, which in this case would be at Beaver Lake IR 17. Monitoring and mitigations explicit to blasting will be described in the Explosive Management Plan that will be submitted as part of the permitting process. Elements of this plan will include site specific monitoring triggers and mitigations.

Under the existing IA for the Touquoy facility, maximum sound levels are prescribed at property boundaries for days, evenings and weekends and monitoring is only required when requested by NSE in response to a complaint or concern. Mitigation measures will be implemented as necessary where sound levels are a concern, i.e., causing annoyance, and monitoring demonstrates exceedances. Mitigation of noise excesses at the property lines are not considered to be critical, as predicted noise levels at the worst-case points of reception are within the applicable limits. To date, no noise complaints have been received or are anticipated. A complaint from the public and/or a First Nation community member would be a trigger for consideration of mitigation, as described below.

Noise monitoring will be completed as directed by regulators or as a result of a complaint or engagement. A draft Engagement Plan (Appendix A.6) will be implemented and based on feedback additional mitigations will be considered.

The existing community complaints process existing for the Touquoy Mine will be expanded to include the Beaver Dam Project. Complaints regarding noise will be documented and investigated immediately. AMNS will work with the local communities to understand specific concerns to determine if additional mitigation measures, adaptive management, will be necessary. This process will evolve through regulatory permitting, as well as public and Mi'kmaw engagement.

6.1.9 Residual Effects and Significance

Residual effects are effects to VCs that are predicted to occur even after the implementation of mitigation measures (Section 6.1.8). Noise is a physical aspect of the environment that may be altered by the Project that can, in turn, affect related biophysical and socioeconomic VCs (Section 6.11 to 6.12 and Section 6.16). Significant residual effects for the Noise VC would be defined as

having high magnitude, occur beyond the PA and LAA, be of long-term to permeant duration, occur at regular intervals or be continuous throughout the Project and be only partially reversible to irreversible (Section 6.1.6).

The effect to noise are predicted to be **low,** diverging from existing conditions but in compliance with appropriate guidelines; effects do not extend into the RAA, are long-term, and are considered reversible. The overall residual effect of the Project on noise is assessed as **not likely** to have significant adverse effects after mitigation measures have been implemented. Thus, predicted residual environmental effects of Project development and production on Noise are assessed to be **not significant** (Table 6.1-11).

A summary of overall conclusions of noise modelling and effects assessment (Section 6.1.6) informing the characterization of residual effects and significance determination is provided below.

In general, construction activities often produce significant noise levels that have the potential to impact the surrounding environment. Thus, noise levels produced by equipment planned for the Construction Phase of the Project have been assessed at the identified worst-case receptors to determine the future impact on residents of the nearest communities. Predicted noise levels produced by worst-case activities during the Construction Phase of the Project low, being are within the applicable Health Canada guideline limits at all identified receptors, including noise emissions from the Beaver Dam Mine Site, the Haul Road, and the Touquoy Mine Site. General guidance has been provided to help ensure that construction noise levels are acceptable, including a specification that construction activities should be restricted to the day and evening time periods.

Mining operations often produce elevated noise levels that have the potential to impact the surrounding environment. Thus, noise levels produced by equipment at the proposed Beaver Dam Mine Project have been assessed at the identified worst-case receptors to determine the future impact on residents of the nearest communities. This is not intended to preclude residents at farther distances but rather is presented to document those residence that are closest and represent a worst-case scenario. The predicted noise levels produced by worst-case activities during the Operation of the Project, including noise emissions from the Beaver Dam Mine Site, the Haul Road, and the Touquoy Mine Site, are considered to be low. That is, within the applicable guideline limits for all identified receptors. Based on these predictions, noise levels at nearby residential receptors are expected to be within the NSEL noise level limits, provided the mitigation measures identified in this report are followed.

The NSEL Pit and Quarry Guidelines also include noise level criteria for assessment at the property boundaries (NSEL 1999). The predicted noise levels from the Project meet the NSEL limits at all locations on the property boundaries of the Beaver Dam Mine Site, the Haul Road, and the Touquoy Mine Site, provided the mitigation measures identified (Section 6.1.8) are followed.

Table 6.1-12: Residual Environmental Effects for Noise

Project - VC Interactions	Summary of Mitigation	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction – Beaver Dam Mine Site and Haul Road Noise from haul trucks, Haul Road widening and construction, and blasting and drilling of in-situ rocks	Equipment maintenance, best management practices, minimize blasting events.	N-L	Beaver Dam Mine Site and Haul Road LAA: Noise generated will likely extend beyond the PA	A	ST Effects can occur up to 1 year	R Effects occur regularly in the construction phase of the Project	R VC will recover to baseline conditions	Increased ambient noise	Not significant
Operations - Beaver Dam Mine Site and Haul Road Noise from haul trucks, blasting and drilling of in-situ rocks and the crushing of ore heavy machinery operation, and site vehicles	Equipment maintenance, dust suppression, hardened surface where practical, vehicle speed reduction, use of large haul vehicles to minimize trips, stabilization of stockpile slopes, covering of haul trucks, minimize blasts. Equipment maintenance, haul truck operations < 24 hours per day to minimize noise disturbance, limited engine idling, shutting off vehicle when parked unless this is precluded for safety or maintenance reasons.	N-L	At Points of Reception for Beaver Dam Mine Site, Haul Road, Touquoy Mine Sire) At Property Lines for Beaver Dam Mine Site, Haul Road LAA: effect extend beyond the PA into the LAA	A	LT Effects may extend beyond 3 years	R Effects occur regularly in the operational phase of the Project	R VC will recover to baseline conditions	Increased ambient noise	Not significant
Operations – Touquoy Mine Site Noise from blasting, crushing of ore, heavy machinery operation and site vehicles	Equipment maintenance, haul truck operations < 24 hours per day to minimize noise disturbance, limited engine idling, shutting off vehicle when parked unless this is precluded for safety or maintenance reasons.	N	At Property Lines LAA Noise generated is predicted to extend beyond the PA	A	LT Effects may extend beyond 3 years	R Effects occur regularly in the operational phase of the Project	R VC will recover to baseline conditions	Increased ambient noise	Not significant

Notes: See Table 6.1-4 and Section 5.11, Table 5.11-1 for definitions of the below characteristics.

Magnitude		Geographic Extent			Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area		N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment	Area	A	Applicable	MT	Medium-Term	S	Sporadic	IR	Irreversible
M	Moderate	RAA	Regional Assessment	Area			LT	Long-Term	R	Regular	PR	Partially Reversible
H	High						P	Permanent	C	Continuous		

6.2 Air

6.2.1 Introduction

6.2.1.1 Summary of Air Before the Updates

Air quality was assessed as part of the 2017 and 2019 Revised EIS (AMNS 2017 and 2019). The air compounds evaluated focused on particulate matter (i.e., total suspended particulates [TSP], particulate matter less than 10 micrometers in aerodynamic diameter [PM_{10}], particulate matter less than 2.5 micrometers in aerodynamic diameter [$PM_{2.5}$]), The Haul Road between the proposed Beaver Dam Mine and the Touquoy Mine site was determined to be the primary emission source responsible for maximum predicted concentration of particulate matter and total suspended solids (i.e., dust). The results of the assessment found that maximum predicted concentrations occurred within 30m of the road and predicted that concentrations would decrease with increasing distance from the road. An 80% to 90% dust mitigation would be required on the Haul road to limit the impacts from dust. A draft Fugitive Dust Control Plan is developed to provide site specific mitigations for the proposed Project.

6.2.1.2 Summary of Updates to Air

The updates to this section are based on the update to the Project Description (Section 2, Project Area [PA] boundary change) as well as in response to Round 2, Information Requests (IR2s) submitted by Impact Assessment Agency of Canada (IAAC, formerly Canadian Environmental Assessment Agency [CEAA 2019]), Nova Scotia Environment (NSE 2019), and Eastern Shore Forest Watch Association (ESFWA 2019), air subsection updates are summarized in Table 6.2-1. Effects assessment methodology have been updated to include updated air emissions and dispersion models, in response to comments from IR2s. Air compounds evaluated included TSP, PM_{10}, $PM_{2.5}$, nitrogen oxides (NO_X), sulfur dioxide (SO_2), and volatile organic compounds (VOC). Greenhouse gases (GHG) are described in Section 6.4. Detailed updated modelling results are presented in Appendix C.1 Air Emission Assessment Technical Report (GHD 2021).

The updated emissions and dispersion modeling show that there are no exceedances predicted for NO_2 and SO_2 (Section 6.2.6.3 and Appendix C.1). There are no guidelines for VOCs and therefore it was assessed relative to baseline, which is determined to be negligible. An 80 to 90% dust mitigation would be required on the Haul road to limit the impacts from dust. A draft Fugitive Dust Control Plan is developed to provide site specific mitigations for the proposed Project.

Air quality emission and dispersion modelling results have been used in the updated Human Health Risk Assessment (Appendix C.2 [Intrinsik 2021]). Cumulative Effects Assessment for Air is discussed in Section 8.

Table 6.2-1: Updated Subsections from the 2019 Revised Environmental Impact Statement

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
-	-	6.4.1 Introduction	• New
6.2.1 Rationale for Valued Component Selection	No	6.2.2 Rationale for Valued Component Selection	• N/A
-	Yes	6.2.3 Baseline Program Methodology	• Included baseline methodology summary from Appendix C.1.
6.2.2 Baseline Conditions	No	6.2.4 Baseline Conditions	• Updated with relevant local TSP background data from 2007 to 2017 is summarised and the 90th percentile used (NSE-2-24).
6.2.3 Consideration of Consultation and Engagement Results	No	6.2.5 Consideration of Consultation and Engagement Results	• This subsection has been updated to reflect recent public and the Mi'kmaq of Nova Scotia recent engagement.
6.2.4 Effects Assessment Methodology – Boundaries	Yes	6.2.6 Effects Assessment Methodology – Boundaries	• Updated to include descriptions for construction, operations, and active closure phases as per the updated Project Description (Section 2) that were used in the updated air emissions and dispersion modelling.
6.2.4 Effects Assessment Methodology – Thresholds for Determination of Significance	Yes	6.2.6 Effects Assessment Methodology – Thresholds for Determination of Significance	• Updated Air VC significant residual effects.
6.2.5 Project Activities and Air Interactions and Effects	Yes	6.2.7 Project Activities, Air Quality Interactions and Effects	• Section updated to summarize the updated air emissions and dispersion modelling from Appendix C.1 Air Emission Assessment Technical Report in response to IR2s CEAA-2-25, CEAA-2-31, NSE-2-128, NSE-2-129, ESFWA-2-33b). • Worst-case sensitive receptors included in the modelling. • All lands outside the property boundaries for the Beaver Dam Mine, the Touquoy Mine and Haul Road.
6.2.6 Modelling Results and Assessment	Yes	6.2.7.3 Air Effects Modelling, Summary	• Section moved under Section 6.2.7 Project Activities, Air Quality Interactions and Effects. • Section updated to summarize the updated air emissions and dispersion modelling from Appendix C.1 Air Emission Assessment Technical Report in response to IR2s CEAA-2-25, CEAA-2-31, NSE-2-128, NSE-2-129, ESFWA-2-33b). • Worst-case sensitive receptors included in the modelling. • All lands outside the property boundaries for the two mines and Haul Road have been modelled.
6.2.7 Preferred Alternative Haul Road	Yes	-	• The Preferred Alternative Haul Road is no longer being considered and has been removed from the Project Description and EIS.
6.2.8 Mitigation	Yes	6.2.8 Mitigation	• Updated to reflect an update to mitigation of 80% to 90% dust control on the Haul Road has been assumed (ESFWA-2-33b).
6.2.9 Residual Effects and Significance	Yes	6.2.9 Residual Effects and Significance	• Updated to reflect updated predictive modelling results and updated mitigation.
6.2.10 Proposed Compliance and Effects Monitoring Program	Yes	-	• Section Updated

Notes: PA = Project Area; LAA = Local Assessment Area; RAA = Regional Assessment Area; - = no update; IR2 = Round 2, Information Requests; CEAA = Canadian Environmental Assessment Agency; NSE = Nova Scotia Environment; ESFWA = Eastern Shore Forest Watch Association; EIS = environmental impact statement; N/A = Not Applicable; TSP = total suspended particulate.

6.2.2 Rationale for Valued Component Selection

Air quality is an important environment factor in ensuring the conservation of local vegetation, wildlife, water quality, and human health. The proposed Project activities will result in air emissions to the ambient environment. The potential change in ambient air quality needs to be assessed to support conservation of the environment and compliance with applicable federal and provincial regulations. Since ambient air quality is a broad term, it is important to define technical boundaries as to select measurable parameters to assess the potential effects of the Project (Section 6.2.6). For this assessment the Air VC is characterized by the following indicators:

- TSP matter;
- PM_{10};
- $PM_{2.5}$; and
- dust deposition.

NO_X as nitrogen dioxide (NO_2), SO_2, and VOCs and carbon monoxide (CO) are assessed in Appendix C.1. The modelling predictions indicate that NO_2, and SO_2, do not exceed guidelines and changes to VOCs from baseline are negligible (Table 6.2-2). Greenhouse Gases Assessment is provided in Section 6.4.

6.2.3 Baseline Program Methodology

The objective of the Air baseline study was to collect information on baseline conditions before commencement of the proposed Project; baseline report for air quality is summarized in the following sections and included in Appendix C.1.

6.2.4 Baseline Conditions

6.2.4.1 Climate and Meteorological Information

To assess air quality, meteorological conditions need to be considered. Meteorology is also a major consideration for the design, construction, and maintenance of the proposed development. Information on meteorological conditions, such as wind and air temperature, is required for air dispersion modelling as they have a large effect on the dispersion of pollutants in the atmosphere. Solar radiation and precipitation data also provide information for the design of water management infrastructure and water balance calculations.

The Project is located with the Eastern Nova Scotia climatic region, which is generally characterized by high rainfall and cool temperatures, due to the influence of the Nova Scotia Current. The nearest climate station with historical data is the Middle Musquodoboit climate station (ID# 8203535) operated by the Meteorological Service of Canada (MSC). The station is located approximately 15 kilometres (km) northwest of the proposed mine site, near Middle Musquodoboit (45° 04 N, 63° 06 N).

The following is a summary of average climate conditions at the Middle Musquodoboit station, based on climate normals published by Environment and Climate Change Canada for the period from 1971 to 2000. Wind data is taken from the Halifax Airport climate station (MSC ID# 202250), which is located approximately 45 km west of the mine site. This is the closest station to the site with wind data.

Mean annual total precipitation is 1,370 millimetres (mm), which includes 165 centimetres (cm) of average snowfall per year (165 mm water equivalent). Highest precipitation generally occurs in the months of October and November, with lowest

precipitation in the month of February. Measurable precipitation occurs on an average of 164 days per year, with 141 days of measurable rainfall, and 31 days of measurable snowfall.

The extreme one-day rainfall for the station is 173 mm on August 15, 1971 and extreme one-day snowfall is 70 cm on February 8, 1981. Average temperature is 6.2ºC, with an average range from -6ºC to 18.1ºC. Temperature extremes can range from -34ºC to 35ºC. There is an average of 312 days per year with an average temperature above 0ºC.

Wind direction is generally westerly to northerly in January through April, southerly in May through October and again westerly to northerly in November and December. Wind speeds average approximately 16.5 kilometres per hour (km/h), with an average range of 13.3 km/h in August to 18.5 km/h in March. Maximum hourly speeds can range from 56 km/h in August to 89 km/h in February, with maximum gusts of up to 132 km/h recorded.

6.2.4.2 Ambient Air Quality Standards

Nova Scotia Environment (NSE) regulates ambient air quality via the Nova Scotia Air Quality Standards (NSAQS). The Canadian Ambient Air Quality Standards (CAAQS) are recommended air quality standards, frequently applied in Provinces or Territories that do not have their own air quality criteria. These standards are summarized in the Table 6.2-2.

There is currently no Nova Scotia or Canada-Wide standard for PM_{10}. For the purposes of comparison, the table below lists an Interim Standard previously reported for the Province of Ontario (MECP 2020a).

Table 6.2-2: Air Quality Standards

Indicator Compound	Averaging Period	Concentration (µg/m³)	Source
Total Suspended Particulate	24-hour	120	NSAQS
	Annual	70	NSAQS
PM_{10}	24-hour	50	Ontario - Interim
$PM_{2.5}$	24-hour	27	CAAQS (2020)
	Annual	8.8	CAAQS (2020)

Note: Ontario Interim guideline for PM_{10} no longer in effect, provided for informational purposes only (MECP 2020b).

$PM_{2.5}$ 24-hour CAAQS for 2020 is based on the 3-year average of the 98th percentile of the daily 24-hour concentrations.

$PM_{2.5}$ Annual CAAQS for 2020 is based on the 3-year average of the annual average concentrations.

CAAQS = Canadian Ambient Air Quality Standards; NSAQS = Nova Scotia Air Quality Standards; PM_{10} = coarse particulate matter; $PM_{2.5}$ = fine particulate matter; µg/m³ = micrograms per cubic metre.

6.2.4.3 Baseline Air Quality Monitoring Program

Appropriate background data was investigated for the Project to evaluate the existing conditions versus the conditions when the proposed Project commences. There are currently no permanent air monitoring stations within the vicinity of the PA. The most recent three years of data (2014-2016) of continuous monitoring data available is sourced from the ambient air quality monitoring data from the National Air Pollution Surveillance Network (NAPS). Associated results are summarized in the underlying sections and detailed in Appendix C.1.

6.2.4.4 Regional Ambient Air Quality

Ambient air quality in Nova Scotia is monitored using a network of 10 sites operated by NSE and Environment and Climate Change Canada (ECCC) through the NAPS. Common air pollutants monitored at these stations include the following:

- SO_2;
- $PM_{2.5}$;
- ozone (O_3); and
- oxides of nitrogen (NO_2, NO, and total NO_X).

Data collected at these stations is used by NSE to report the Air Quality Index (AQI) and by ECCC to report the Air Quality Health Index (AQHI). There are currently no permanent air monitoring stations within the vicinity of the PA. The Beaver Dam Mine Site is located in a relatively undeveloped rural region of Nova Scotia with infrequent industrial operations that would affect air quality. As the NAPS monitoring stations are typically located in areas with local industry, measured concentrations of indicators are likely lower at the Beaver Dam Mine Site than at NAPS stations.

The nearest representative stations which report concentrations for the air quality parameters assessed include:

- Lake Major, Nova Scotia (Station ID 030120) – $PM_{2.5}$, NO_2, and SO_2;
- Port Hawkesbury, Nova Scotia (Station ID 030201) – $PM_{2.5}$, NO_2, and SO_2;
- Aylesford Mountain, Nova Scotia (Station ID 030701) – $PM_{2.5}$, and NO_2; and
- Pictou, Nova Scotia (Station ID 030901) – $PM_{2.5}$, and NO_2.

VOCs are not measured at these stations. PM10 are not measured in many areas in Canada. Of the locations which do measure PM_{10}, most are in British Columbia urban centres, four are in Manitoba cities, one is in Regina, Saskatchewan, and four are in the Northwest Territories. In terms of locations that are somewhat comparable to the Project site (human habitation, regional activities that may generate airborne particulate, etc.), Norman Wells, NWT Regional Office (Station ID 129102) appears the most appropriate location that has recent data available (Appendix C.1).

The NAPS background air concentrations are provided in Table 6.2-3, which shows the 25th, 50th, 75th, and 90th percentile values for 1-hour and 24-hour NO_2, 1-hour and 24-hour SO_2, and 24-hour PM_{10} and $PM_{2.5}$ for the 2014 through 2016 period (the most recent complete years for which continuous monitoring data are available for this reporting period). It is recognized that the nitrogen oxide (NO_X as NO_2), SO_2, and CO are also important indicators of greenhouse gases, which are assessed separately, as part of the Greenhouse Gases Assessment (Section 6.4).

Air quality was assessed using the 90th percentile measured concentration as “background”. This is a conservative approach but excludes extreme high values that are very rarely measured (the “maximum” values). The bolded values in Table 6.2-3 are those that were carried forward for use in the combined assessment case (i.e., proposed Beaver Dam Mine site, existing Touquoy Mine Site). Annual values for $PM_{2.5}$ and PM_{10} are represented by the “Average” values for 24-hour.

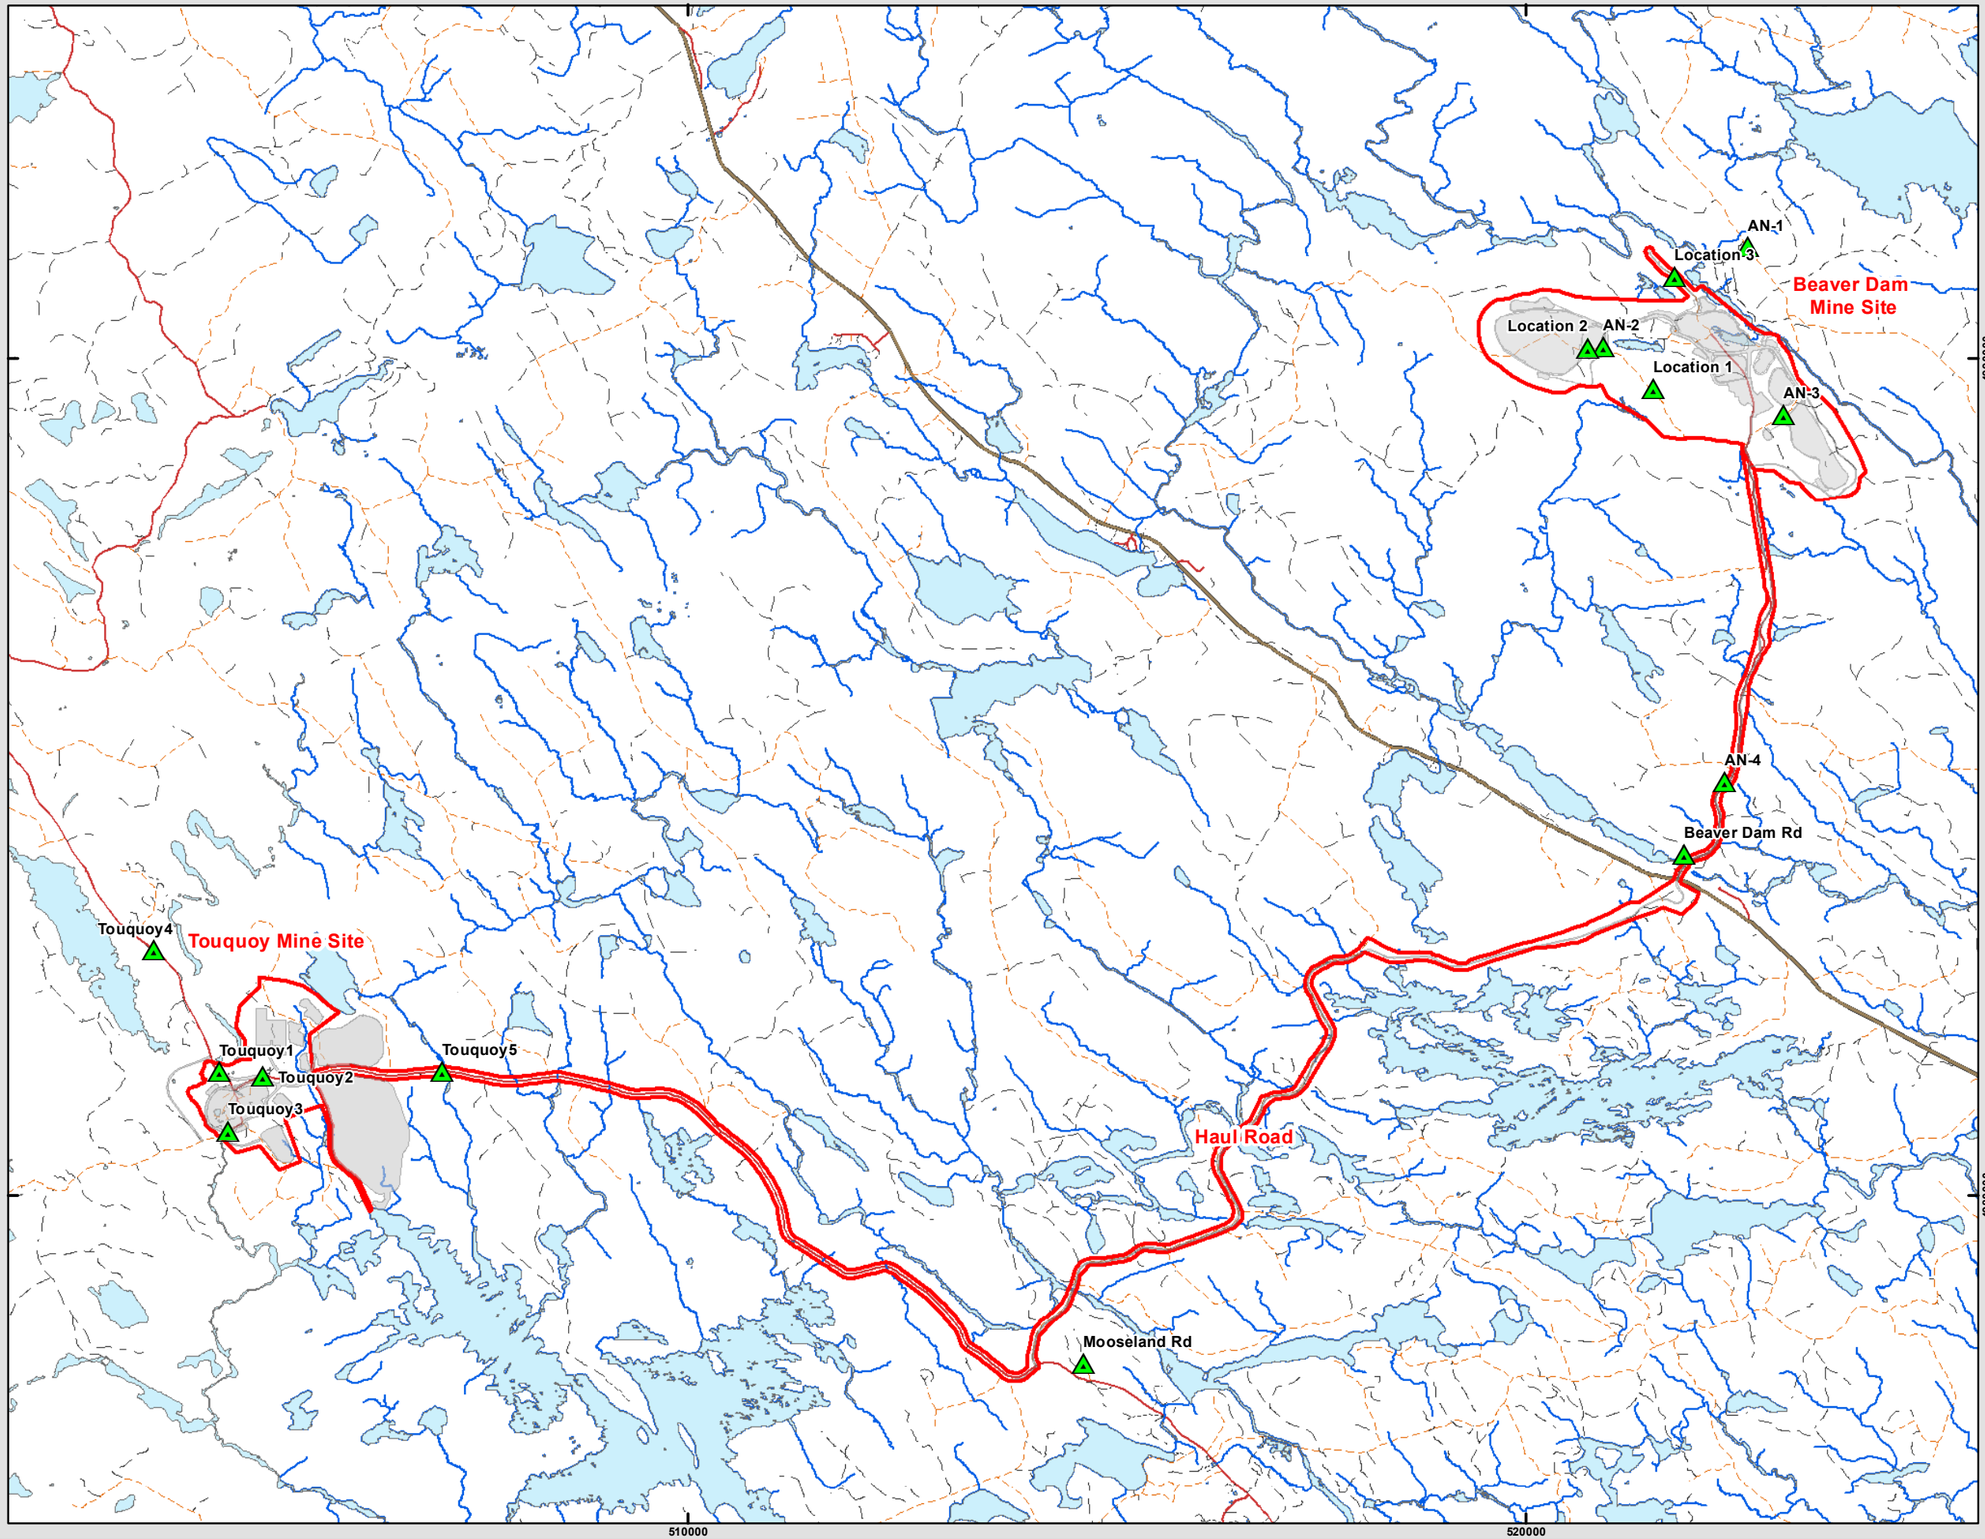
NAPS = National Air Pollutant Surveillance program; µg/m³ = micrograms per cubic metre; PM_{10} = particulate matter less than 10 micrometres in aerodynamic diameter; $PM_{2.5}$ = particulate matter less than 2.5 micrometres in aerodynamic diameter; NO_2 = nitrogen dioxide; SO_2 = sulphur dioxide; CO = carbon monoxide; — = not measured or reported.

6.2.4.4.1 Project-Specific Baseline Studies



The RAA and LAA for air quality are presented in Section 6.2.6 and considered in baseline studies and subsequent effects assessment. Preliminary baseline particulate monitoring was undertaken for TSP and PM_{10}. Baseline air quality measurements were obtained from nine locations near the Beaver Dam Mine Site and along the proposed Haul Road, five locations on the Touquoy Mine Site, two locations near the proposed Fifteen Mille Stream Gold Project, and two locations near the proposed Cochrane Hill Gold Project and the data is presented in Table 6.2-4.

Table 6.2-4: Beaver Dam Mine Project Background Air Quality Sampling Data

Location	Program Date	24-hour Total Suspended Particulate (TSP) (µg/m³)	24-hour PM_{10} (µg/m³)
Location #1	June 5-6, 2008	19.4	9.1
Location #2	June 5-6, 2008	41.7	13.1
Location #3	June 5-6, 2008	12.9	7.1
AN#1	October 20-21, 2014	6.9	—
AN#2	October 20-21, 2014	4.6	—
AN#3	October 20-21, 2014	1.7	—
AN#4	October 20-21, 2014	3.9	—
Beaver Dam Road	September 7-8, 2016	9.7	—
Mooseland Road	September 7-8, 2016	5.8	—
Location #1 (Touquoy)	January 3, 2007	11.6	—
Location #2 (Touquoy)	January 3, 2007	10.5	—
Location #3 (Touquoy)	January 4, 2007	14.0	—
Location #4 (Touquoy)	January 4, 2007	16.1	—
Location #5 (Touquoy)	January 4, 2007	14.4	—
Fifteen Mile Stream	November 2017	9.6	9.2
Fifteen Mile Stream	November 2017	14.0	9.5
Cochrane Hill	November 2017	10.7	10.5
Cochrane Hill	November 1, 2017	10.7	9.7
Average		12.1	
90th percentile		17.1	

µg/m³ = micrograms per cubic metre; PM_{10} = particulate matter less than 10 micrometres in aerodynamic diameter.

Further, baseline particulate monitoring including TSP and PM_{10} was conducted following United States Environmental Protection Agency (USEPA) sample methodology (USEPA 2011). The locations during each monitoring event is shown in Figure 6.2-1, except Fifteen Mile Stream and Cochrane Hill Locations. The date and locations were determined based on meteorological forecasts for the sampling period, and the proximity to sensitive receptors and proposed mine features. A 24-hour sample was collected on an 8x10 filter utilizing a high-volume sampler calibrated at a flow rate of approximately 40 cubic feet per minute (CFM). Pre-weighed filters were submitted to Maxxam Analytics in Sydney, Nova Scotia, for final particulate weights. Concentrations of TSP and PM_{10} were calculated based on the final weight of particulate on the filters and the total volume of air sampled. Baseline particulate data was compared to the NSAQS (Table 6.2.4).

Document Name: BD_EIS_Figure6-2-2Air Baseline

A summary of these baseline measurements is presented in Table 6.2-4. Baseline TSP concentrations ranged from 1.7 to 41.7 micrograms per cubic metre (µg/m³), with the highest value obtained at Location #2 during monitoring in June 2008. Results for PM_{10} concentrations ranged from 7.1 to 13.1 µg/m³, with the highest value also obtained at Location #2 during monitoring in June 2008. This monitoring station was located in a recently clear-cut area, which may have contributed to higher particulate levels in comparison to the other locations. This area was resampled in 2014 (AN#2). The 2014 results for that area were 4.6 µg/m³. All samples collected were below the NSAQS for TSP, there is no NSAQS for PM_{10}.

The data obtained as part of the baseline program reported herein provides a preliminary snapshot of air quality in the area of the Beaver Dam Mine Site and Haul Road, and a general understanding of local air quality. Due to a lack of other sources of data for ambient TSP, the background concentration for TSP is based on the maximum measured 24-hour TSP concentration (there are insufficient data to provide a meaningful 90th percentile value), and the average of all the TSP measurements. There is uncertainty in how representative these values might be for background, but they represent the best available data at this time.

6.2.5 Consideration of Engagement Results

Key concerns raised during public engagement (Section 3 and Appendix A.4a) and the Mi'kmaq of Nova Scotia engagement (Section 4 and Appendix A.5) relating to atmospheric environment include potential dust from mining operations at the Beaver Dam Mine Site and trucking along the Haul Road. The Haul Road was updated to include 4 km of new road to the south and away from existing turn-off from Highway 224 to address safety concerns communicated by Millbrook First Nation regarding the proximity of residents in Beaver Lake IR. Concerns about greenhouse gas emissions specifically associated with the trucking were also noted. Greenhouse gases are assessed in Section 6.4.

The results of the public and the Mi'kmaq of Nova Scotia engagement have been considered in the environmental effects assessment, including the AMNS' commitments on mitigation and monitoring measures and proposed compliance and effects monitoring programs, as well as AMNS' broader commitment to ongoing public and Mi'kmaq engagement throughout the life of the Project.

Recent engagement with the public and First nation undertaken since the February 2019 EIS submission is provided Section 3 and Section 4. Dust originate from the Haul Road has raised as the main concern with respect to Air.

6.2.6 Effects Assessment Methodology

6.2.6.1 Boundaries

6.2.6.1.1 Spatial Boundaries

The spatial boundary used for the air effects assessment are described below and presented in Figure 6.2-2.

The PA encompasses three primary components from Marinette to Moose River Gold Mines, Halifax County, Nova Scotia. The proposed Beaver Dam Mine Site is located at the end of the Beaver Dam Mines Road and the Haul Road will span from the Beaver Dam Mine Site to he Touquoy Mine Site. The existing Touquoy mine will process ore and deposit tailings in a slurry sub-aqueously in exhausted pit and therefore dust is not expected.

The LAA encompasses the distance the 15 km zone in all directions form the PA (Figure 6.2-2).

The RAA encompasses a 35 km buffer from the PA, maximum zone of influence. The RAA covers the extent of the modelling domain (Figure 6.2-2).

As the Project has the potential to cause direct and indirect effects of air outside of the PA, the LAA is the most appropriate spatial boundary for air.

6.2.6.1.2 Temporal Boundaries

Effects to air quality and generation of fugitive have the potential to occur throughout project phases and from specific components of the Beaver Dam Mine Site. These include construction phase activities initially and during operational phase, the open pit, waste rock storage area, quarries, process plant, crushing operations and the service complex. The temporal boundaries used for the assessment of effects to Air are the Construction, Operational, and Active Closure phases.

Construction Phase (1 Year)

In the updated Project Description, the timeline for construction is now planned for one 1 year; and was previously anticipated to be up to 2 years (AMNS 2017). For construction activities lasting less than 1 year, Health Canada's "Guidance for Evaluating Human Health Impacts in Environmental Assessment: Air Quality" (Health Canada 2017) categorizes the air effects as 'short-term construction air exposure'.

Operations Phase (5 Years)

Ore from the Project will be transported by truck via the Haul Road to the existing and fully permitted Touquoy Mine. Processing of ore from the Beaver Dam gold deposit at the existing the Beaver Dam Mine Site is anticipated to begin construction in 2022, come into production in 2023, cease operations in 2027 and then be reclaimed. The timeline is subject to EIS and permitting approval.

Active Closure (2 Years)

The active closure phase will involve infrastructure demolition, earthworks, site reclamation and environmental monitoring activities. Monitoring will extend beyond 2 years of active closure until the reclamation performance measures indicate that the site is physical, chemical and biologically stable and self-sustaining.

6.2.6.1.3 Technical Boundaries

Since ambient air quality is a broad term, it is important to define technical boundaries as to select measurable parameters to assess the potential effects of the Project. For this assessment ambient air quality is characterized by the following indicators:

- TSP matter;
- PM_{10}; and
- $PM_{2.5}$;

It is recognized that the nitrogen oxide (NO_X as NO_2), SO_2, and CO are also important indicators of Air Quality. These are assessed separately, as part of the Greenhouse Gases Assessment (Section 6.4).

McCallum Environmental Ltd.

Document Name: BD_EIS_Figure6.3-1 Light Spatial Boundaries

6.2.6.1.4 Administrative Boundaries

Air quality is provincially regulated via the NSAQS (Table 6.2-2).

Air compounds that are of most concern from project operations include TSP and $PM_{2.5}$. PM_{10} has been included for reference, as a particulate size fraction between TSP and $PM_{2.5}$ but is limited in determining compliance or significance due to a lack of background monitoring data. Where Nova Scotia has air quality criteria, these have been used as the Assessment Criteria. If there were no Nova Scotia criteria for compounds of interest, then Canada-wide standards have been assumed to apply. PM_{10} is not regulated in either Nova Scotia or federally. Ontario has an Interim Ambient Air Quality Criteria (AAQC) for PM_{10}, but this value is not used to assess compliance for single facilities or operations and is generally applied at the regional level. This Interim criterion has been provided for context for this assessment but is not considered a guideline for the Project.

6.2.6.2 Thresholds for Determination of Significance

Residual effects are effects to VCs that are predicted to occur even after the implementation of mitigation measures (Section 6.2.8). Residual effects of the Project on Air Quantity VC identified are characterized using standard criteria, including magnitude, geographical extent, duration, frequency, reversibility, and context of the effect (Table 6.2-5). The residual effects assessment concludes with a determination of Significance. The screening of project effects, and mitigation measures, are assessed in aggregate to determine whether the residual impacts are "Not Significant" or "Significant" according to the following definitions:

Table 6.2-5: Air Quality Characterization Criteria for Residual Effects

Criteria	Groundwater Quality Impact Description
Magnitude	• **Negligible**: predicted change of air quality indicator is less than 10% of background conditions, (i.e., no measurable change of state of indicator from background conditions) and no exceedances of guidelines. • **Low**: indicator is predicted to be greater than guidelines and increase by greater than 10% over baseline levels but remains well within the observed range of natural variation (defined as 25th to 75th percentile baseline groundwater quality). • **Medium**: indicator is predicted to be greater than guidelines and differ substantially from baseline levels and approaches upper observed limits of natural variation (defined as 75thth to 95th percentile baseline groundwater quality). • **High**: indicator is predicted to be greater than guidelines and differ substantially from baseline water quality (outside of 75thth to 95th baseline water quality), resulting in a detectable change beyond the range of natural variation.
Geographical Extent	• **Discrete**: effect is limited to the immediate footprint or Project Area (PA). • **Local**: effect is limited to the near-field Local Assessment Area. • **Potential Regional**: effect persists to the far-field Local Assessment Area.
Timing	• Timing represents seasonal occurrence of the effect (e.g., winter, spring, summer and fall) and represents and the effect criteria for designated water users (aquatic resources, human health). The characterization of effect of changes to groundwater on designated water resources is assessed in their respective; for surface water quality timing is considered redundant to duration and frequency criteria and is not further considered here.
Duration	• **Short term**: effect is restricted to Construction and/or Operations Phases. • **Medium term**: effect occurs in Construction Phase and Operations. • **Long term**: Effect occurs in Construction Phase and EOM Phase and/or persists in PC.
Frequency	• **Intermittent**: VC interaction or effect will occur at irregular intervals throughout any Project Phase. • **Regular**: effect occurs on a regular basis but not continuous basis. • **Continuous**: effect occurs constantly (e.g., every model timestep in a given Project Phase).
Reversibility	• **Reversible**: effect can be reversed. • **Partially reversible**: effect can be partially reversed. • **Irreversible**: effect cannot be reversed, is of permanent duration.

Not Significant Residual Effect: to Surface Air Quality VC is defined as: negligible to moderate magnitude, are restricted to the LAA, are of intermittent or short-term duration, occur at any frequency and are reversible.

Significant Residual Effect: to Air Quality residual effects have high magnitude (i.e., an **exceedance** applicable criteria), be of potential regional geographic extent and of medium to long term duration, occur at any frequency and only be partially reversible to irreversible.

Significant residual effects for the Air VC would be defined as having high magnitude (i.e., an **exceedance** applicable criteria), occur beyond the LAA, be of long-term to permeant duration, occur at regular intervals or be continuous throughout the Project, and be only partially reversible to irreversible.

6.2.6.3 Air Effects Modelling, Summary

To support the effects assessment of the Air VC, air dispersion modelling was performed. The air dispersion modelling is provided in Appendix C.1 and contains further details on the modelling methodology, background air concentrations, and all modelling results. A summary is presented in this section.

Emission rates from the Project-related sources were calculated using USEPA AP-42 (5th Edition) emission factors for the Beaver Dam Mine Site and Haul Road dust emissions, and MOBILE6.2 (M6.2) for Haul Road vehicle emissions. There is currently no guidance on the use of models in Nova Scotia, and therefore the O.Reg. 419/05 requirements were used as a framework. The version of the air dispersion model used in this project is currently accepted in Ontario, and AERMOD is used across Canada and throughout the United States as a regulatory model of choice. AERMOD is an advanced steady state plume model that has the ability to incorporate building cavity downwash, actual source parameters, emission rates, terrain and historical meteorological information to predict ground level concentrations (GLCs) at specified locations.

Air compounds evaluated included TSP, PM_{10}, $PM_{2.5}$, NO_X, SO_2 and VOC.

As identified in Section 6.2.4, nitrogen oxide (NO_X as NO_2), SO_2, and CO are also important indicators of Air Quality and these are assessed separately, as part of the Greenhouse Gases Assessment (Section 6.4). Particle deposition was also modelled, and the results were provided to the human health risk component of this Environmental Assessment (Appendix C.2). Per default model setup, plume depletion was turned on, such that material that settled out of the plume (deposited on the ground) was removed from the airborne concentrations reported by the model. Deposition is typically reported in grams per square metre (g/m^2) and the results may be used further to estimate health risks based on biological intake (i.e., ingestion).

Haul Road emissions calculations assume that the roads are unpaved, and a dust management plan (targeting 80 to 90% dust suppression efficiency). This will be achieved through the implementation of a fugitive dust control plan that includes the use of dust suppressant (Section 6.2.8 and Appendix C.3).

The Beaver Dam Mine Site mining, crushing, and transfer operations will primarily operate from adjacent to the open pit. Although vehicle traffic is also expected, it was assumed that most of these operations also occur adjacent to the open pit. Therefore, the Beaver Dam Mine Site emissions were modelled using as an open pit source such that all emissions from mining operations were summed and attributed to the pit source. As discussed in Project Description (Section 2) the Beaver Dam Mine site may not rely on a primary crusher if the ore can be broken using jawbreaker and other mining equipment. For the purposes of this air assessment, a conservative assessment approach has been applied and assumed that a primary crusher would be in use.

The Touquoy Mine Site consists of crushers and mining sources as volume sources. These sources were previously modelled in AERMOD for an Emissions Summary and Dispersion Modelling Assessment (CRA 2007a). As the Beaver Dam Mine Site will use the Touquoy Mine Site for its refining capabilities, the crushing and mining operations remained unchanged.

A series of discrete receptor grids and discrete receptors located at ground level were used to identify the maximum point of impingement (MPOI) outside the two mine sites and along the connecting Haul Road.

Around the Touquoy Mine Site, the receptor grids were set up with the following grid spacing:

- 20 metres (m) spacing within 200 m of the edge of a bounding box that encompassed all onsite facility sources;
- 50 m spacing from 200 to 500 m;
- 100 m spacing from 500 to 1,000 m;
- 200 m spacing from 1,000 to 2,000 m; and
- 500 m spacing from 2,000 to 5,000 m.

A property line ground level receptor grid with 10 m spacing was used to evaluate the maximum property boundary concentration. No receptors were placed inside either Mine's property line.

Around Beaver Dam Mine, the receptors were set up with the following spacing:

- 20 metres (m) spacing within 200 m of the edge of a bounding box that encompassed all onsite facility sources;
- 50 m spacing from 200 to 500 m;
- 100 m spacing from 500 to 1,000 m;
- 200 m spacing from 1,000 to 2,000 m; and
- 300 m spacing from 2,000 to 3,000 m.

No receptors were placed inside Beaver Dam Mine's property line.

Along the four modelled road sections, receptors were spaced at 40 m parallel to the road and at the following distances perpendicular to the road:

- 30 m from road centerline;
- 45 m from road centerline;
- 55 m from road centerline;
- 65 m from road centerline; and
- 75 m from road centerline.

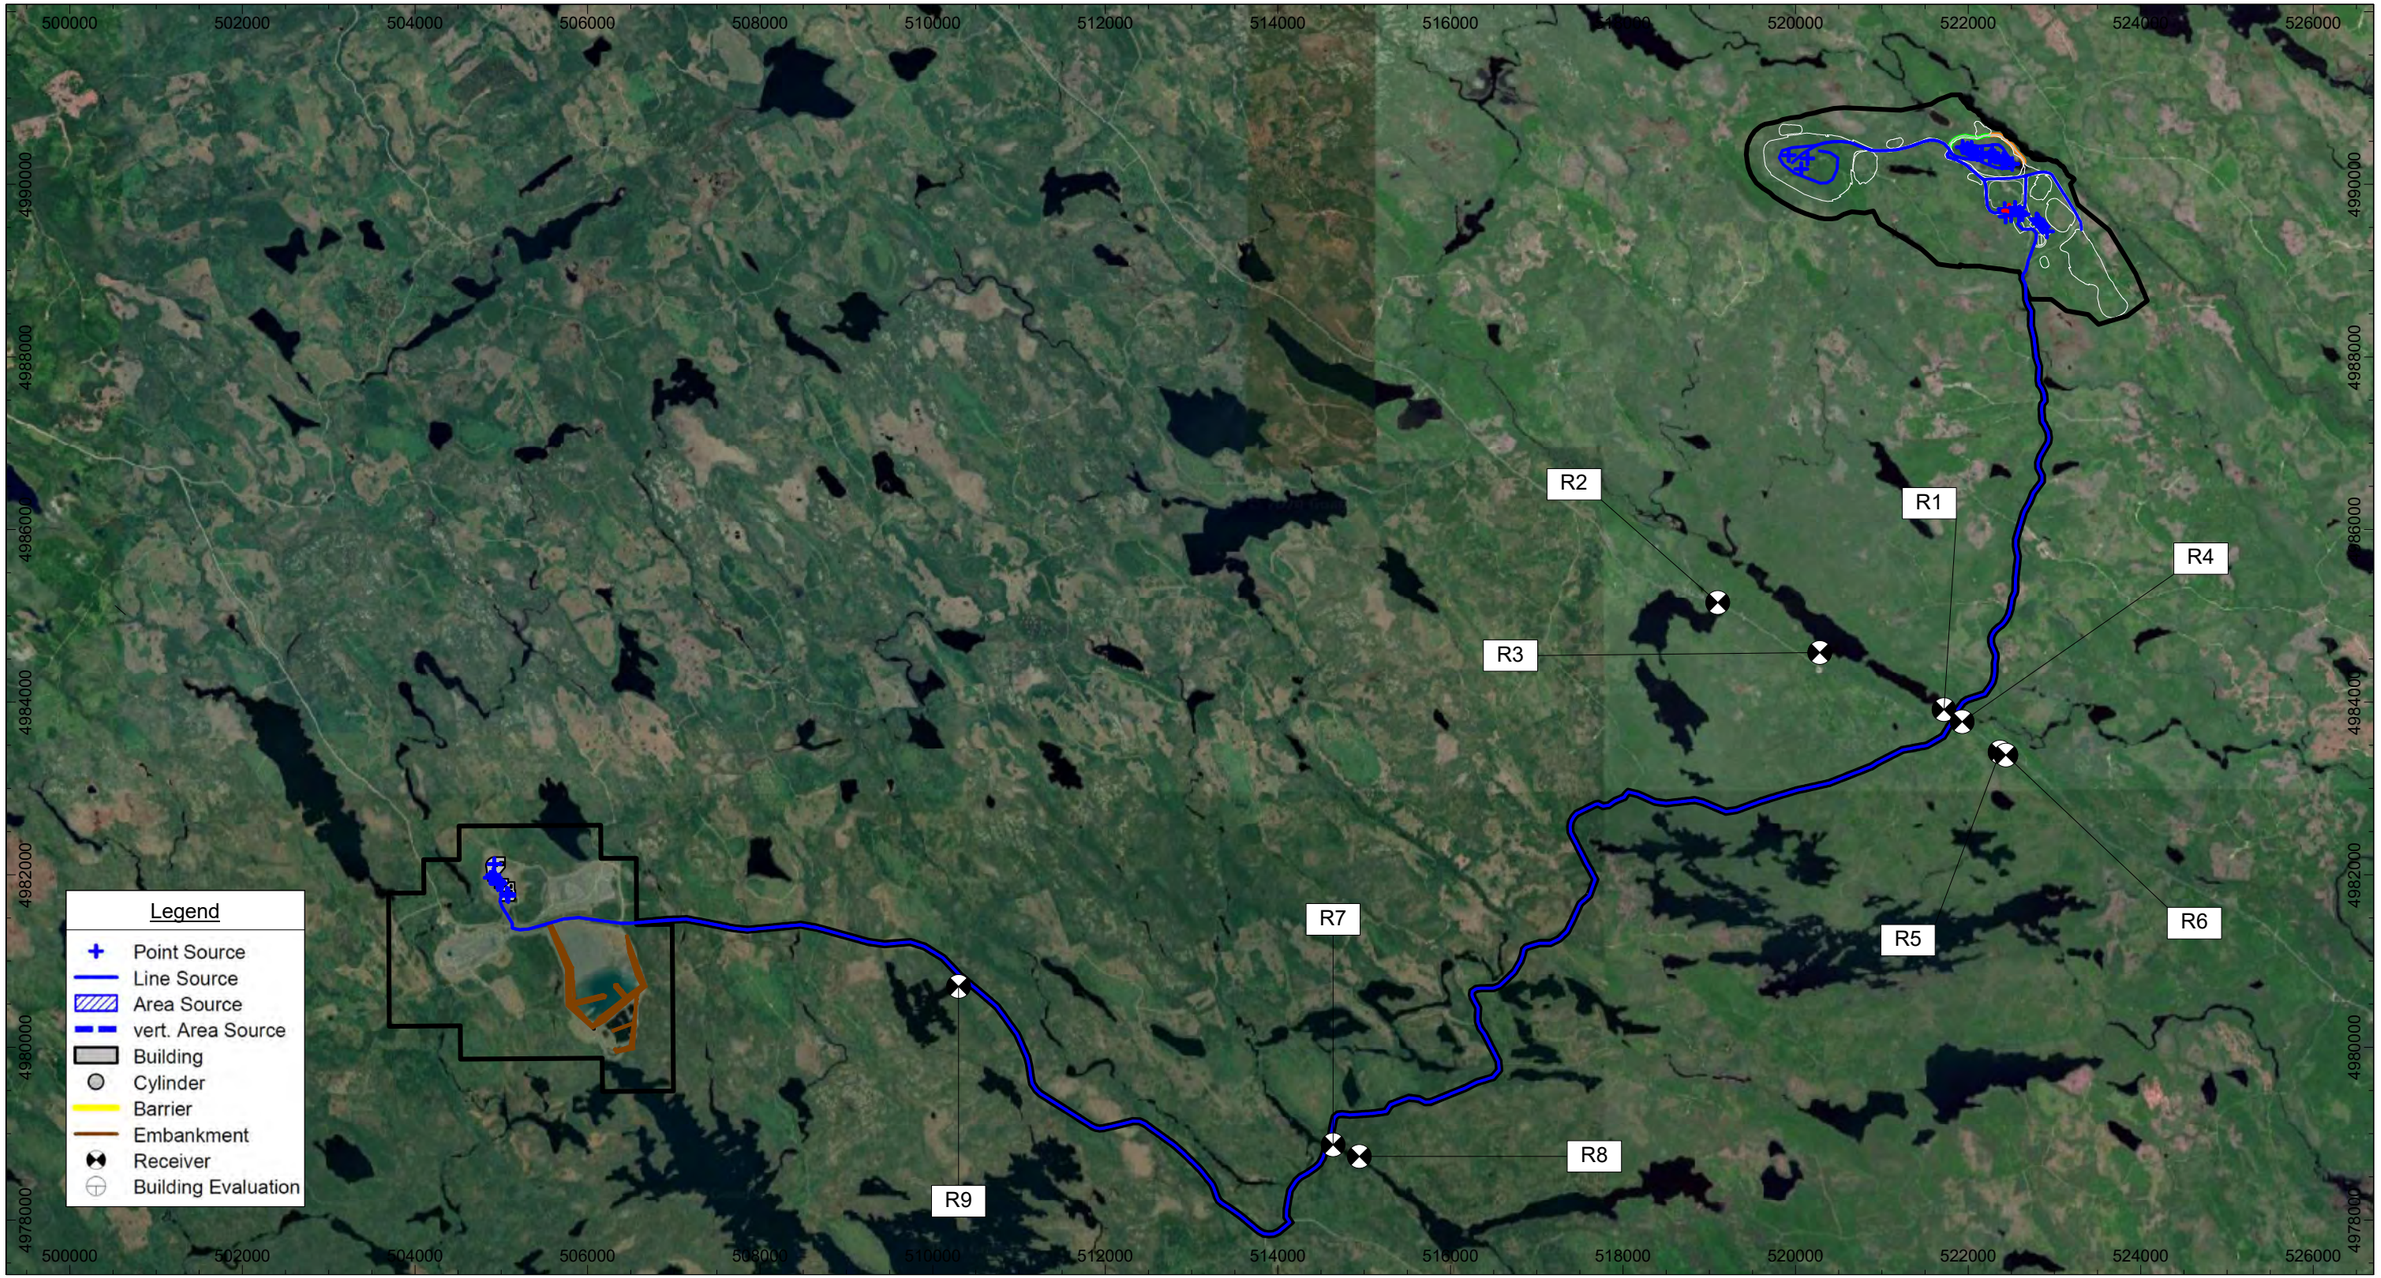
Modelling was also completed for selected sensitive receptors that are near the Haul Road or mine sites and have the potential to be impacted by air emissions. The sensitive receptors that were considered are included in Figure 6.2-3, and listed below:

- Sensitive Receptor 1 (R1) – 9 Beaver Dam Mines Road (Marlborough/Goodland Property);
- Sensitive Receptor 2 (R2) – 4112 Highway 224 (Beaver Lake IR 17);

- Sensitive Receptor 3 (R3) – 4115 Highway 224 (Cottage on Crown land);
- Sensitive Receptor 4 (R4) – 3492 Highway 224 (Hobbs Property);
- Sensitive Receptor 5 (R5) – 3379 Highway 224 (McLeod Property);
- Sensitive Receptor 6 (R6) – 3373 Highway 224 (Smith Property);
- Sensitive Receptor 7 (R7) – Tangier River (Deepwood Estates Property);
- Sensitive Receptor 8 (R8) – Tangier River (Musquodoboit Lumber Co Ltd. Property/John Dickson Lease); and
- Sensitive Receptor 9 (R9) – 5579 Mooseland Road (Lloy Property).

6.2.7 Project Activities/Interactions with Air Quality

The Project will result primarily in the generation and airborne transport of fugitive dust particles and exhaust emissions from equipment. Fugitive dust typically refers to small particles of geological or other origin that are moved into the atmosphere from non-ducted, open sources. Fugitive dust sources can originate from both stationary and mobile sources such as open fields, open burning, agricultural activity, construction sites, logging road traffic, vehicle traffic on paved and unpaved roads, aggregate pits and storage piles, as well as open pit mines. By contrast, non-fugitive sources are where emissions are discharged to the atmosphere in a confined flow stream, such as stacks, vents and vehicle exhausts. Stacks or vents at industrial or commercial facilities typically operate under some form of government authorization.



The potential interactions identified for the development and use of the proposed Haul Road between Beaver Dam Mine Site and the Touquoy Mine Site, and associated air dispersion modelling results are presented in the following sections. The evaluation of exposure potential related to potential dust deposition from Haul Road traffic on human health, including gathering and hunting of vegetation/country foods, which is assessed separately, in Appendix C.2.

Isopleths of the predicted concentrations from the dispersion modelling are shown in Figures 6.2-4 to 6.2-8, the individual results associated with each mine site, and the Haul Road, are described below. In all figures, where there is no colour, the predicted concentrations are below the lowest value provided in the colour scale on the figure; shades of green indicate areas where the predicted concentrations are times; yellow indicates areas where the mines and Haul Road operations meet the air quality standards on their own, but may exceed guideline values when background concentrations are added (cumulative effects); and red indicates where the mines and Haul Road operations exceed relevant air quality standards.

Note, Active Closure will involve infrastructure demolition, site reclamation and environmental monitoring activities. The dust generated by these activities will be substantially reduced relative to other Project phases. For these reasons, effects to Air during Active Closure are considered appropriately bounded by predictions for Construction and Operation phases, are not considered further.

6.2.7.1 Prediction of Air Effects, Beaver Dam Mine Site

The potential interactions identified for Beaver Dam Mine Site are presented in Table 6.2-6; emissions estimates for the operations phase (Haul Road traffic during mine operations) are provided in Table 6.2-7.

McCallum Environmental Ltd.

Document Name: BD_EIS_Figure6-2-7Air Annual 2.5

Dust emissions are the primary atmospheric issue for the Beaver Dam Mine Site and airborne particulate matter will be generated during construction and operation phases of the Project. Sources of project-related particulate matter at the Beaver Dam Mine Site may include the following:

- overburden (e.g., topsoil, till and organic) removal;
- blasting;
- rock crushing option;
- onsite heavy truck traffic;
- material loading;
- wind erosion of material storage piles;
- construction of mine site roads; and
- operation of other heavy machinery.

During operation, most of the dust will be generated at the Beaver Dam Mine Site will be due to material handling and crushing processes and trucking operations. Estimated emissions for the Beaver Dam Mine Site are provided in Table 6.2-7. The total emissions (in grams per second or g/s) are provided as the sum of the emissions from all sources as this site was modelled as an open pit source.

Table 6.2-6: Potential Air Interactions with Project Activities at Beaver Dam Mine Site

Project Phase	Duration	Relevant Project Activity
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction. • Drilling and rock blasting in preparation of construction. • Till and waste rock from site preparation transport and storage. • Watercourse and wetland alteration in preparation of construction. • Mine site road construction. • Surface infrastructure installation and construction. • Collection and settling pond construction. • General management of waste rock and soil derived from preparation and construction activities. • Accidents and malfunctions to include fuel and other spills, forest fires, slope failure, an unplanned explosive event, and mobile equipment accident.
Operations and Maintenance	5 years	• Rock blasting and ore extraction. • Management of waste rock produced from crushing and preparing ore for transport. • General management of waste rock derived from operation and maintenance activities.
Closure	2 years	• Infrastructure Demolition. • Site reclamation activities. • Accidents and malfunctions to include fuel and other spills, slope failure, and forest fires.
Post-closure	10+ years (monitoring)	• N/A

N/A = not applicable.

Table 6.2-7: Estimated Particulate Emissions from Beaver Dam Mine

Activity	Emission Rate (g/s)		
	TSP	PM_{10}	$PM_{2.5}$
Conveyors	2.87E-02	9.44E-03	2.67E-03
Crusher Option	2.46E-01	1.11E-01	2.05E-02
Truck Loading	6.57E-03	3.29E-03	1.64E-03
Total	**2.84E-01**	**1.24E-01**	**2.48E-02**

g/s = grams per second; PM_{10} = coarse particulate matter; $PM_{2.5}$ = fine particulate matter; TSP = total suspended particulate.

Results of air dispersion modelling for maximum predicted concentrations of emitted particulate species from the Beaver Dam Mine Site are presented in Table 6.2-8. This table summarizes the particulate size fraction considered, the averaging period, the assessment criteria against which the results are compared, the maximum predicted concentration from the modelling, the ambient background concentration, the combined effect (the modelled concentration from the site added to the assumed existing background concentration for that averaging period), and the percentage of the assessment criteria for the site modelling results alone and the cumulative effects.

For this site, maximum predicted concentrations occurred at the property boundary. Predicted concentrations for all indicator compounds and averaging periods were lower than existing background concentrations, and well below relevant assessment criteria. The cumulative effects were also found to be below the assessment criteria for all compounds and averaging periods.

Table 6.2-8: Maximum Predicted Concentrations due to Beaver Dam Mine Site Operations

Compound	Averaging Period	Assessment Criteria (Ambient Air Quality Standard) (µg/m³)	Maximum Predicted Concentration (µg/m³)	Percentage of Assessment Criteria (%)	Background Concentration (µg/m³)	Combined Effect (µg/m³)	Percentage of Assessment Criteria for Cumulative Effect (%)
TSP	24-hour	120	3.8	3	41.7	45.5	38
	Annual	70	0.8	1	12.4	13.2	19
PM_{10}	24-hour	50	3.7	7	31.0	34.7	69
$PM_{2.5}$	24-hour	27	1.4	5	9.0	10.4	39
	Annual	8.8	0.3	3	5.7	6.0	68

µg/m³ - micrograms per cubic metre; PM_{10} = coarse particulate matter; $PM_{2.5}$ = fine particulate matter; TSP = total suspended particulate.

6.2.7.2 Prediction of Air Effects, Haul Road

Airborne particulate matter will be generated during construction and operation of the proposed Haul Road. Sources of project-related particulate matter would include upgrading the existing road to be suitable for the mine traffic, and truck traffic hauling ore from Beaver Dam Mine to the Touquoy Mine Site for processing. Dust can be generated from mine haul truck tires interacting with gravel surfaced Mine Haul Roads and Beaver Dam Haul Roads. Dust is also generated during the truck loading and dumping activities. Dust is not expected from uncovered trucks because the ore material is of a size that is unlikely to generate dust. Dust can be tracked across asphalt roads and re-entrained by traffic or by the wind.

The potential interactions identified for the development and use of the proposed Haul Road between Beaver Dam Mine Site are presented in Table 6.2-9; the interactions are expected to be the same for the Haul Road as for the mine sites, except the construction phase will be shorter. Further, as the road is not currently anticipated to be decommissioned, there are no effects associated with the Active Closure. Emissions estimates for the operations phase (Haul Road traffic during mine operations) are provided in Table 6.2-10.

Table 6.2-9: Potential Air Interactions with Project Activities along the Haul Road

Project Phase	Duration	Relevant Project Activity
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Drilling and rock blasting in preparation of construction • Till and waste rock from site preparation transport and storage • Watercourse and wetland alteration in preparation of construction • Haul road construction and upgrades • Accidents and malfunctions to include fuel and other spills, forest fires, and a haul truck accident
Operations	5 years	• Ore transport • Haul road maintenance and repairs • Accidents and malfunctions to include fuel and other spills, forest fires, and a haul truck accident
Active Closure	2 years	• N/A[(a)]
Post-closure	10+ years (monitoring)	• N/A

[(a)] Decommissioning and Reclamation of the Haul Road is not expected. The Haul Road will be returned to owner for forestry Industry.

N/A = not applicable.

Table 6.2-10: Estimated Particulate Emissions from the Haul Road

Activity	Emission Rate (g/s)		
	TSP	PM_{10}	$PM_{2.5}$
Haul Trucks	4.28E01	1.16E01	1.16E00

g/s = grams per second; PM_{10} = coarse particulate matter; $PM_{2.5}$ = fine particulate matter; TSP = total suspended particulate.

Results of air dispersion modelling for maximum predicted concentrations of emitted particulate species from the Haul Road are presented in Table 6.2-11. This table summarizes the particulate size fraction considered (i.e., TSP, PM_{10} and $PM_{2.5}$), the averaging period, the assessment criteria against which the results are compared, the maximum predicted concentration from the modelling, the ambient background concentration, the combined effect (the modelled concentration from the site added to the assumed existing background concentration for that averaging period), and the percentage of the assessment criteria for the site modelling results alone and the cumulative effects.

For this site, maximum predicted concentrations occurred within 30 m of the road, and predicted concentrations decreased, with increasing distance from the road. The maximum predicted concentrations for all compounds occurred in close proximity to the road, in areas that are not continuously occupied. Maximum predicted concentrations presented occur at 30 m from the road and decrease rapidly with distance. The TSP cumulative effects concentrations decline to values below assessment guidelines at all times within approximately 200 m of the road or less (Appendix C.1, Section 6.1) A cumulative effects assessment for the Project, including the Haul Road, is presented in Section 8.

Table 6.2-11: Maximum Predicted Concentrations due to Haul Road Operations

Compound	Averaging Period	Assessment Criteria Ambient Air Quality Standard) (µg/m³)	Maximum Predicted Concentration (µg/m³)	Percentage of Assessment Criteria (%)	Background Concentration (µg/m³)	Combined Effect (µg/m³)	Percentage of Assessment Criteria for Combined Effect (%)
TSP	24-hour	120	251.1	209	41.7	292.8	244
	Annual	70	84.4	121	12.4	96.7	138
PM_{10}	24-hour	50	146.3	293	31.0	177.3	355
$PM_{2.5}$	24-hour	27	16.2	60	9.0	25.2	93
	Annual	8.8	5.1	58	5.7	10.8	123

µg/m³ - micrograms per cubic metre; PM_{10} = coarse particulate matter; $PM_{2.5}$ = fine particulate matter; TSP = total suspended particulate.

For all the TSP size fraction, predicted concentrations decrease rapidly with distance and predicted cumulative effects are anticipated to be below guideline values at approximately 200 m distance from the road or less.

The PM_{10} cumulative effects concentrations are more strongly affected by the assumed background concentration (which is, itself, 62 percent of the assessment criteria). Using this highly conservative assessment, it is estimated that PM_{10} cumulative effects concentrations would decline to values below the assessment guideline at all times within 800 m of the road. If background PM_{10} were found to be half the current estimate, this distance would drop to approximately 350 m from the road, and in many areas less, demonstrating that accurate background data are needed to fully understand this issue.

Modelled $PM_{2.5}$ from road activities alone was predicted to meet 24-hour CAAQS even at the 30 m distance, possibly exceeding annual guidelines at this maximum location, but over half of the contribution to annual concentrations was found to be from background sources. The exceedance of the annual average $PM_{2.5}$ guideline in the combined effects assessment is limited to a very few individual roadside receptors (30 m from the road), and is not predicted to occur over a wide area or at any of the sensitive receptors.

6.2.7.3 Prediction of Air Effects, Touquoy Mine Site

The Touquoy Mine Site is currently in operation. The primary effect of the continued use of the Touquoy Mine Site is the continued generation of dust due to haul truck traffic on the site. There are no new or additional effects to air quality anticipated to be caused by the processing of ore and the management of tailings (exhausted pit) from the Project, as no new construction or disturbance is required at the Touquoy Mine Site related to the processing of Beaver Dam ore. Air emissions generated from the Touquoy Mine Site associated with the processing of Beaver Dam ore will include emissions generated from the processing plant, including the carbon reactivation furnace, the electrowinning cells, and the barring furnace (gold smelting), as well as mobile equipment sources (Table 6.2-12). Air emissions will occur from the processing plant, including CO_2, ammonia, off-gassing of hydrogen cyanide, and nitrogen oxides.

The Air Dispersion Modelling Assessment completed by GHD Ltd. (2019) considered the Touquoy processing facility as an input source, as the Beaver Dam Mine Site will use the Touquoy Mine Site for its refining capabilities. The crushing and mining emissions rates remained unchanged since being previously modelled for an Emissions Summary and Dispersion Modelling Assessment however emissions estimates have been updated using standard United States Environmental Protection Agency (US EPA) AP-42 emission factors and new dispersion modelling carried out. The emissions estimates are provided in Table 6.2-13. Emissions are shown from the two most significant sources at the Touquoy Mine Site: the crushing system (comprising primary, secondary,

and tertiary crushing) and the ROMTRANS, which comprise the transfer operations around the Raw Material Storage Pile, including material handling, transferring and conveying, loading the Run of Mine (ROM) stockpiles, and unloading from the ROM stockpiles.

Table 6.2-12: Potential Air Interactions with Project Activities at Touquoy Mine Site

Project Phase	Duration	Relevant Project Activity
Operations	5 years	• Ore management and processing. • Accidents and malfunctions to include fuel and other spills, forest fires, and mobile equipment accidents.
Active Closure	2 years	• Accidents and malfunctions to include fuel and other spills, forest fires, and mobile equipment accidents.

Table 6.2-13: Estimated Particulate Emissions from Touquoy Mine Site

Activity	Emission Rate (g/s)		
	TSP	PM_{10}	$PM_{2.5}$
Crushers	9.38E-02	4.22E-02	7.81E-03
ROMTRANS	8.42E-02	3.17E-02	1.58E-02

g/s = grams per second; PM10 = coarse particulate matter; PM2.5 = fine particulate matter; TSP = total suspended particulate.

Results of air dispersion modelling for maximum predicted concentrations of emitted particulate species from the Haul Road are presented in Table 6.2-11. Maximum predicted concentrations of emitted particulate species from the Touquoy Mine Site are presented in Table 6.2-14. This table summarizes the particulate size fraction considered, the averaging period, the assessment criteria against which the results are compared, the maximum predicted concentration from the modelling, the ambient background concentration, the cumulative effect (the modelled concentration from the site added to the assumed existing background concentration for that averaging period), and the percentage of the assessment criteria for the site modelling results alone and the cumulative effects.

For this site, maximum predicted concentrations occurred at the property boundary. Predicted concentrations for all indicator compounds and averaging periods were lower than existing background concentrations, and well below relevant assessment criteria. The cumulative effects were also found to be below the assessment criteria for all compounds and averaging periods.

Table 6.2-14: Maximum Predicted Concentrations due to Touquoy Mine Site Operations

Compound	Averaging Period	Assessment Criteria Ambient Air Quality Standard) (µg/m³)	Maximum Predicted Concentration (µg/m³)	Percentage of Assessment Criteria (%)	Background Concentration (µg/m³)	CombinedEffect (µg/m³)	Percentage of Assessment Criteria for CombinedEffect (%)
TSP	24-hour	120	3.1	3	41.7	44.8	37
	Annual	70	1.1	2	12.4	13.4	19
PM_{10}	24-hour	50	3.1	6	31.0	34.1	68
$PM_{2.5}$	24-hour	27	1.3	5	9.0	10.3	38
	Annual	8.8	0.4	5	5.7	6.1	70

µg/m³ - micrograms per cubic metre; PM_{10} = coarse particulate matter; $PM_{2.5}$ = fine particulate matter; TSP = total suspended particulate.

6.2.8 Mitigation

Mitigation measures used to reduce and control air pollutants during construction, operation, and decommissioning phases are outlined in Table 6.2-15. A draft Fugitive Dust Control Plan is provided in Appendix C.3. The overall goal of this Plan is to provide a framework for the control of fugitive dust which will enable protection of the health and safety for mine workers and the public, as well as to mitigate potential effects to the natural environment (e.g., impacts to flora and fauna). The draft Fugitive Dust Control Plan (Appendix C.3) will include procedures for inspection, monitoring, and reporting.

Table 6.2-15: Mitigation for Air

Project Phase	Mitigation Measure
C, O	• Use wet suppression controls on unpaved surfaces.
C, O	• Utilize paved surfaces where available.
C, O	• Speed reduction.
O	• Apply stabilized covers on inactive stockpiles.
O	• Use mechanical sweeper on paved surfaces to prevent dust from remobilizing.
O	• Apply dust suppressants, when and where practicable, to target 80% effectiveness.
O	• Size haul vehicles appropriately to minimize trip frequency.
O	• Implement appropriate dust suppression measures for crusher trains and associated activities/stockpiles.
O	• Implement Dust Suppression Plan as part of the Fugitive Dust Control Plan (Appendix C.3).
O	• A procedure, including a response plan, will be available for public to be able to register complaints regarding dust concerns.
CL	• Stabilize slopes on inactive stockpiles to a safe and long-term angle of repose.
CL	• Use soil and organics stockpiles for final capping and stabilization. Hydroseed as required.

Notes: C = construction; O = operations; CL = active closure (decommissioning and reclamation); VC = Valued Component.

The Plan has been developed based on:

- experience gained from the Touquoy Mine, which has been in operational since October 2017 and in the construction phase was in 2016 to 2017;
- industry best practice; and
- available guidance documents are also considered, including those provide by the Ontario Ministry of the Environment, Conservation and Parks (MECP).

The MECP guidance document is very useful because it is an overview that incorporates best management practices for industrial sources of fugitive dust emissions from a broad list of references collected from jurisdictions worldwide.

The control of dust from the mining operations will focus on provision of moisture control measures, such as spraying with water as required. In-pit operations will not generally have much direct off-site impact but could contribute to general dust levels at critical times if not controlled. The crushed ore stockpile at the Touquoy Mine Site will be covered to minimize wind and rain erosion; stockpiles will not be covered at the Beaver Dam Mine Site and may contribute to airborne dust. Dust control requires careful and consistently applied mitigation measures throughout the Project to ensure non-compliant or nuisance levels are avoided. The proposed mitigation measures for various process components are outlined below. These are similar to measures routinely used at most other Nova Scotia surface mine operations that allow for compliance with air quality guidelines at residential receptors.

Wind erosion from elevated waste rock piles containing finely divided material can be a major source of dust at mine sites. To prevent this occurrence, slopes on inactive stockpiles will be stabilized with mulching and/or vegetation, where appropriate. Waste rock piles will be sprayed with water as necessary to minimize fugitive dust.

Preventative measures to minimize dust produced on-site (Beaver Dam and Touquoy) and along the Haul Road include:

- wet suppression controls on unpaved surfaces;
- hardened surfaces where practical;
- speed reduction to keep dust levels at minimum;
- use of large haul vehicles so as to minimize trip frequency; and
- stabilized slopes and cover on inactive stockpiles.

The application of mitigation measures that are outlined in Table 6.2-15 to reduce airborne particulate matter will be determined by maintaining regulatory compliance with the NSE Maximum Permissible Ground Level Concentrations listed in the NSAQS and with the CAAQS for fine particulate matter and ozone. There are no federal or Nova Scotia provincial air quality criteria for PM_{10}.

Ongoing monitoring will determine compliance with these standards, and any exceedance or complaint by the general public or First Nations will be discussed with regulators and/or the Citizen Liaison Committee (CLC), and mitigation programs and operational practices will be reviewed to determine the appropriate course of action.

In the event that the monitoring program identifies the need for additional dust mitigation measures for the Haul Road, options exist for further reduction in particulates including:

- an enhanced dust suppression application schedule;
- use of other suppressants that are biodegradable;
- road re-surfacing or treatments to reduce silt content; and
- paving portions of the Haul Road.

A complaint from the public and/or First Nations will be a trigger to evaluate mitigation options. The Site Manager will be responsible for consideration of preventative mitigative actions listed in Table 6.2-15 and Table 6.2-16. Dust suppression on the Haul Road is a planned mitigation (targeting 80 to 90% effectiveness).

6.2.9 Residual Effects and Significance

Residual effects are effects to VCs that are predicted to occur even after the implementation of mitigation measures. Significant residual effects for the Air VC would be defined as having high magnitude (i.e., an exceedance applicable criteria), occur beyond the PA, be of long-term to permanent duration, occur at regular intervals or be continuous throughout the Project, and be only partially reversible to irreversible.

Modelling of sources at the Beaver Dam Mine Site and the Touquoy Mine Site showed maximum predicted concentrations at their respective fence lines well below applicable air quality criteria, which are unlikely to cause adverse effects. The Haul Road between the proposed Beaver Dam and the Touquoy Mine Sites is the source primarily responsible for the maximum predicted concentrations at both the gridded receptors and the sensitive receptors identified for this assessment.

Table 6.2-16: Residual Environmental Effects for Air

Project – Valued Component Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction – Beaver Dam Mine Site and Haul Road (Dust from haul trucks, Haul Road widening and construction)	Equipment maintenance, best management practices, minimize blasting events.	N Does not exceed guidelines or threshold	LAA Dust generated will likely extend beyond the PA	N/A VC is not expected to be affected by timing	MT Effects can occur beyond 12 months	R Effects occur regularly in the construction	R VC will recover to baseline conditions	Increased ambient dust	Not significant
Operations- Mine Site and Touquoy Mine Site at Property Lines and Points of Reception (Dust from onsite activities, vehicle travel, material handling and the crushing of ore)	Equipment maintenance, dust suppression, hardened surface where practical, vehicles to minimize trips, stabilization of stockpile slopes, cover of haul trucks, minimize blasts	N Does not exceed guidelines or threshold	LAA Dust generated will likely extend beyond the PA	N/A VC is not expected to be affected by timing	LT Effects may extend beyond 3 years	R Effects occur regularly during Operations	R VC will recover to baseline conditions	Increased ambient dust	Not significant
Operations- Haul Road at Property Lines (Dust from haul trucks)	Haul truck operations to minimize road surface disturbance during nighttime hours, implementation of Road Dust Best Management Practices Plan (with 80-90% or greater targeted dust suppression efficiency).	L Exceeds guidelines or threshold values by more than 20%	LAA Dust generated will likely extend beyond the PA	N/A VC is not expected to be affected by timing	LT Effects may extend beyond 3 years	S Exceedances are maximum values, sporadic to regular occurrence at Property Lines.	R VC will recover to baseline conditions	Increased ambient dust	Not Significant
Operations - Haul Road at Points of Reception (Dust from haul trucks)	Haul truck operations to minimize road surface disturbance during nighttime hours, implementation of Road Dust Best Management Practices Plan (with 80-90% or greater targeted dust suppression efficiency).	L Marginally exceeds guidelines or threshold values	LAA Dust generated will likely extend beyond the PA	N/A VC is not expected to be affected by timing	LT Effects may extend beyond 3 years	R Effects occur regularly in the operational phase of the Project	R VC will recover to baseline conditions	Increased ambient dust	Not Significant

Notes: See Table 6.2-5 and Section 5.11, Table 5.11-1 for definitions of the below characteristics.

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	IR	Irreversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	PR	Partially Reversible
H	High					P	Permanent	C	Continuous		

Maximum predicted $PM_{2.5}$ concentrations did not exceed the CAAQS for either the 24-hour or annual averaging periods at any of the sensitive receptor locations, based on Project alone predictions, or Project plus background. PM_{10} was predicted to exceed the Ontario Interim 24-hour guideline at Deepwood Estates up to 2% of the time without background) and up to 57% of the time with background concentration included. PM_{10} was also predicted to exceed the Ontario Interim 24-hour guideline at 9 Beaver Dam Mines Road up to 13% of the time with background concentration included but met the guideline without background. TSP was predicted to exceed the 24-hour Nova Scotia Air Quality Standard up to 0.3% of the time with background included at the Deepwood Estates receptor however once the dust mitigation is applied this will be reduced to negligible to low. There is uncertainty in the presented background concentrations of both PM10 and TSP. The Deepwood Estate property, the most impacted, has been acquired by AMNS so there will be no permanent or seasonal resident at this property. In addition, this property will likely be used as part of the monitoring to confirm impact predictions and assess the effectiveness of the mitigations.

The residual effects characterization for Air is presented in Table 6.2-16.

6.2.10 Proposed Follow-up and Monitoring Program

Prior to the start of construction, a baseline ambient air quality monitoring program will be undertaken at select locations on the Beaver Dam Mine Site and along the Haul Road. Air quality monitoring is currently ongoing at the Touquoy mine site and will continue throughout the construction and operations phase. The data collected will be used to better understand potential effects and refine mitigation and monitoring requirements prior to the processing of Beaver Dam ore.

Table 6.2-15 summarizes the mitigation activities that will be completed throughout the life of the Project. The details of the monitoring programs will be determined in consultation with regulatory agencies and will be described in the application for an Industrial Approval for the site operations following the EA process.

The objectives of the atmospheric environment monitoring programs are to:

- review predicted effects in the EIS;
- confirm the continuing effectiveness of mitigation measures;
- identify the need for any new mitigation measures; and
- confirm compliance with regulatory approvals and requirements.

Details of proposed dust monitoring for the Beaver Dam Project are included in Appendix C.3 draft Fugitive Dust Control Plan.

6.3 Light

6.3.1 Introduction

6.3.1.1 Summary of Light Before the Updates

This section describes the methods and results of baseline characterization as well as predictive studies that were undertaken to support characterization of potential project effects on the Light Valued Component (VC). Light level limits are not directly regulated through the provincial or federal regulatory regime. Changes (i.e., increases or changes to occurrence timing) to ambient light levels have the potential to adversely affect fauna and birds, as well as increase level of light pollution experienced by the general public or specific populations.

Light impact assessments were conducted for the Touquoy Gold Project in 2007 (CRA 2007a), and for the Beaver Dam Mine Project in 2017. The impacts of the proposed lighting installations were quantified and compared with guidelines published by the Institution of Lighting Professionals (ILP, previously known as Institution of Lighting Engineers [ILE]) in the document entitled "Guidance Note for the Reduction of Obtrusive Light" (ILE 2005). Limits recommended by the ILP guidelines were met at the identified receptors.

6.3.1.2 Summary of Updates to Light

The updates to this section are based on the update to the Project Description (Section 2, Project Area [PA] boundary change) as well as in response to Round 2, Information Requests (IR2s) submitted by Impact Assessment Agency of Canada (IAAC, formerly Canadian Environmental Assessment Agency [CEAA 2019]), Nova Scotia Environment (NSE 2019), and Eastern Shore Forest Watch Association (ESFWA 2019), light subsection updates are summarized in Table 6.3-1. Effects assessment methodology has been updated to include updated light modelling in response to comments from IR2s.

The calculated light levels at all receptors are below the limits recommended by the ILE guidelines during both pre- and post-curfew conditions (i.e., between 11 PM and 7 AM and before 11 PM; Section 6.3.7.1, Table 6.3-7 and Figure 6.3-2). The assessment considers worst-case operating conditions, for example, if all mobile equipment was in use at the same time and illuminating towards the receptors and the potential for light from both the Beaver Dam Mine Site and the Haul Road trucks to affect a receptor in a cumulative way. The calculated light levels from the Haul Road are also below the limits recommended by the ILP guidelines (Section 6.3.7.1, Table 6.3-7 and Figure 6.3-2).

Ambient night-time (i.e., post-curfew) light levels at the Beaver Dam Mine Site are predicted to meet the 1 lux guideline within 1.6 km from the site and as such not anticipated to affect the Beaver Lake IR 17 or other receptors. Detailed updated modelling results are presented in Appendix D.1 Light Impact Assessment.

The updated section includes a more thorough discussion of sky glow and a lightshed map (Figure 6.3-2) that shows that the light levels from the Beaver Dam Mine Site reach maximum 0.1 Lux (background level) at a distance of 5,082 m from the source. During pre-curfew conditions when the Haul Road is in operation, when two trucks pass the same point simultaneously, the ambient light may be above background (above 0.1 Lux) up to a distance of 279 m (Appendix D.1). The lightshed maps will inform the response to IR2 CEAA 2-05 in consideration of Beaver Lake IR 17 and areas identified for current use practices and shows light trespass from Beaver Dam Mine Site and Haul Road traffic to be discussed in Section 6.14.

The resulting area of illumination elevated above background conditions (sky glow) from the Beaver Dam Mine Site will be seen within 5,082 m. This encompasses receptors R1, R2, R3, and R4 (Section 6.3.7.1, Figure 6.3-2). The predicted illuminance levels

represent the worst-case operating conditions of the Beaver Dam Mine Site. The assessment considers when all of the mobile equipment at the mine would be in use at the same time, illuminating towards receptors. The areas surrounding the site are wooded with varying topography and inhibit the spread of light. It was conservatively assumed for screening purposes that 50% of the light will not reach the receptors due to directionality and line of sight obstructions. The amount of light blocked by the surrounding woodland and topographic changes, however, will likely be much greater than this (>90%), especially during the seasons when deciduous trees are leaf on (Appendix D.1). It is therefore not expected that the illumination will cause any significant visual impact, due to a combination of distance and the screening effects of topography and vegetative cover.

Notes: PA = Project Area; LAA = Local Assessment Area; RAA = Regional Assessment Area; - = no update; IR2 = Round 2, Information Requests; CEAA = Canadian Environmental Assessment Agency; EIS = environmental impact statement; N/A = not applicable.

6.3.2 Rationale for Valued Component Selection

Light level limits are not directly regulated through the provincial or federal regulatory regime. Changes (i.e., increases or changes to occurrence timing) to ambient light levels have the potential to adversely affect fauna and birds, as well as increase level of light pollution experienced by the general public or specific populations.

6.3.3 Baseline Program Methodology

A background light assessment for illuminance was conducted at the Touquoy Mine Site on the night of August 23, 2007 as part of the 2007 Touquoy Mine Project Focus Report (CRA 2007a). Post curfew measurements (after 11 pm) were conducted utilizing a Skeonic L-358 flash meter. Measurements were taken in the EV mode and converted into illuminance (lux) values. Illuminance refers to the amount of light that covers a surface and is quantified in terms of lux (i.e., one lux is the illuminance of 1 m^2 surface uniformly lit by one lumen (lm) of luminous flux – the quantity of energy emitted per second in all directions). One lux is the accepted equivalent to moonlight. Baseline sky glow, or sky brightness, conditions were not assessed for as part of the 2007 Focus Report (CRA 2007a).

The conditions around Beaver Dam Mine Site, Haul Road, and surrounding area are similar to that of the Touquoy Mine Site background conditions due to the proximity and remote, rural and mostly wooded, location. Ambient nighttime light conditions are minimal and typical of a rural area. The largest artificial light sources in the Beaver Dam Mine Site are from the nearest residences, the Beaver Lake IR 17, and the occasional all-terrain vehicle. The largest artificial light sources along the Haul Road are from Beaver Lake IR, 17 vehicles on Highway 224, the community of Mooseland, and other rural residences nearby. As such, additional on-site baseline light monitoring was not required to support the light impact assessment.

The ILP has developed an Environmental Zone classification system whereby the existing ambient light levels at a site are used to determine the recommended maximum amount of light trespass (i.e., the spilling of light beyond the boundary of the area being lit) to nearby receptors.

Light impact assessments were conducted for the Touquoy facility in 2007 (CRA 2007a), and for the Beaver Dam Mine Project in 2017 - updated in 2019. The impacts of the proposed lighting installations were quantified and compared with guidelines published by the ILP in the document entitled “Guidance Note for the Reduction of Obtrusive Light” (ILP 2020). Light assessment modelling methodology is detailed in the effects assessment methodology Section 6.3.6.2.

6.3.4 Baseline Conditions

The proposed Project is located in a historical mining area surrounded by forest, waterbodies, watercourses and wetlands. The nearest residential receptor to the Beaver Dam Mine Site is the Beaver Lake IR 17 located approximately 5 kilometres (km) southwest. A proposed haul route for transporting ore will connect the Beaver Dam Mine to the Touquoy Processing Plant, located approximately 30 km southwest.

The existing baseline light conditions around Beaver Dam Mine Site, Haul Road, and surrounding area are similar to that of the Touquoy Mine Site background conditions (CRA 2007a) due to the proximity, remote, rural, and mostly wooded location. Ambient nighttime light conditions are minimal and typical of a rural area. The largest artificial light sources near the proposed Project are from the closet residences, the Beaver Lake IR 17, and the occasional all-terrain vehicle. The largest artificial light sources along the Haul Road are from Beaver Lake IR 17, vehicles on Highway 224, the community of Mooseland, and other rural residences nearby. As such, additional on-site baseline light monitoring was not required to support the light impact assessment (Appendix D.1). The Beaver Dam Mine Site, Haul Road, background conditions for the Touquoy Mine Site (CRA 2007a), and

surrounding area also fall under the classification for rural areas, small villages, or relatively dark urban areas: "E2 Low District Brightness Areas" (ILP 2020).

6.3.5 Consideration of Engagement Results

Key concerns raised during public and Mi'kmaq of Nova Scotia engagement relating to ambient light include light from mining operations at the Beaver Dam Mine Site and trucking along the Haul Road. The change to the Haul Road reduced these concerns with respect to passing by existing residences, especially concerns of Millbrook First Nation regarding its residents in Beaver Lake.

The results of the public and Mi'kmaq of Nova Scotia engagement have been considered in the environmental effects assessment, including AMNS's commitments on mitigation and monitoring measures and proposed compliance and effects monitoring programs, as well as AMNS's broader commitment to ongoing public and Mi'kmaq of Nova Scotia engagement (Sections 3 and 4). Specific to evaluating the effect of ambient light, these are found within the following environmental effects assessment.

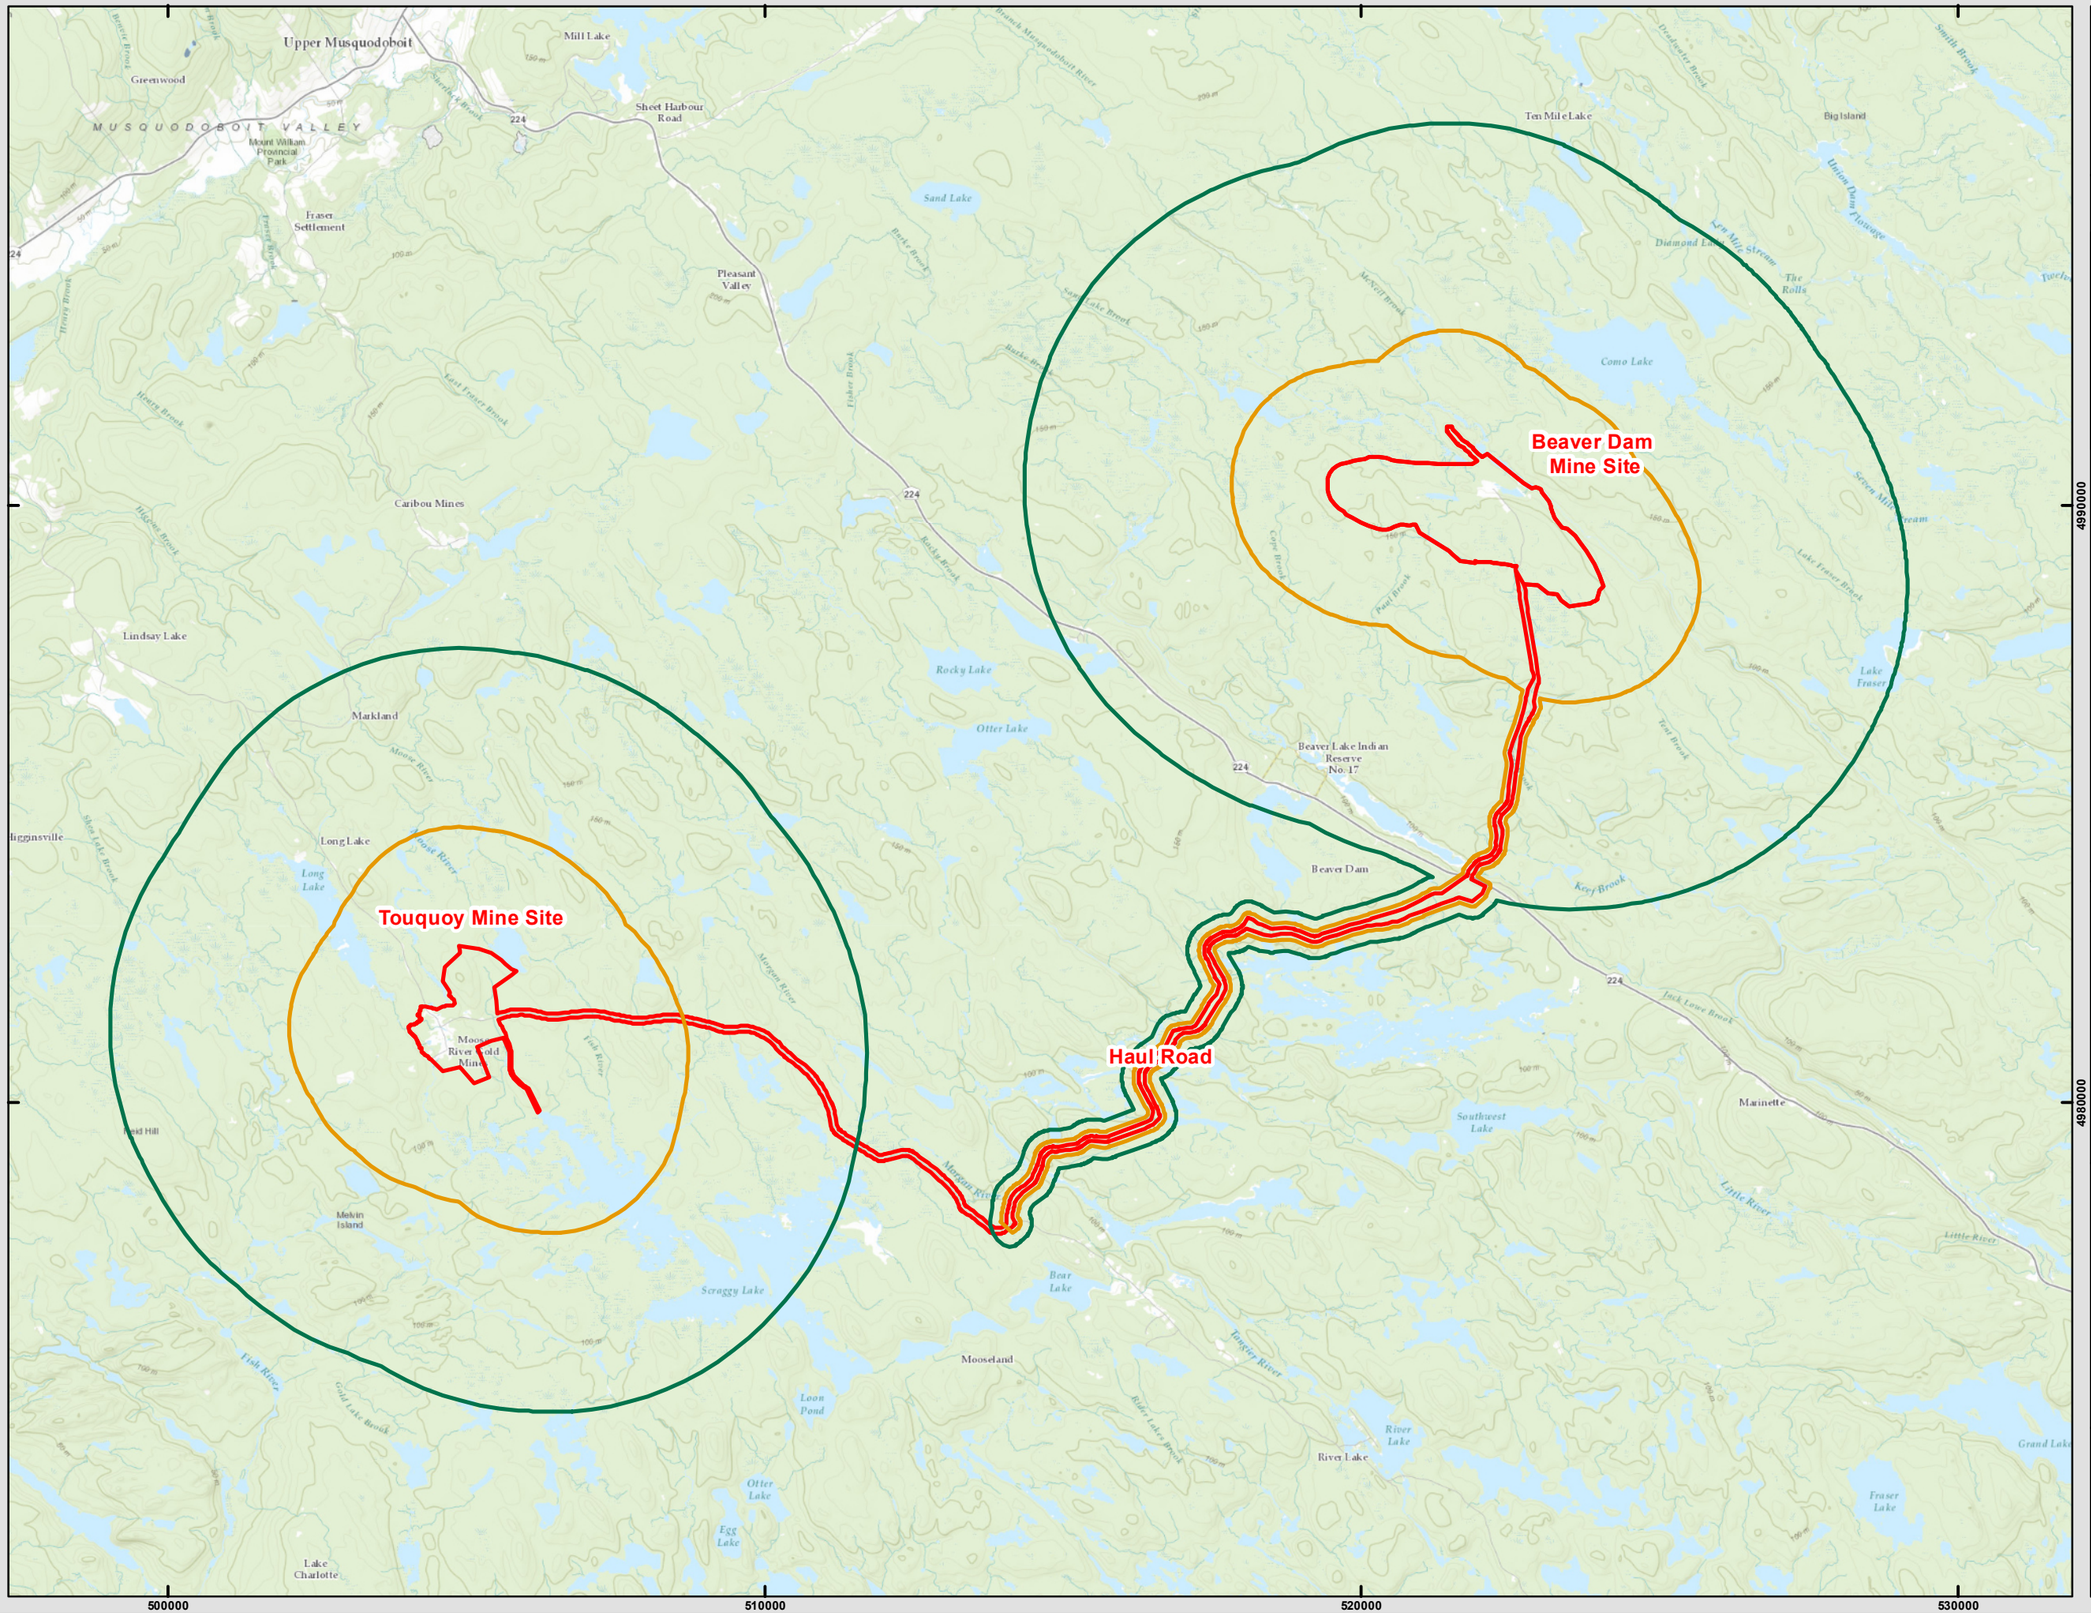
Engagement with Mi'kmaq communities, especially the Millbrook First Nation, has determined that community members living within close proximity to the Beaver Dam Mine Site are concerned with changes to the baseline sky conditions from the proposed Project.

6.3.6 Effects Assessment Methodology Update

6.3.6.1 Boundaries

6.3.6.1.1 Spatial Boundaries

The Regional Assessment Area (RAA) and Local Assessment Area (LAA) boundaries have been updated from the Revised 2019 EIS (AMNS 2019) to reflect the changes to the Project Description (Section 2) and the corresponding PA.



The spatial boundary used for the assessment of effects of ambient light are discussed below.

The PA consists of the three project components - Beaver Dam Mine Site, Haul Road, and Touquoy Mine Site and extends from Marinette to Moose River Gold Mines, Halifax County, NS. The Beaver Dam Mine Site is located at the eastern end of the Beaver Dam Mines Road and has been extended to the west and southeast to allow for micro-siting of the waste rock stockpile and organic material stockpile, respectively. The Haul Road spans from the Beaver Dam Mine Site to the Touquoy Mine Site.

The LAA is variable based on 1 lux threshold for light trespass into residential dwelling windows at sensitive receptor locations as determined by preliminary modelling and evaluation of light (Figure 6.3-1). At the Touquoy Mine Site, the boundary was defined based on the nearest modelled receptor (i.e., person canoeing on Scraggy Lake).

The RAA is based on the maximum extent of light propagation (measured by 0.1 lux) (Figure 6.3-1).

The RAA is the appropriate spatial boundary to evaluate potential effects from light on the Project due to the potential to cause direct and indirect effects of ambient light outside of the PA and LAA.

Document Name: BD_EIS_Figure6.3-1 Light Spatial Boundaries

6.3.6.1.2 Temporal Boundaries

The temporal boundaries used for the assessment of effects of ambient light are the construction phase, operational phase, and decommissioning and reclamation phase.

6.3.6.1.3 Technical Boundaries

Canada Occupational Health and Safety Regulations (SOR/86-304) direct the minimum illumination levels required at various workplace locations.

6.3.6.1.4 Administrative Boundaries

No administrative boundaries were identified for the effects assessment of ambient light.

The ILP have produced suggested maximum guidelines on reduction of obtrusive light (ILP 2020), which were consulted in the assessment of the Project. The thresholds for light trespass (into windows post-curfew) for each Environmental Zone Classification is presented in Table 6.3-2.

Table 6.3-2: Maximum Values of Vertical Illuminance on Properties – Post-curfew

Environmental Zone Classification	Night-time Light Trespass Threshold into Windows Post-curfew (lux)
E1	1[(a)]
E2	1
E3	2
E4	5

Source: ILP 2020, Table 3.

Note: [(a)] From public road lighting installations only.

Classification results in an E2 classification for the Beaver Dam Mine Site and Touquoy Mine Site. As a result, a 1 lux threshold has been conservatively assigned for light trespass into windows (residential receptors). The Haul Road will not operate in post-curfew conditions (i.e., between 11 PM and 7 AM).

6.3.6.2 Light Assessment Modelling Methodology

6.3.6.2.1 Beaver Dam Mine Site and Haul Road Methodology

The light impact assessment was updated to reflect the current infrastructure for the Project as of 2020 (Appendix D.1). The impacts of the proposed lighting installations at the Beaver Dam Mine Site and lighting from haul trucks along the Haul Road on nearby sensitive receptors (Table 6.3-3) were compared with the guidelines published by the Institution of Lighting Professionals in the "Guidance Note for the Reduction of Obtrusive Light" (ILP 2020).

The Beaver Dam Mine Site, Haul Road and surrounding area falls under the Environmental Zone classification for rural areas, small villages, or relatively dark urban areas: "E2 Low District Brightness Areas" (ILP 2020). Based upon this classification, the light trespass limit at an off-site receptor after curfew (i.e., typically considered to be 11 PM) for the Beaver Dam Mine Site is 1 lux, which is the accepted equivalent to moonlight. The after curfew (i.e., post-curfew: between 11 PM and 7 AM) limit was used to

assess the impact of lighting from the proposed mine as mining operations under full-scale operation are scheduled to be 24 hours per day.

Table 6.3-3: Sensitive Receptors Used in Light Impact Assessment

Receptor	Location Description
R1	9 Beaver Dam Mine Road (Marlborough Property)
R2	4112 Highway 224 (Beaver Lake IR 17)
R3	4115 Highway 224 (Cottage on Crown Land)
R4	3492 Highway 224 (Hobbs Property)
R5	3379 Highway 224 (McLeod Property)
R6	3373 Highway 224 (Smith Property)
R7	Tangier River (Deepwood Estates Property)
R8	Tangier River (Musqudoboit Lumber Co. Ltd. Property/John Dickson Lease)
R9	5579 Mooseland Road (Lloy Property)

The ILP trespass limit at an off-site receptors before curfew (i.e., before 11 PM) is 5 lux (ILP 2020). AMNS has indicated that trucking transport along the Haul Road will occur approximately 16 hours a day, and not during post-curfew hours (i.e., not between the hours of 11 PM and 7 AM). No other proposed lighting will exist along the Haul Road. As such, the light trespass at receptors along the haul route was evaluated against the before curfew (pre-curfew) limit of 5 lux.

Luminous flux (i.e., the quantity of the energy of the light emitted per second in all directions) was calculated for a complete list of proposed light sources to be installed at the site and the haul trucks (complete list included in Appendix D.1). After determining luminous flux (lumens) estimates for each light source, the impacts of the incident light at the identified sensitive receptors can be determined. There are four main areas where lighting is to be located:

1. Open Pit
2. Operational Facilities
3. Waste Rock Storage
4. Haul Road

As a worst-case scenario, the illuminance for the Haul Road was considered from two trucks at the closest location on the haul route to each nearby individual sensitive receptor shining light towards each receptor were considered (Appendix D.1). Other than the hauling trucks, no other lighting sources will be present along the haul route (e.g., street lights, traffic lights). For simplicity, the two trucks were combined as a single stationary source (Appendix D.1). Lighting will not be installed along the Haul Road.

The illuminance level at a receptor is equal to the combined total from each light source. It has been conservatively assumed that 50 percent of the incident light will not reach the receptor due to the dense tree cover at the site and surrounding area. This was then compared to the applicable pre- and post-curfew light trespass thresholds.

In response to IR2 CEAA 2-05, and to determine the impact of potential elevated sky brightness, or sky glow, the total luminous flux (lumens) was calculated for the Beaver Dam Mine Site and Haul Road, the same 50% incidence considering directionality and

line of site obstructions was applied, and the distance to background light levels was modelled (Appendix D.1). Because there were no baseline light measurements taken, the most conservative 0.1 lux light level, which is considered the limit of possible impact, was used as background. For context, the 0.1 lux light level is also the maximum illuminance assessment criteria during post-curfew for the environmental zone E1 which is considered a natural, relatively uninhabited rural area such as national parks and areas of outstanding natural beauty.

Section 5 of Light Impact Assessment Report (Appendix D.1) provides details relating to the modelling methodology for the Project light effects as well as potential cumulative effects from the shared proposed usage of the Beaver Dam Haul Road by trucks from the Fifteen Mile Stream Gold Project, the Cochrane Hill Gold Project, and current baseline forestry activity. Conclusions relating to potential cumulative effect is described in the Cumulative Effects Section (Section 8).

Sensitive Receptors

Sensitive receptors were identified around the Beaver Dam Mine Site, and Haul Road (Table 6.3-3). The nearest permanent residential receptor to the mine is the Beaver Lake IR 17 (R2), at a distance of approximately 5 km southwest from the Beaver Dam Mine Site boundary. Five other residential receptors, farther away from the mine and located along Highway 224, are also considered; Marlborough property (R1), the cottage on crownland (R3), the Hobbs property (R4), the McLeod property (R5) and the Smith property (R6). These six residential receptors were mainly used in the analysis of the impacts of light trespass from the mine.

Sensitive receptors were also considered along the proposed Haul Road. Three seasonal residences located within 320 m of the haul route were assessed for light impacts from hauling trucks travelling along the route; the Deepwood Estates property (R7), the Musquodoboit Lumber Co property/John Dickson Lease (R8) and the Lloy property (R9) (Table 6.3-3). These three residential receptors were mainly used in the analysis of the impacts of light trespass from transport trucks travelling along the Haul Road. As previously mentioned, the illuminance from the haul route was evaluated against pre-curfew limits due to the hauling schedule.

Marlborough property (R1), the Hobbs property (R4), McLeod property (R5) and the Smith property (R6) were assessed for impacts of light trespass from both the transport trucks travelling along the haul route during pre-curfew conditions and light trespass from the mine during pre-curfew and post-curfew conditions.

Effects to wildlife, birds, and the Mi'kmaq of Nova Scotia from predicted light are further discussed in Sections 6.11, 6.12, and 6.14.

6.3.6.2.2 Touquoy Mine Site Methodology

In the 2007 Focus Report (CRA 2007a), the impacts of the proposed lighting installations at the Touquoy Mine Site were quantified and compared with guidelines published by the Institution of Lighting Professionals (ILP) in the document entitled "Guidance Note for the Reduction of Obtrusive Light" (ILE 2005). A threshold of 1 lux was determined to be the limit of noticeable impact from light. The extent of the 1 lux threshold was compared to nearby sensitive receptors to determine potential effects. Sensitive receptors included Camp Kidston (3 km to the north), the Scraggy Lake Area (2 km to the south) and the nearest residence (5 km to the northwest).

Effects to wildlife, birds, and the Mi'kmaq of Nova Scotia from predicted light are further discussed in Sections 6.11, 6.12, and 6.14.

6.3.6.3 Thresholds for Determination of Significance

The adverse effects of light trespass on human receptors are due both to an increase in general illuminance that may cause annoyance and may disrupt sleeping patterns, and from the direct view of the light source that can cause glare issues. The adverse effects of light trespass from exterior lighting are influenced by a number of factors:

- Light trespass is more likely to be perceived as obtrusive if the lighting installation is located above the observer. Lighting installations are usually directed towards the ground and an observer could hence have a direct view of the luminaire.
- The surrounding topography and site infrastructure, including distance, hills, trees, and buildings, generally have a positive effect by shielding the observer from the light source.
- Pre-existing lighting in the area. Light from a particular light source is seen as less obtrusive if it is located in, or perceived in, an area where the lighting levels are already high, e.g., along roads and near built up areas.
- The zoning of the area. A residential area is seen as more sensitive compared to commercial areas where high lighting levels are seen as more acceptable.
- Time of use. Clearly light will be seen as being more obtrusive during nighttime. This is generally considered to be between 11:00 pm and 7:00 am.

This section has been updated to reflect responses to IR2s CEAA 2-02 and CEAA 2-04 (AMNS 2021). For the purpose of this assessment, the threshold of determination of significant effects from light at the Beaver Dam Mine Site was determined to be 1 lux light trespass into windows at the nearest receptor location. This was determined as a result of the baseline environmental light classification of E2 at the Beaver Dam Mine Site.

For light, the following logic was applied to assess the magnitude of a predicted change in light levels:

- Negligible – background light levels (0.1 lux) are met at the property boundary.
- Low – increased light trespass above background levels beyond property boundaries, however, comply with relevant guidelines for light trespass into windows at the residential receptors.
- Moderate – increased light trespass above background levels beyond property boundaries, however, exceed relevant guidelines for light trespass (1 lux) into windows at the residential receptors up to 5 lux.
- High – increased light trespass above background levels beyond property boundaries, however, exceed guidelines for light trespass (1 lux) into windows at a residential receptor above 5 lux.

For light, the following logic was applied to assess the timing of a predicted change in light levels. Timing has been determined to not be applicable because the modelling was completed assuming that 50% of the light would not reach receptors due to directionality and line of sight obstructions. In reality the amount of light blocked by the surrounding woodland and topographic changes will likely be much greater than this (>90%) especially during seasons when trees are in full bloom, and thus results are conservatively high. Light trespass during daylight hours would be negligible and thus, this assessment focusses on dark or nighttime conditions.

6.3.7 Project Activities, Light Interactions, and Effects

The key sensitive receptors for light from the Beaver Dam Mine Site and Haul Road in the area is the Beaver Lake IR 17; a satellite community of the Millbrook First Nation located approximately 5 km south of the Beaver Dam Mine Site. Eight other receptors including a permanent resident, seasonal camps and cottages, are also located along the Beaver Dam Mines Road near Highway 224 and along the Haul Road as described in Table 6.3-3.

Camp Kidston, which operates only in the summer months, is located 3.5 km northeast of Touquoy. According to AMNS, the nearest permanent full-time occupied residences to the Touquoy Mine Site are located approximately 5.8 km to the north of the open pit along Caribou Road. The Touquoy facility is currently in operation. The primary effect of the continued use of the Touquoy Mine Site is the continued lighting of facilities and vehicular traffic during the processing of Beaver Dam ore. There are no new or additional effects from light anticipated to be caused by the processing of ore and the management of tailings (exhausted pit) from the Beaver Dam Mine Site, as no new construction or disturbance is required at the Touquoy Mine Site related to the processing of Beaver Dam ore. The effects of light previously described for the Touquoy Mine Site in the 2007 Focus Report (CRA 2007a) are presented in the Section 6.3.6.2.

The potential interactions identified for Beaver Dam Mine Site, the Haul Road, and the Touquoy Mine are presented in Tables 6.3-4 to 6.3-6.

Table 6.3-4: Potential Ambient Light Interactions with Project Activities at the Beaver Dam Mine Site

Project Phase	Duration	Relevant Project Activity
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Drilling and rock blasting in preparation of construction • Till and waste rock removal from site preparation transport and storage • Existing settling pond dewatering in preparation of construction • Watercourse and wetland alteration in preparation of construction • Mine Site road construction • Lighting of construction areas • Surface infrastructure installation and construction • Collection and settling pond construction • General management of wastes derived from preparation and construction activities
Operations and Maintenance	5 years	• Rock blasting to access and extract ore • Management of waste rock produced from crushing and preparing ore for transport • Petroleum products management • Site maintenance and repairs • Lighting of facilities and Beaver Dam Mine Site roads • Environmental monitoring of atmospheric environment • General management of wastes derived from operation and maintenance activities
Active Closure	2 years	• Infrastructure demolition • Site reclamation activities
Post-closure	10+ years (monitoring)	N/A

Note: N/A = not applicable.

Table 6.3-5: Potential Light Interactions with Project Activities along Haul Road

Project Phase	Duration	Relevant Project Activity
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of transport and storage • Till and waste rock from site preparation transport and storage • Watercourse and wetland alteration in preparation of construction • Haul Road upgrades
Operations and Maintenance	5 years	• Ore transport • Haul Road maintenance
Active Closure	2 years	• N/A[(a)]
Post-closure	10+ years (monitoring)	• N/A

Note: [(a)] Active Closure (i.e., decommissioning and reclamation) of the Haul Road is not expected. There is no plan to reclaim the Haul Road which is anticipated to conform with the existing and future land uses (i.e., forestry). N/A = not applicable.

Table 6.3-6: Potential Light Interactions with Project Activities at Touquoy Mine Site

Project Phase	Duration	Relevant Project Activity
Construction	1 year	• Tailings pipeline, make-up water pipeline alteration, and relocation of reclaim infrastructure
Operations and Maintenance	5 years	• Ore management and processing • Lighting of facilities and mine site roads
Active Closure	2 years	• N/A
Post-closure	10+ years (monitoring)	• N/A

Note: N/A = not applicable.

6.3.7.1 Beaver Dam Mine Site and Haul Road

A light impact assessment (Appendix D.1) was completed for the Project and included nine points of reception (Table 6.3-3 and Figure 6.3-2). For the purposes of this assessment, "pre-curfew" was assumed to be before 11 PM, and included road activity, and "post-curfew" was between 11 PM and 7 AM and included only overnight activities at the Beaver Dam Mine Site. The assessment of light impacts along the Haul Road was completed by considering a “worst case” scenario when two trucks are closest to each receptor and shining light towards the receptor. Because receptors along the Haul Road are not located on any road bends, with limited line of site to the travelling trucks, the assessed light impacts to these receptors were likely overestimated (Appendix D.1).

The calculated light levels at all receptors are below the limits recommended by the ILP guidelines during both pre- and post-curfew conditions (i.e., between 11 PM and 7 AM and before 11 PM; Table 6.3-7 and Figure 6.3-2). The assessment considers worst-case operating conditions, for example, if all mobile equipment was in use at the same time and illuminating towards the receptors and the potential for light from both the Beaver Dam Mine Site and the Haul Road trucks to affect a receptor in a cumulative way.

The calculated light levels from the Haul Road are also below the limits recommended by the ILP guidelines (Table 6.3-7 and Figure 6.3-2).

Table 6.3-7: Comparison of Light Levels at Receptors (2021)

Receptors	Illuminance (lux)		ILP Guidance Limit[a] (lux)		Percentage of Guidance Criteria	
	Pre-curfew[b]	Post-curfew	Pre-curfew[b]	Post-curfew	Pre-curfew[b]	Post-curfew
R1	8.49E-01	6.86E-02	5	1	16.97%	6.86%
R2	8.21E-02	8.21E-02	5	1	1.64%	8.21%
R3	7.88E-02	7.88E-02	5	1	1.58%	7.88%
R4	1.45E+00	6.57E-01	5	1	29.05%	6.57%
R5	8.06E-02	5.89E-02	5	1	1.61%	5.89%
R6	7.55E-02	5.84E-02	5	1	1.51%	5.84%
R7	4.88E+00	-	5	n/a[c]	97.5%	-[c]
R8	7.62E-02	-	5	n/a[c]	1.52%	-[c]
R9	1.39E+00	-	5	n/a[c]	23.73%	-[c]

Notes:

[a] Based on assumed classification of the area as Environmental Zone E2 – low district brightness areas (Guidance Note for the Reduction of Obtrusive Light [ILP 2020]).

[b] Curfew = the time after which stricter requirements for the control of obtrusive light will apply. If not defined by the local planning authority, the ILP suggest 11 PM (ILP 2020).

[c] Haul road operations will only occur between 7 AM and 11 PM (i.e., during pre-curfew hours).

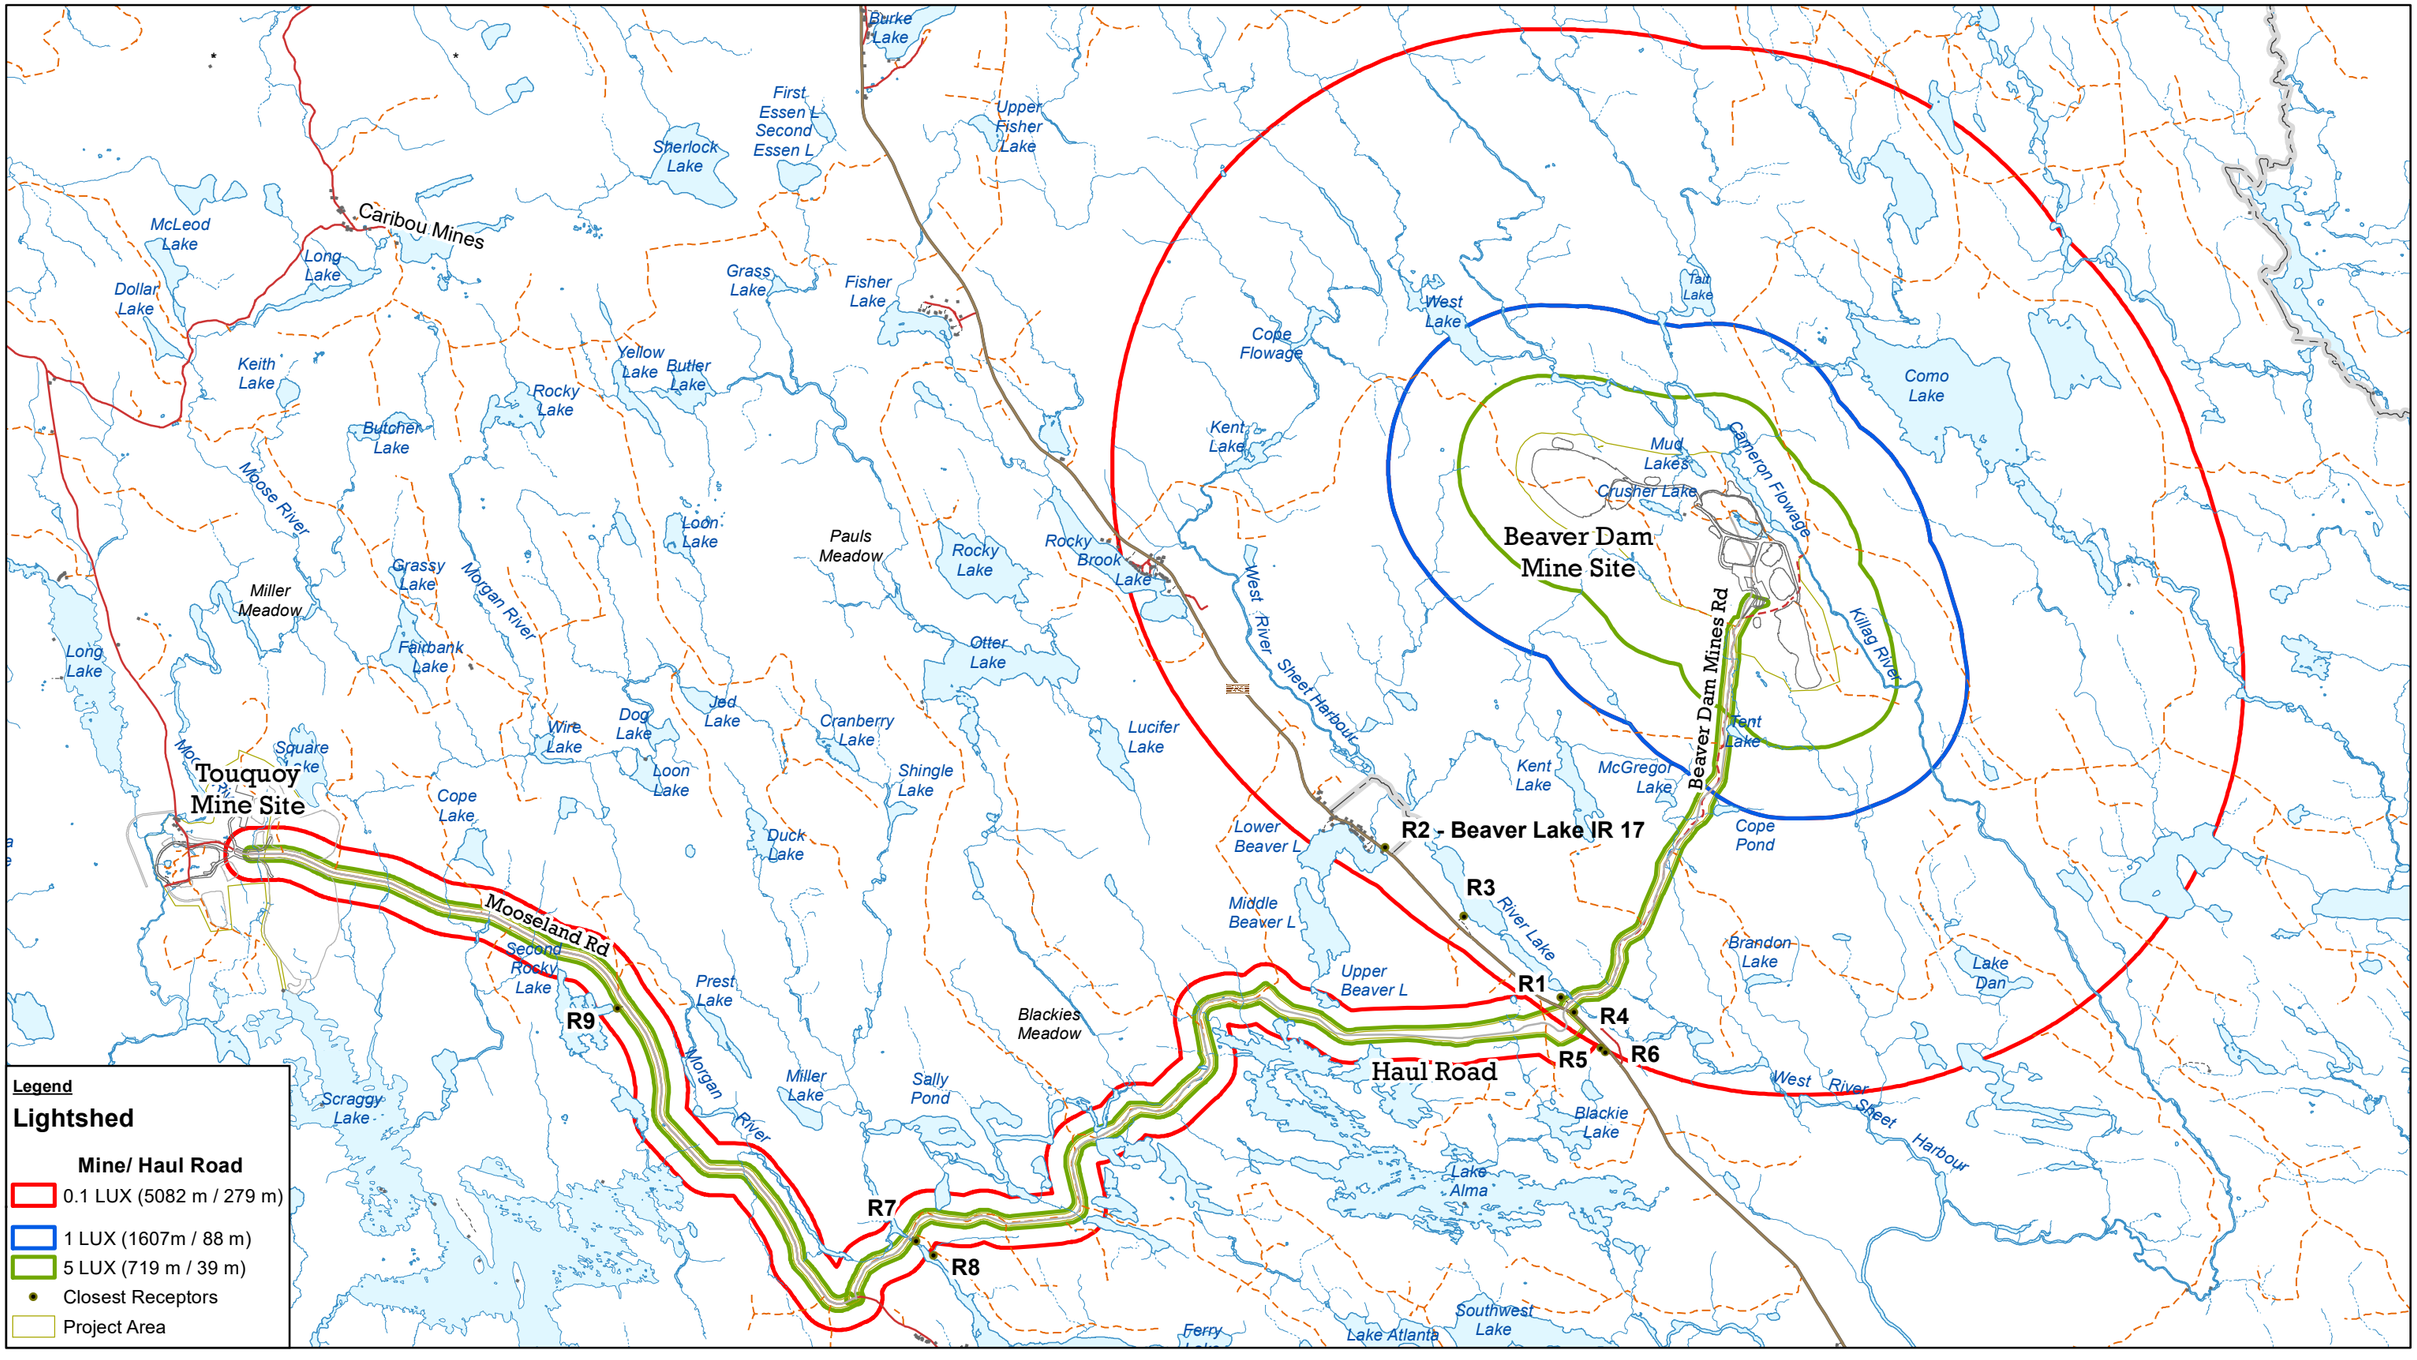
Lights will be installed in active construction and operational areas and at the Beaver Dam Mine Site, including site roads. Lights will be operational at all times to provide for a safe working environment. Vehicle headlights moving around the site as well as entering and exiting the site will also be introduced. Temporary lighting systems (including portable lights) may be used during construction to illuminate specific areas and ensure the safety of staff.

Increased light may cause disturbance or displacement of species, while attracting other species, or general behavioral changes (DaSilva, Valcu and Kempenaers, 2015). For those species which may be attracted to lights, lights may increase potential for direct mortality of these species or may increase habitat suitability by supplementing their source of prey. Birds may become attracted to or disoriented by open pit lighting at night, particularly during periods of migration, which could lead to mortality (Jones and Francis, 2003). Light can also alter habitat quality and sleep/wake cycles for terrestrial fauna within the immediate vicinity of the PA. This may decrease efficiency of nocturnal hunters. Some opportunistic wild species may be attracted to the site as a result of increased access and available food sources (natural prey or anthropogenic food sources), potentially increasing interactions between site personnel and wildlife. Interactions of light with wildlife, birds, and the Mi'kmaq of Nova Scotia is further discussed in Sections 6.11, 6.12, and 6.14.

Ambient night-time (i.e., post-curfew) light levels at the Beaver Dam Mine Site are predicted to meet the 1 lux guideline within 1.6 km from the site and as such not anticipated to affect the Beaver Lake IR 17 or other receptors. The Beaver Lake IR 17 is located approximately 5 km southwest of the Beaver Dam Mine Site and is separated from the Beaver Dam Mine Site by forest and two topographic ridges. These ridges block direct views from the houses to all work areas. The pit is located in a topographic depression and therefore, the distance to any sensitive receptor location would mitigate light effects. The lighting effects would have a lower intensity, although it could be more diffuse, especially if moisture or particulate matter are present in the atmosphere.

Distance to Sky Glow dissipation is summarized in Table 6.3-8 along with total luminous flux from the Beaver Dam Mine and Haul Road, and distance to the 5.0 lux and 1.0 lux assessment criteria. Table 6.3-8 shows the distance to a maximum 0.1 lux illuminance level which is considered as background light level for this assessment. Figure 6.3-2 shows the lightshed map depicting these distances. The lightshed map (Figure 6.3-2) shows that the light levels from the Beaver Dam Mine Site reach maximum 5 lux at a distance of 719 m from the source, maximum 1 lux light level at distance of 1,607 m from the source and maximum 0.1 lux (background level) at a distance of 5,082 m from the source. Table 6.3-8 and Figure 6.3-2 also show that during pre-curfew conditions when the Haul Road is in operation, when two trucks pass the same point simultaneously, the ambient light may be 5 lux or more out to a maximum distance of 39 m from the Haul Road (on an instantaneous basis, this will not be a continuous light level, it will occur only where two trucks are passing each other, and only for the brief period they are both affecting the same receptor). At a distance of 279 m, the light under these same conditions will be less than 0.1 lux (or less than background) (Appendix D.1). This map will inform the response to IR2 CEAA 2-05 in consideration of Beaver Lake IR 17 and areas identified for current use practices and shows light trespass from Beaver Dam Mine Site and Haul Road traffic to be discussed in Section 6.14.

Table 6.3-8: Distance to Sky Glow Dissipation



Component	Total Luminous Flux (Lumens)	Distance to Below 5.0 Lux (m)	Distance to Below 1.0 Lux (m)	Distance to Below 0.1 Lux (m)
Beaver Dam Mine Site (Based on 50% incident light)	5,165,700	719	1,607	5,082
Haul Road (Based on 50% incident light)	15,600	39	88	279

Source: ILP 2020.

Notes: 1.0 lux is approximately the brightness of a full moon under a clear sky.

0.1 lux is less bright than a full moon, but brighter than a moonless night.

On particularly overcast nights, sky glow may be visible farther due to reflection from low cloud cover.

FIGURE 6.3-2

GIS File: N:\CA\Halifax\Projects\661\088664\GIS\Maps\Deliverables\088664-REPORT\088664-RPT(017)\088664(017)GIS-HX011.mxd

The resulting area of illumination elevated above background conditions (sky glow) from the Beaver Dam Mine Site will be seen within 5,082 m. This encompasses receptors R1, R2, R3, and R4 (Figure 6.3-2). The predicted illuminance levels represent the worst-case operating conditions of the Beaver Dam Mine Site. The assessment considers when all of the mobile equipment at the mine would be in use at the same time, illuminating towards receptors. The areas surrounding the site are wooded with varying topography and inhibit the spread of light. It was conservatively assumed for screening purposes that 50% of the light will not reach the receptors due to directionality and line of sight obstructions. The amount of light blocked by the surrounding woodland and topographic changes, however, will likely be much greater than this (>90%), especially during the seasons when deciduous trees are leaf on (Appendix D.1). It is therefore, not expected that the illumination will cause any significant visual impact, due to a combination of distance and the screening effects of topography and vegetative cover.

Section 5 of Light Impact Assessment Report (Appendix D.1) provides details relating to the modelling methodology for the Project light effects as well as potential cumulative effects from the shared proposed usage of the Beaver Dam Haul Road by trucks from the Fifteen Mile Stream Gold Project, the Cochrane Hill Gold Project, and current baseline forestry activity. Conclusions relating to this potential cumulative effects are described in Section 8.

6.3.7.2 Touquoy Mine Site

The predicted light spill anticipated to occur at the identified points of reception (Camp Kidston, Scraggy Lake Area and the nearest residence) ranges between 0.0587 and 0.294 lux, well below the established 1 lux threshold used at the Touquoy Mine Site for the Touquoy Gold Project (CRA 2007a).

The primary effect of the continued use of the Touquoy Mine Site is the continued lighting of facilities and vehicular traffic during the processing of Beaver Dam ore. There are no new or additional effects from light anticipated to be caused by the processing of ore and the management of tailings from the Project that would affect the conclusions presented above for the Touquoy Mine Site based on the Touquoy Gold Project evaluation of light.

Effects to wildlife, birds, and Mi'kmaq of Nova Scotia from light are further discussed in Sections 6.11, 6.12, and 6.14.

Although the light impacts from the Touquoy Mine Site and Beaver Dam Mine Site were not evaluated in combination, it is expected that the ILP limits at nearby receptors will not be exceeded from light trespass at both facilities. This is expected due to the low illuminance levels assessed at each receptor in both assessments and due to the large distances from the receptors to the sources of light at the other facilities. For example, the Beaver Lake IR 17 sits on the edge of the potential sky glow dissipation to background point (approximately 5 km) from Beaver Dam Mine Site but over 13 km from Touquoy Mine Site so it would be well outside the sky glow of the Touquoy Mine so would not be impacted by both sites. Conclusions relating to potential cumulative effects are described in the Cumulative Effects Section (Section 8).

6.3.8 Mitigation

The use of lights will be limited to the amount necessary to ensure safe operation, with the recognition that excessive lighting can be disruptive to wild species. Light pollution will be reduced by installing downward- facing lights on site infrastructure and Mine Site roads, as well as at the Touquoy Mine Site. Wherever possible, motion-sensing lights will be installed to ensure lights are not turned on when they are not necessary. Only direct and focused light will be used for worker safety.

Bird collisions with Project lighting and subsequent mortality are expected to be rare, but if it occurs, it will not likely have significant effects on migratory birds (Section 6.12). Efforts will be made to reduce the effect of lighting on migrating birds. Practices will be reviewed on an annual basis for BAPs, including illumination. No additional monitoring is recommended for the Project related to night-time light levels.

Ore will be hauled to the Touquoy Mine Site for approximately 16 hours per day (i.e., 7 AM to 11 PM) during the operation phase. The Haul Road will not be used for ore transport during post-curfew period (i.e., 11 PM to 7 AM), although maintenance activities may occur.

Table 6.3-9: Mitigation for Light

Project Phase	Mitigation Measures
C	Temporary lighting will be directly focused on work areas and shielded where practicable to avoid light trespass
C, O, CL	Use of only downward-facing lights on site infrastructure and Mine Site roads
C, O, CL	Install motion-sensing lights, where practicable
C, O, CL	Only use direct and focused light when needed for worker safety
C, O, CL	All floodlights will employ full horizontal cutoff, as appropriate
C, O, CL	Lighting not in use will be turned off, whenever practicable
C, O, CL	Site perimeter lighting will be directed to minimize light offsite light trespass
C, O, CL	Utilize efficient sources of light to reduce overall magnitude of light, wherever practicable
C, O, CL	A procedure, including a response plan, will be available for public to be able to register complaints regarding light concerns

Note: C = construction; O = operations; CL = active closure.

6.3.9 Residual Effects and Significance

During the construction and operation of the Beaver Dam Mine Site and Haul Road, ambient lighting will increase, noticeably at first as an offset to the original undeveloped area. Increases in and the subsequent effects of light on potential receptors can be minimized through effective lighting design and operational schedule. Ongoing monitoring of site activity will inform on areas where light reductions are warranted.

Given the distance of the Beaver Dam Mine Site and Haul Road to surrounding properties/residences, the natural topography and vegetation, the modelling has shown no significant adverse effects due to light trespass into a receptor from the site or Haul Road will be experienced.

The predicted residual environmental effects of Project on ambient light are assessed to be adverse, but not significant. The overall residual effect of the Project on light is assessed as not likely to have significant adverse effects after proven mitigation measures have been implemented.

Table 6.3-10: Residual Effects for Light

Project - VC Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction and Active Closure – Beaver Dam Mine Site and Haul Road (Lights from haul trucks, site lighting)	Equipment maintenance, limited vegetation clearing.	L (qualitative assessment only – predicted to be less light propagation than operations phase described below)	RAA Lighting impacts may extend beyond the PA	A Seasonal aspects may affect VC (i.e., daylight hours)	MT Effects can occur beyond 12 months and up to 3 years	S Effects occur at regular intervals throughout the Project	R VC will return to baseline conditions	Increased ambient light	Not significant
Operational – Beaver Dam Mine Site, Haul Road, Touquoy Mine Site (Lights from haul trucks, site lighting)	Equipment maintenance, haul truck operation <24 hours per day, minimize lighting (downward facing lighting, motion sensor lights, light positioning away from property boundaries were practical).	L Less than or equal to appropriate guidelines or threshold values	RAA Lighting impacts may extend beyond the PA	A Seasonal aspects may affect VC (i.e., daylight hours)	LT Effects may extend beyond 3 years	R Effects occur at regular intervals throughout the Project	R VC will return to baseline conditions	Increased ambient light	Not significant

Notes: See Section 5.11, Table 5.11-1 for definitions of the below characteristics.

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	IR	Irreversible
M	Moderates	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	PR	Partially Reversible
H	High					P	Permanent	C	Continuous		

A significant adverse environmental effect for light has not been predicted for the Project for the following reasons, with consideration of the ecological and social context of the RAA surrounding the Project:

- During Construction: Light will be elevated above baseline conditions potentially extending into the RAA. However, light spill will be limited by surrounding topography prior to reaching the nearest receptors. Given the remote location of the Project the likelihood of mobile receptors being regularly in close proximity to light generation sites is very low. Light trespass has been qualitatively assessed during construction and is predicted to be lower than during operations, which was modelled and is described below.
- During Operations: Light spill is predicted to extend a maximum of 5 km from the Beaver Dam Mine Site into the RAA for the Project. However, light levels will be limited by surrounding topography prior to reaching the nearest receptors and given the remote location of the Project the likelihood of mobile receptors being regularly in close proximity to light generation sites is very low.
- During Active Closure: Light levels will be elevated above baseline conditions potentially extending into the RAA during decommissioning activities, then drop to baseline conditions for the post closure period. Light trespass has been qualitatively assessed during Closure and is predicted to be lower than during operations, which was modelled and is described above.

6.3.10 Proposed Compliance and Effects Monitoring Program

The applicable thresholds for light are expected to be met within 1.6 km of the Beaver Dam Mine Site and 39 m of the Haul Road. Routine monitoring of the light levels at the Beaver Dam Mine Site, once constructed and operational, using a light meter will provide an opportunity to monitor light levels. More refined light level measurements could assist in further quantifying the effects of light sources on the sensitive receptors. A Complaints Protocol will be followed to provide a mechanism to register concerns and discuss them with Project representatives. Additional ambient light monitoring would occur if directed by regulators or as a result of a complaint.

Proposed follow-up and monitoring programs have been reviewed with the Mi'kmaq of Nova Scotia during engagement efforts including meetings, sharing of technical documents (Draft Impact Statement, Proposed Mitigation Measures, Plain Language Summary). On-going engagement with the Mi'kmaq will continue through the EA process and associated permitting relating to follow-up programs and monitoring.

6.4 Greenhouse Gases

6.4.1 Introduction

6.4.1.1 Summary of Greenhouse Gases Before the Updates

The Greenhouse gases (GHG) effects assessment outlines the project boundaries and thresholds for determination of significance. The effects assessment identifies the sources and GHG emission estimates for each phase, Project site and the projected contribution of Project GHG emissions to the total Nova Scotia GHG emissions. A summary is provided of the key issues raised during engagement related to atmospheric environment along with Atlantic Mining NS Inc. (AMNS) commitments on mitigations and monitoring measures. The predicted residual environmental effects of the Project on the atmospheric environment are assessed and the significance of these effects are determined. The proposed compliance and effects monitoring program is outlined.

6.4.1.2 Summary of Updates to Greenhouse Gases

The GHG effects assessment has been updated to identify the primary source of GHG emissions as diesel fuel use from diesel power generators and haul road trucks. Updated emulsion and GHG emission estimates have been provided for the Beaver Dam Mine Site, Haul Road and Touquoy Mine Site.

Table 6.4-1: Updated Subsections from the 2019 Revised Environmental Impact Assessment – Greenhouse Gases

Notes: GHG = greenhouse gases; - = no update; EIS = environmental impact statement; N/A = not applicable.

6.4.2 Rationale for Valued Component Selection

GHGs are drivers of climate change, which are created through the combustion of fuel during equipment operation, blasting within the pit, and vehicle use associated with project activities. GHGs are the focus of provincial policies and regulations for the electricity sector; however, there exists no province-wide standard for greenhouse gas emissions.

6.4.3 Baseline Program Methodology

No additional preliminary baseline monitoring was completed for greenhouse gases, separate from air quality. See Section 6.2 Air, specifically Sections 6.2.3 and 6.2.4 for baseline air quality monitoring methodology and results, as well as local and regional air quality.

6.4.4 Baseline Conditions

6.4.4.1 Provincial and Federal Greenhouse Gas Limits

The National Pollutant Release Inventory (NPRI) is Canada's legislated and publicly accessible inventory of pollutant releases to air, water, and land. The NPRI is managed by Environment and Climate Change Canada (ECCC) and currently tracks over 300 substances and groups of substances (NPRI 2021). Under the authority of the *Canadian Environmental Protection Act* (CEPA), owners or operators of facilities that meet the NPRI reporting requirements published in the Canada Gazette, Part I are required to report to the NPRI.

Accurate tracking of GHG emissions is an important part of assessing Canada's overall environmental performance. In March 2004, the Government of Canada announced the introduction of the Greenhouse Gas Emissions Reporting Program. All facilities that emit the equivalent of 50 kilotonnes (kt) or more of GHGs in carbon dioxide equivalent units (CO_2e) per year are required to submit a report. Facilities with emissions falling below the reporting threshold of 50 kt per year can voluntarily report their GHG emissions. AMNS voluntarily reports GHG at the Touquoy Mine and will continue to do so should Beaver Dam Mine Project be approved.

In 2009, Nova Scotia Environment (NSE) released the Greenhouse Gas Emissions Regulations, made under Section 112 of the *Environment Act*, establishing GHG emission caps on the electricity sector. These regulations apply to any facility located in the

province of Nova Scotia that emits greater than 10 kt of CO_2e GHGs in a calendar year. The facility owner must submit an annual report no later than March 31 of the following year. AMNS reports on GHG at Touquoy as required in the Industrial Approval.

The Beaver Dam Mine Site is located in a relatively undeveloped rural region of Nova Scotia with infrequent industrial operations that would contribute to GHG emissions. Existing GHG emissions would be generated primarily through recreational vehicle usage, local traffic, and limited forestry operations.

The ECCC document, "National Inventory Report 1990-2018: Greenhouse Gas Sources and Sinks in Canada – Part 3" (ECCC 2020), the total GHG emissions from Nova Scotia were identified to be 17,000 kt CO_2e during 2018.

6.4.5 Consideration of Engagement Results

Key issues raised during public consultation and Mi'kmaq engagement relating to atmospheric environment include potential dust and noise from mining operations at the Project and trucking along the Haul Road. The change to the Haul Road, through the construction of 4 km of new road to bypass the residence include those from the Millbrook First Nation Beaver Dam IR 17 was undertaken in to address concerns. Concerns about GHG emissions specifically associated with the trucking/hauling ore were also noted.

The results of the public and Mi'kmaq engagement have been considered in the environmental effects assessment, including AMNS commitments on mitigation and monitoring measures and proposed compliance and effects monitoring programs, as well as AMNS's broader commitment to ongoing public and Mi'kmaq engagement. AMNS will continue to evaluate opportunities to reduce GHGs at their existing and proposed operations. Additional information on climate change and GHG is provided in the Project Description (Section 2.1).

6.4.6 Effects Assessment Methodology

6.4.6.1 Boundaries

6.4.6.1.1 Spatial Boundaries

The spatial boundary used for GHGs are described below:

- The Project Area (PA) encompasses three primary components from Marinette to Moose River Gold Mines, Halifax County, NS. The Beaver Dam Mine Site will be located at the end of the Beaver Dam Mines Road, and the Haul Road will span from the Beaver Dam Mine Site to Moose River Gold Mines, where the Touquoy Mine (processing and exhausted pit [to be used to dispose Beaver Dam Mine tailings]) is located.
- The Local Assessment Area (LAA) encompass a 15 kilometre (km) zone in all directions from the PA, based on the expected maximum extent of potential ground level emissions (Figure 6.4-1).
- The Regional Assessment Area (RAA) encompasses the province of Nova Scotia. GHG emissions will be compared to Nova Scotia targets and totals (Figure 6.4-1).

As the Project has the potential to cause direct and indirect effects of GHGs, as well as cumulative effects compounded spatially and temporally from other Projects, the RAA is the most appropriate spatial boundary.

6.4.6.1.2 Temporal Boundaries

The temporal boundaries used for the assessment of effects to GHGs are the construction phase, operational phase, and active closure phase.

6.4.6.1.3 Technical Boundaries

No technical boundaries were identified for the effects assessment of GHGs.

6.4.6.1.4 Administrative Boundaries

In 2009, NSE released the Greenhouse Gas Emissions Regulations, made under Section 112 of the *Environment Act*, establishing GHG emission caps on the electricity sector. These regulations apply to any facility located in the province of Nova Scotia that emits greater than 10 kt of CO_2e GHGs in a calendar year. The facility may be required to report to the NPRI an inventory of pollutant releases to air, water, and land. There exists no province-wide standard for GHG emissions.

There may be other requirements for monitoring of the atmospheric environment through provincial approvals to be obtained prior to the start of the Project, specifically the Industrial Approval.

6.4.6.2 Thresholds for Determination of Significance

The *Nova Scotia Environmental Goals and Sustainable Prosperity Act*, requires a reduction in provincial GHGs of at least 10 percent (%) below 1990 levels by the year 2020 (NS 2019). The *Environmental Goals and Sustainable Prosperity Act* 2017–19 Progress Report (NS 2019) indicated that NS achieved the goal for reducing greenhouse gas emissions four years early (2016), which is approximately 18% below 1990 levels. The electricity sector is responsible for about half of the province's GHG emissions. Guidance for targets to that industry are specific in regulation both provincially and federally. To achieve these reductions, Nova Scotia has imposed emissions caps on electricity generation sector for 2025 and 2030 and is working to increase efficiency in the transportation sector. Reduction of the use of electricity from fossil fuels helps to meet these targets through use of energy efficient LED lighting and low-emission sourced renewable power (e.g., solar, wind, water).

The transportation sector generates about a quarter of the province's GHG emissions. Reductions in GHG from onsite mining activity can be achieved implementing no idling policies, burning low-sulphur fuels, and regular equipment maintenance.

Table 6.4-2 provides a summary of the characterization criteria used to assess residual impacts. Although there is no province or national wide standard for GHGs it is important to select a range of criteria for monitoring impact predictions. As a result, in the absence of standards relative change from 2018 levels provide a suitable alternative to determine magnitudes.

Table 6.4-2: Greenhouse Gas Characterization Criteria for Residual Effects

Criteria	Greenhouse Gases Impact Description
Magnitude[(a)]	• **Negligible:** GHGs are predicted to be less than 0.1% of NS 2018 (CO_2e) levels. • **Low:** GHGs are predicted to be greater than 0.1% but less than 0.2% of NS 2018 (CO_2e) levels. • **Medium:** GHGs are predicted to be greater than 0.2% but less than 0.3% of NS 2018 (CO_2e) levels. • **High:** GHG's are predicted to greater than 0.3% of NS 2018 (CO_2e) levels.
Geographical Extent	• **Discrete:** effect is limited to the immediate footprint or Project Area (PA). • **Local:** effect is limited to the near-field Local Assessment Area. • **Regional/Provincial/National**: effect persists to regional, provincial and national scale.
Timing	• N/A
Duration	• **Short term:** effect does not extend beyond 1 year of the Project. • **Medium term:** greater than 1 year and over the life of the project (1 year construction, 5 years operation and 2 years active closure). • **Long term:** Effects persist to post-closure 10+ years. • **Permanent:** Effects represent a permanent change.
Frequency	• **Intermittent:** VC interaction or effect will occur at intermittent intervals throughout any Project Phase. • **Regular:** effect occurs on a regular basis but not continuous basis. • **Continuous:** effect occurs constantly.
Reversibility	• **Reversible:** effect can be reversed. • **Partially reversible:** effect can be partially reversed. • **Irreversible:** effect cannot be reversed, is of permanent duration.

Notes: [(a)] GHGs predications are based on Nova Scotia's GHG emissions submitted in 2018 (ECCC 2020) and emissions rates provided in Table 6.4-5 and 6.4-6.
GHG = greenhouse gases; % = percent; NS = Nova Scotia; CO_2e = carbon dioxide equivalents; N/A = not applicable.

Residual effects of the Project on from GHGs are described using standard criteria, including magnitude, geographical extent, duration, frequency, reversibility, and context of the effect (Table 6.4-2). The residual effects assessment concludes with a determination of Significance. Residual effects after mitigations determines "Not Significant" or "Significant" according to the following definitions:

- **Not Significant Residual Effect:** GHG VC is defined as, negligible to low magnitude, a regional, provincial, and national scale and of short to medium term duration, occurring continuously and are reversible.
- **Significant Residual Effect:** GHG is defined as residual effects have medium to high magnitude, a regional, provincial and national scale and of long-term duration, occur at continuous frequency and only be partially reversible to irreversible.

6.4.7 Project Activities/Interactions with Greenhouse Gas

The key sensitive receptor in the area is the Beaver Lake Indian Reserve (IR) 17; a satellite community of the Millbrook First Nation located approximately 5 km south of the Beaver Dam Mine Site. A permanent resident, seasonal camps and cottages are also located along the Beaver Dam Mines Road near Highway 224. Camp Kidston, which operates only in the summer months, is approximately 3.5 km northeast of the site. According to AMNS, the nearest permanent full-time occupied residences are located approximately 5.8 km to the north of the Touquoy Mine Site open pit along Caribou Road.

The Touquoy Mine Site is currently in operation. The primary effect of the continued use of the Touquoy Mine Site is the continued generation of GHG emissions during the processing of Beaver Dam Mine ore. There are no new or additional effects to GHGs anticipated to be caused by the processing of ore and the management of tailings (exhausted pit) from the Project, as no new construction or disturbance is required at the Touquoy Mine Site related to the processing of Beaver Dam Mine ore. The effects to GHGs previously described for the Touquoy Mine Site in the Environmental Assessment Registration Document (EARD) (CRA 2007a) and Focus Report (CRA 2007b) are presented in Table 6.4-5.

Table 6.4-3: Potential Project Activities/Interactions with Greenhouse Gas at Beaver Dam Mine Site

Project Phase	Duration	Project Interaction
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Drilling and rock blasting in preparation of construction • Till and waste rock from site preparation transport and storage • Watercourse and wetland alteration in preparation of construction • Mine Site road construction • Haul road construction • Lighting of construction areas • Surface infrastructure installation and construction • Collection and settling pond construction • General management of wastes derived from preparation and construction activities
Operation and Maintenance	5 years	• Rock blasting to access and extract ore • Management of waste rock produced from crushing and preparing ore for transport • Petroleum products management • Site maintenance and repairs • Lighting of facilities and Mine Site roads • General management of wastes derived from operation and maintenance activities
Active Closure	2 years	• Infrastructure Demolition • Site reclamation activities
Post-closure	10+ years (monitoring)	• N/A

Note: N/A = not applicable.

Table 6.4-4: Potential Project Activities/Interactions with Greenhouse Gas along Haul Road

Project Phase	Duration	Project Interaction
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Drilling and rock blasting in preparation of construction • Till and waste rock from site preparation transport and storage • Watercourse and wetland alteration in preparation of construction • Haul Road construction and upgrades
Operation and Maintenance	5 years	• Ore transport • Road lighting • Haul Road maintenance and repairs
Active Closure	2 years	• N/A[(a)]
Post-closure	10+ years (monitoring)	• N/A

Note: [(a)] Decommissioning and Reclamation of the Haul Road is not expected. The Haul Road will be returned to owner for forestry industry.
N/A = not applicable.

Table 6.4-5: Potential Project Activities/Interactions with Greenhouse Gas at Touquoy Mine Site

Project Phase	Duration	Project Interaction
Construction	1 year	• Tailings pipeline, make-up water pipeline alteration, and relocation of reclaim infrastructures
Operation and Maintenance	5 years	• Ore management and processing • Lighting of facilities and Mine Site roads
Active Closure	2 years	• Decommissioning and reclamation activities
Post-closure	10+ years (monitoring)	• N/A

Note: N/A = not applicable.

The primary sources of GHG emissions were considered for each phase of the Project (construction, operation, and active closure). The primary sources of emissions from each work phase are stationary and mobile fuel combustion sources. These fuel combustion GHG-specific emissions include carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O). During the construction and operation phase of the Beaver Dam Mine Site, GHG emissions that would be generated from explosives used in rock blasting were also considered. For rock blasting, the explosive considered is emulsion (30% Ammonium Nitrate Fuel Oil [ANFO] and 70% emulsion), which is an explosive used by AMNS at other project sites. Under ideal conditions, the sole GHG emission from this explosive is CO_2, though small amounts of CH_4 and N_2O may also form as a result of the combustion. For the purposes of these emission estimates, it has been assumed the emulsion will be combusting under ideal conditions, with the primary CO_2 emissions being included only.

Other key assumptions used as part of the GHG emission estimates include:

- Sources of stationary and mobile combustion are operational 24 hours a day during the mine operation phase and during the construction and decommissioning phases would be limited to 16 hours. Down-time for equipment is assumed to occur up to 10 days out of a year due to weather conditions. This is a conservative estimate as additional downtime would be required for equipment maintenance/repair during this period.
- The primary source of GHG emissions is diesel fuel use. Estimates for diesel fuel use have been made for the construction, operation and active closure phases. Diesel emissions occur from mine diesel power generators and from the haul road trucks.

- The emulsion use during the operation phases has been estimated by AMNS based on prior mining experience at similar sites to be approximately 3,744 tonnes/year.

6.4.7.1 Beaver Dam Mine Site and Haul Road

The projected GHG emission estimates for the life of the Project, based on the available information, are presented in Table 6.4-6. It is expected that as the phase milestone activities approach, the information driving the emissions estimates below can be refined based on known rather than projected data.

Table 6.4-6: Predicted Greenhouse Gas Emissions (Beaver Dam Mine Site and Haul Road)

Phase	Period	Greenhouse Gas	Phase Emissions	
			(tonnes)	Tonnes CO_2e
Primary Haul Road and Mine Construction	2022	CO_2	2,408.16	2,426.19
		CH_4	0.05	-
		N_2O	0.05	-
Operation	2023 to 2027	CO_2	39,928.46	40,638.55
		CH_4	1.01	-
		N_2O	2.30	-
Active Closure	2028 to 2029	CO_2	8,970.17	9,114.01
		CH_4	0.21	-
		N_2O	0.47	-

Note: CH_4 = Methane; CO_2 = Carbon dioxide; CO_2e = Carbon dioxide equivalents; N_2O= Nitrous Oxide; - = not applicable.

GHG emissions from Nova Scotia reported in 2018 were 17,000 kt CO2e (ECCC 2020). Based on the Project GHG assessment, in an average full year of operation of the Project (most GHG-intensive phase), the site would emit 8.13 kt CO2e - approximately 0.05% of the reported 2018 GHG total for Nova Scotia.

6.4.7.2 Touquoy Mine Site

At the Touquoy Mine Site, GHG emissions will be generated from light and mobile fuel combustion sources, as well as emissions from the processing plant during the period of full-scale operations (2022 to 2029). The projected annual GHG emission estimates for the Touquoy Mine Site, based on the 2019 GHG emissions reported to the NPRI, is presented in Table 6.4-7.

Table 6.4-7: Estimated Greenhouse Gas Emissions (Touquoy Mine Site)

Phase	Period	Greenhouse Gas	Phase Emissions	
			(tonnes)	Tonnes CO2e
Maximum Annual Emissions	2022 to 2029	CO_2	13,183.2	13,560.8
		CH_4	1.3	-
		N_2O	0.2	-

Note: CH_4 = Methane; CO_2 = Carbon dioxide; CO_2e = Carbon dioxide equivalents; N_2O= Nitrous Oxide; - = not applicable.

GHG emissions from Nova Scotia reported in 2018 were 17,000 kt CO_2e (ECCC 2020). The 2019 GHG emissions for the Touquoy Mine Site was 13.56 kt CO_2e - approximately 0.08% of the reported 2018 GHG total for Nova Scotia.

6.4.7.3 Overall Project

In an average full year of operation of the Project (most GHG-intensive phase), including operation of the Beaver Dam Mine Site, hauling of ore, and the processing of ore at the Touquoy facility, the Project facilities would emit 21.69 kt CO_2e - approximately 0.128% of the reported 2018 GHG total for Nova Scotia (ECCC 2020).

6.4.8 Mitigation

AMNS will take steps to minimize GHG emissions associated with the Project, through activities such as reducing engine idling, where possible, and considering the use of more fuel-efficient vehicles and equipment. GHG emissions will also be minimized through the adoption of good maintenance practices, including undertaking regular maintenance as specified by suppliers. A review of emissions will be completed on an annual basis. AMNS will seek to use Best Available Practices (BAP) that will evolve over time.

Mitigation measures at the Touquoy Mine processing facility are also described in the Air Quality Management Plan that was completed as part of the Industrial Approval application for this facility. These mitigation measures include regular equipment maintenance, choosing more efficient equipment and vehicles, and reduction of vehicle travel distances and idling where possible. These mitigation measures are anticipated to continue throughout the life of the Project.

Table 6.4-8: Mitigation for Greenhouse Gases

Project Phase	Mitigation Measure
C, O, CL	Limit engine idling, where practicable
C, O, CL	Implement fuel efficiencies, where practicable
C, O, CL	Implement preventative maintenance plans for all mobile and stationary equipment.
C, O, CL	Use renewable energy where reasonable (e.g., solar-powered lights)

Notes: C = Construction; O = Operations; CL = Active Closure.

6.4.9 Residual Effect and Significance

The predicted residual environmental effects of Project development and production on the atmospheric environment are assessed to be adverse, but not significant. The overall residual effect of the Project on GHGs is assessed as not likely to have significant adverse effects after mitigation measures have been implemented.

Table 6.4-9: Residual Environmental Effects for Greenhouse Gases

Project - VC Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction – Beaver Dam Mine Site and Haul Road (Haul Road widening and construction, use of heavy machinery, haul trucks and site vehicle emissions)	Equipment maintenance, implementing fuel efficiencies, limited engine idling, use of more fuel efficient vehicles.	L	RAA	N/A	ST	C	R	Increased greenhouse gas emissions during operations	Not Significant
Operation – Beaver Dam Mine Site, Haul Road and Touquoy Mine Site (Emissions from haul trucks, site vehicles, heavy machinery, blasting and drilling of in-situ rocks)	Equipment maintenance, implementing fuel efficiencies, minimizing blasts, limited engine idling, use of more fuel efficient vehicles.	L	RAA	N/A	MT	C	R	Increased greenhouse gas emissions	Not Significant
Active Closure – Beaver Dam Mine Site (Emissions from haul trucks, site vehicles, heavy machinery)	Equipment maintenance, implementing fuel efficiencies, limited engine idling, use of more fuel efficient vehicles.	N-L	RAA	N/A	MT	I	R	Increased greenhouse gas emissions	Not Significant

Notes: See Table 6.4-2 for definitions of the below characteristics and Section 5.11, Table 5.11-1.

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	I	Intermittent	IR	Irreversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	PR	Partially Reversible
H	High					P	Permanent	C	Continuous		

A significant adverse environmental effect for GHG has not been predicted for the Project for the following reasons, with consideration of the ecological and social context of the LAA surrounding the Project:

- **During Construction:** GHG will be elevated above baseline but not a significant contributor with a low magnitude (above 1% NS 2018 levels) that will be intermittent and short-term in duration and reversible.
- **During Operations:** GHG will be elevated above baseline during this period but not a significant contributor with a low magnitude (i.e., combined 21.69 kt CO_2e 21.69 kt CO_2e - approximately 0.128% above NS 2018 levels) that will be continuous but mid-term in duration and reversible.
- **During Active closure:** GHG will be elevated above baseline but expected to be negligible in magnitude (i.e., less that 0.1% above NS 2018 Levels) intermittent to allow for earthworks and reclamation activities and medium-term duration (i.e., 2 years in duration) and reversible.

Mitigations presented in Table 6.4-8 will be established to reduce the impact to GHGs from Project activities.

6.4.10 Proposed Compliance and Effects Monitoring Program

GHG monitoring reporting will be completed to verify the predicted environmental effects and the effectiveness of the mitigation measures outlined in Table 6.4-8. An Air Quality Management Plan will be developed as part of the Industrial Approval application for the Beaver Dam Mine Project. In addition, GHG emissions will be reviewed on an annual basis throughout the construction, operation and closure.

6.5 Geology, Soils, and Sediment Quality

6.5.1 Introduction

6.5.1.1 Summary of Geology, Soils, and Sediment Quality Before the Updates

Prior to updates, Section 6.5 described the methods and results of baseline characterization as well as predictive studies that were undertaken to support characterization of potential Project effects on the Geology, Soils, and Sediment Quality Value Component (VCs). Geology, Soils, and Sediment Quality represent physical components of the natural environment.

Prior to updates, the Geology, Soils, and Sediment Quality assessment was developed to incorporate quantitative data from baseline reports as well as geochemical test-work and prediction of the potential for metal leaching and acid mine drainage (ML/ARD). The subsequent assessment of residual effects incorporated mitigation and management plans for Project effects and, although residual effects were identified, they were characterized as Not Significant.

Changes related to Geology, Soils and Sediment Quality VC s provided in Section 6.5 were used to support the Effects Assessment on water quality, fish and fish habitat, and wetlands.

6.5.1.2 Summary of Updates to Geology, Soils, and Sediment Quality

The Geology, Soils, and Sediment Quality EA for the Project has been updated to reflect updates of the Project Description (Section 2) and to address Round 2, Information Requests (IR2) issued by the Impact Assessment Agency of Canada (IAAC, formerly the Canadian Environmental Assessment Agency [CEAA 2019]) and Nova Scotia Environment (NSE 2019). This includes:

- Compilation of soil sediment quality results, including results from 2019 (Stantec 2019a) and 2020 (Stantec 2020) field surveys for the Beaver Dam Mine Site and are included in Appendix E.7 and E.8, respectively;
- Updated metal leaching and acid rock drainage assessment (ML/ARD) and description of the geochemical baseline based on ongoing test-work for the Project (Appendix E.2);
- Updated kinetic test-work results and geochemical source terms for the Project, including predictions of drainage quality (Appendix E.3 and Appendix E.4);
- Updated ML/ARD Management Plan (Appendix E.5);
- Nitrogen Monitoring Plan (Appendix P.3) and
- Beaver Dam Mine Project Geotechnical Investigation (Appendix A.2c).

Notes: PA = Project Area; LAA = Local Assessment Area; RAA = Regional Assessment Area- = no update; CEAA = Canadian Environmental Assessment Agency; EIS = Environmental Impact Statement; IR2 = Round 2. Information Requests; NSE = Nova Scotia Environment; CEAA = Canadian Environmental Assessment Area.

6.5.2 Rationale for Valued Component Selection

A component, to be considered for assessment, must be of recognized as important to a society, the local community, or the environment, and there must be a perceived likelihood that the component will be affected by the proposed Project. Geology, Soils, and Sediment Quality represent physical attributes of the environment that, if affected (i.e., there is a positive or negative change in the baseline condition), act as a pathway to pass on those changes to biological components of the environment and/or other receptors (such as surface water quality, wetlands, and fish and fish habitat) thereby having the potential to also affect or change the baseline condition of those VCs.

Geology, Soils, and Sediment Quality as a VC is centered on the potential for Metal Leaching and Acid Rock Drainage (ML/ARD). Metal leaching (ML) refers to the process by which metals that are bound to minerals are mobilized in an aqueous solution. Acid Rock Drainage (ARD) occurs when sulphide minerals are exposed to oxygen and water and naturally oxidize without the presence of sufficient quantities of neutralizing minerals. Acidic drainage accelerates the rate of ML, although neutral ML may also occur. There is the potential for ML/ARD to be produced during exposure of Halifax Group or sulphide-bearing bedrock to oxygen and surface water runoff; and the potential for impacts to soil and sediment from the Project. ARD is provincially regulated through the Sulphide Bearing Material Disposal Regulations.

Soil and sediment quality may facilitate exposure of birds, fauna, and fish to contaminants through ingestion. Exposure of soil from Project activities may increase the potential for siltation of watercourses from surface water runoff. Contaminated soil and sediment are provincially regulated via the Contaminated Sites Regulations.

6.5.3 Baseline Program Methodology for Soil and Sediments

Baseline studies have been conducted at various intervals since 2014 to support the effects assessment (EA) for the Project. Baseline programs characterized the Geology, Soils, and Sediment Quality that could potentially be affected either directly or indirectly by the Project. The main objectives of the baseline studies program were to:

- identify soil characteristics that may be sensitive Project related disturbances;
- provide sufficient information to develop an effects assessment, mitigations, management and monitoring plans (e.g., reclamation and closure); and
- determine soil and sediment baseline metal concentrations.

The information collected during the baseline program was used to carry out the effects assessments, develop management and mitigation plans, and guide the reclamation and closure plan.

For sediment quality investigations, detailed results including, and sediment descriptions are provided in Appendix H (Fish and Fish Habitat 2015-2017 Baseline) of Appendix J.2 (Baseline Fish and Fish Habitat 2019-2020 Technical Report) and Appendix E.1 (Tabulated Sediment Quality Data). Additional sediment sampling conducted in 2019 and 2020 at the Beaver Dam Mine is presented in E.6 to E.8, which includes laboratory results. This was undertaken to better define historic tailings on site, which is presented in Table 6.5-4.

Geotechnical Investigations for the Project are detailed in Appendix A.2a and A.2c.

The baseline program methodology is summarized below, including delineation of the baseline study area and identification of monitoring locations; results of baseline characterization studies most salient to the EA presented in Section 6.5.4.

6.5.3.1.1 Beaver Dam Mine Site and Haul Road, Geological and Geochemical Baseline

Geochemical studies for the Project are referenced in Appendix E.2, Appendix E.3, and Appendix E.5. The objective of these studies was to characterize local geology and geochemistry at the Beaver Dam Mine site, including assessment of potential for ML/ARD (Section 6.5.6.3). Samples collected as part of these efforts were evaluated for acid base accounting (ABA) characteristics, kinetic test-work, mineralogy and particle size distribution. The Beaver Dam geological units and sample descriptions are provided in Table 6.5-2.

Table 6.5-2: Beaver Dam Mine Geological Units and Sample Descriptions

Source. Appendix E.2 Beaver Dam Project ML/ARD Assessment Report (Lorax 2020).

6.5.3.1.2 Beaver Dam Mine Site Soil and Sediment Baseline

As part of quantifying baseline soil and sediment quality at the proposed Beaver Dam Mine Site, two Environmental Site Assessments (ESAs) were conducted. An initial Phase II ESA was conducted between July 10 to 11, 2019 and an Extended Phase II ESA was conducted between July 20 to 28, 2020 (Appendix E.7 and E.8).

During these periods, a total of 94 test pits and 13 sediment locations were sampled for available (acid extractible) metals, including mercury within the proposed Beaver Dam Mine Project Area (PA) and the nearby Killag River (Appendix E.8, Drawing A-2 and A-3).

As outlined in the Beaver Dam ESA Phase I report, the proposed Beaver Dam Mine site was previously subject to gold mining activities (Stantec 2019b). Gold mining and exploration activities had intermittently occurred at the site between 1867 and 1989 and resulted in the production of tailings and waste rock. In addition to quantifying baseline conditions at site, test pit locations were chosen based on areas of concerns (tailings and waste rock) identified during the review of historical records, digital elevation model (DEM) data and the location of proposed mine infrastructure.

Test pits were manually excavated using a hand-held shovel and metal bar or a Dutch auger. Test pit excavations were monitored, where detailed logs and photographic records of sub-surface conditions encountered and obtained representative soil samples. Test pits were advanced to depths generally ranging between 0.2 metres below ground surface (mbgs) to approximately 1 mbgs, at which point refusal of the hand-held shovel, bar or Dutch auger was encountered. Representative bulk soil samples were then collected from the test pits. The soil samples were examined in the field for evidence of impacts (visual or olfactory), placed in laboratory supplied glass jars, placed on ice, and submitted to an accredited laboratory for analysis.

Sediment sample location were limited: the bottoms of Site waterbodies were often too rocky, vegetated, or loose to permit sample collection. Sediment samples were collected at depths ranging from 0.3 to 1.8 m below the waterbody floor, at which point refusal of the hand-held sampling equipment was generally encountered, and/or the water depth was too great to continue with the hand-held sampling equipment. The majority of samples were collected using a hand-held shovel, Dutch auger, or sludge judge from

either a boat or the shoreline. A Petit Ponar was also used in deep water locations but proved to be ineffective due to the presence of a thick organic layer inhibiting the penetration of the Ponar grab in the underlying substrate. The sediment samples were examined in the field for evidence of impacts (visual or olfactory) and placed in jar, placed on ice and submitted to an accredited laboratory for analysis.

The Beaver Dam site having previously been subject to mining activities, analytical results for soil have been compared to the applicable Nova Scotia Tier 1 Environmental Quality Standards (EQS) for an industrial site with non-potable groundwater use and coarse-grained soil (standards for coarse-grained soil are more conservative than standards for fine-grained soil). For metals, the Tier 1 EQS for a potable and non-potable site are equivalent.

Analytical results for sediment have been compared to the Tier 1 EQS as well as to the Canadian Sediment Quality Guidelines. Tier 1 EQS for sediment are largely identical to the Canadian probable effect levels with the exception of antimony, iron, manganese, nickel, and strontium, for which Tier 1 EQS exist but federal guidelines do not.

The Canadian Council of Ministers of the Environment (CCME) have developed interim sediment quality guidelines (ISQG) for the protection of aquatic life (CCME 1999). They have also developed or compiled probable effect levels (PEL) above which adverse biological effects are usually or always observed. The PEL is less stringent than the ISQG for all metals.

Analytical results for sediment have been compared to the applicable ISQG and PEL for a freshwater environment. For metals, ISQG and PEL are only available for arsenic, cadmium, chromium, copper, lead, mercury, and zinc.

Soil and sediment quality results for Beaver Dam are summarized in Section 6.5.4.

6.5.3.1.3 Haul Road Baseline

Eleven soil samples were collected along the Haul Road during the Human Health Risk Assessment (Appendix C.2). Where Project components/activities are not expected to interact with the VC, these components and activities are considered to have no potential effects and are not considered in the assessment. That is, interactions between the Project and soils and sediment quality along the Haul Road are restricted to accidents and malfunctions during Haul Road use and potential spills; these are related to occurrences of low likelihood outside of normal operating conditions and associated potential effects are addressed in Section 6.18 Accidents and Malfunctions, as well as the draft Spill Contingency Plan (Appendix A of Appendix P.1).

As such, soil and sediment quality was not systematically assessed along the Haul Road as background sediment quality is not required when remediating contamination resulting from accidents and malfunctions. In the event of an accident such as a hydrocarbon spill or haul truck upset, contaminated sediment and/or soil would be remediated to federal and provincial sediment and soil quality guidelines rather than to background values. In this context, AGNS understands that a generalized understanding of probable sediment quality, based on regional results, is sufficient for the purposes of environmental assessment; no additional sediment sampling is proposed before construction. Note that road salts and magnesium chloride will not be used regularly on the Haul Road and the trucks will be covered to prevent metal concentrate and dust from impacting nearby soils and sediments.

Further note, the water features along the Haul Road are not expected to have been impacted by past industrial activity. Background sediment quality can be estimated using the regional sediment quality.

Assessment of soils and sediment quality along the Haul Road is not considered further in this assessment.

Additional baseline soil sampling was completed along the Haul Road as part of the Human Health Risk Assessment is included in Appendix C.2.

6.5.3.1.4 Touquoy Mine Site Baseline

The Touquoy Mine Site was previously subjected to a sediment quality investigation that consisted of the collection of sediment samples from ten locations on the Touquoy site and surrounding area watercourses in January 2007. Three of these locations had organic substrate not suitable for chemical analysis for soils (CRA 2007a).

Historical till and soil geochemical regional data is available from the DNR. The documents entitled Compilation of Seabright Resources Inc. Till and Soil Geochemical Data over the Meguma Terrane (NSDNR 2006) and Till Geochemical Survey over Mainland Nova Scotia (NSDNR 2006a) were reviewed. Till samples were collected from 1986 to 1989 by Seabright Resources Inc. and Seabright Explorations Inc., and from 1977 to 1982 by the Department of Regional Economic Expansion and Nova Scotia Department of Mines, respectively. Samples were submitted for chemical analysis of select metals. The results of the historical till investigations are summarized below.

6.5.4 Baseline Conditions

6.5.4.1 Regional Overview

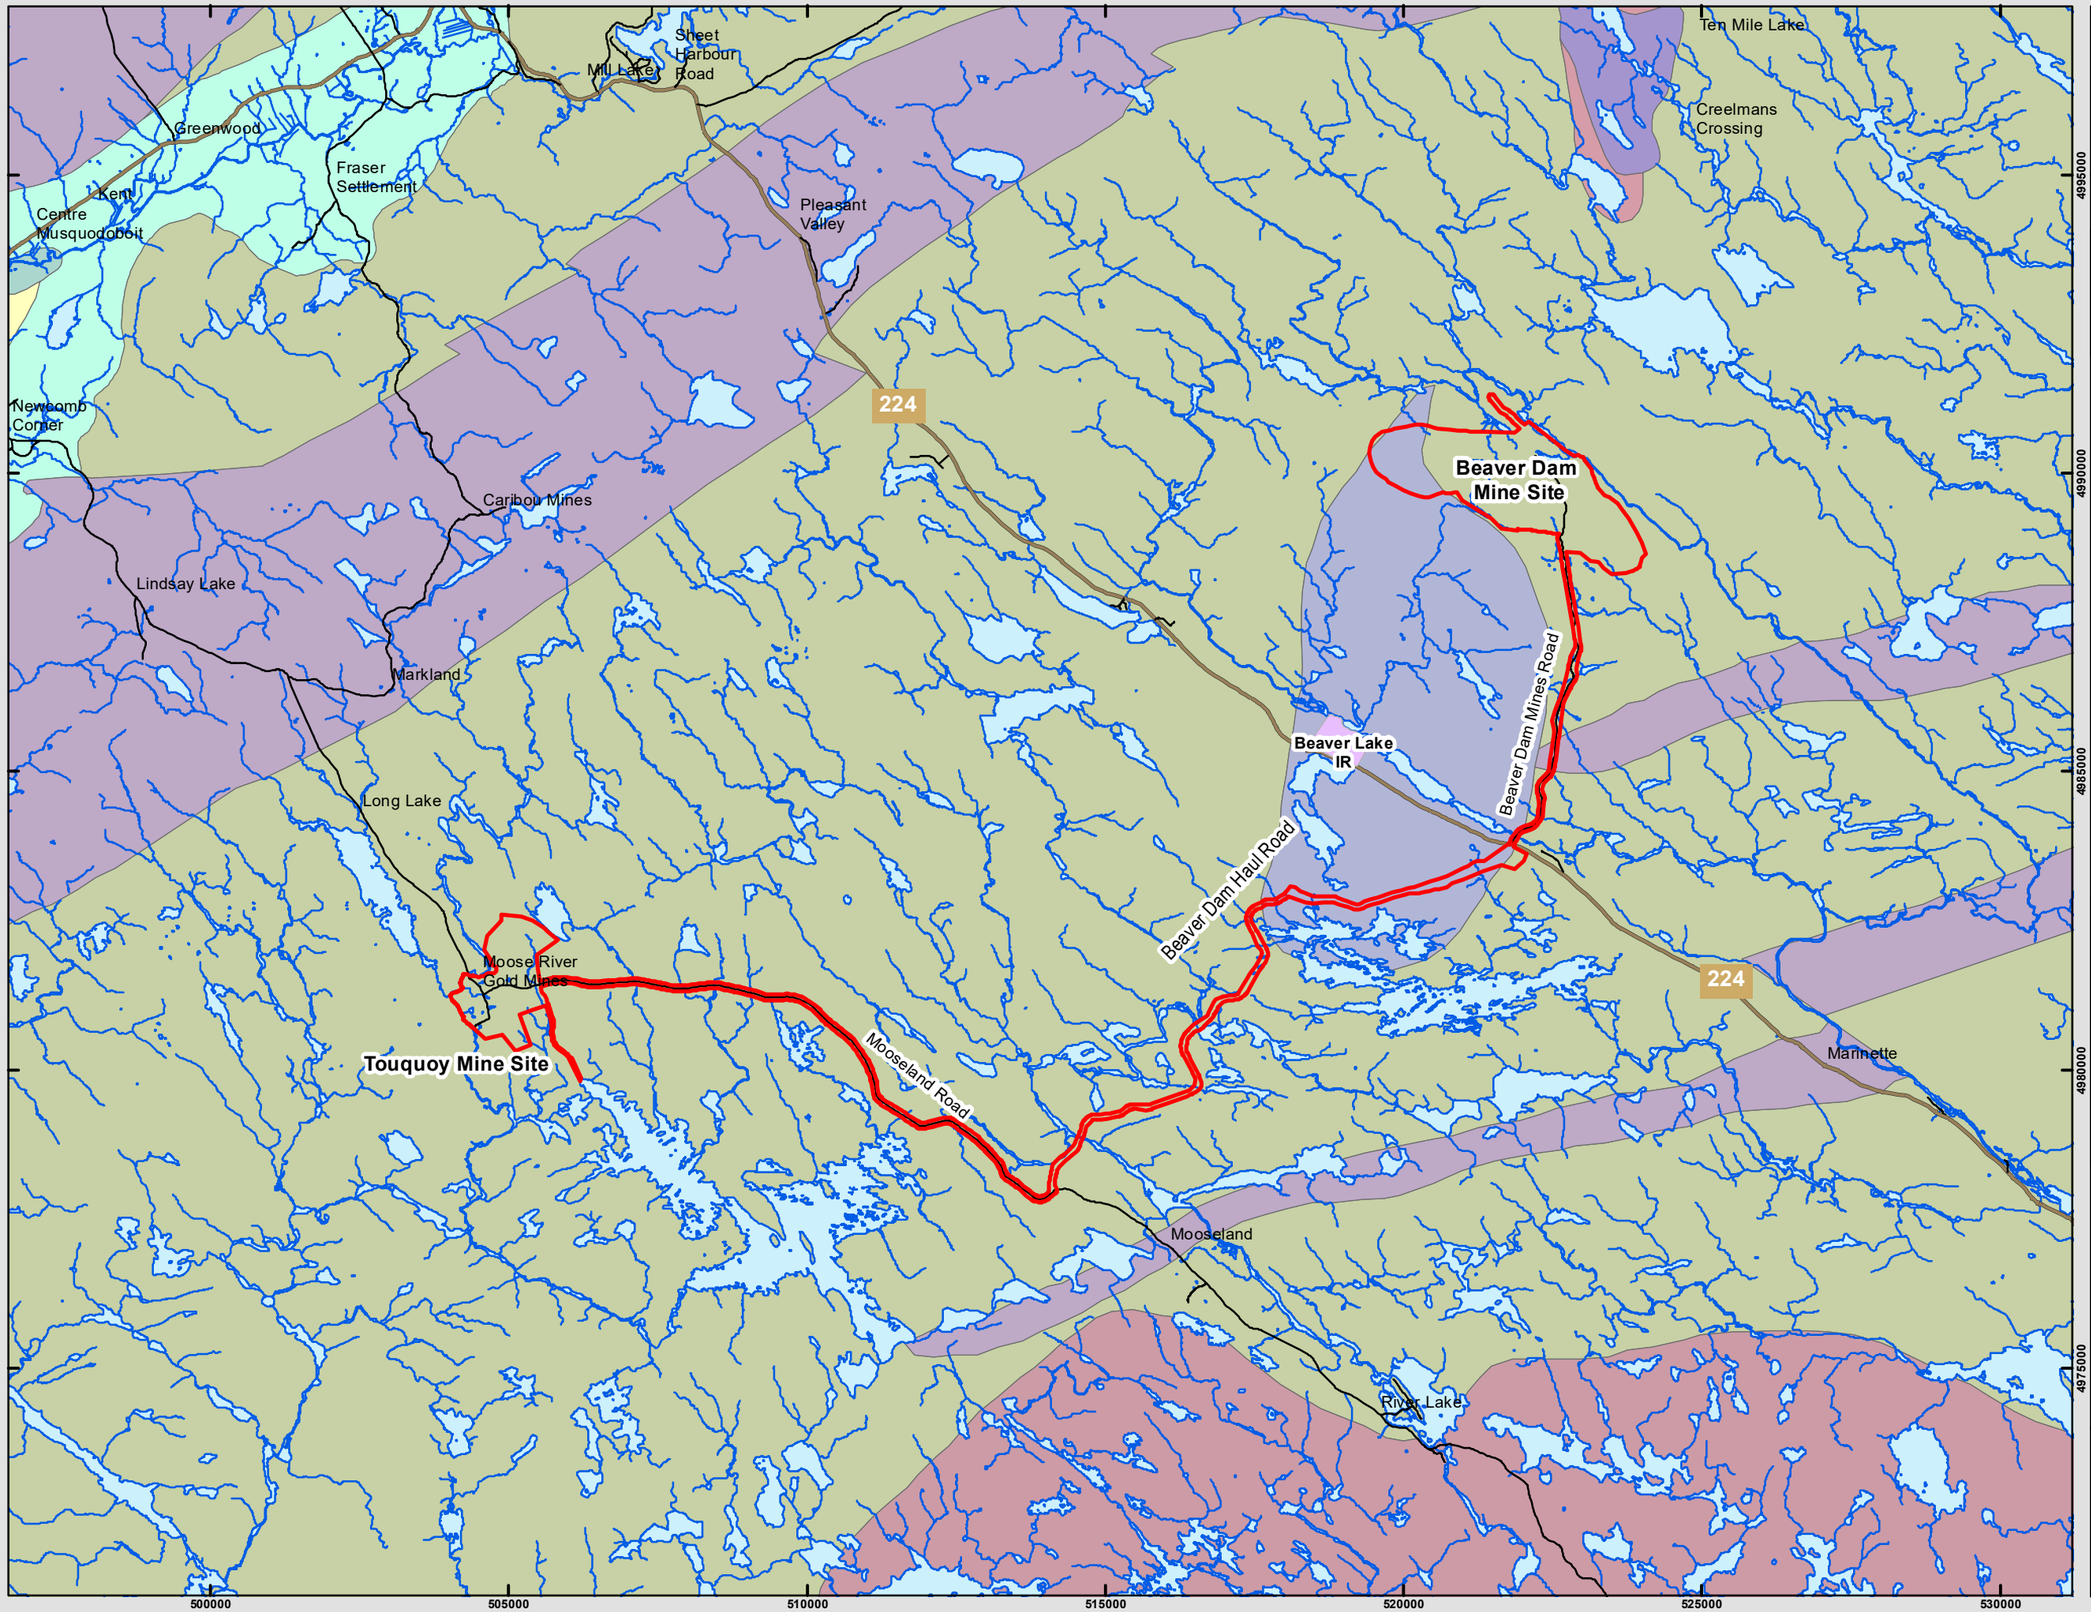
6.5.4.1.1 Regional Geology and Geohazards

Nova Scotia can be divided into two distinct metallogenic terranes; the Avalon Terrane to the north and the Meguma Terrane to the south (Keppie et al., 2000). These two terranes developed independently until they were juxtaposed along the Cobequid-Chedabucto Fault Zone during the mid-Devonian Acadian Orogeny.

The Beaver Dam site and existing Touquoy Mine site is within the southern Meguma Terrane, while the Avalon Terrane is located to the north of the fault zone. The Meguma Terrane includes the Cambrian to Ordovician Meguma Group and Late Ordovician to Early Devonian volcanic and sedimentary rocks (FSSI, 2015). After the collision of the Meguma and Avalon terranes in the mid-Devonian period, sedimentary material was deposited over both terranes during the Carboniferous to Early Cretaceous period. The sedimentary units include siliciclastic rocks, calcareous rocks, evaporites, coal, kaolinitic clay and silica sand (FSSI, 2015). The majority of the gold mineralization occurs within the units of the Meguma Group. The Meguma Group is divided into the Goldenville Formation and the overlying Halifax Formation (Figure 6.5-1).

The metamorphic facies in both Meguma Group units vary from greenschist to amphibolite facies. The Goldenville Formation is a greywacke unit that is >5,600m thick, while the Halifax Formation is primarily argillite with an average thickness of approximately 4,400 m. Both the Goldenville Formation and the Halifax Formation are made up of deep marine turbidite deposits.

Isostatic Uplift and Subsidence



During the most recent major advance of the North American ice sheet complex, known as the Wisconsinan Glaciation, the Appalachian Glacier Complex covered the Maritimes. These glaciers formed and grew locally, independent of the Laurentide Ice Sheet due to a combination of increased snowfall, cold temperatures, and isolation from continental glaciers by deep ocean channels and the Appalachian mountain range. The glaciers were centred in the Maritimes, and advanced and retreated at least four times. During each of these cycles, glaciers were centered on land masses and flowed towards the Scotian Shelf and Laurentian Channel or radiated from central Nova Scotia and New Brunswick (NSDNR 2012).

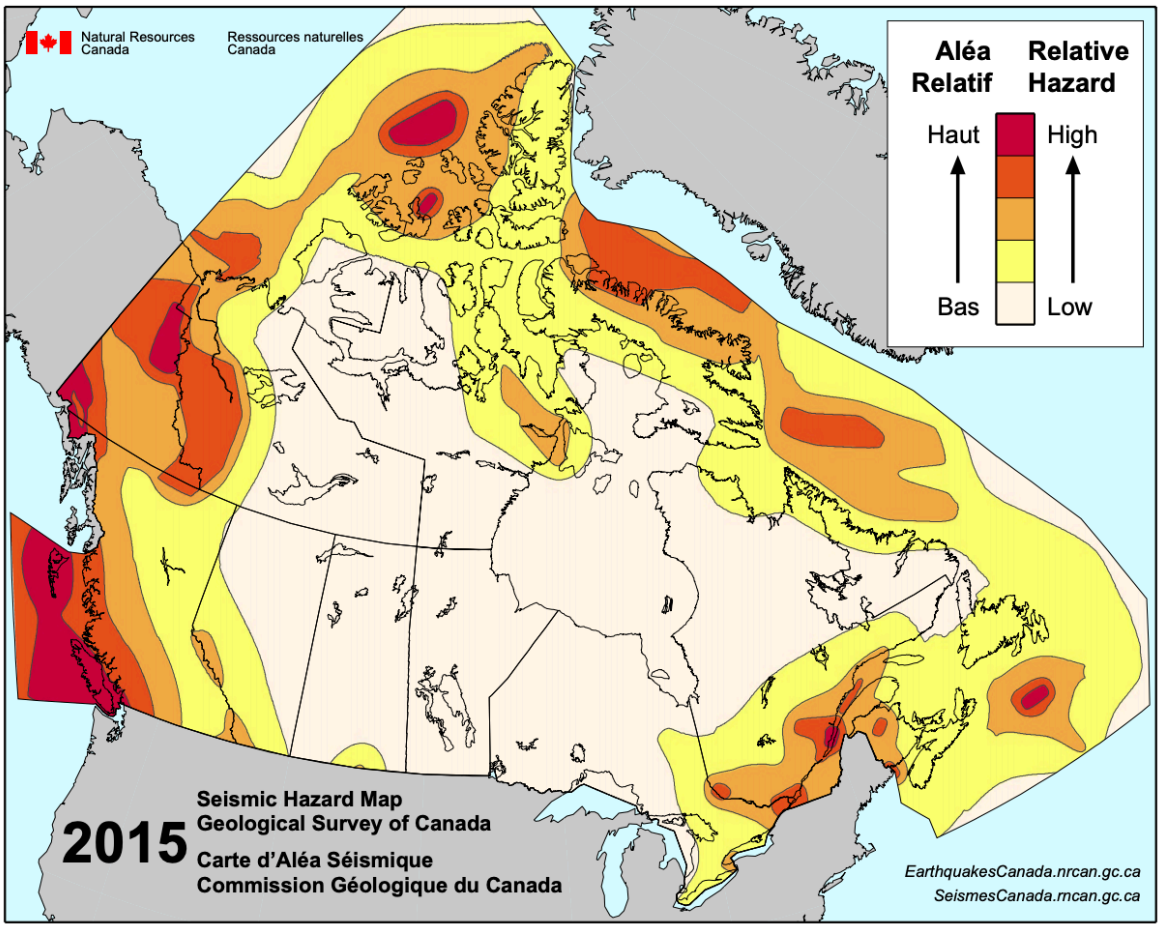
McCallum Environmental Ltd.

The enormous weight of the Appalachian Glacier Complex caused the surface of the Earth's crust to deform and warp downward, forcing the viscoelastic mantle material beneath to flow away from the central loading region. This caused the central land masses in Nova Scotia and New Brunswick to depress and the outer regions at the limits of the glacier complex to flux upward. Following retreat of the glacier complex, the central land masses in Nova Scotia began to rise to their pre-glaciation position, while the outer regions began to subside. This concept is called isostatic rebound and exacerbates the effects of global sea level rise.



Given the Project is located approximately 30 km from the coast and average elevation is 140 masl, it is unlikely the effects of isostatic rebound will impact the Project, nor will the Project impact isostatic rebound.

Seismic Activity

The North American Plate has a stable interior but along the edges more seismic activity is likely to occur. Eastern Canada is part of the stable interior; however; unlike the subduction zone on the west coast of North American where plates are colliding, crustal stresses on the east coast are more difficult to explain and likely depend on their local tectonic context.

Although seismic activity is unpredictable, all of Nova Scotia is in a moderately low hazard zone. The southern Bay of Fundy is a moderate hazard zone. The Laurentian Slope is a moderate to high hazard zone (NRCAN 2015). Figure 6.5-2 displays the relative earthquake hazards across Canada as determined by the Geological Survey of Canada (NRCAN 2015).

Figure 6.5-2: Relative Earthquake Hazard Map of Canada

Each year, approximately 450 earthquakes occur in eastern Canada, of which four will exceed magnitude 4, 30 will exceed magnitude 3, and 25 events will be reported as felt. A decade will likely include three events greater than magnitude 5. Nova Scotia, in particular, has low seismic activity with records (since 1925) showing a max magnitude of 3.5 (Yarmouth - 2015) and most of the activity occurring in SW Nova Scotia (Figure 6.5-3).

The Northern Appalachians Seismic Zone is located in southwest Nova Scotia. The Project is located east of this zone. The nearest earthquake to Marinette, NS was recorded with a magnitude of 2.7 in 1999 and was located northeast approximately 20 km north of the PA. Magnitudes of intensity less than 3.0 are not felt by people except under especially favourable conditions and cause no damage to buildings. The global frequency of earthquakes with magnitude 2.0 to 2.9 is over one million per year.

If an earthquake occurs, seismic activity may affect the Project through primary impacts such as infrastructure damage facilitated by ground vibrations and secondary impacts such as fires facilitated by damaged infrastructure. Tsunami's, should they be created by offshore earthquakes, are unlikely to impact the Project. The Project is located approximately 30 km from the coast and at an elevation of 140 masl.

Given that Nova Scotia is located in a low hazard zone and the limited extent and duration of the Project, the potential risk of seismic activity affecting the Project is very low and not significant.

A geotechnical stability assessment was undertaken for the waste rock and soil stockpiles (Golder 2021; Appendix A2.C), which included an assessment of potential seismic activities on design. The assessment concluded that the overall stability of the stockpiles is within acceptable safety factors. A geotechnical stability assessment is also being undertaken by Golder (In Progress) on the open pit design. Recommendations from this assessment will be applied to final open pit design.

Landslides, Slope Erosion, and Subsidence Following Project Activities

Geotechnical work has been completed at the Touquoy site and the expertise gained from working with these materials will be applied to the final design of the Beaver Dam disturbed areas using actual geotechnical data collected at Beaver Dam to supplement the abundant public information available. Features constructed from site materials such as waste rock stockpiles and overburden stockpiles will use the collected data for final design to produce features with appropriate safety factors to reduce the possibility of landslides, slope erosion and subsidence. With many stockpiles it is common to have subsidence in the short-term creating a landscape that is varied in topography. This is in line with NSL&F objectives for reclamation to have surfaces that are not uniform but offer safe long-term landscapes with a variety of features. General reclamation goals to have heterogeneous landscapes that offer habitat features greater than simply a hydro seeded mat are important and can be assisted by some variation in the topography through subsidence.

6.5.4.1.2 Regional Soil Quality

Soil quality, at a regional scale, is influenced by physiographic, geomorphological and topographic conditions. The Beaver Dam Mine Project is located in the Eastern Ecoregion of the Acadian Ecozone. Ecoregions express macroclimate as a distinctive ecological response to climate through soils and vegetation (Neily et al. 2005). The ecoregion has extensive wetland and rock barrens, which support stunted black spruce, larch, and heath.

Ecoregions are further subdivided into Ecodistricts, which reflect macro elements of the physical and biological attributes of ecosystems which will ultimately influence biodiversity. The three primary Project locations are spread across the further subdivided Eastern Interior and Eastern Drumlin Ecodistricts (Figure 6.5-4). The Eastern Interior Ecodistrict is generally characterized by highly visibly bedrock where glacial till is very thin, exposing the ridge topography. Where till is thicker, ridged topography is masked and thick softwood forests occur. There are a few drumlins and hills scattered throughout the Ecodistrict and fine textured soils are derived from slates. The Eastern Drumlin Ecodistrict is underlain by Meguma Group greywacke and slate, blanketed by fine-textured till derived from these underlying and adjacent rocks. Drumlins are derived from carboniferous rocks from the north, as well as material from the Cobequid Hills and Pictou Antigonish Highlands.

The Beaver Dam Mine Site is in an area of low topographic relief at 140 masl with scattered drumlins reaching 165 to 175 masl and Cameron Flowage channeling through a topographic low of 130 masl. Drainage is to the southeast along a number of poorly drained streams, shallow lakes, and wetlands.

A variety of landforms are found in this ecoregion, including rolling till plains, drumlin fields, extensive rockland, and wetlands. The bedrock is highly visible in those areas where the glacial till is very thin, exposing the ridge topography.

At a regional scale, local area soils are composed of a variety of soil types, but is dominated by the Danesville, Halifax, and Gibraltar series. Surface soil and subsoils of the Danesville series are typically dark grayish brown sandy loam over yellowish-brown sandy loam with parent material consisting of dark brown sandy loam till derived from quartzite. Surface and subsoils of the Gibraltar series are typically brown sandy loam over strong brown sandy loam with parent material consisting of pale brown coarse sandy loam till derived from granite.

The Project is in a highly mineralized region and the geology contributes to naturally elevated concentrations of metals in soils and sediments, including iron, arsenic and aluminum. The occurrence of naturally elevated concentrations in surface waters is commonly observed in regions of planned/proposed mining activities, all over the world (e.g., “Golden Triangle“ of northwestern British Columbia, Canada). In such regions, naturally elevated concentrations of certain parameters generally occur where exposure of rock or other geologic materials to oxygen and water results in natural weathering processes, including chemical oxidation and leaching of solid-phase constituents (e.g., metals), which are then transported to soils and sediments, Historical studies completed by Nova Scotia Department of Natural Resources (DNR) show areas sampled around Beaver Dam Mine Site are below CCME Soil Quality Guideline for Inorganic Arsenic. The Killag Historic Gold Mining area is located approximately 9 km to the southeast of the project site. Studies show areas with elevated arsenic values over the CCME SQG (12 mg/kg) despite no known historic mining activity or mineral occurrences, and therefore, it can be assumed that elevated values are attributed to background levels. Regional studies of till samples show high levels of arsenic that have no mineral occurrences, and therefore it can be concluded that the elevated arsenic levels are attributed to natural background levels, or higher areas of mineral enrichment.

McCallum Environmental Ltd.

6.5.4.1.3 Regional Sediment Quality

The soils of Halifax County have developed almost entirely from glacial drift and, in most cases, mirror the distribution of underlying rock formations. This is particularly true for coarse-textured materials derived from granite and quartzite. Finer-textured materials were transported more readily by glaciers and typically accumulated in drumlin or drumlin-like mound deposits (Hilchey et al. 1963).

Sediment is derived from the movement of soils and in some instances bedrock materials being transported by water to areas frequented by water. Soil and bedrock quality is therefore a good indicator of what sediment quality is in the absence of anthropogenic activities that could affect sediment directly. Sediment quality for the Beaver Dam Mine Site and Touquoy Mine Site are discussed below.

6.5.4.2 Local Baseline Study Results

6.5.4.2.1 Local Geology

The Meguma Group is the dominant unit occurring in the area near the Beaver Dam site and at the existing Touquoy mine site (located 19 km to the southwest of the Beaver Dam Mine Site); both sites are located within the Goldenville Formation of the Meguma Group.

The Goldenville Formation is further subdivided, from oldest to youngest, into the Moose River Member, the Tangier Member and the Taylors Head Member. Claystone and siltstone are present in the Moose River and Tangier Members but are minor in the Taylors Head Member. Overall here is a decrease in the proportion of fine-grained sediments from the oldest to the youngest units within the Goldenville Formation. Both the Beaver Dam Mine Site and the Touquoy Mine Site are located within the Moose River Member (FSSI, 2015). The Moose River Member is at its widest in the Beaver Dam Mine Site vicinity and is folded into three sub-parallel anticlines.

Mineralization at the Beaver Dam Property occurs in the north-dipping southern limb of an overturned anticline with gold hosted both within quartz veins and disseminated through the intervening inter-bedded argillite and greywacke. The Moose River-Beaver Dam Anticline is sinisterly offset into segments by two northwest trending faults:

- the Mud Lake Fault; and
- the Cameron Flowage Fault .

The Mud Lake Fault has been described as a 2 to 3 m wide zone of gouge within a 10 to 20 m wide brecciated zone (PCA, 2015). Duncan (1987) stated an average thickness of 12 m, ranging from 5 to 26 m, for the Mud Lake Fault and that the Mud Lake Fault usually can be sub-divided into three zones consisting of:

- Hanging Wall Breccia (2 to 10 m) consisting of greywacke and minor argillite orthobreccia and minor parabreccia;
- Gouge Zone (2 to 10 m) consisting of graphitic argillite gouge and minor greywacke; and
- Footwall Breccia (1 to 5 m) consisting of greywacke and argillite ortho-and parabreccia.

While these many unique lithologies and geologic structures are tracked during core logging, argillite and greywacke along with two interbedded intermediates (argillite- and greywacke-dominated) represent the four major rock types by volume identified on site. In an effort to be consistent with the geological observations from site while simultaneously allowing for a representative and simplified geo-environmental model, these four major rock types are being carried forward in this ML/ARD assessment. Description of the Beaver Dam geologic units and sample descriptions are provided in Table 6.5-2.

The overburden at the Beaver Dam Mine Site consists of glacial till deposits of varying thickness and occasional shallow peat bogs. Stea and Fowler (1979) describe the overburden as a blue-greenish-grey, loose, cobbly silt-sand till that will grade into a sandier, coarser till, sometimes with red clay inclusions. A typical composition of the glacial till matrix is 80 percent sand, 15 percent silt and 5 percent clay. Surficial geology in the area is described on geology maps (Stea et al. 1992) as consisting of stony till plains and drumlins with minor organic deposits. Till is typically 2 to 20 m thick and primarily comprised of a stony and sandy matrix material derived from local bedrock sources, while drumlin facies are typically 430 m thick and siltier due to erosion and incorporation of older till units by glaciers. Figure 6.5-5 displays regional surficial geology.

Hydrostratigraphy

Description of local study area hydrostratigprahy was performed by Conestoga-Rovers & Associates (CRA 2007a,b) and Peter Clifton & Associates (PCA 2007). These results supported development of a 3D geological model for the Beaver Dam Mine Site as well as the hydrogeological modelling and solute transport modelling (Appendix F.5 and F.6). Three hydrostratigraphic units based on lithology and hydraulic properties were identified:

- glacial till;
- weathered fractured bedrock; and
- competent fractured bedrock.

These hydrostratigraphic units were further subdivided into zones based on the surficial geology in the overburden (Appendix F.6).

The overburden hydrostratigraphic units include:

- Stony Till;
- Silt Till;
- Organics; and
- Silty Drumlin.

Bedrock stratigraphic units identify include Cunard, Beaverbank, Taylor's Head, Tangier and Moose River, and Moose River

6.5.4.2.2 Local Soil Quality

Beaver Dam Mine Site

The Beaver Dam Mine Site is primarily composed of soils belonging to the Bridgewater and Halifax series. Surface soil and subsoils of the Bridgewater series are typically medium-textured brown shaley loam over yellowish-brown shaley loam with parent material consisting of olive shaley loam till derived from Precambrian slates. Surface soil and subsoils of the Halifax series are typically brown sandy loam over yellowish sandy loam with parent material consisting of olive to yellowish-brown stony sandy loam till derived from quartzite (Figure 6.5-6). These soils correlate to the NS Forest Soil Type – ST2, common in upland forests throughout the province. Soil depths to sea horizon are typically up to 18 inches. No mapping currently exists to depict soil depth by horizon.

McCallum Environmental Ltd.

The area of the proposed open pit is largely reworked soils associated with an historical settling pond (Appendix E.9 draft Historic Tailings Management Plan). Suspected tailings were observed within the proposed open pit area near the historical settling pond, north of Crusher Lake between the lake and the proposed road, and to the north of the proposed road near the historical Mill Shaft Pit area (proposed topsoil/sub-soil stockpile [TSSP] area). Several trenches and pits with nearby suspected waste rock were located within the proposed pit area, to the south and east of the pit area, north of Crusher Lake between the lake and the proposed road, and to the north of the proposed road near the historical Mill Shaft Pit area (proposed TSSP area). These trenches and pits are suspected to be historical mine workings (Appendix E.8 Beaver Dam Mine Project Extended Phase II Environmental Site Assessment).

Soil sampling conducted in 2019 and 2020 at the Beaver Dam Mine Site showed that arsenic exceeded the Tier 1 EQS at several locations. Levels of arsenic ranged from non-detected to 3,900 mg/kg. Lead and mercury which have been associated with historical mining activities in Nova Scotia, were relatively elevated but did not exceed applicable Tier 1 EQS. The maximum identified lead concentration was 200 mg/kg versus a Tier 1 EQS of 740 mg/kg, and the maximum identified mercury concentration was 40 mg/kg versus a Tier 1 EQS of 99 mg/kg (Table 6.5-3 and Appendix E.8, Drawing A-5).

Table 6.5-3: Summary of Soil Contamination (2019 and 2020)

Standard Exceedances	Tier 1 EQS	Exceeding (Samples)	Exceeding (Test Pits)
Arsenic	31 mg/kg	73 of 96 samples[(a)]	72 of 94 test pits[(a)]
Other Metals	Various	None	None

Source: Appendix E.7 (Limited Phase II - Environmental Site Assessment [Beaver Dam Property]) and Appendix E.8 (Extended Phase II Environmental Site Assessment [Beaver Dam Project Property]).

Notes: Numbers of exceedances do not include field duplicate samples.

(a) There are more soil samples than test pit locations as two soil samples, rather than one, were collected from two of the test pits.

mg/kg = milligram per kilogram; PEL = Canadian Council of Ministers of the Environment (CCME) probable effects level; Tier 1 EQS = Nova Scotia Tier 1 Environmental Quality Standards for Contaminated Sites.

The existing topsoil and overburden are considered suitable for use in reclamation. Topsoil will be stockpiled in two locations during construction and used for revegetation at the end of the mine life and, when practical, during operation. Plant material and vegetation that was able to grow on the overburden and topsoil prior to disturbance is assumed to be able to grow on the area post reclamation. Organic debris (roots, stumps, brush) will also be stockpiled and mulched to provide biomass for reclamation. All disturbed areas, most notably the waste rock and till storage piles, will be reclaimed with topsoil and growing medium to a depth matching the native surroundings.

Touquoy Mine Site

The Touquoy Mine Site can be used as a surrogate to understand how to manage historic tailings at the Beaver Dam Mine Site. The soils are primarily composed of the Danesville series (CRA 2007a,b), whereas, the soils at the Beaver Dam Mine Site are primarily composed of Halifax and Bridgewater series (Figure 6.5-6). Lessons learned from water treatment and historic tailings disposal have been applied to the Beaver Dam Mine. Water Management during construction to address metals associated with historic tailings is described in Appendix F.1 of Water Management Plan Appendix P.4. A draft Beaver Dam Historic Tailings Waste Rock Management Plan is provided in Appendix E.9

Regional till and soil data was reviewed and compared to CCME Soil Quality Guidelines (SQG) for the Protection of Environmental and Human Health for industrial property use. A review of the regional till samples collected by Seabright Resources Inc. and Seabright Exploration Inc. in the Compilation of Seabright Resources Inc. Till and Soil Geochemical Data over the Meguma Terrane identified that 98 samples were located in the vicinity of the PA. Results available for review included samples analyzed for arsenic, tungsten, gold, and antimony. Data was not provided for additional metals that may have been analyzed. The results indicate that

arsenic concentrations were identified to be above the CCME soil quality guidelines of 12 mg/kg in 29 of the 98 samples, and antimony concentrations were identified to be below the CCME SQG of 40 mg/kg in all samples collected. Tungsten results were presented with negative concentrations; therefore, they are not included in the discussion. There are no applicable guidelines for gold.

A review of the till samples collected by the Department of Regional Economic Expansion and Nova Scotia Department of Mines in the Till Geochemical Survey over Mainland Nova Scotia identified three soil samples in the vicinity of the PA. Samples were identified to have been collected from Lake Alma, MacGreggor Lake, and River Lake, located adjacent to the Haul Road. Results available for review included samples analyzed for silver, copper, lead, zinc, cadmium, nickel, cobalt, iron, manganese, calcium, magnesium, mercury, arsenic, molybdenum, uranium, tin, tungsten, and barium. Based on a review of the analytical results, copper was identified to exceed the CCME SQG of 91 mg/kg in one of three samples collected. No other parameters were identified to exceed the CCME SQGs, where they exist.

6.5.4.2.3 Local Sediment Quality

Beaver Dam Mine Site

Sediment sampling conducted in 2020 within Crusher Lake, a historical settling pond (within the proposed pit footprint) and the Killag River showed that levels of arsenic, cadmium, chromium, copper, iron, lead, manganese, mercury, selenium, strontium, and zinc exceeded the Tier 1 EQS guidelines at one or more sample locations.

Arsenic in sediment ranged from 3.1 to 2,800 mg/kg, with the highest concentration located upstream within the Killag River approximately 800 m north-northwest of the proposed open pit, which also had cadmium, iron, lead, and manganese above applicable criteria. Arsenic exceeded ISQG at all locations other than at the east end of Crusher Lake (Table 6.5-4 and Appendix E.8, Drawing A-6).

Table 6.5-4: Summary of Sediment Contamination (2020)

Criteria Exceedances	Criteria (mg/kg)			Exceeds ISQG	Exceeds PEL	Exceeds Tier 1 EQS
	ISQG	PEL	Tier 1 EQS			
Arsenic	5.90	17.00	17	10 of 13	9 of 13	9 of 13
Cadmium	0.60	3.50	3.5	3 of 13	1 of 13	1 of 13
Chromium	37.30	90.00	90	2 of 13	0 of 13	0 of 13
Copper	35.70	197.00	197	3 of 13	0 of 13	0 of 13
Iron	-	-	43,766	-	-	2 of 13
Lead	35.00	91.30	91.3	4 of 13	2 of 13	2 of 13
Manganese	-	-	1,100	-	-	1 of 13
Mercury	0.17	0.486	0.486	4 of 13	2 of 13	2 of 13
Selenium	-	-	2	-	-	1 of 13
Strontium	-	-	1	-	-	11 of 13[(a)]
Zinc	123.00	315.00	315	3 of 13	1 of 13	1 of 13
Antimony and nickel	-	-	25 and 75	-	-	0 of 13

Notes: [(a)] Strontium exceedances of Tier 1 EQS exclude concentrations below the laboratory's reportable detection limits (RDL) where the RDL exceeds the EQS.

Numbers of exceedances do not include field duplicate samples.

ISQG = Canadian Council of Ministers of the Environment (CCME) interim sediment quality guideline; mg/kg = milligram per kilogram; PEL = CCME probable effects level; Tier 1 EQS = Nova Scotia Tier 1 Environmental Quality Standards for Contaminated Sites.

Further information on analytical results for soils and sediments at the Beaver Dam mine site can be found in the Beaver Dam Extended Phase II ESA (Appendix E.8).

Touquoy Site

The following is provided to show how information from historic tailings information the Beaver Dam Mine site assessment, planning and mitigation measures.

A sediment quality investigation at the Touquoy site consisted of the collection of ten sediment samples from the site and surrounding area watercourses in January 2007. Three of these locations had organic substrate not suitable for chemical analysis for soils. A summary of the analytical results from the Touquoy site is presented below. Arsenic levels above the CCME probable effects level (PEL) and Tier 1 NSE EQS were found at Sediment Sites 1, 2, 3, 5, 6, 7 and 8. Sites 1, 6, 7 and 8 are above the existing open pit or in a different catchment. All the locations exceed the CCME interim sediment quality guideline (ISQG).

Only Station 5 (0.81 mg/kg) exceeds the ISGQ (0.6 mg/kg) but not the PEL (3.5 mg/kg) limits for cadmium. Station 9 along the shore of Scraggy Lake is close to the ISGQ at 0.58 mg/kg.

Sediment at Site 3, 5, 6 and 10 exceed the ISQG limit (35 mg/kg Pb) for lead but not the PEL limit (91.3 mg/kg Pb). Sediment from the shore at Scraggy Lake far exceeded both limits at 1,100 mg/kg Pb. Such a high concentration in a relatively pristine area appears to be anomalous and suggests that the lake requires further investigation.

Mercury was found at Sites 3 and 9 at concentrations above the ISQG limit (0.17 mg/kg), and at Site 2 (0.52 mg/kg) above the PEL (0.48 mg/kg). It was detected at all sites between concentrations of 0.02 to 0.16 mg/kg.

The concentration of zinc was relatively consistent across all sites. Site 9 at 150 mg/kg was elevated above the ISQG limit of 123.0 mg/kg, but well below the PEL of 315.0 mg/kg.

Cyanide was included in the analysis to monitor for its presence once the mine is operating. Cyanide is naturally present in some foods and in certain plants and seeds such as peach pits. Cyanide is contained in over 800 plant species, some foods and a great number of microorganisms, cigarette smoke and the combustion products of synthetic materials such as plastics. In manufacturing, cyanide is used to make paper, textiles, and plastics. It is present in the chemicals used to develop photographs. Cyanide salts are used in metallurgy for electroplating, metal cleaning, and removing gold from its ore. Cyanide gas is used to exterminate pests and vermin in ships and buildings. If accidentally ingested (swallowed), chemicals found in acetonitrile-based products that are used to remove artificial nails can produce cyanide. Cyanide was not used in the previous milling operations.

Cyanide was detected at low levels in Sites 5, 9 and 10, all sites that are well removed from the open pit. It was below the detection limit of 0.5 mg/kg at all other sites (CRA 2007a,b).

6.5.5 Consideration of Consultation and Engagement Results

Key issues raised during public consultation and Mi'kmaq engagement relating to geology, soil and sediment include potential ARD, suspended solids and leaching of metals from the rock at the Beaver Dam Mine Site which may affect receiving water and its fish habitat, specifically Cameron Flowage, the closest watercourse to the Site.

The results of the public consultation and Mi'kmaq engagement have been considered in the environmental effects assessment, including AMNS's commitments on mitigation and monitoring measures and proposed compliance and effects monitoring programs, as well as AMNS's broader commitment to ongoing public and Mi'kmaq engagement. Specific to evaluating the effect on geology, soil and sediment, these are found within the following environmental effects assessment.

Engagement updates undertaken in 2019 to 2021 with the Public and Mi'kmaq of Nova Scotia including Millbrook First Nation is provided in Section 3 and Section 4, respectively.

6.5.6 Effects Assessment Methodology

6.5.6.1 Boundaries

6.5.6.1.1 Spatial Boundaries

The spatial boundary used for the assessment of effects to geology, soil, and sediment is the PA. As the Project has the potential to cause direct and indirect effects to Geology, Soil, and Sediment Quality within and immediately adjacent to but not outside the Project Area, the PA is the most appropriate spatial boundary.

The PA encompasses three primary components from Marinette to Moose River Gold Mines, Halifax County, NS. The Beaver Dam Mine Site will be located at the end of the Beaver Dam Mines Road and the Haul Road will span from the Beaver Dam Mine Site to Moose River Gold Mines, where the Touquoy Mine [processing and exhausted pit (to be used to dispose Beaver Dam tailings)] is located.

The evaluation of effects was completed at the PA level, as direct and indirect impacts to Geology, Soil, and Sediment Quality are expected only within the PA boundaries (Figure 6.5-1 shows the PA boundary).

No RAA was necessary for geology, soil, and sediment as a footprint analysis was completed on this VC, and impacts were only expected within the PA.

6.5.6.1.2 Temporal Boundaries

Temporal boundaries reflect those periods during which planned Project activities are reasonably expected to potentially affect a VC. The temporal boundaries used for the assessment of effects to Surface Water are the Construction, Operations, Active Closure and Post-closure phases.

The temporal boundaries used for the assessment of effects to geology, soil, and sediment are the construction, operations, active closure, and post-closure phases.

6.5.6.1.3 Technical Boundaries

The Geology, Soils, and Sediment Quality assessment was developed to incorporate quantitative data from baseline reports as well as geochemical characterizations studies. Geology, Soils, and Sediment Quality represent physical components of the natural environment; changes related to Geology, Soils and Sediment Quality VCs provided in the subsequent sections are to support the Effects Assessment on Surface Water, Wetlands, and Fish and Fish habitat (Sections 6.7, 6.8, and 6.9).

Project effects to Geology are here constrained by the ML/ARD assessment and geochemical characterizations programs; these results (Section 6.5.6.3) informed predictive water quality modelling and the Surface Water Quality and Quantity Effects Assessment (Section 6.7). The goals were to remove as much subjectivity as possible from the assessment and to increase certainty in the predictions of alteration of the Surface Water VC, residual effects, and the determination of significance to ensure a robust, transparent, and defensible approach to the effects assessment.

Changes to soil and sediment quality may have negative, neutral, or beneficial effects on soil or sediment characteristics. Examples of this include increases in productivity (such as mixing of organic material with surface horizons or addition of nutrients through dust deposition) or degradation of soil and sediment quality, caused by ML/ARD processes. Soil and Sediment Quality degradation

may result from Project Activities causing increases in surface runoff and siltation, local soil erosion, or loss of soil structure due to disturbances such as excavation, soil transport.

6.5.6.1.4 Administrative Boundaries

A number of legislated requirements exist to guide mining proponents on the development of a mine site and on the management of bedrock geology and surface soil disturbance; these were used to support the effects assessment as well as for the planning and implementation of proposed mitigate measures (Table 6.5-5).

ARD is provincially regulated through the Sulphide Bearing Material Disposal Regulations. Contaminated soil and sediment are provincially regulated via the Contaminated Sites Regulations. Sediment quality is compared to the CCME ISQGs and PELs, and the NSEQSs for freshwater sediment.

Table 6.5-5: Relevant Guidelines and Standards informing Effects Assessment for Geology, Soils, and Sediment Quality

Legislation and/or Standard	Applicability to Geology, Soils and Sediment Valued Component	Related Valued Components and Sections
Federal *Fisheries Act* (1985)	Relevant information requirements set under the Fish Habitat Protection and Pollution Prevention provisions of the *Fisheries Act* (1985) include descriptions of measures that will be taken to avoid or minimize any effects on the aquatic environment, shoreline, or riparian areas during Project development or its subsequent operation (Section 37). The *Fisheries Act* (1985a) also regulates the discharge of harmful substances, including sediment (Section 34), into the fish habitat. Consideration of the above legislation is particularly important in cases when Project development takes place near shorelines, or riparian areas where migration of chemical contaminants and sediment into the aquatic environment could occur.	Potentially contaminated soils is assessed in Section 6.18 Accidents and Malfunctions. Management and monitoring plans are provided in Appendix E.5, E.9, J.3, P.1 and P.4 .
Canadian Soil Quality Guidelines for the Protection of Environment and Human Health (CCME 2007)	These guidelines provide Canada-wide standards that suggest maximum limits of various toxic substances (e.g., metals, hydrocarbons, pesticides, etc.) in the soil.	The assessment of effects of the Project on human health, as well as biological components of the environment (i.e., wetlands and fish and fish habitat) are assessed separately in Appendix C.2, Section 6.8, and 6.9.
Sulphide Bearing Material Disposal Regulations pursuant to Section 66 of the Nova Scotia *Environment Act*	In Nova Scotia, the potential for ML/ARD is regulated by the Environment Act administered by NSE.	N/A
Contaminated Sites Regulations.	Exposure of soil from Project activities may increase the potential for siltation of watercourses from surface water runoff. Contaminated soil and sediment is provincially regulated via the Contaminated Sites Regulations.	N/A
Manual for prediction of Drainage chemistry from Sulphidic Geologic Material (Price1997, 2009) and Guidelines and Recommended Methods for the Prediction of Metal Leaching and Acid Rock Drainage at mine sites in British Columbia Price (Price et al. 1998)	Characterization of geology and baseline geochemical studies, including ML/ARD assessment, followed industry best practices and available guidance documents for determining and obtaining geochemical data to be used as inputs for mitigation and management plans as well as ML/ARD assessment	Geological and geochemical baseline studies results informed predictive water quality modelling (Appendix D of Appendix P.4), and mine site water management for the Project (Appendix P.4).

6.5.6.2 Thresholds for Determination of Significance

There are no regulated or proposed thresholds for geology. Sediment and soil have regulated thresholds that are well understood by the proponent and can be quantified through the monitoring program proposed. Tier 1 NSE and CCME Soil and Sediment Criteria in conjunction with background considerations and percent change, in context with NSE policy and guidance documents are the thresholds.

Sediment and soils that become mobilized have a linkage with surface water quality that have regulated thresholds and can are assessed through predictive efforts for the Surface Water Quality and Quantity and Fish and Fish Habitat VCs (Section 6.7 and 6.9) or through the monitoring program proposed.

6.5.6.3 Metal Leaching and Acid Rock Drainage Assessment

The Project is in a highly mineralized region and the geology contributes to naturally elevated concentrations of metals. The occurrence of naturally elevated concentrations in soils, sediments and surface waters is commonly observed in regions of planned/proposed mining activities, all over the world (e.g., "Golden Triangle" of northwestern British Columbia, Canada). In such regions, naturally elevated concentrations of certain parameters generally occur where exposure of rock or other geologic materials to oxygen and water results in natural weathering processes, including chemical oxidation and leaching of solid-phase constituents (e.g., metals), which are then transported to soils and sediments.

The Project has the potential to increase concentrations of metals, and other parameters, in soils, sediment and surface water by excavating and disturbing overburden and bedrock, i.e., mining activities. To support the Project, geochemical characterization studies and ML/ARD assessment were completed to characterize and predict potential of for metal leaching (ML) and acid rock drainage (ARD). ML/ARD is typically associated with the weathering of sulphide-bearing geologic materials. While this is a natural process, the exposure of fresh particle surfaces produced by mining activity enhances the reaction rates associated with ML/ARD. Results of the ML/ARD assessment were accessed to predict drainage chemistry and contact water quality from various Beaver Dam facilities including waste rock storage areas, temporary stockpiles (i.e., topsoil, till, and organics), and pit walls.

Detailed results of geochemical studies are presented in Appendix E.2, Appendix E.3 and Appendix E.5 and are summarized in the underlying sections. ML/ARD results further informed the Surface Water Quality and Quantity (Section 6.7), where effects on indicators of Surface Water Quality and Quantity (total and dissolved metals, anions, and nutrients; mg/L) were either assessed quantitatively by predictive water modelling or qualitatively based on geochemical characterization studies and professional judgement and experience (e.g., pH, TSS). Appendix E.3 (Geochemical Source Term Update, Table 1-1) provides an overview of the facilities where geochemical source terms were produced. Appendix E.3 also describes the sources terms uses the Surface Water Quality predictions (Section 6.7).

Summary of Assessment

The ML/ARD assessment of the Beaver Dam mine rock includes static testing for a dataset of 70 samples from the main geologic units encountered at the project (Appendix E.5). Acid-base accounting (ABA) was completed for all samples, while 30 samples were analyzed for solid phase elements. The main purpose of ABA characterization is to identify acid-producing and acid-neutralizing phases as ARD will only result from the weathering of sulphide-bearing rocks if there is insufficient alkalinity produced to buffer the acidity generated by the sulphide oxidation process. The ABA results were used to calculate the acid generating potential and the neutralization potential of the samples (Table 6.5-6). These parameters are then used to calculate the net potential ratio (NPR) which can be used as an indicator for the likelihood of a given sample to generate net acid upon exposure to the atmosphere. ABA results indicate that approximately 40% of the Beaver Dam samples were classified as potentially acid generating

(PAG) based on having an NPR-threshold of 2, where samples with an NPR of <2 are considered PAG, while samples with a NPR of ≥2 are non-acid generating (NAG). This NPR value is consistent with the criteria proposed in Price (2009). Generally, argillitic samples have a higher proportion of PAG samples than the greywacke sample population. The full set of ABA analyses for all mine rock samples is presented in Appendix E.2 (Metal Leaching and Acid Rock Drainage Assessment).

Table 6.5-6: Acid-base Accounting Summary

Sample ID	Paste pH	Total S (%)	Sulphate S (%)	Sulphide S (%)	Total C (%)	CaNP (kg $CaCO_3$/t)	Modified NP (kg $CaCO_3$/t)	NPR (ModNP/AP)

Source: Appendix E.2 Metal Leaching and Acid Rock Drainage Assessment, Appendix 4-2.

Notes: n = number of samples used in statistical distribution

A hyphen indicates the parameter was not analyzed.

Values in grey italics are below the analytical detection limit. Values were set at the detection limit for calculation of NP, AP and NPR values.

Sulphate S is calculated using the HCl method.

AP (acid potential) calculated using sulphide sulphur (% non-sulphate sulphur x 31.25); CaNP (carbonate neutralization potential) calculated using total inorganic carbon (% TIC x (100.09/12.01) x 10); Modified NP is obtained by the modified Sobek method.

NPR = neutralization potential ratio; calculated as Modified NP / AP.

During construction and operations, regular testing of rock will be conducted for acid generating potential. A sampling frequency of 8 to 10 samples per 100,000 tonnes of rock generated is recommended based on the guidelines in Price (2009). Parameters of potential concern identified by the solid phase elemental analysis include As, Cu, Mn and Pb. Of these, As is considered the species with the greatest potential for deleterious effects on mine contact water.

To understand sulphide oxidation and metal leaching rates from Beaver dam mine-specific materials, eight humidity cells (one PAG cells and one NAG cell four each of the four major waste rock types) were initiated using representative samples from this

dataset to represent a range of sulphur values from the main geologic units. Ex-ray diffraction and petrographic analyses were completed on the humidity cell samples. The main sulphide mineral identified by petrography was pyrrhotite (<1 to 3%). Humidity cell testing are currently underway. After 24 weeks of testing, the leachates from all humidity cells show neutral pH (Appendix E.3). To support updated EA. Updated kinetic test-work results are included in Appendix E.4.

Two humidity cells with PAG materials (HC4 and HC6) have been running for 107 weeks; while the remaining six humidity cells were terminated after 39 weeks. The leachate pH from all humidity cells that were terminated after 39 weeks of operation has remained circum-neutral falling between 7.1 and 8.6. HC4 and HC6 show a decreasing trend in pH as per the purpose of their continued operation. HC4 leachate, initially producing pH of approximately 7.5, has decreased to pH stabilizing just above 3.0 in the most recent weeks of testing. HC6 has decreased from pH 7.6 to values just below 4.0. The majority of PAG samples are expected to take several years to become acid producing, which will be confirmed through additional source term monitoring (ML/ARD) Monitoring Plan and Water Management Plan (P.4). As noted is the conceptual reclamation plan, post closure monitoring will be may be extended based on information gathered during construction, operations and active closure.

Metal leaching analyses from the kinetic test-work results indicate that As is the main parameter of concern (Appendix E.3 and Appendix E.4). Results indicate the six terminated humidity cells show a decrease in As loading rates over the duration of the experiments to values in the range of approximately 0.005 to 0.01 mg/kg/wk in the later test cycles and, further, the major effect of pH on As mobility which appears to be at a minimum within a pH range of 6.5 to 7.5.

In addition to the ML/ARD assessment (Appendix E.5) of the mine rock, five overburden samples and five Haul Road samples were also analyzed. The overburden samples were collected from within the proposed Beaver Dam pit. These samples have low sulphur content; however, they lack any significant neutralization potential. The samples along the Haul Road were collected from bedrock outcrops. The results indicate that the bedrock along the Haul Road is not potentially acid generating; however, additional samples may be required depending on the Haul Road design and blast depth (Section 2 Project Description). Source materials for the Haul Road will require physical and chemical testing to determine suitability for construction of the Haul Road. Materials may be sourced from small quarries (<4 ha) along the Haul Road, Touquoy Mine, Beaver Dam Mine or a commercial quarry.

Appendix E.2 and Appendix E.3 detail the ML/ARD Assessment Report and the Geochemical Source Term Predictions for waste rock, low-grade ore, tailings and overburden.

Possible Onset of Acid Rock Drainage from Waste Rock: Beaver Dam Mine Site

Lorax Environmental has provided predictions relating to ARD potential from the waste rock pile at the Beaver Dam Mine Site. Initial predictions indicate the range may be approximately 10 to 30 years for half of the Beaver Dam PAG waste rock to generate acidic leachate. However, in response to IR2 NSE-2-44, the PAG humidity cells that are expected to become acidic, the time to NP depletion theoretically corresponds to the time to onset of acid generating conditions, although the grain liberation is an important factor. Note that for the purposes of calculating NP depletion rates and the time for complete depletion of NP, the initial sulphate production rates, which reflect the flushing of non-acid generating surface oxidation products such as gypsum, were not incorporated in the calculation. Rather the relatively stable NP depletion rates in later cycles of the tests more appropriately reflect depletion based on sulphate produced by sulphide oxidation. This will prevent underestimating the amount of available NP and the lag time to the onset of acidic conditions. The model results suggest that will be depleted between around 7 to 10 years for the PAG humidity cells.

To provide a more realistic estimate that considers the slowing of sulphide oxidation at the Beaver Dam Mine Site in response to colder temperatures and/or freezing of parts of the waste rock, the sulphate leaching rate was corrected by a factor of 0.3. This value is consistent with the temperature-dependent sulphide oxidation rate and sulphate release rate observed around 10°C

(Dockrey and Mattson, 2016), which is somewhat higher than the mean annual temperature measured at the Beaver Dam site. Note that this approximation is only applicable for waste rock exposed to ambient air temperatures such as pit walls, since waste rock piles may have a different temperature profile. As discussed in NSE 2-44, Plotting humidity cell total sulphur (ST) contents against the respective temperature-corrected NP depletion rates shows a positive correlation (Figure 4-11a of Appendix E.2 ML/ARD Assessment Report) that can be written as:

$$\text{NP depletion rate} = 0.0013 \times \ln [ST] + 0.0064$$

This function was then applied to the PAG samples within the Beaver Dam static test population to quantify a range of lag times that can be expected until these PAG samples release net acidic drainage. The results of this exercise are shown in Figure 4-11b within Appendix E.2 and show that it will take around 20 years for 10% of all PAG samples and 28 years for 50% of all PAG samples to turn acidic. For additional details refer to ML/ARD Assessment Report included in Appendix E.2.

There is no expectation for acidic conditions during Beaver Dam Mine operations based on an assessment of the geochemical characteristics of the mine rock (refer to Appendices E.3 Geochemical Source Term Update). However, during the closure phase, current studies suggest that acidic conditions may occur. The proposed ML/ARD Management Plan will inform the scope of the ML/ARD monitoring and mitigation measures to be adopted during the operational and closure phases of the Project. The Plan will outline geochemical test work to be conducted during the construction and the operational mining phases.

The scope of the ML/ARD Management Plan for the pre-mining phase will fill in gaps and reduce uncertainties identified in the initial geochemical characterization work as presented in Appendix E.3. The results from this ML/ARD Management Plan will further be used to inform the submission of the NSE Industrial Approval Application. The scope of work addressed in this Plan will comprise, but not limited to, the following:

- Tailings testing consisting of static characterization of Beaver Dam tailings samples as part of an overall metallurgical testing program when undertaken. This work will be used to assess whether the use of Touquoy tailings as a geochemical surrogate for Beaver Dam tailings is valid.
- Based on the results of the above, kinetic testwork including humidity cells and/or saturated columns may be conducted on Beaver Dam tailings.
- Confirmation sampling and additional static testing of samples collected from deeper till horizons.
- Collection of additional (non-surface) haul road samples to increase spatial coverage and confidence in material geology and geochemistry.
- Collection of naturally oxidized, high-sulphide sample(s) for kinetic testwork and assessment of pH and metal leaching potential of this material under acidic conditions.
- Incorporation of available static test results into geological/geochemical block model that can be used to refine the PAG versus NPAG waste rock tonnages for the deposit.

The results of the pre-mining geochemical characterization will also be used to inform the operations phase ML/ARD Management Plan (Appendix E.5), which consists of the following:

- Definition of geochemical analyses required for the classification or environmental rock types.
- Derivation of proxies and criteria to classify PAG versus NPAG materials rapidly on site.

- Definition of optimum sampling frequency of waste rock, ore, tailings and overburden throughout the life of mine based on the observed geochemical variability.
- Definition of criteria distinguishing construction from non-construction materials.
- Development of material handling and ARD prevention/mitigation strategies.

The implementation of the above ML/ARD Management Plan (Appendix E.5) will confirm whether acidic conditions can be anticipated during the active closure phase as well as the timeframe when this will occur. Moreover, this plan will inform the adoption of appropriate mitigation to be applied (refer to Section 6.5.8 for mitigation measures).

6.5.7 Project Activities Interactions and Effects

6.5.7.1 Overview of Potential Project Interactions

The purpose of this section is to identify how the Geology, Soil and Sediment Quality VCs may be affected by with the Project's components and activities (Tables 6.5-7 to 6.5-9). The Project is part of the Moose River Consolidated (MRC) Project, which includes the existing and fully permitted Touquoy Gold Project, located in Moose River Gold Mines, Nova Scotia. The Project will operate as a satellite surface mine to the MRC Project, and crushed ore from the will be transported by truck via the Haul Road to the existing and fully permitted Touquoy Mine.

Geology, Soils, and Sediment Quality represent physical components of the natural environment; changes related to Geology, Soils and Sediment Quality VCs provided in the subsequent sections are to support the Effects Assessment on water quality, wetlands, and fish and fish habitat (Sections 6.7, 6.8, and 6.9).

Project effects to Geology are here constrained by the ML/ARD assessment and geochemical characterizations programs; these results (Section 6.5.6.3) informed predictive water quality modelling and the Surface Water Quality and Quantity Effects Assessment (Section 6.7). The goals were to remove as much subjectivity as possible from the assessment and to increase certainty in the predictions of alteration of the Surface Water VC, residual effects, and the determination of significance to ensure a robust, transparent, and defensible approach to the effects assessment.

Changes to soil and sediment quality that have neutral or beneficial effects on soil or sediment characteristics. Examples of this include increases in productivity (such as mixing of organic material with surface horizons or addition of nutrients through dust deposition) or degradation of soil and sediment quality, caused by ML/ARD processes. Soil and Sediment Quality degradation may result from Project Activities causing increases in surface runoff and siltation, local soil erosion, or loss of soil structure due to disturbances such as excavation, transport.

6.5.7.2 Potential Project Interactions, Beaver Dam Mine Site

The Beaver Dam Mine Site is currently an advanced exploration site with existing conditions as described in other sections. Effects to geology, soil, and sediment caused by project activities will include the blasting in geology, materials movement of soil and geology, and changing sediment. Any anticipated effects are outlined and further discussed in related VC Sections including, groundwater, surface water, and wetlands, with further residual effects from Project activities on geology, soil, and sediment described in Section 6.5.9. All site areas used for storage of natural materials such as the Till Stockpile, Waste Rock stockpiles, LGO would be monitored throughout the life of the Beaver Dam facility as per any approval relative to operation and any approval relative to closure and reclamation plan for the Project. Surface water and groundwater monitoring programs would include

locations in proximity to areas where soils, sediment and geology (rock materials) would be disturbed so these programs would outline effects and compare them to applicable guidelines.

Table 6.5-7: Potential Soils and Sediment Interactions with Project Activities at the Beaver Dam Mine Site

Project Phase	Duration	Relevant Project Activity
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of transport and storage • Till, historical tailings and waste rock from site preparation transport and storage • Existing settling pond dewatering in preparation of construction • Watercourse and wetland alteration in preparation of construction • Mine Site road construction • Surface infrastructure installation and construction • Collection and settling pond construction
Operations and Maintenance	5 years	• Rock blasting to access and extract ore • Mine dewatering of facilitate access to and extraction of ore • Management of waste rock produced from crushing and preparing ore for transport • Surface Water Management
Active Closure	2 years	• Infrastructure demolition • Site reclamation activities
Post-closure	10+ years (monitoring)	N/A

Note: N/A = not applicable.

6.5.7.3 Potential Project Interactions, Haul Road

The baseline conditions along the Haul Road have been previously described and consist of existing forestry type roads of varying widths, surfaces and conditions. With the upgrades of the Haul Road, there are anticipated activities that have the potential to affect geology, soil, and sediment anticipated to be caused through activities as outlined on the table above. Surface water and sediment monitoring programs would include locations in proximity to areas where geology (rock materials), soils, and sediment quality would be disturbed as part of road upgrades so these programs would outline effects and compare them to applicable guidelines. During Active Closure of the Haul Road it is not expected as either option would be returned to the owner(s) for forestry industry activities.

Table 6.5-8: Potential Soils and Sediment Interactions with Project Activities along Haul Road

Project Phase	Duration	Relevant Project Activity
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of transport and storage • Till and waste rock from site preparation transport and storage • Watercourse and wetland alteration in preparation of construction • Haul Road upgrades
Operations and Maintenance	5 years	• Ore transport • Haul Rock maintenance
Active Closure	2 years	• N/A[(a)]
Post-closure	10+ years (monitoring)	• N/A

Note: [(a)] Decommissioning and Reclamation of the Haul Road is not expected. The Haul Road will be returned to owner for forestry Industry. N/A = not applicable.

6.5.7.4 Potential Project Interactions, Touquoy Mine Site

The Touquoy facility is currently in operation. There are no effects to geology, soil, and sediment anticipated to be caused by the processing of ore and the management of tailings (exhausted pit) from the Project at the Touquoy Mine Site. The use of the Touquoy facility for the processing of Beaver Dam ore will not involve construction or operation at the Touquoy Mine Site or use of the Tailings Management Facility; therefore, no effects are anticipated at the Touquoy facility related to the processing of Beaver Dam ore, with the exception of the continued potential for accidents and malfunctions and continued environmental monitoring. The waste rock stockpile will continue to be monitored throughout the life of the Touquoy Mine Site as per the approved closure and reclamation plan for the Touquoy Mine; this facility will not be used as part of the Project.

Table 6.5-9: Potential Soils and Sediment Interactions with Project Activities at Touquoy Mine Site

Project Phase	Duration	Relevant Project Activity
Construction	1 year	• Tailings pipeline, make-up water pipeline alteration, and relocation of reclaim infrastructure
Operations and Maintenance	5 years	• N/A
Active Closure	2 years	• Decommissioning and reclamation activities
Post-closure	10+ years (monitoring)	• N/A

Note: N/A = not applicable.

6.5.8 Mitigation

Design and operation of sedimentation and erosion controls, as well as waste and water management infrastructure, represents a key aspect of planned mitigation and management activities for the Project to mitigate potential effects to Geology, Soils, and Sediment Quality VC. Geology, Soils, and Sediment Quality represent physical components of the natural environment; changes related to Geology, Soils and Sediment Quality VCs described here informed the Effects Assessment on Surface Water, Wetlands, and Fish and Fish habitat (Sections 6.7, 6.8, and 6.9). As such, fulsome discussion of proposed mitigation and management measures are presented Surface Water (Section 6.7.9), Wetlands (Section 6.8.8), and Fish and Fish Habitat (Section 6.9.8). A summary of the most salient aspects specific to Geology, Soils and Sediment Quality VCs are presented in this section and summarized in Table 6.5-10.

Table 6.5-10: Summary of Mitigation for Geology, Soils, and Sediment Quality

Project Phase	Mitigation Measure
C, O, CL	Use of the following routine controls, as needed: • Silt fences • Silt curtains • Riprap • Check dams • Settling ponds
C, O, CL	Segregate and manage waste rock with the potential for acid generation
C, O	Implement Erosion and Sediment Control Plan
C, O	Secure overburden stockpiles using a combination of mulching, hydroseeding, and slope stabilization
C, O, CL	Limit exposed soil
CL	Use soil and organics stockpiles for final capping and stabilization. Hydroseed as required

Note: C = construction; O = operations; CL = active closure.

Geology and Soils

Geology and soils outside the disturbed areas at the sites have no potential for generating impacts and are therefore not part of any mitigation or monitoring program. Soils, excluding historic tailings will be stored in temporary stockpiles and at active closure used for reclamation. Historic tailings will be transported off site and disposed of in the Touquoy mined out pit. Therefore, there is no need for mitigation or compensation measures, or for monitoring of site soils.

Soil Erosion and Sedimentation

A draft Erosion and Sediment Control Plan (Appendix C of Appendix P.4 Mine Water Management Plan) will be implemented during construction and operation to mitigate the release of sediment from the mine site to the receiving surface water systems. A draft Erosion and Sediment Plan is included in Appendix C of Appendix P.4.

General strategies for erosion prevention are:

- minimizing clearing and grubbing dimensions during construction activities;
- controlling and directing runoff from disturbed areas by grading slopes and ditching;
- re-vegetating disturbed areas;
- limiting the length and steepness of bare, exposed slopes to minimize runoff energy;
- applying appropriate surface drainage techniques (e.g., ditch blocks, ditch surface lining, and rip-rap);
- stabilizing water diversion channels and ditches and protecting channel banks with rocks, gabions, or fibre mats; and
- protecting disturbed areas from water erosion and collecting surface water from disturbed areas for treatment, if required, to meet discharge standards prior to release.

Where soil erosion may still occur despite preventative measures, sediment control strategies may be implemented to capture sediments before they are released to the receiving environment. Sediment control measures may include installation of, for example:

- silt fences;
- weed-free straw bales;
- check dams;
- fabric-covered triangular dikes;
- gravel or sand-filled burlap bags;
- sedimentation ponds; and
- rip-rap along channels and ditches.

Sediment Quality

Sediment is a valued part of aquatic habitats and needs to be afforded the protection from new inputs of potential impacts (suspended solids, elevated metals) that can affect invertebrates and other aspects of the aquatic environments dependent on invertebrates such as fish species for example. Fulsome discussion of mitigation specific to aquatic habitats (i.e., wetlands and fish and fish habitat) are provided in Sections 6.8 and 6.9.

6.5.9 Residual Effects and Significance

Table 6.5-11 presents a summary of the assessment of potential environmental effects on Geology, Soil and Sediment Quality VC. The assessment of residual effects incorporated mitigation and management plans for Project effects as described in Appendix P.4. However, the proposed mitigation cannot eliminate the Project-related residual effects, and the following residual effects were identified:

- change in soil and sediment quality via migration of contaminants via dust deposition and runoff events, including ML/ARD interactions; and
- change soil and sediment quality as a result of slope destabilization and road widening activities associated with Haul Road construction.

Significant residual effects for Geology, Soils and Sediment Quality are not anticipated at any of the PA components (Beaver Dam Mine Site, Touquoy Mine Site [Beaver Dam Mine Site ore processing], or Haul Road) for the following reasons, with consideration of the ecological and social context of the LAA surrounding the Project:

- During Construction: Changes are restricted to a small footprint in the broader ecological and social context of the LAA.
- During Operations: Changes are restricted to a small footprint in the broader ecological and social context of the LAA.
- During Closure: Changes are limited in footprint and the landscape returns to near baseline conditions.

Project effects to Geology are here constrained by the ML/ARD assessment and geochemical characterizations programs; these results (Section 6.5.6.3) informed predictive water quality modelling and the Surface Water Quantity and Quality Effects Assessment (Section 6.7); residual effects relevant to Geology VC are thus described in Section 6.7.9 (Residual Effects to Surface Water).

The soils and sediments in the Beaver Dam Mine Site, some areas of the Haul Road and the soils are currently disturbed in many areas as well. Overburden and soils will be stored temporarily for future reclamation use and some overburden will be reclaimed in its stored location at the Beaver Dam Mine Site. Soils and materials not used in construction along any Haul Road option would be stored and remediated, as necessary, in a manner that is permanent with no residual impacts predicted.

Sediment has the potential for changes that have possible effects in the short-term mitigation and monitoring programs have been designed to outline (if they actually occur) and avoid and monitor any identified long-term residual impacts.

Table 6.5-11: Residual Effects for Geology, Soils, and Sediment Quality

Project - VC Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction and Operation – Beaver Dam Mine Site (exposure of acid generating material, impacted soil/sediment through migration of contaminants via dust deposition and runoff events.)	Select removal of impacted materials, wet dust suppression controls, hardened surfaces where practical, covering of haul trucks to reduce dust during transportation, vehicle speed reduction to minimize dust, spill preparedness. reclaiming/spreading stockpiles, soil/sediment quality,	L Minor changes from baseline conditions	LAA Potential adverse effects to soil/sediment quality and quantity outside the PA	A Seasonal aspects may affect VC (i.e., wind)	LT Effects may extend beyond 3 years	S Effects occur at irregular intervals throughout the Project	IR VC will not recover to baseline conditions	Soil and sediment quality, increased dust impact (i.e., flora and fauna/habitat, human health, etc.)	Not significant
Construction and Operational – Haul Road (Haul Road widening and construction, trucking activity, and sediment quality impacts through migration of contaminants via dust deposition and runoff events.	Slope stabilization, sediment and erosion control, best management practices, spill preparedness. reclaiming/spreading stockpiles, soil/sediment quality	L Minor changes from baseline conditions	PA Potential adverse effects confined to the PA	N/A VC is not expected to be affected by timing	MT Effects can occur beyond 12 months and up to 3 years	O Potential effects to occur once during the construction phase	R Sediment Quality will recover to baseline conditions after cessation of activities/ closure of the mine IR Soil under the footprint of the road will be lost.	Erosion, soil and sediment quality	Not significant
Operational – Touquoy Mine Site (soil/sediment quality)	Covering of haul trucks to reduce dust during transportation onsite, vehicle speed reduction to minimize dust onsite. reclaiming/spreading stockpiles, soil/sediment quality	L Minor changes from baseline conditions	LAA Potential adverse effects to soil/sediment quality and quantity outside the PA	A Seasonal aspects may affect VC (i.e., wind)	LT Effects may extend beyond 3 years	S Effects occur at irregular intervals throughout the Project	R Soil Sediment Quality will recover to existing conditions after cessation of activities/ closure of the mine	Soil and sediment quality, increased dust impact (i.e., flora and fauna/habitat, human health, etc.)	Not significant

Notes: See Section 5.11, Table 5.11-1 for definitions of the below characteristics.

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible

M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	PR	Partially Reversible
H	High					P	Permanent	C	Continuous		

6.5.10 Proposed Compliance and Effects Monitoring Program

Monitoring will be completed to verify the predicted environmental effects and the effectiveness of the mitigation measures for Geology, Soils and Sediment Quality VC. Monitoring will occur outlined in the following plans:

- Erosion and Sediment Control Plan (Appendix C of the Appendix P.4 Mine Water Management Plan);
- ML/ARD Mitigation and Monitoring Plan (Appendix E.5); and
- Mine Water Management Plan (Appendix P.4).

Management and monitoring plans represent living documents and will be developed through regulatory permitting, as well as public and Mi'kmaw engagement.

6.6 Groundwater Quality and Quantity

6.6.1 Introduction

6.6.1.1 Summary of Groundwater Quality and Quantity Before the Updates

The Beaver Dam Mine hydrogeology consists of a fractured rock aquifer system which is overlain by a thin aquifer in the till. Based on previous studies of the hydrogeology of this deposit and others in the area, the degree of hydraulic connection amongst the smaller bedrock fracture systems is likely poor to moderate, and the main zones that are capable of storing and transmitting relatively large amounts of groundwater are the larger scale faults. The water table is close to the surface across the mine site, reflecting flat lying terrain, low permeability bedrock and the excess of annual rainfall over evaporation. The bedrock sequence and part of the overlying tills will be saturated with groundwater under ambient conditions.

The historic and recent data (collected up to 2018) from the site describes physical hydrogeology of the site and interactions that were examined as part of the groundwater Valued Component (VC). Modeling results contributed to an assessment of surface water quantities (i.e., baseflow and water levels) and potential impacts to wetlands. An evaluation of impacts to potable water in the vicinity of the mine site was undertaken and determined to be not significant.

Groundwater at the Touquoy Mine was assessed to evaluation potential impacts from the deposition of tailings in the mined-out pit. A series of geotechnical/hydrogeological drill holes were sampled at the Touquoy Mine Site for groundwater quality). Samples were analyzed for general chemistry and metals at this time. Since 2016, groundwater monitoring has been ongoing at the Touquoy Mine Site as per regulatory requirements (32 pairs of wells). Results indicate that the groundwater is slightly basic with an elevated hardness. Certain metals such as aluminum, arsenic, manganese, strontium and zinc are elevated relative to guidelines for drinking water in Canada but within ranges found in groundwater in Nova Scotia. The groundwater assessment concluded that there would be no impact to the Moose River resulting from tailings deposition.

6.6.1.2 Summary of Updates to Groundwater Quality and Quantity

The groundwater assessment for the Beaver Dam Mine Site has been updated to reflect additional hydrogeologic data collected since the Revised 2019 EIS (AMNS 2019), updates to Project layout, additional Contaminant of Concern (COC) source terms and comparison of predicted COC concentrations in groundwater to NSE Tier 1 EQS for potable groundwater, GCDWQ or NSE Tier 2 PSS for groundwater discharge to surface water (>10 m) (Section 6.6.7.1) and in response to Round 2, Information Requests (IR2s) from the Impact Agency of Canada (IAAC; formerly the Canadian Environmental Assessment Agency [CEAA 2019]) and Nova Scotia Environment (NSE 2019). Responses to theses IR2s include: CEAA-2-35, NSE-2-2, NSE-2-35, NSE-2-135, NSE-2-145, NSE-2-150, NSE-2-166.

The hydrogeological model has been updated to address IR2s and provide additional details on groundwater predictions. The maximum, not average, simulated concentrations in groundwater discharge are used to evaluate potential health risks from the consumption of surface and/or groundwater that may be impacted by mining activities. In response to IR2 CEAA-2-41, only advection and dispersion were considered for contaminant transport to provide a conservative bias for predicted COC concentrations, which is discussed in Sections 7.1.5.1 and 7.1.5.2 of Appendix F.5 (Hydrogeologic Modelling Report). The Post-closure (PC) transport simulations were run for 500 years to approximate a steady-state condition thereby simulating the maximum extent and concentration of potential COCs. For End-of-Mine (EOM), it is assumed the EOM COC sources will persist for approximately double the predicted duration to provide a further conservative bias towards simulating the maximum extent and concentration of potential COCs.

Groundwater drawdown predictions were updated to include cross-sections through the Beaver Dam open pit showing simulated drawdown (Figures 7.4a through 7.6b in Appendix F.5 [Hydrogeologic Modelling Report]). Updates in predicted drawdown from 2019 is attributed to changes in proposed site infrastructure. In general, there was a greater amount of simulated drawdown south of the pit in the 2019 that related to the proposed unlined surface water management ditches surrounding an eastern waste rock pile. The eastern waste rock pile had been removed therefore, the simulated drawdown south of the proposed pit decreased as there was no proposed infrastructure in that area. The simulated drawdown north of the proposed pit is similar between the 2019 and 2021 EIS. During PC, a greater amount of drawdown is simulated in the vicinity of the PAG waste rock stockpile due to the proposed engineer cover that will limit infiltration over the PAG waste rock stockpile.

A seepage face is also simulated along the pit walls at depth and porosity assessment are provided to evaluate potential impacts to overall water balance including inputs to changes in baseflow in the Cameron Flowage/Killag River at EOM and PC (i.e., responses to IR2s CEAA-2-14, CEAA-2-41, CEAA-2-42, NSE-2-162, NSE-2-163, NSE-2-190). The estimated total average annual flow in Cameron Flowage is 103,881 cubic metres per day (m^3/d). The estimated average annual baseflow for Cameron Flowage is 23,426 m^3/d, which is approximately 23% of the total average annual flow (Section 6.6.4.2.1). The estimated average annual baseflow in Cameron Flowage provides a baseline condition to compare predicted baseflow at the end of mine life and post-closure (Appendix F.5). The simulated change in baseflow throughout the Cameron Flowage watershed is presented in Table 7.4 of Appendix F.5 (Hydrogeologic Modelling Report). The simulated baseflow reduction ranges from 677 to 754 m^3/d at EOM and from 446 to 620 m^3/d at PC. The range in baseflow reduction represents 2 to 3% of total baseflow in the Cameron Flowage watershed and is under 1% of the total average annual flow in Cameron Flowage (Section 6.6.4.2.1).

An updated assessment at Touquoy has been undertaken based on additional sampling as well as comparisons with NSE Tier 1 EQS for potable groundwater GCDWQ or NSE Tier 2 PSS for groundwater discharge to surface water (NSE-2-145). The updated Groundwater Flow Solute Transport Model (Appendix F.6) has been updated to included additional monitoring data (NSE-2-146) along with Moose River Accumulation Study (Appendix F.8) to assess potential impacts to Moose River from disposal of Beaver Dam Mine Tailings. The calculated mean annual baseflow in Moose River is 28,814 m^3/d, and the mean summer baseflow for 2019 and 2020 are 9,848 and 9,143 m^3/d, respectively (Section 6.6.4.2.2). As discussed, in Section 6.6.7.1, in the summer months, the dewatering of the Touquoy open pit occurs at a rate of 444 m^3/d, which is anticipated to reduce the flow in Moose River by 339 m^3/d. This accounts for approximately 1.7% of the mean summer flow at Moose River of 18,938 m^3/d at SW-2.

NSE Tier 1 = Nova Scotia Environment Tier 1 Environmental Quality Standard (EQS) for potable groundwater; NSE Teir 2 = Nova Scotia Environment Tier 2 Pathway Specific Standard (PSS); GCDWQ = Guidelines for Canadian Drinking Water Quality.

6.6.2 Rationale for Valued Component Selection

Groundwater quality and quantity is provincially regulated via many legislative avenues within the *Nova Scotia Environment Act* and protects ecological components, as well as the health of the general public.

Groundwater quality and quantity as a VC is centered on its potential ecological value in recharging surface water and wetlands. From a hydrological and hydrogeological perspective, the potential disconnection between bedrock aquifers and surface water in the project area may limit groundwater recharging, or being recharged, by surface water. In a mine dewatering scenario at the Beaver Dam mine site, groundwater drawdown will affect surface water quantity in Cameron Flowage/Killag or adjacent watercourses or wetlands. This groundwater drawdown is considered in base flow predictions used to assess impacts to Wetlands (Section 6.8) and Fish and Fish Habitat (Section 6.9). Groundwater quality as a component of the surface water quality is assessed in the Surface Water Quality and Quantity (Section 6.7), Wetlands (Section 6.8) and the Fish and Fish Habitat (Section 6.9) Groundwater is also assessed for the Touquoy Mine Site operation as that pit is being used for Beaver Dam Mine Site tailings deposition in the exhausted or mined-out pit. The groundwater assessment at Touquoy is focused on changes to groundwater quality and quantity as inputs to Surface Water (Section 6.7), Wetlands (Section 6.8) and Fish and Fish Habitat (Section 6.9) Groundwater quality and quantity also has a socio-economic importance due to its potential to provide potable water through drilled and dug wells. The nearest potable well is approximately 5 kilometres (km) southwest of the Beaver Dam Mine Site. Camp Kidston, that operates only in the summer months, is located 3.5 km northeast of the Touquoy Mine Site and the nearest permanent full-time residences are located approximately 5.8 km to the north of the Touquoy Mine Site along Caribou Road.

6.6.3 Baseline Program Methodology

Baseline conditions at the Beaver Dam Mine and Touquoy Mine Sites were assessed and developed as follows:

- publicly available data including well records, reports and groundwater quality and quantity data were reviewed and compiled;
- site-specific reports, and geologic cross-sections and maps developed from past drilling programs were reviewed and compiled;
- a groundwater monitoring network was installed at both Beaver Dam Mine and the Touquoy Mine to collect groundwater quality/quantity information to establish baseline conditions and to provide ongoing monitoring; and
- a numerical groundwater flow model was developed for both Beaver Dam Mine Sites and the Touquoy Mine. The numerical models were applied to simulate current baseline groundwater quantity conditions, which form the basis of comparison for predicted groundwater quantity conditions under future mining conditions.

The assembled data and groundwater monitoring networks installed at Beaver Dam and Touquoy Mine Sites are described in Section 6.6.3.1 and Section 6.6.3.2, respectively.

Baseline conditions at the Beaver Dam Mine Site have been updated in the Hydrogeologic Modelling Beaver Dam Mine Site Report (Appendix F.5) to include additional baseline sampling (Appendix F.4). A combination of changes in Project Description (Section 2) and specifically the mine layout (Section 2, Figure 2.3-2) along with additional baseline sampling have resulted to updates to the groundwater modelling predictions (Section 6.6.6.2) from the Revised 2019 EIS. The specific appendices that support the Beaver Dam Mine Groundwater Assessment include:

- Appendix F.1 Assessment of Potential Open Pit Groundwater inflows at the Beaver Dam Mine Gold Project, Nova Scotia (Peter Clifton and Associates April 2015);

- Appendix F.2 Hydrogeologic Investigation - Beaver Dam Mine, July 30, 1986 (Jacques Whitford and Associates Ltd. 1986);
- Appendix F.3 Field Activity Report Beaver Dam Mine Project – (November 8, 2018);
- Appendix F.4 Baseline Groundwater Program (Beaver Dam) Memo – (March 20, 2021);
- Appendix F.5 Hydrogeologic Modelling Beaver Dam Mine Site Report – updated modelling – (April 15, 2021); and
- Appendix F.9 Response to Information Request Nos. CEAA-2-36, CEAA-2-37, and NSE-2-130 Evaluation of Potential Impacts from Metals COCs to Groundwater and Surface Water from Dust Deposition along the Haul Road Beaver Dam Mine Project Marinette, Nova Scotia – (April 14, 2021).

Touquoy modelling has been updated based on updates to Beaver Dam Mine Project Description, production schedule and tailings. In addition, the following Touquoy supporting appendices include:

- Appendix F.6 Groundwater Flow and Solute Transport Modelling to Evaluate Disposal of Beaver Dam Tailings in Touquoy Open Pit - Beaver Dam Gold Project – (April 12, 2021);
- Appendix F.7 Touquoy Integrated Water and Tailings Management Plan - Beaver Dam Gold Project – (April 15, 2021);
- Appendix F.8 Beaver Dam Gold Project Assimilative Capacity Study of Moose River – Touquoy Pit Discharge – (April 12, 2021); and
- Appendix F.10 Simulating the Cumulative Effects of Deposition of Tailings to the Touquoy Pit – (April 8, 2021).

6.6.3.1 Beaver Dam Mine Site Baseline Program Methodology Update

The Beaver Dam Mine Site is in an area of Nova Scotia that has been well studied from a geologic and hydrogeologic perspective. Publicly available information is abundant including important studies such as Lin (1970). The Nova Scotia Well Log Database (NS Well Log Database) that contains thousands of records of wells drilled and dug in Nova Scotia was reviewed to determine the proximity and construction details for potable wells in the area of the Beaver Dam Mine Site. Data was reviewed for applicability to the Beaver Dam Mine Site geology and hydrogeology and was used in the assessment of this VC. Hydrogeological maps and cross-sections for the mine area are well characterized from past drilling programs. The stratigraphy and general hydrogeological conditions have been described in Appendix F.5 (Hydrogeologic Modelling Report).

Peter Clifton & Associates (PCA) completed a hydrogeological assessment of the Beaver Dam Mine Site (PCA, 2015). The report provides an assessment of potential groundwater inflows to the proposed open pit at the Beaver Dam Mine Site and includes a review of previous hydrogeological investigations completed at the Mine Site by Jacques Whitford and Associates Ltd. (JWA) in 1986 (JWA, 1986a) and Stantec Consulting Ltd. (Stantec) in 2014 (Stantec, 2015). The PCA (2015) and JWA (1986a) reports are included in Appendix F.1 and Appendix F.2, respectively. Additional reports reviewed for background information such as fault mapping, previous hydrogeologic evaluations, and geologic interpretations include *Assessment Report on 1987 Exploration Programme on Development License 0078* (Duncan, 1987) and *Environmental Assessment of Gold Mining Exploration, Beaver Dam, Nova Scotia* - (JWA, 1986b).

To further define baseline conditions at the Beaver Dam Mine Site, a monitoring well drilling, installation and hydrogeologic investigation program was conducted from March 29, 2018 to May 7, 2018 (Appendix F.3). In total, 49 nested monitoring wells were installed (Figure 6.6-1). At each nested location, one shallow well was drilled to intercept the water table, or the first occurrence of saturated conditions, typically encountered within the overburden above bedrock. A second monitoring well was also installed at every monitoring well nest, typically screened within shallow competent bedrock. A series of deeper bedrock wells (approximately 30 metres [m] below ground surface [bgs]) were installed at 12 locations, designed to assess more regional

groundwater flow patterns in the deeper bedrock and determine the relationship between shallow and deep bedrock groundwater flow conditions. Finally, three additional wells were installed at depths of approximately 60 m bgs to evaluate bedrock groundwater flow conditions at this greater depth near the proposed open pit mine. The drilling program is documented in the Field Activities Report for the Beaver Dam Mine Project (Appendix F.3) including the location of wells, boreholes logs, and associated hydraulic testing conducted to assess the hydraulic properties of the overburden and bedrock.

Following drilling, packer and slug tests were conducted at selected well locations to determine the hydraulic conductivity of the overburden and bedrock. Biweekly synoptic monitoring of groundwater and surface water elevations began July 5, 2018. Following the installation of transducers in monitoring well for automated recording of water levels, the manual monitoring frequency was reduced to quarterly, weather permitting. Nine quarterly rounds of water quality sampling from all newly installed monitoring wells have been completed from June 2018 to November 2020 (Section 6.7.5.2). Measured groundwater elevations and groundwater quality sample results are presented in Appendix F.4 Baseline Groundwater Program. Groundwater quality data is compared to Nova Scotia Environment (NSE) Tier 1 Environmental Quality Standard (EQS) for potable groundwater, the NSE Tier 2 Pathway Specific Standard (PSS) for groundwater discharge to surface water (>10 m) and the Guidelines for Canadian Drinking Water Quality (GCDWQ) maximum acceptable concentration. Hydraulic conductivity testing, groundwater elevation measurements, and water quality sampling results are discussed in Section 6.7.5.2.

Previous drilling programs and recent monitoring support that the Beaver Dam Mine Site hydrogeologic conditions are very similar in nature to those at the Touquoy Mine Site. This is expected as the Touquoy Mine Site is located in the same geologic formation as the Beaver Dam Mine Site. The understanding of the groundwater system at Beaver Dam Mine Site will therefore grow with the collection and analysis of data from the compliance monitoring program at the Touquoy Mine Site that has been ongoing since the spring of 2016. Data collected at the Touquoy Mine Site will be used to supplement the ongoing data collection at the Beaver Dam Mine Site. Relationships between surface water and groundwater systems at the Touquoy Mine Site will be better understood in these intervening years and this knowledge will be applied to the monitoring and data collection programs for the Beaver Dam Mine Site throughout the construction, operation, and reclamation phases. Empirical data has significant value in this situation and will be used to the fullest extent, and preferentially over modelling.

The historic and recent data from the Beaver Dam Mine Site, supplemented by data collected at the Touquoy Mine Site provides thorough picture of the physical hydrogeology of the Beaver Dam Mine Site as well as possible interactions that were examined as part of the groundwater VC. Based on the observed hydrogeologic conditions at the Beaver Dam Mine Site, a hydrogeologic conceptual site model (CSM) was developed to describe observed geologic, hydrogeologic, and hydraulic condition, including groundwater and surface water interactions. The Beaver Dam Mine Site CSM is presented in Appendix F.5 Hydrogeologic Modelling Report.

Based on the CSM, a three-dimensional (3D) numerical groundwater flow model was developed for the Beaver Dam Mine Site in accordance with British Columbia Ministry of the Environment guidelines (Wels et al., 2012). The Beaver Dam Mine Site 3D numerical groundwater flow model (Beaver Dam Model) was applied to simulated baseline groundwater quantity conditions, which provides a basis of comparison for predicted groundwater quantity conditions at end of mine life and post-closure. The Beaver Dam Model is also applied to improve understanding of hydrogeologic interactions and to simulate transport of constituents of concern (COCs) at the Beaver Dam Mine Site. Detailed documentation of the Beaver Dam Model, including background information, CSM development, model construction, model calibration, and model application is included in Appendix F.5 Hydrogeologic Modelling Report.

6.6.3.2 Touquoy Mine Site Baseline Program Methodology

PCA also completed a hydrogeological assessment of the Touquoy Mine Site (PCA, 2007). The report provides an assessment of potential groundwater inflows to the proposed open pit at the Touquoy Mine Site. The assessment used a series of geotechnical/hydrogeological drill holes that were also sampled for groundwater quality. The holes were purged using an airlift method and then sampled after fully developing and purging the wells to obtain a representative groundwater sample. The water obtained from the drill holes represents groundwater from bedrock at the site. Samples were analyzed for general chemistry and metals. Test pits were also excavated in June 2006 to evaluate groundwater flow in the till between the open pit and Moose River. Additional assessment work completed in September 2006 included a temperature survey of surface water to determine possible areas of upwelling groundwater.

JWA (2008) prepared a Groundwater Monitoring Plan as part of the Industrial Approval application for the Touquoy Mine Site. The series of 32 multi-level well pairs, proposed in the plan were installed by GHD at the Touquoy Mine Site (GHD 2016a,b), and groundwater monitoring has been ongoing at the Touquoy Mine Site to characterize the groundwater conditions in the overburden and bedrock (water levels and chemistry). The baseline groundwater conditions are described in the 2017 Annual Report of Surface Water and Groundwater Monitoring (Stantec 2018).

The historical and recent data from the site provided a thorough picture of the physical hydrogeology of the Touquoy Mine Site as well as possible interactions that were examined as part of the groundwater VC. Based on the observed hydrogeologic conditions at the Touquoy Mine Site, a hydrogeologic CSM was developed to describe groundwater and surface water interactions at the site. The CSM for the Touquoy Mine Site is presented in Appendix F.6 Groundwater Flow and Solute Transport Modelling to Evaluate Disposal of Beaver Dam Tailings in Touquoy Open Pit – Beaver Dam Gold Project.

A three-dimensional (3D) groundwater flow model was developed based on the CSM in accordance with the BC Guidelines for Groundwater Modelling to Assess Impacts of Proposed Resource Development Activities (Wels et al. 2012). The Touquoy Mine Site numerical groundwater flow model (Touquoy Model) was applied to simulate baseline groundwater quantity conditions for the disposal of the Beaver Dam tailings into the Touquoy pit. Baseline conditions correspond to the fully dewatered conditions at the end of mine life, which provide a basis of comparison for predicted groundwater quantity conditions during closure (i.e., as the Touquoy pit is filling) and post closure (i.e., after the groundwater conditions have stabilized following the filling of the Touquoy pit). The Touquoy Model is also applied to improve understanding of hydrogeologic interactions and to simulate transport of constituents of concern at the Touquoy Mine Site. Detailed documentation of the Touquoy Model, including background information, CSM development, model construction, model calibration and model application is included in Appendix F.6 Groundwater Flow and Solute Transport Modelling to Evaluate Disposal of Beaver Dam Tailings in Touquoy Open Pit – Beaver Dam Gold Project.

6.6.4 Baseline Conditions

Baseline conditions in terms of geology, hydrogeology, and groundwater quality are described in this section on a regional basis, for the PAs surrounding the Beaver Dam Mine, Haul Road and Touquoy Mine. The Beaver Dam Mine Site, Haul Road, and Touquoy Mine Site are assessed at the local scale.

6.6.4.1 Regional Baseline Conditions

The Beaver Dam Mine Site is located in a rural, sparsely populated area of Halifax County. The nearest potable well is approximately 5 km southwest from and up gradient of the Beaver Dam Mine Site. Potable wells located along Hwy 224 are a mix of drilled and dug wells based on a review of the NS Well Log Database. Some of the drilled wells in the NS Well Log Database are reported as completed in granite. Granite was encountered at one well location during the monitoring well drilling program at

the Beaver Dam Mine Site, consistent with the location of granite mapped by Nova Scotia Department of Natural Resources (NSDNR). Based on this mapping, the granite intrusion is expected to terminate approximately 100 m southwest of the proposed west waste rock pile location and granite bedrock is not anticipated beneath mine features. Therefore, regional wells completed in granite may not be representative of the hydrogeologic conditions in the fractured slates and quartzite bedrock present beneath the Beaver Dam Mine Site. Drilled wells over 60 m bgs typically intersect only one or two sets of discrete water-bearing fractures and have relatively low yields, (typically 5 to 10 litres per minute [L/min]). Static groundwater levels measured at the Beaver Dam Mine Site range from 3 to 12 m bgs.

Potable groundwater resources in the area are typically vulnerable to surface water entry and associated coliform bacteria issues, and have elevated iron and manganese concentrations (Lin, 1970). A response to IR2 CEAA-2-35 provides an assessment of groundwater discharges to surface water that has the potential to effect human health (Appendix C.2). Potable water is also addressed in IR2 NSE-2-35. Both responses are addressed in detail in Section 7.4.5 of the Hydrogeologic Modelling Report (Appendix F.5) and in Section 6.6.7. Tables 6.6-2 and 6.6-3 below summarize the water quality identified in nearby drilled and dug wells.

Table 6.6-2: Till Groundwater Analysis for Dug Well in area of Beaver Dam Mine Site

Parameter	NSE Tier 1 EQS	CDWQ Guidelines	CDWQ Source	Units	Dug Well
Sodium		200	AO	mg/L	2.0

In relation to the Touquoy Mine Site, Camp Kidston, that operates only in the summer months, is located 3.5 km northeast of the Touquoy Mine Site. According to Atlantic Mining NS Inc. (AMNS), the nearest permanent full-time occupied residences are located approximately 5.8 km to the north of the Touquoy Mine Site along Caribou Road. The next closest permanent residences to the Touquoy Mine Site are approximately 7.4 km to the northwest and 11.7 km to the southeast.

A review of the Nova Scotia Groundwater Observation Well Network 2015 report (NSE 2015c) identifies that there are two regional observation wells located near the PA: one, in Sheet Harbour, and the other in Musquodoboit Harbour. This is the most recent report completed under this program. The report identifies that in general across the Province, aquifers have higher groundwater levels in the spring months and lower levels in the summer months. The typical seasonal variation in groundwater levels in Nova Scotia aquifers is usually less than 3 m. Lower groundwater levels may also be observed in February, depending on winter conditions including snowfall amounts and frost, which can limit recharge. Similar seasonal changes in groundwater levels have been observed at the Touquoy Mine Site where groundwater elevation monitoring has been ongoing since 2016. Trend analysis has not been conducted on the two nearest regional observation wells in this network due to insufficient data collected to date (less than 10 years of usable data). In general, groundwater levels have remained relatively consistent at the Musquodoboit Harbour observation well since its installation in 2008, and groundwater levels have increased by approximately 1 m in the Sheet Harbour observation well since its installation in 1987.

Figures 6.6-2 and 6.6-3 below provide a summary of the groundwater elevations observed (NSE 2020) in these two regional observation wells.

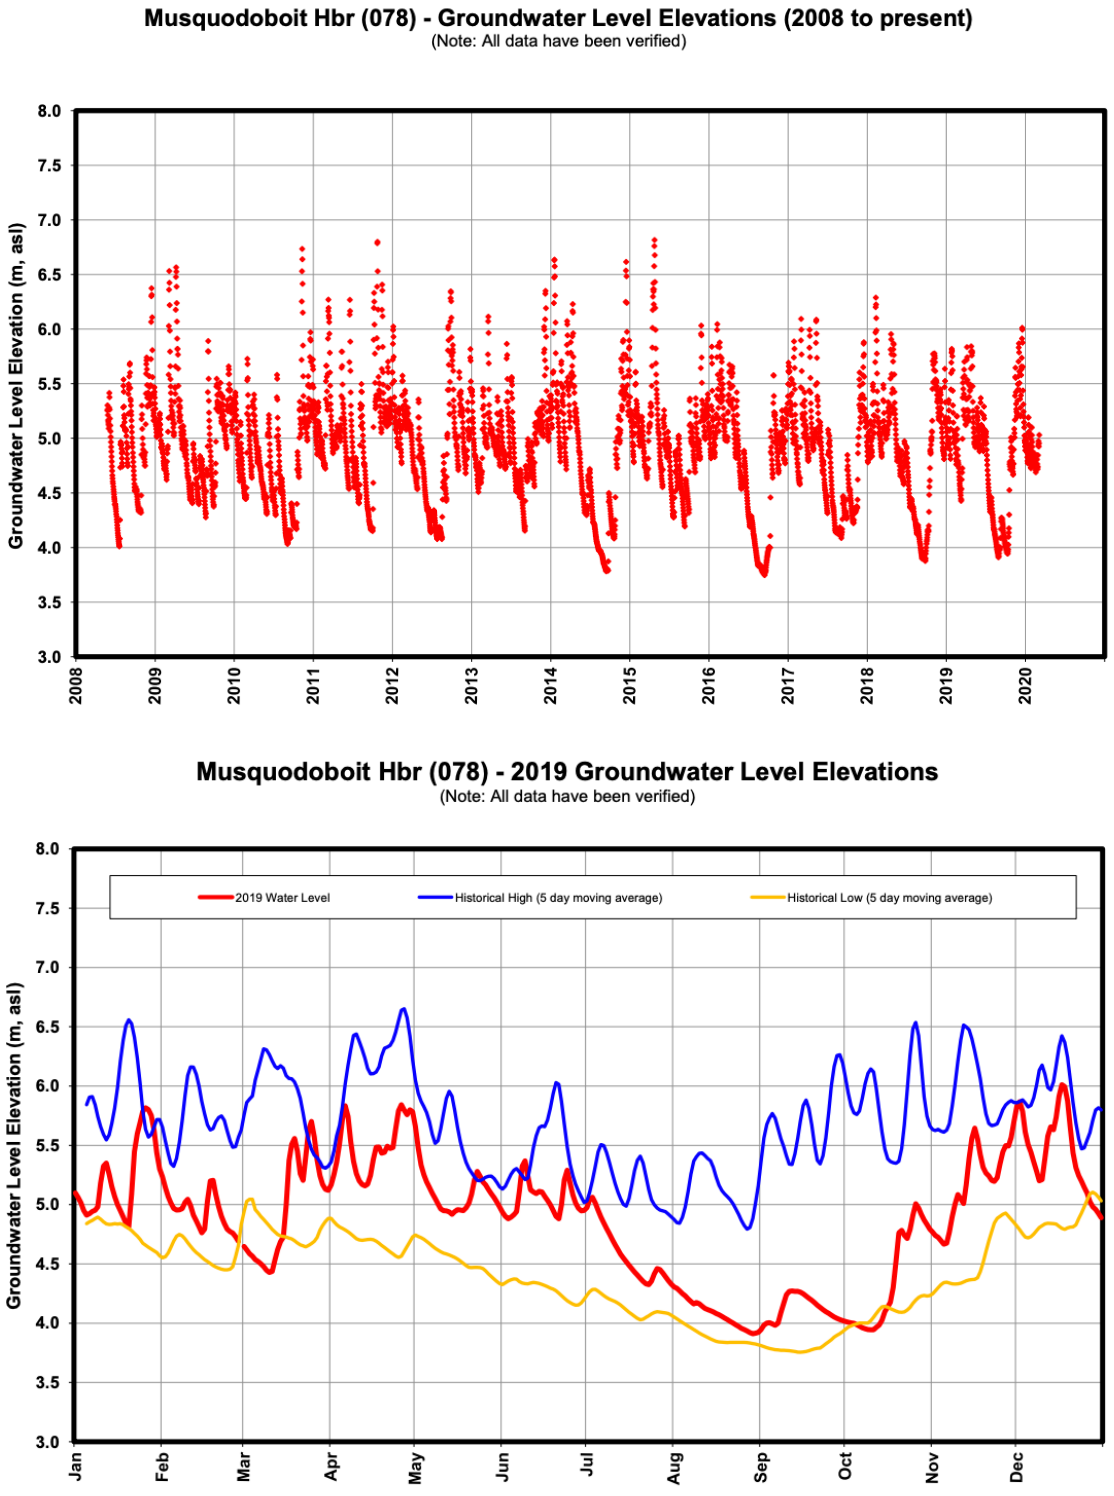

Figure 6.6-2: Summary of Groundwater Elevations Observed in Sheet Harbour Observation Well

Source: NSE (2020).

6.6.4.2 Project Area Baseline Conditions

In general, the hydrogeology for the PA surrounding the Beaver Dam and Touquoy Mine Sites consists of a fractured rock aquifer system that is overlain by a thin till overburden layer. These two hydrogeologic units are present on a regional scale and extend beyond the limits of the Mine Sites. The bedrock can be subdivided into a shallow weathered fractured zone and deep fractured zone. Prior to 2018, most of the site-specific hydrogeologic data collected were focused on determining the rate of groundwater flow in bedrock for the purpose of determining pit dewatering requirements.

The till within the PA is orange brown to olive brown silty sand and gravel. It contains quartzite and slate cobbles and boulders up to 1 m in diameter. Grain size analysis indicates the till averages approximately 60% gravel, 25% sand, 15% silt, and 1% clay. Topography throughout the PA is relatively flat. Till thickness is controlled by the depth to the undulating bedrock surface and the glacial depositional environment which has left scattered drumlins located throughout the region. Till thickness ranges from 0.5 to 22 m, but typically ranges from 3 to 5 m thick.

The degree of groundwater saturation within the till varies. A series of test pits installed at the Beaver Dam Mine Site encountered groundwater at a depth of 0.6 m bgs but this was close to a bog area and may have indicated a perched water table condition. The water table was encountered at depths of 1.5 to 1.8 m bgs in several test pits, while others were terminated at bedrock at depths of up to 4 m bgs without encountering groundwater. Groundwater levels observed for the Beaver Dam Mine Site monitoring network typically vary between 2 and 5 m bgs. Groundwater flow in the till mimics the topography, with recharge occurring in elevated areas and groundwater flowing towards and discharging into surface water bodies in low-lying areas.

The till, as well as bedrock, have temporal variations in flow and static groundwater levels based on the amount of rainfall and infiltration. Groundwater levels in monitoring well locations are observed to respond quickly to precipitation events, consistent with what would be expected for systems consisting of shallow till overburden overlaying fractured bedrock. Rainfall and infiltration can be highly variable due to the local and regional weather patterns. Infiltration can be limited by both periods of frozen ground conditions and dry periods. Seepage discharge rates from the till are expected to be greatest following the spring thaw and during the early summer months.

6.6.4.2.1 Beaver Dam Mine Site Baseline Conditions

Results from the ongoing groundwater monitoring program at the Beaver Dam Mine Site indicate that the groundwater has an approximately neutral acidity (pH ranges from 5.15 to 8.31, average of 7.0) and has an elevated hardness (2.2 to 270 milligrams per litre [mg/L], average of 37 mg/L as Calcium Carbonate [$CaCO_3$]). Metals including aluminum, arsenic, total copper, iron, total lead, manganese, total silver, and zinc are naturally elevated relative to NSE PSS for GW and NSE Tier 1 EQS for potable groundwater, NSE Tier 2 PSS for groundwater discharge to surface water (>10 m) and/or GCDWQ MAC. However, these metals are within ranges typically found in groundwater throughout Nova Scotia. Groundwater analytical results for the Beaver Dam Mine Site are presented in the Baseline Groundwater Program Memo (Appendix F.4). The actual volume of groundwater stored in the bedrock aquifer is relatively small, which is reflective of relatively small primary porosity of these rocks.

JWA conducted a hydrogeological investigation at the Beaver Dam Mine Site in 1986 (JWA, 1986a) and Stantec conducted a hydrogeological investigation in 2014 (Stantec 2015). Based on the results of pumping tests and packer tests, the geometric mean (approximate median) of the hydraulic conductivity values obtained by JWA (1986a) and Stantec (2015) is relatively low at 4.5 x 10^{-8} metres per second (m/s). The results of extensive packer testing within bedrock drill holes at the Beaver Dam Mine Site did not identify any large-scale permeable zones from which high rates of groundwater seepage into an open pit could be expected. As discussed further in this section, the packer tests specifically targeted the Mud Lake Fault Zone and results indicate that the Mud Lake Fault has a hydraulic conductivity similar to the surrounding bedrock.

GHD (2018) (included as Appendix F.3 Field Activities Report) conducted further packer testing in summer 2018 at three deep drill holes installed surrounding the proposed pit location. These packer tests were conducted to better define hydraulic conductivity values surrounding the pit and better support pit inflow calculations. Each deep drill hole was tested at 10 depth intervals for a total of 30 packer tests. Hydraulic conductivity results from the packer tests range from 2.1×10^{-6} to 7.2×10^{-10} m/s with a geometric mean of 3.2×10^{-8} m/s, consistent with the previous packer test results summarized by PCA (2015). The packer test results indicate the bedrock has a low hydraulic conductivity, which is consistent with the lithology observed in diamond drillhole cores drilled at the Beaver Dam Mine Site.

The bedrock hydraulic conductivity at the Beaver Dam Mine Site generally decreases with depth. The shallow bedrock zone (referred to as the top 22 m of bedrock by JWA, 1986a) has a geometric mean hydraulic conductivity (across all packer and slug tests) of 5.6×10^{-7} m/s, while the geometric mean hydraulic conductivity of bedrock below 22 m is 2.9×10^{-8} m/s. Therefore, the amount of groundwater flow is expected to be greater in the shallow bedrock relative to the deep less permeable bedrock.

JWA (1986a) reported that during drilling completed in the 1980s at the Beaver Dam Mine Site, most of the diamond drill holes had static groundwater levels within 0.3 m of ground surface. Drill holes that penetrated the Mud Lake Fault Zone were often flowing, albeit at very low rates (less than 5 litres per minute [L/min]). This indicates an area where bedrock groundwater is discharging upward into the overlying wetland systems near the proposed open pit mine. The same observation was made by GHD (2018) (Appendix F.3 Field Activities Report) during recent fieldwork completed to evaluate groundwater/surface water interaction (Table 6.6-4), which included the installation of well points at select locations where groundwater discharge was suspected.

Based on previous studies of the hydrogeology of the bedrock formation at the Beaver Dam Mine Site and surrounding the area, the degree of hydraulic connection between smaller bedrock fracture zones is likely poor to moderate. The water table is close to the surface (typically within 2 to 5 m of ground surface) across the Beaver Dam Mine Site, reflecting flat lying terrain, low permeability bedrock, and an excess of annual rainfall beyond evapotranspiration rates. Thus, a portion of the overlying tills will be saturated with groundwater under ambient conditions.

The bedrock at the Beaver Dam Mine Site consists of three sub-parallel anticlines. The gold deposit is associated with beds that dip to the north at between 75° and 90°. The Mud Lake Fault and the Cameron Flowage Fault trend northwest near the Beaver Dam Mine Site. The Mud Lake Fault is described from drill cores as a 2 to 3 m zone of gouge within a 10 to 20 m wide brecciated zone. Locally, bedrock groundwater flows predominantly southeast along the fault trends, with flows to the northeast and east directions caused by secondary structural features. The fractures that were encountered displayed evidence of groundwater flow (iron staining) but were infrequently spaced with variable orientations.

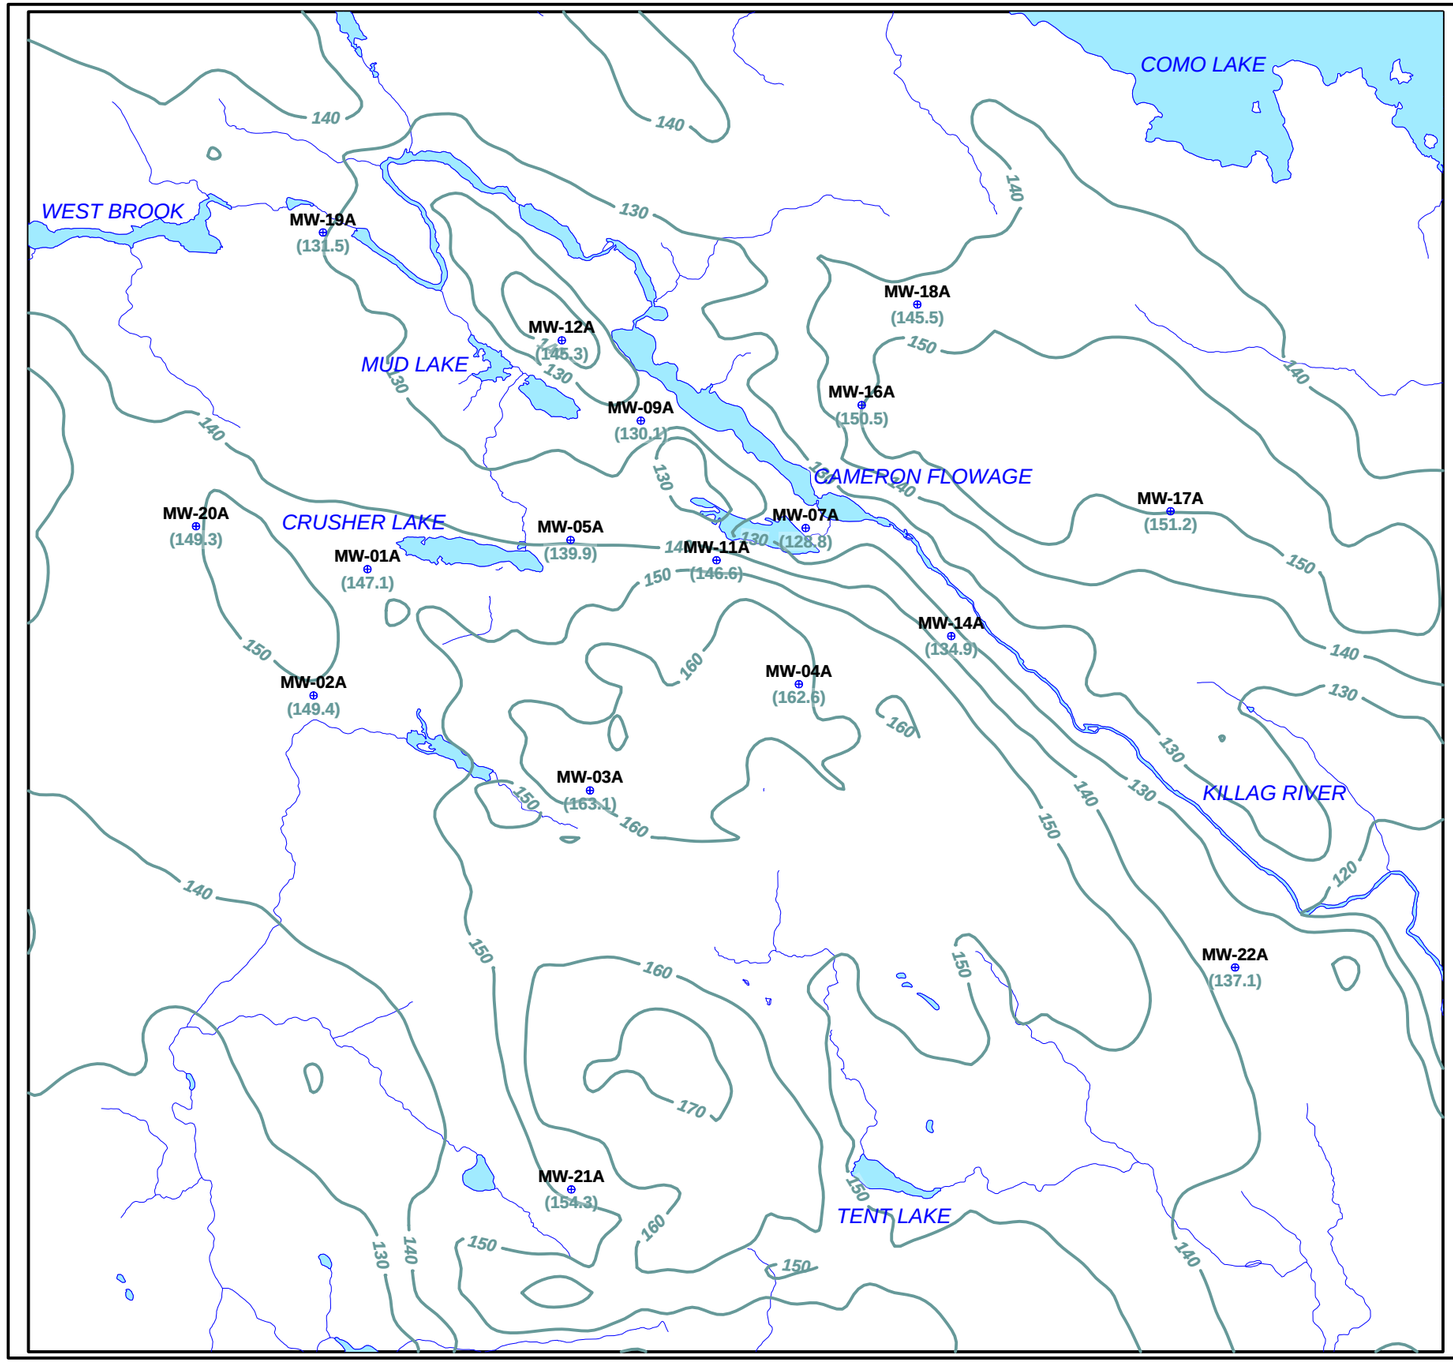
Fracture orientation depended on location relative to the anticline (i.e., which side of the anticline) and proximity to the Mud Lake Fault.

Considering all packer testes conducted in bedrock drill holes at the Beaver Dam Mine Site (JWA 1986; Stantec 2015 and Appendix F3 Field Activities Report), bedrock hydraulic conductivity values ranged from 1.0 × 10-10 m/s to 2.1 × 10-6 m/s with a geometric mean of 3.4 × 10-8 m/s. Six packer tests were conducted at drill hole intervals that intersected the Mud Lake Fault. Hydraulic conductivity results determined from these tests ranged from 1.2 × 10-9 m/s to 1.9 × 10-6 m/s with a geometric mean of 1.2 × 10-8 m/s, which is only slightly less than the geometric mean hydraulic conductivity calculated for all packer test results. This indicates that the Mud Lake Fault is likely of similar permeability or lower permeability than the surrounding bedrock. This is consistent with the observation by JWA (1986a) that the Mud Lake Fault is infilled with clay-like gouge. Additional work undertaken by Golder Associates to assess the overall pit design is described in the Project Description (Section 2). This assessment evaluated the geotechnical stability of the pit design including potential for faults (Golder *In Progress*).

Table 6.6-4: Groundwater-Surface Water Interactions

Location ID	Description	GPS Coordinates	Rationale for Location	Results Summary	Notes
Location #1 Wellpoint and SED1	Downstream of site on Cameron Flowage	523247 4990039	To assess interaction between Cameron Flowage and local groundwater system down gradient of site	Delta of 4 cm indicates slight downward gradient from stream to groundwater system. Cameron Flowage has minor contribution to local groundwater system at this location	Inspection completed of stream bank to 100 m from well point site up-gradient and down-gradient with no seepage points noted or up-welling in stream bed obvious. Stream has bedrock exposed and cobbles with coarse sand bottom
Location #2 Wellpoint and SED2	Upstream of site, west bank of Cameron Flowage	521989 4990921	To assess interaction between Cameron Flowage and groundwater system at this location up-stream of mine area	No delta in levels inside and outside well point at this location indicating no groundwater and surface water interaction	Inspection completed of stream bank to 100 m from well point site up-gradient and down-gradient with no seepage points noted or up-welling in stream bed obvious. Stream has coarse sand and cobble substrate with minor sands
Location #3 Wellpoint and SED3	Down-gradient from planned Waste Rock Pile	521560 4990242	To assess interaction between groundwater and surface water at this location	No delta in levels inside and outside well point at this location indicating no groundwater and surface water interaction	No visible areas of discharge noted within 50 m of site up-gradient and down-gradient. Stream has gravelly cobble substrate with some silt and boulders
Location #4 Wellpoint and SED4	Down-gradient from planned Waste Rock Pile	521941 4990172	To assess interaction between groundwater and surface water at this location	Delta of 6 cm indicates slight downward gradient from stream to groundwater at this location	No visible areas of discharge noted within 40 m of site up-gradient and down-gradient. Stream has an organic substrate underlain by silty sand with some cobbles
Location #5 Wellpoint and SED5	Down-gradient from planned Waste Rock Pile	521829 4990207	To assess interaction between groundwater and surface water at this location	No delta in levels inside and outside well point at this location indicating no groundwater and surface water interaction	No visible areas of discharge noted within 50 m of site up-gradient and down-gradient. Stream has an organic substrate underlain by silty sand with some cobbles
Location #6 Wellpoint and SED6	Down-gradient from Cameron Flowage	522960 4990277	To assess interaction between groundwater and surface water at this location	Delta of 3 cm indicates slight downward gradient from stream to groundwater at this location.	No visible areas of discharge noted within 50 m of site up-gradient and down-gradient. Stream has a silt substrate with organics and some boulders
Location #7 Wellpoint and SED7	Downstream of planned facilities, ore storage, and crushing facilities	522730 4990130	To assess interaction between groundwater and surface water at this location	No delta in levels inside and outside well point at this location indicating no groundwater and surface water interaction	No visible areas of discharge noted within 60 m of site up-gradient and down-gradient. Stream has a silt substrate with minor organics and some boulders and cobbles
Location #8 Wellpoint and SED8	Downstream of planned Waste Rock Pile	522658 4989053	To assess interaction between groundwater and surface water at this location	No delta in levels inside and outside well point at this location indicating no groundwater and surface water interaction	No visible areas of discharge noted within 40 m of site up-gradient and down-gradient. Stream has a silt substrate with heavy organics and boulders, minor cobbles
Location #9 Wellpoint and SED9	Downstream of planned Waste Rock Pile	521841 4989133	To assess interaction between groundwater and surface water at this location	No delta in levels inside and outside well point at this location indicating no groundwater and surface water interaction	No visible areas of discharge noted within 50 m of site up-gradient and down-gradient. Stream has a silt substrate with organics

Notes: GPS = Global Positioning System; cm = centimetre; m = metre.



The vertical and horizontal extents of the Mud Lake Fault, defined based on exploratory drill hole records and regional fault mapping, were incorporated into the Beaver Dam Model. Through model calibration, it was determined that the best match to observed groundwater elevations was obtained by assigning a hydraulic conductivity value to the Mud Lake Fault that was lower than, or similar to, that of the surrounding bedrock. This further supports that the Mud Lake Fault has a similar hydraulic conductivity value to that of the surrounding bedrock and does not act as preferential flow path at the Beaver Dam Mine Site.

Groundwater flow at the Beaver Dam Mine Site occurs primarily in the till overburden and the shallow bedrock zone, with less flow expected within the deeper less permeable bedrock. Groundwater flow in the till overburden typically follows topographic relief, and is expected to mirror the topographic surface, with recharge occurring on the basin boundaries and uplands and discharge occurring to low-lying areas containing wetland areas and tributaries of the Killag River Watershed. Figure 6.6-4 in shows a groundwater elevation contour map based on groundwater elevations measured in the overburden on July 18, 2018. Figure 6.6-4 further demonstrates that shallow groundwater flow mirrors topographic relief and that groundwater recharge in areas of topographic highs and discharges to low-lying surface waterbodies. **PCA (2015) further states that groundwater occurs at shallow depths at the Beaver Dam Mine Site and that Cameron Flowage is a likely area of groundwater discharg**e.

Groundwater flow in the shallow weathered bedrock is controlled by secondary permeability caused by fracturing. Locally, groundwater flow in shallow bedrock is directed predominantly to the south-east along the direction of dominant fault trends, with a smaller component of groundwater flow towards the northeast and east.

The degree of hydraulic connection amongst the shallow bedrock fractures is likely poor to moderate. The volume of groundwater stored in the shallow bedrock aquifer is probably small, and this reflects the relatively small primary porosity of these rocks. Some of the larger bedrock fractures may be hydraulically connected to surface waterbodies, which may become sources of aquifer recharge under a mine dewatering scenario.

Groundwater can be expected to seep into the open pit developed at the Beaver Dam Mine Site largely through the surficial glacial till, and through fractures in the shallow bedrock. The more competent deep bedrock is not expected to contribute significant groundwater inflow to the open pit. As the pit dewatering progresses and groundwater levels in the near the open pit are lowered, a reduction in baseflow (i.e., the groundwater contribution to stream flow) may be observed in nearby water bodies (i.e., some surface water bodies ,which are presently groundwater discharge areas, may receive reduced groundwater discharge or become areas of groundwater recharge).

Both total stream flow and baseflow were estimated for Cameron Flowage through analysis and review of stream flow data collected at nearby hydrometric stations. The nearest four hydrometric stations are Pembroke River at Glenbervie, Musquodoboit River Near Upper Musquodoboit, Musquodoboit River Near Middle Musquodoboit, and Musquodoboit River at Crawford Falls, which have drainage areas of 7,330 hectares (ha), 14,100 ha, 33,400 ha, and 65,000 ha, respectively. A baseflow value was estimated for each drainage area using a recursive digital filter (Eckhardt, 2005) and scaled to the total drainage area of approximately 3,871 ha for Cameron Flowage. The estimated total average annual flow in Cameron Flowage is 103,881 cubic metres per day (m^3/d). The estimated average annual baseflow for Cameron Flowage is 23,426 m^3/d, which is approximately 23% of the total average annual flow. The estimated average annual baseflow in Cameron Flowage provides a baseline condition against which to compare predicted baseflow at the end of mine life and post-closure (Appendix F.5).

To confirm the average annual baseflow estimates, preliminary stage-discharge relationships were developed for six gauging locations using available flow monitoring measurement events and corresponding surface water elevations measured at the gauging locations. The preliminary stage-discharge relationships will be further refined as additional flow monitoring measurement events are conducted. The preliminary stage-discharge relationships were applied to estimate stream discharge (flow) at each of the six gauging locations. Two gauging locations, SW2A and SW1A, are located immediately upstream and downstream of Cameron Flowage, respectively, and were selected to verify the total flow and baseflow estimates calculated using the nearest four hydrometric stations. Consistent with the method applied for the nearest four hydrometric stations, a recursive digital filter (Eckhardt, 2005) as implemented in WHAT: Web-based Hydrograph Analysis Tool (Lim et al. 2005) was applied to the average daily discharge data for SW2A and SW1A to estimate baseflow at those gauge locations. The average annual baseflow estimated for SW2A and SW1A is 24,686 m^3/d, with an average annual total flow of 112,420 m^3/d. Based on these values, the average annual baseflow to at SW2A and SW1A represents approximately 22% of the total average annual flow at those gauge locations. **The estimated average annual baseflow at SW2A and SW1A is within approximately 5% of the estimated average annual baseflow estimated from the nearest four hydrometric station for Cameron Flowage**. This comparison verifies that the estimated average annual baseflow from the nearest four hydrometric stations is reasonable and provides an appropriate baseline conditions against which to compare the relative predicted baseflow at end of mine life and post-closure.

6.6.4.2.2 Touquoy Gold Mine Site Baseline Conditions

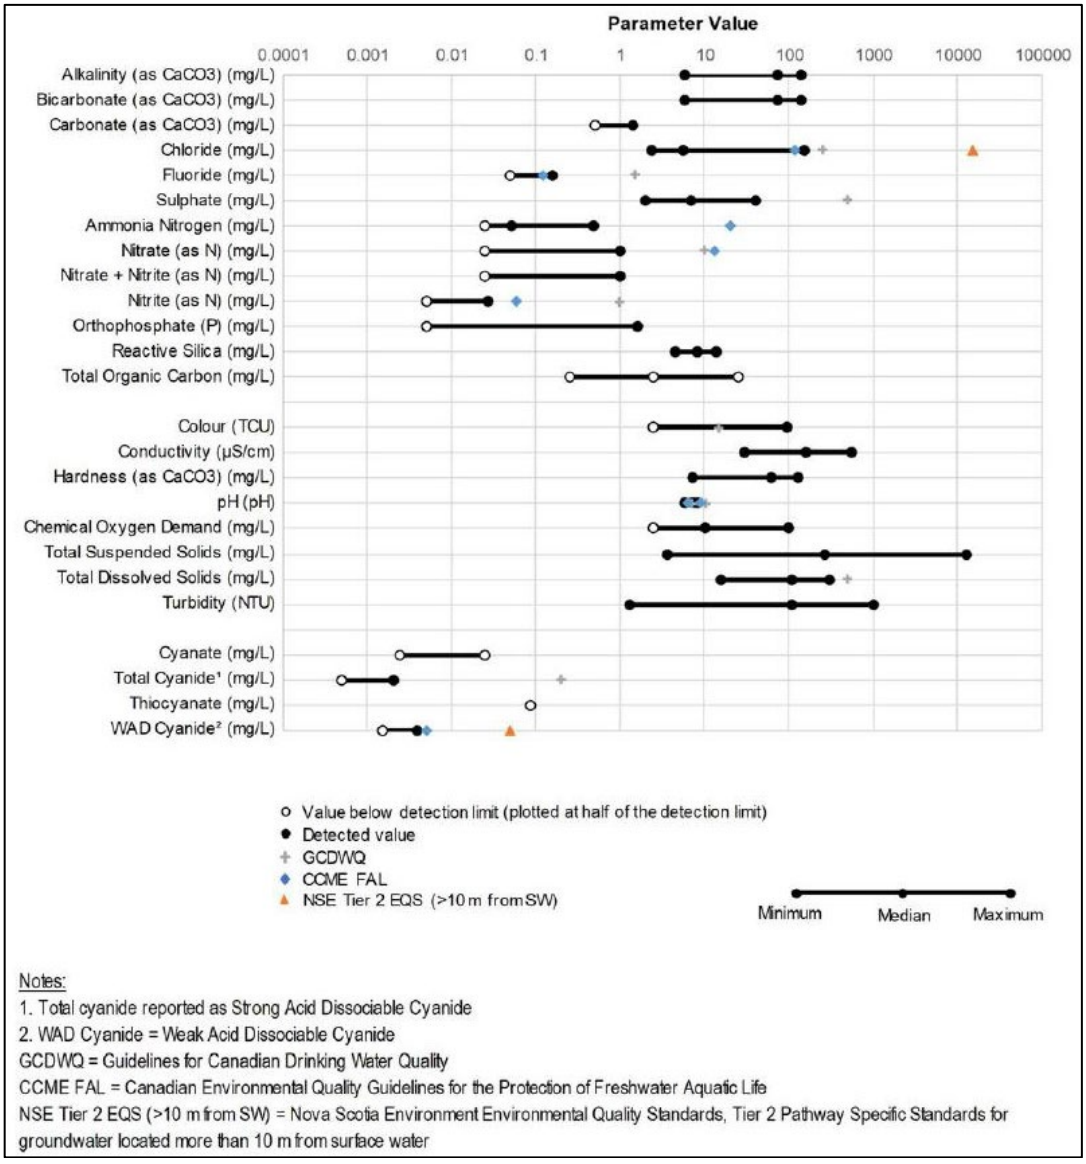
As identified in the Touquoy Gold Project Focus Report (CRA 2007a), the Touquoy Mine Site is located within a metamorphic bedrock hydrostratigraphic unit, cross cut by structural features (faults, anticlinal axes) that may represent separate hydrostratigraphic units. Groundwater inflows and outflows will be controlled by these relatively low permeability and fracture-controlled bedrock units. Given the high water table in the study area and combined with the high water surplus and general low permeability of the area, the groundwater flow system can be characterized as a "local" system, with topographic highs representing recharge zones that would discharge into the adjacent topographic lows. The till overburden hydrostratigraphic unit acts as a confining unit that creates non-flowing artesian conditions within the bedrock, Groundwater-surface water interaction is limited by the presence of this confining till, with flow rates controlled by the thickness, continuity and permeability of the till.

Single-well response tests conducted on wells across the Touquoy Mine Site including all of the monitoring wells installed as part of the groundwater monitoring plan (GHD, 2017a,b). The hydraulic conductivity estimates were fairly consistent across the site, in both the silty-sand till overburden (geometric mean of 1.8 × 10 -6 m/s), and in the relatively shallow bedrock (geometric mean of 1.0 × 10 -6 m/s). No differentiation of hydraulic conductivity in the bedrock was observed in wells constructed in the two dominant rock lithologies: argillite; and greywacke.

Seepage into the open pit at Touquoy from the till and bedrock was expected to range from 550 cubic metres per day (m^3/d) to 1,450 m^3/d (PCA, 2006). An additional assessment completed as part of the Touquoy Gold Project Focus Report (CRA 2007a) to

determine the potential linkage between Moose River and the local groundwater system identified that groundwater upwelling was not measured from temperature profiling conducted through the portion of Moose River that lies adjacent to the proposed Touquoy open pit. The limited linkage between the Moose River and Touquoy Pit has been confirmed to date (Appendix F.6 Groundwater Flow and Solute Transport Modelling to Evaluate Disposal of Tailings in Touquoy Open Pit) by ongoing flow monitoring at the site during operations under the Touquoy Gold Project Industrial Approval.

The presence of faults in the vicinity of the Touquoy pit have been characterized by AMNS, including water bearing faults. Water bearing faults were identified on the pit wall in the vicinity of monitoring well OPM-2A/B. The faults are typically to be saturated relative to the rock mass surrounding the faults, significant volumes of flow to the Touquoy open pit have not been observed. The hydraulic conductivity of the shallow bedrock at OPM-2B based on single-well response testing was within the range of other bedrock wells installed at the Touquoy mine site.



Groundwater seepage into the Touquoy open pit is largely through the surficial glacial till, and through fractures in the shallow bedrock. The more competent deep bedrock is not expected to contribute significant groundwater inflow to the open pit. As the pit dewatering progresses and groundwater levels in the vicinity of the open pit are lowered, a reduction in baseflow (i.e., the groundwater contribution to stream flow) is inferred in Moose River, although uncertainty in stream flow measurements in Moose River upstream and downstream the Touquoy site appear to overestimate the reduction in baseflow compared to the observed pit inflow rates.

Both total stream flow and baseflow were estimated for Moose River at SW-2 through analysis and review of stream flow data collected at nearby hydrometric stations. Mean annual flow in Moose River is estimated to be 1.15 m^3/s. Baseflow indices were calculated using a recursive baseflow filter implemented in the BFLOW software code (Arnold et al., 1995) for annual and monthly streamflow rates observed in Moose River at SW-2. **The mean annual baseflow index for Moose River is estimated to be 0.29, with summer baseflow indices 0.52 in 2019 and 0.34 in 2020. The calculated mean annual baseflow in Moose River is 28,814 m^3/d, and the mean summer baseflow for 2019 and 2020 are 9,848 and 9,143 m^3/d, respectively**.

6.6.4.2.3 Groundwater Quality at the Touquoy Mine Site

Baseline groundwater quality at the Touquoy Mine Site indicates that the groundwater is slightly basic (pH range 7.02 to 8.08) and an elevated hardness (45 to 160 mg/L). Groundwater quality results from samples collected near the open pit at the Touquoy Mine Site (i.e., the OPM-series wells) are summarized on Figures 6.6-5 and 6.6-6. As shown on these figures, the groundwater quality generally meets the NSE Tier 2 PSS for groundwater greater than 10 m from surface water criteria. The GCDWQ and the CCME FAL guidelines are also presented on Figures 6.6-5 and 6.6-6 for illustrative purposes, but are no discussed, as groundwater at the Touquoy Mine Site is not used as a potable water supply, and the NSE Tier 2 PSS already account for groundwater discharging to surface water bodies. The Touquoy groundwater monitoring program results (for OPM-series wells) are reported annually to NSE based on the requirements of the Industrial Approval which regulates operational activities and monitoring at the Touquoy Mine Site (Stantec 2020).

Source: Stantec (2019).

Figure 6.6-6: Summary of Groundwater Quality near the Open Pit at Touquoy Mine Site – Dissolved Metals

Source: Stantec (2019).

Groundwater quality exceedances of the NSE Tier 2 PSS were noted in 2017 for aluminum, arsenic, cadmium, copper, iron, mercury, silver, and organics that were common in the 2016 baseline period, and therefore were not attributed to the operation of the mine. The development of site-specific criteria for the Mine Site should be considered to determine thresholds for water quality that consider the elevated concentrations of parameters under baseline conditions. Until such time as site-specific criteria are developed, the evaluation of potential water quality effects from the operation of the mine is based on long-term upward or downward trends in comparison to the baseline levels, and not exclusively on any exceedances of NSE EQS or PSS criteria. The current monitoring record representing operation is too short to distinguish any potential effects of the mine water quality compared to the natural variability, as operation only began in October 2017.

Arsenic was noted to consistently exceed the Tier 2 PSS at OPM-1A/B in both 2016 and 2017. These elevated arsenic concentrations are not attributed to operation and may be from historical tailings and/or the Touquoy ore body itself. A remedial action plan was completed by AMNS in 2018 that involved the delineation, removal, and management of these historical tailing piles around the open pit area.

The Groundwater Contingency Plan (Stantec 2017b) presents contingency action levels for groundwater quality around the mine for indicators of operation-related effluent impacts to groundwater compared to the baseline water quality record. However, the monitoring record for the baseline period is relatively short, therefore, as observed for the upstream surface water quality, the natural variability of groundwater quality may not have been captured in the baseline period, and therefore the action levels defined in the groundwater contingency plan may be overly conservative for evaluating potential mine effects on groundwater quality.

Single, discontinuous groundwater quality results above action levels were identified in the 2016 baseline and 2017 operating data, however, these were not attributed to mine operations, but may be the result of natural variability not captured during the baseline period. Groundwater quality will continue to be monitored closely in 2018 and will be ongoing to identify potential indicators of groundwater seepage from mine operations.

6.6.5 Consideration of Engagement Results

Key concerns raised during public and Mi'kmaq engagement relating to groundwater included potential effects on groundwater levels from open pit mining at the Beaver Dam Mine Site and potential groundwater quality impacts associated with Project activities at the both the Beaver Dam and the Touquoy Mine Sites. Concerns were specifically expressed by the Millbrook First Nation regarding effects on groundwater quality and quantity in terms of potable water wells and the health of its residents in Beaver Lake IR 17. These concerns were identified in relation to potential effects on groundwater quality from unplanned releases due to accidents and malfunctions, specifically during mine operations.

The results of the public and Mi'kmaq engagement have been considered in the environmental effects assessment, including AMNS's commitments to mitigation and monitoring measures and proposed compliance and effects monitoring programs, as well as AMNS's broader commitment to ongoing public and Mi'kmaq of Nova Scotia engagement. Specific evaluations of the potential effects on groundwater quality and quantity are presented within the following environmental effects assessment.

AMNS continued to engage with the public and Mi'Kmaq on the Beaver Dam Mine Project. The most recent engagement undertaken since the February 2021 revised EIS is provided in Section 3 and Section 4.

6.6.6 Effects Assessment Methodology Update

6.6.6.1 Boundaries

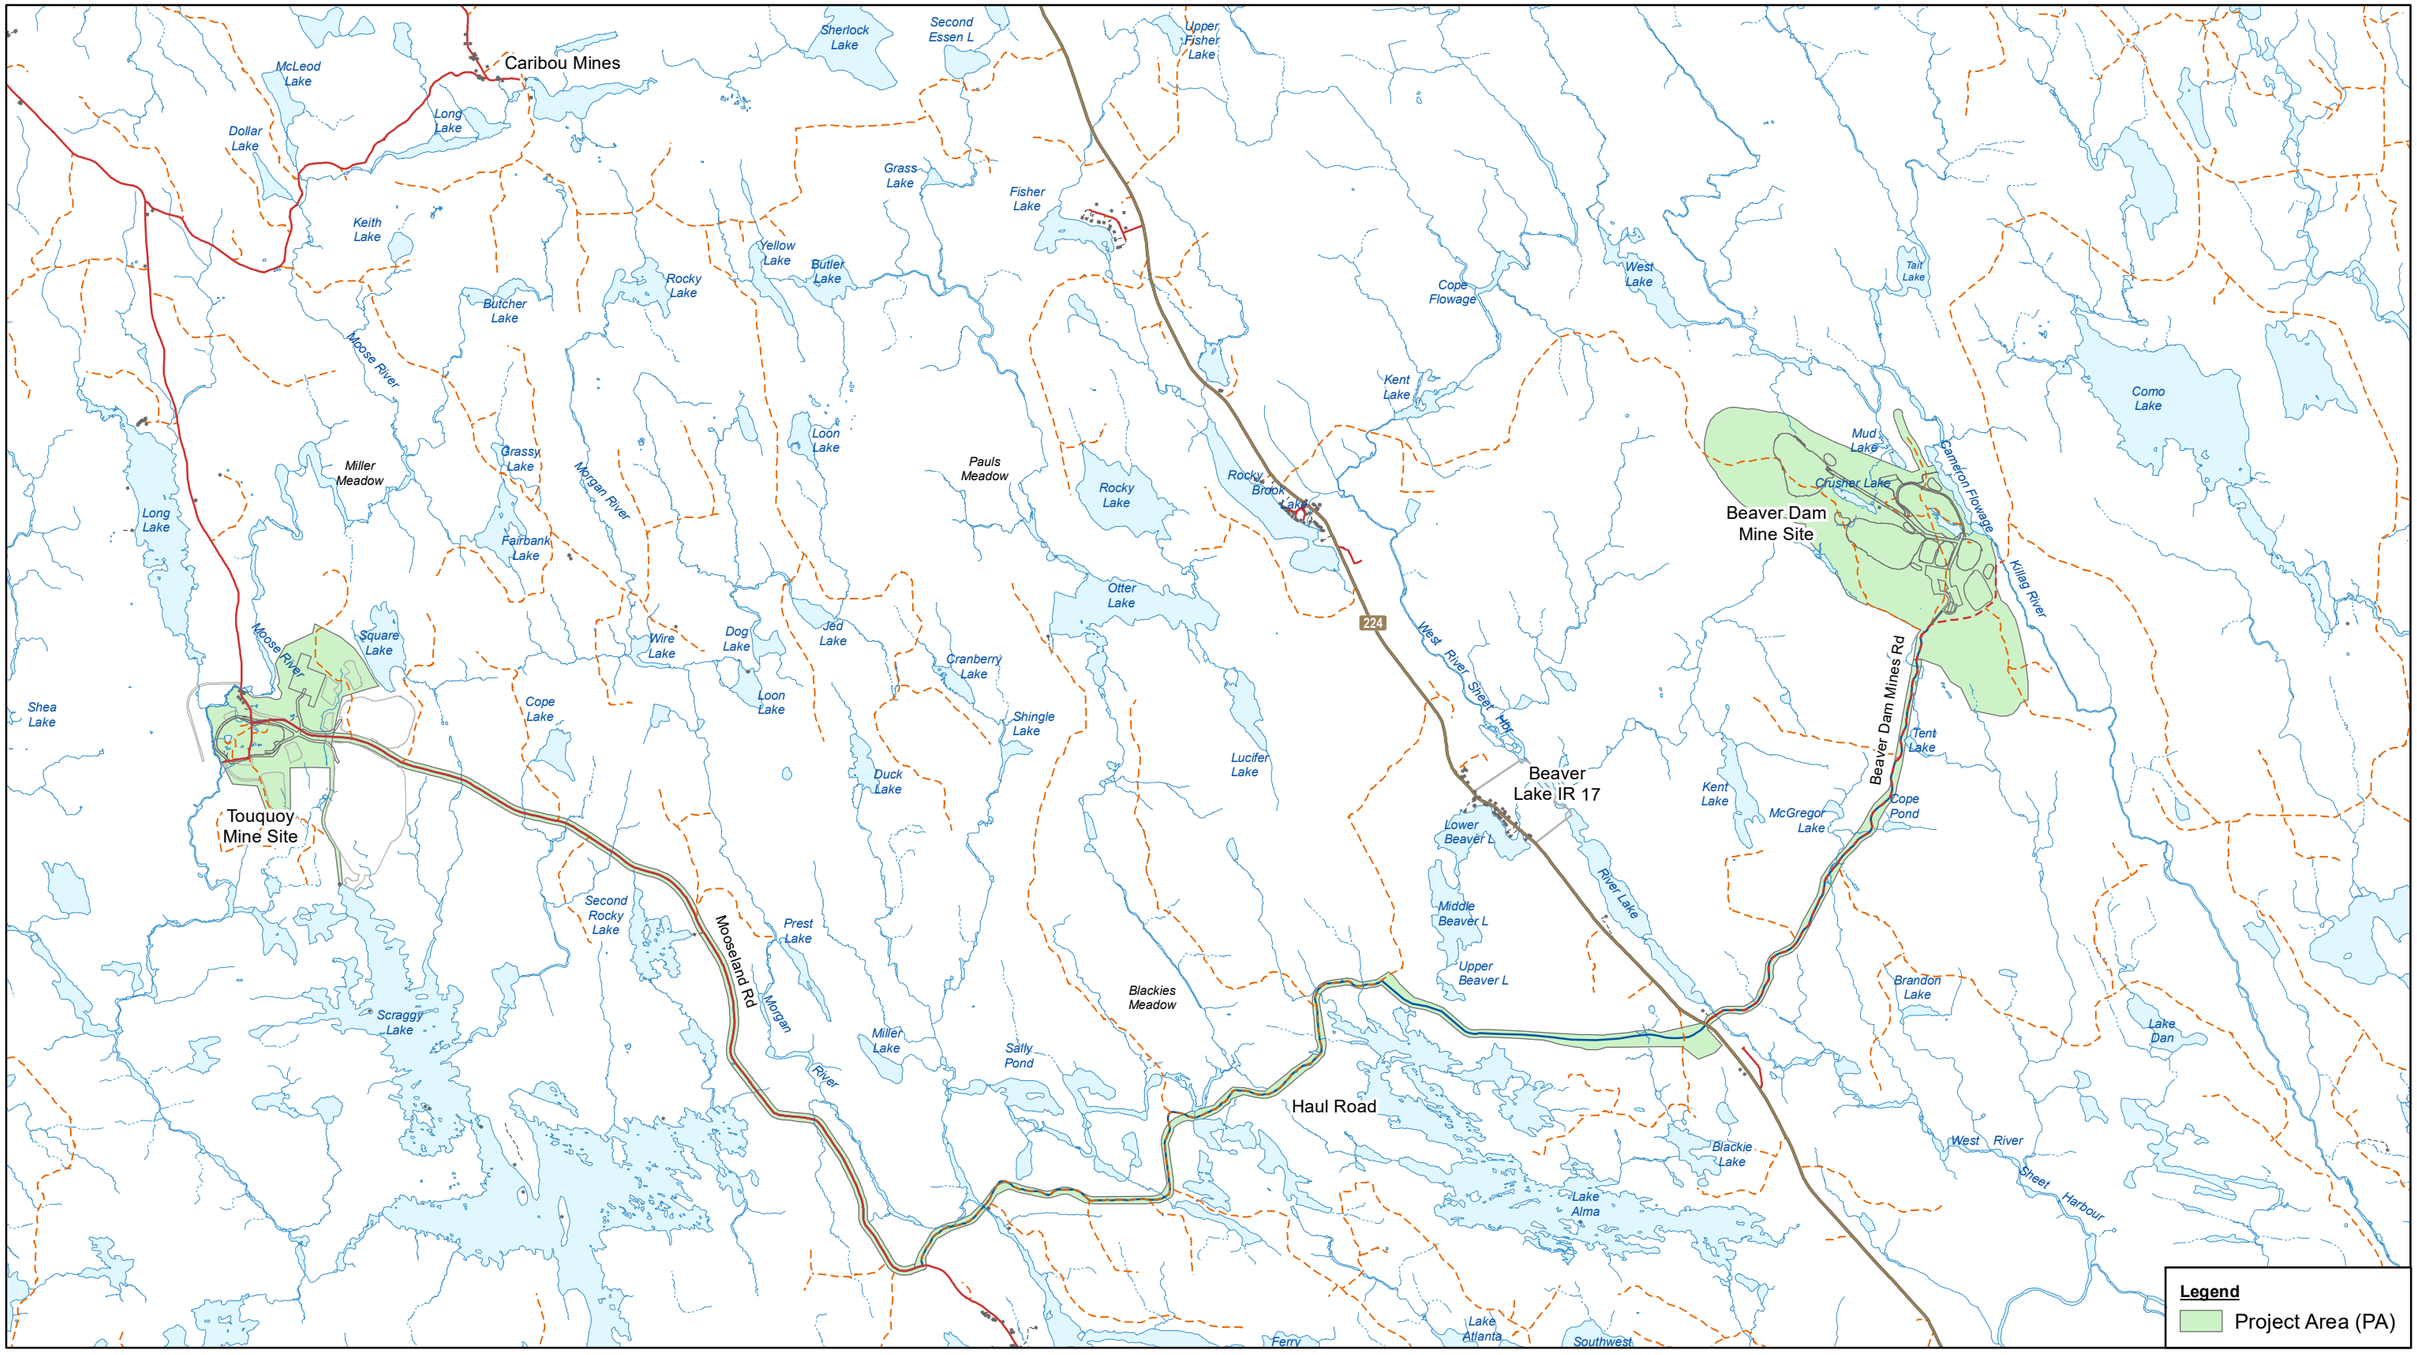
6.6.6.1.1 Spatial Boundaries

The spatial boundaries used for the assessment of effects to groundwater quality and quantity are defined below:

- The PA encompasses three primary component the Beaver Dam Mine Site, located at the end of the Beaver Dam Mines Road, the Haul Road, spans from the Beaver Dam Mine Site to Moose River Gold Mines and Touquoy Mine Site, where the Beaver Dam ore will be processed and disposed sub-aqueously in the mined out pit (Figure 6.6-7).
- The Local Assessment Area (LAA) encompasses an 800 m buffer around the PA, 800 m buffer along a portion of the Haul Road that are up-gradient of receptors, and down-gradient from the Touquoy Mine Site. The LAA is the maximum extent of direct and indirect impacts on groundwater (Figure 6.6-8).
- The Regional Assessment Area (RAA) encompasses a 6 km that includes the Tertiary Watersheds intersecting the PA and represents the maximum cumulative zone of influence and corresponds with the groundwater flow model domains (Figure 6.6-8).

As the Project has the potential to cause direct and indirect effects to groundwater outside of the PA, the LAA is the appropriate boundary for evaluation of this VC.

6.6.6.1.2 Temporal Boundaries



The temporal boundaries used for the assessment of effects to groundwater quality and quantity are the construction, operation, active closure/reclamation and post-closure phases.

6.6.6.1.3 Technical Boundaries

No technical boundaries were identified for the effects assessment of groundwater quality and quantity.

6.6.6.1.4 Administrative Boundaries

Groundwater Quality at the Beaver Dam Mine Site, the Touquoy Mine Site, and along the Haul Road will be compared to NSE Tier 1 EQS for potable groundwater, GCDWQ, NSE Tier 2 PSS for groundwater discharge to surface water and baseline conditions/background groundwater concentrations, where applicable. The comparison to potable groundwater quality is in recognition that the Project is occurring on crown land and although there are no current potable groundwater uses, there could be in the future. There may be other requirements for monitoring of groundwater as an outcome of the provincial approval process (i.e., Industrial Approval) that AMNS will integrate into the monitoring before the start of Beaver Dam Mine Site Project Construction. A draft Groundwater Monitoring Plan (Appendix G of Appendix P.4 Mine Water Management Plan) is provided to assess groundwater during construction, operation, active closure and post-closure of the Beaver Dam Mine Site.

6.6.6.2 Beaver Dam Mine Site Groundwater Modelling Methodology

A 3D groundwater flow model for the Beaver Dam Mine Site (Beaver Dam Model) was developed by GHD for the following purposes:

- To enhance the understanding of groundwater flow conditions at and surrounding the Beaver Dam Mine Site to facilitate developing a hydrogeologic CSM to use as the basis for developing the numerical groundwater flow model.
- To construct and calibrate the numerical groundwater flow model consistent with the CSM to represent observed Beaver Dam Mine Site conditions.
- To apply the calibrated groundwater flow model to evaluate potential changes in groundwater quality and quantity with respect to groundwater flow and groundwater interactions with surface water at the Beaver Dam Mine Site under End of Mine (EOM) and Post-closure (PC) conditions.

The Beaver Dam Model was based on site-specific and available regional data including surface water features, topography, water well records and geologic information. The scope of work completed by GHD to develop the Beaver Dam Model and apply the model to evaluate potential impacts to groundwater and surface water flow regimes included the following:

- Compilation, review, and interpretation of the geologic, groundwater flow, and surface water flow data available for the Beaver Dam Mine Site and surrounding area.
- Development of a 3D geologic model, a CSM, and a 3D groundwater flow model of the Beaver Dam Mine Site and surrounding area based on available regional and site-specific data. The Beaver Dam Model was calibrated under steady-state conditions and the sensitivity of the model calibration was evaluated with reference to model input parameters such as measured groundwater elevations, groundwater flow directions, and estimated baseflow.
- Application of the calibrated Beaver Dam Model to evaluate potential changes in groundwater quality and quantity with respect to groundwater flow and groundwater interactions with surface water at the Beaver Dam Mine Site under EOM and PC conditions.

The detailed methodology and results of the Beaver Dam Model are documented in the Hydrogeologic Modelling Report (Appendix F.5).

6.6.6.3 Touquoy Mine Site Groundwater Modelling Methodology

A groundwater flow and solute transport model (Appendix F.6) has been developed to evaluate:

- Evaluate the dewatering rate from the Touquoy open pit and changes in groundwater flow conditions and discharges when it is fully dewatered which will be used as the baseline conditions to assess impacts.
- Evaluate the groundwater seepage rates to the Touquoy open pit as it is filled with Beaver Dam tailings.
- Identify areas where water in contact with the Beaver Dam tailings disposed in the Touquoy open pit is discharged to the receiving environment, and the potential for surface and groundwater interactions.
- Predict the potential impacts of discharging groundwater from the Touquoy open pit to the receiving environment.

The groundwater flow model was based on site-specific and available regional data including surface water features, topography, water well records and geologic information. The scope of work completed by Stantec to develop the groundwater flow model and apply the model to evaluate potential impacts to groundwater and surface water flow regimes included the following:

- Compilation, review, and interpretation of the geologic, groundwater flow, and surface water flow data available for the Touquoy Mine Site and surrounding area.
- Development of a CSM and steady-state 3D groundwater flow model of the Touquoy Mine Site and surrounding area. The groundwater flow model was calibrated under mean annual and summer low-flow steady-state conditions and the sensitivity of the model calibration was evaluated with reference to model input parameters such as measured groundwater elevations, groundwater flow directions, and estimated baseflow.
- Application of the calibrated groundwater flow model to evaluate potential changes in groundwater quality and quantity with respect to groundwater flow and groundwater interactions with surface water at the Touquoy Mine Site under Baseline (conditions prior to the deposition of Beaver Dam tailings at the Touquoy Mine Site, in the exhausted pit), end of Operations (conditions at the end of deposition of Beaver Dam tailings at the Touquoy Mine Site, in the exhausted pit), and Post-closure conditions.

The detailed methodology and results of the groundwater flow model for the Touquoy Mine Site were documented in the Groundwater Flow and Solute Transport Modelling to Evaluate Disposal of Tailings in Touquoy Open Pit which is included in Appendix F.6.

6.6.6.4 Thresholds for Determination of Significance

In response to IAAC (CEAA 2019) IR2 CEAA-2-02, the significance determination is revised and is described in Table 6.6-5. Changes in groundwater chemistry and quantity are assessed as input or pathway to determining impacts to surface water quantity and quality (Section 6.7), wetlands (Section 6.8) and Fish and Fish Habitat (6.9) Sections

Significant adverse effect from the Project on groundwater is focused on effects to potable groundwater resources defined as an effect on groundwater quality exceeds the NSE Tier 1 EQS for potable groundwater or GCDWQ. Specifically, the predicted COC concentrations in groundwater are compared against the lower of the Tier 1 EQS for potable groundwater or GCDWQ, hereafter referred to as the 'Potable Criteria'. The residual effects of this groundwater VC are characterized using standard criteria, including magnitude, geographical extent, duration, frequency, reversibility, and context of the effect (Table 6.6-5). The residual effects assessment concludes with a determination of significance with respect to potable groundwater resources. The screening of project effects, mitigation measures, and the subsequent groundwater results are assessed in aggregate to determine whether the residual impacts are "Not Significant" or "Significant" according to the following definitions:

- **Significant Residual Effect:** residual effects have high magnitude, be of potential regional geographic extent and of medium to long term duration, occur at any frequency and only be partially reversible to irreversible.
- **Not Significant Residual Effect:** is defined as: negligible to moderate magnitude, are restricted to the PA are of sporadic or short-term duration, occur at any frequency and are reversible to partially reversible.

Table 6.6-5: Definitions of Characterization Criteria for Residual Effects on Groundwater

Criteria	Description of Ratings
Magnitude	• **Negligible:** no measurable change in groundwater quality exceeds the Potable Criteria • **Low:** a measurable change in groundwater quality exceeds the Potable Criteria but does not exceed background levels • **Moderate:** a measurable change in groundwater quality exceeds the Potable Criteria and exceeds background levels but does not represent a decrease in the reasonable use of groundwater (i.e., if arsenic concentrations are predicted to increase, but background concentrations of arsenic already exceed Potable Criteria, then the reasonable use of groundwater as a potable resource is not reduced by the increase in arsenic concentrations) • **High:** a measurable change in groundwater quality exceeds the Potable Criteria and exceeds background levels to all receptors.
Geographical Extent	• **Discrete:** effect is limited to receiving environments in the immediate footprint or Project Area (PA). • **Local:** effect is limited to the Local Assessment Area (LAA). • **Potential** Regional: effect is limited to the Regional Assessment Area (RAA).
Timing	• Timing represents seasonal occurrence of the effect (e.g., spring vs winter; high flows vs. low flows) and represents effect criteria for designated water users (aquatic resources, human health).
Duration	• **Short term:** effect is restricted to Construction Phase or EOM modelling. • **Medium term:** effect occurs in Construction Phase and EOM Phase. • **Long term:** Effect occurs in Construction Phase, EOM Phase, or PC Phase and persists in PC.
Frequency	• **Sporadic:** VC interaction or effect will occur at irregular intervals throughout any Project Phase. • **Regular:** effect occurs on a regular basis but not continuous basis. • **Continuous:** effect occurs constantly (e.g., every modelled timestep throughout a given Project Phase).
Reversibility	• **Reversible:** effect can be reversed. • **Partially reversible:** effect can be partially reversed. • **Irreversible:** effect cannot be reversed, is of permanent duration.

6.6.7 Project Activities/Interactions with Groundwater Quality and Quantity

Potential interaction between Project activities and groundwater quality and quantity within the PA is outlined in Tables 6.6-6 to 6.6-8 below and in Table 6.6-4 for Groundwater-Surface Water Interactions.

Table 6.6-6: Potential Project Activities/Interactions with Groundwater Quality and Quantity at the Beaver Dam Mine Site

Project Phase	Duration	Project Interactions
Construction	1 year	• Rock blasting in preparation of construction • Watercourse and wetland alteration in preparation of construction • Mine Site road construction
Operation and Maintenance	5 years	• Rock blasting to access and extract ore • Surface mine dewatering to facilitate access to and extraction of ore • Effluent treatment as required of site surface water runoff and surface mine pumped water
Active Closure	2 years	• Infrastructure demolition • Site reclamation activities
Post-closure	10+ years (monitoring, adaptive management)	• Water treatment as required • Water quality and quantity

Table 6.6-7: Potential Project Activities/Interactions with Groundwater Quality and Quantity along the Haul Road

Project Phase	Duration	Project Interactions
Construction	1 year	• Rock blasting in preparation of construction • Watercourse and wetland alteration in preparation of construction • Haul road construction and upgrades
Operation and Maintenance	5 years	• N/A[(a)]
Active Closure[(b)]	2 years	• N/A[(b)]
Post-closure	10+ years (monitoring, adaptive management)	• N/A

Notes: [(a)] No impacts to groundwater are expected during operation of the Haul Road.

[(b)] Decommissioning and Reclamation of the Haul Road is not expected. The Haul Road will be returned to owner for forestry industry.

N/A = not applicable.

Table 6.6-8: Potential Project Activities/Interactions with Groundwater Quality and Quantity at the Touquoy Mine Site

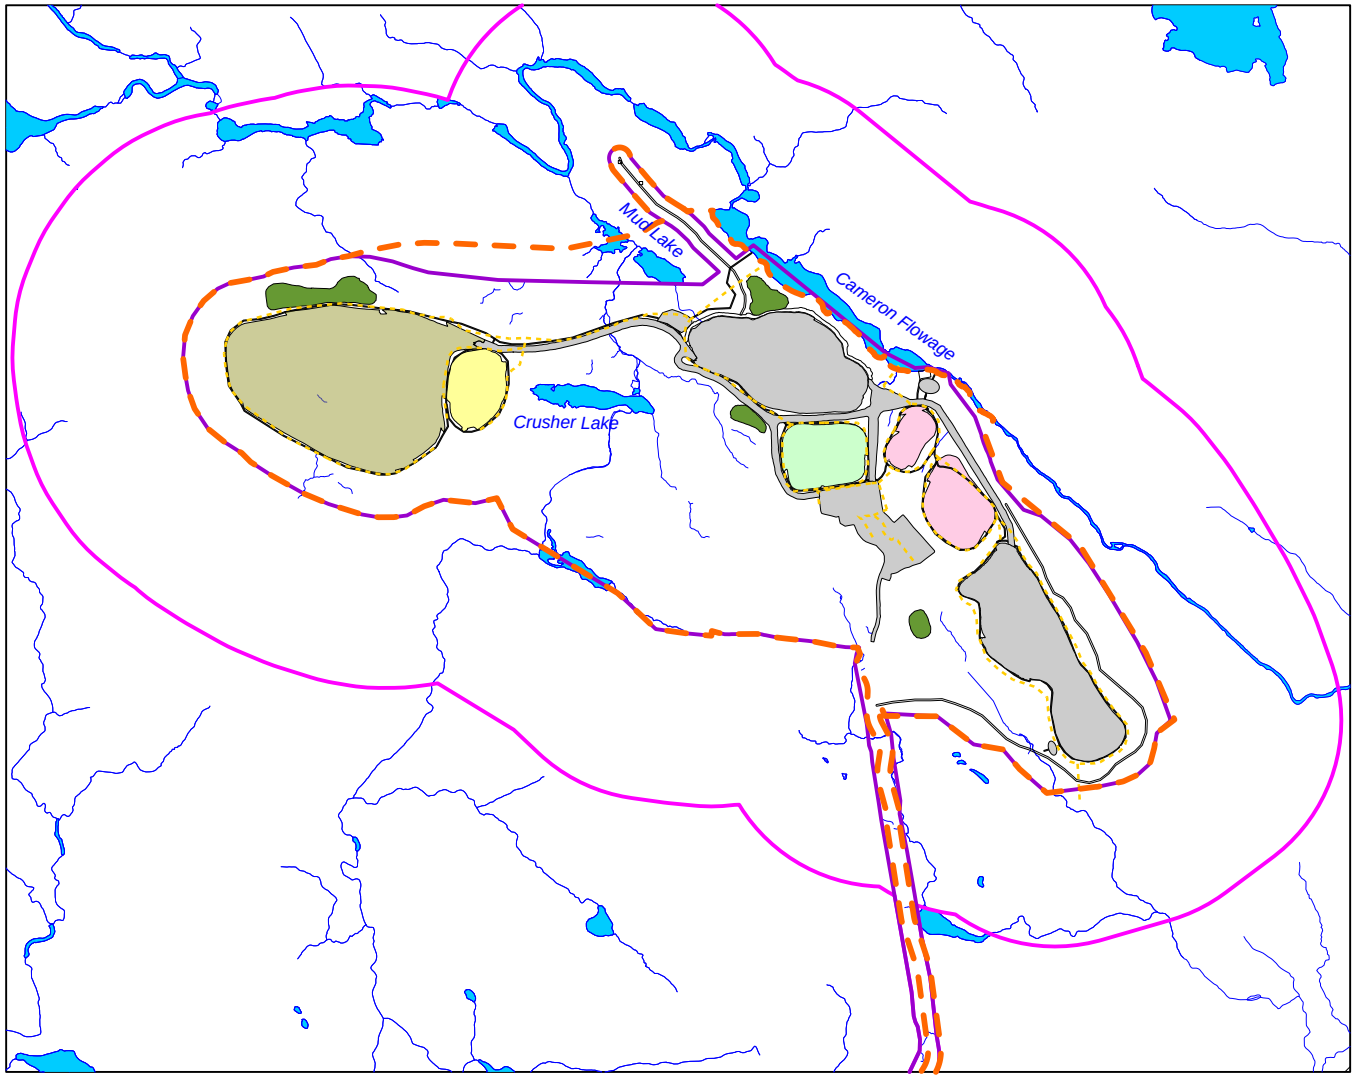
Project Phase	Duration	Project Interactions
Construction	1 year	• Tailings pipeline, make-up water pipeline alteration, and relocation of reclaim infrastructure
Operation and Maintenance	5 years	• Disposal of tailings from processing the Beaver Dam Mine or at Touquoy Mine Site into the exhausted Touquoy Pit
Active Closure	2 years	• Tailings from processing the Beaver Dam Mine ore within the Touquoy Site pit lake
Post-closure	10+ years (monitoring, adaptive management)	• Water treatment as required • Water quality and quantity monitoring (e.g., groundwater monitoring wells)

Note: Reclamation and closure for Touquoy Mine Site is part of a separate Industrial Approval.

6.6.7.1 Beaver Dam Mine Site

The groundwater assessment for the Beaver Dam Mine Site has been updated to reflect additional hydrogeologic data collected since the Revised 2019 EIS (AMNS 2019), updates to Project layout, additional Contaminant of Concern (COC) source terms and comparison of predicted COC concentrations in groundwater to NSE Tier 1 EQS for potable groundwater, GCDWQ or NSE Tier 2 PSS for groundwater discharge to surface water (>10 m) (Section 6.6.7.1) (CEAA-2-35, NSE-2-2, NSE-2-35, NSE-2-135, NSE-2-145, NSE-2-150, NSE-2-166) (CEAA 2019; NSE 2019).

Groundwater and surface water at the Beaver Dam Mine Site interact in many areas with the main controls including topography, bedrock permeability, and surface water bodies. Areas of recharge are typically the elevated areas with discharge occurring in the low-lying areas. Evidence of groundwater discharge to the surface water systems are abundant and mainly appear in the form of seeps and wetlands. Abundant groundwater/surface water interactions are supported by high levels of precipitation (an average of approximately 1,357 millimetres per year [mm/yr] from Environment Canada's Middle Musquodoboit climate station [Station ID 8203535, 1981 to 2010]), undulating topography, and relatively low permeable shallow bedrock overlain by permeable soil and till units. As discussed in Section 6.6.6.1, the most appropriate spatial boundary at which to evaluate projected impacts is the LAA. Effects will range from locally significant to insignificant. No adverse groundwater impacts from the Beaver Dam Mine Site are predicted beyond the boundary of the RAA, and in general, the majority of impacts do not extend beyond the LAA.



Potential impacts of Project activities on groundwater quality and quantity at the Beaver Dam Mine Site were predicted through the application of the Beaver Dam Model. The Beaver Dam Model was applied to predict pit inflow rates, groundwater elevation drawdowns, COC transport, and changes in baseflow within the PA, LAA, and RAA, where appropriate.

Simulated steady-state inflow rates to the open pit at the Beaver Dam Mine Site range from 531 to 655 m^3/d under average dry and average wet conditions, respectively. A sensitivity analysis was conducted to examine the impact of both the Mud Lake Fault and Cameron Flowage Fault on pit inflow rates. The sensitivity analysis was conducted in accordance with British Columbia Ministry of the Environment guidelines (Wels et al., 2012) and consistent with the fault representation and analysis method presented in BGC Engineering Inc. (2015) for groundwater modelling in support of the environmental impact statement developed for the AJAX Project near Kamloops, British Columbia. The sensitivity analysis presented in Table 7.6 of Appendix F.5 (Hydrogeologic Modelling Report), shows that simulated steady-state inflow rates increase by 24% to 829 m^3/d when the hydraulic conductivity of the Mud Lake Fault Zone is increased by two orders of magnitude above the calibrated hydraulic conductivity value. Pit inflow rates are insensitive to changes in the hydraulic conductivity of the Cameron Flowage Fault Zone as it does not intersect the proposed pit.

The sensitivity analysis of simulated pit inflow rates also included testing variations in bedrock hydraulic conductivity. As shown in Table 7.6 of Appendix F.5 (Hydrogeologic Modelling Report), the simulated steady-state pit inflow rates under wet conditions range from 655 to 1,835 m^3/d for all pit inflow sensitivity simulations. However, the maximum steady-state inflow rate of 1,835 m^3/d corresponds to a significant deterioration in model calibration statistics, and thus, is not supported by observed groundwater elevations. As a result, the expected range in simulated steady-state pit inflow rates under wet conditions obtained through the sensitivity analysis is 655 to 829 m^3/d, which compares well with the range estimate pit inflow rates of 550 to 1,450 m^3/d presented in PCA (2015).

The Beaver Dam Model was applied to assess changes in groundwater flow and groundwater/surface water interactions under end of mine life conditions (open pit excavated to maximum proposed depth) and post-closure conditions (open pit infilled with water to an elevation of 127 masl). Specifically, drawdown (i.e., the degree to which groundwater levels decrease) and changes in baseflow were evaluated. Figures 6.6-9 and 6.6-10 show simulated drawdown under base case conditions for EOM and PC, respectively. Figures 6.6-11 and 6.6-12 show simulated drawdown under dry conditions for EOM and PC and Figures 6.6-13 and 6.6-14 show simulated drawdown contours under wet conditions for EOM and PC, respectively. The greatest extent of simulated drawdown is shown on Figure 6.6-11, corresponding to simulated dry conditions at end of mine life. Figure 6.6-12 shows that a maximum drawdown of 0.5 m is simulated adjacent to Cameron Flowage within the PA during PC. Simulated drawdown is generally less than 10 cm outside of the PA, and simulated drawdown is negligible beyond the LAA. Simulated water levels recover slightly under post-closure conditions, as demonstrated by a reduction in drawdown shown on Figures 6.6-10, 6.6-12, and 6.6-14 but remain depressed relative to baseline conditions. Additional details are provided in Appendix F.5.

The maximum radius of groundwater drawdown influence under dry (conservative) conditions has been simulated at 1 km (in a southerly direction) and less in all other directions from the pit, with the exception some localized drawdown at the surface water management ditches surrounding the Beaver Dam Mine Site infrastructure. At the horizontal extent of this radius of influence, there is a predicted drawdown of 10 cm. Beyond this radius of influence, there is little to no potential impact from the Beaver Dam Mine Site development on groundwater quantity interactions with surface water features or potable wells.

HEG file: Z:\HEG\088664\DOCUMENTATION\RPT\088664-RPT-13\FIGURES\Figure 7.3b - Simulated Drawdown Wet Condition - PC.srf

The simulated change in baseflow throughout the Cameron Flowage watershed is presented in Table 7.4 of Appendix F.5 (Hydrogeologic Modelling Report). The simulated baseflow reduction ranges from 677 to 754 m^3/d at EOM and from 446 to 620 m^3/d at PC. The range in baseflow reduction represents 2 to 3% of total baseflow in the Cameron Flowage watershed and is under 1% of the total average annual flow in Cameron Flowage. Approximately 50 to 60% of the total baseflow reduction is simulated to occur within the Property Boundary, and the remaining 40 to 50% of total baseflow reduction is simulated to occur between the Property Boundary and the LAA, indicating that Beaver Dam Mine Site operations will not impact the baseflow contribution to Cameron Flowage beyond the LAA. Further analysis of the potential effects of this baseflow reduction to Cameron Flowage are discussed in Section 6.7 (Surface Water Quality and Quantity).

The Beaver Dam Model was also applied to simulate the transport of COCs from potential source zones (e.g., waste rock piles, low grade ore stock pit, and pit lake) to surface water bodies. The COC concentrations discharging to surface water were estimated for both base case and upper case source term concentrations developed for EOM and PC conditions (Appendix E.3 Geochemical Source Terms). A conservative tracer (i.e., considering the solute transport processes of advection and dispersion only) at a unit concentration was applied to simulate COC migration from each source. The simulated tracer concentration in groundwater was scaled based on the source term concentrations developed to estimate the COC concentrations throughout the Beaver Dam Mine Site and surrounding area (Appendix E.3). All simulated COC mass loadings from groundwater to surface water were provided as input to the Predictive Water Quality Model (Appendix D of Appendix P.4 Mine Water Management Plan) to estimate the cumulative impact of groundwater and surface water loadings to surface waterbodies (Section 6.7). The COC transport simulations are described in detail in Section 7.1.5 of Appendix F.5.

The COC transport simulations were conducted to estimate the extent and significance of potential COC impacts to groundwater and surface water. The potential COC impacts to groundwater are assessed by comparing predicted COC concentrations in groundwater against the lower of the Tier 1 EQS for potable groundwater or GCDWQ, hereafter referred to as the 'Potable Criteria'. Predicted COC concentration distributions are presented for COCs that are simulated to exceed the Potable Criteria. For these COCs, the extent of the simulated exceedance is compared to the spatial boundaries described in Section 6.6.6.1.

The potential COC impacts to surface water are assessed through comparing predicted COC concentrations in groundwater against Tier 2 PSS and through developing simulated groundwater COC mass loadings to surface water for all COCs. The simulated groundwater COC mass loadings to surface water are provided as inputs into the Predictive Water Quality Assessment (Appendix D of Appendix P.4 Mine Water Management Plan). Within the Predictive Water Quality Assessment, the groundwater COC mass loadings are combined with COC mass loadings from surface water runoff to assess the combined potential impact of surface water and groundwater discharge from the Beaver Dan Mine Site on Killag River surface water quality.

Figures 7.7 through 7.13 in Appendix F.5 (Hydrogeologic Modelling Report) present the simulated COC exceedances of the Potable Criteria for the base case and upper case source terms under base case conditions for EOM, as follows:

- Arsenic (Figures 7.7 and 7.8 in Appendix F.5) is predicted to exceed its Potable Criteria in the vicinity of the NAG and PAG waste rock stockpiles for both the base case and upper case source terms, and in the vicinity of the topsoil stockpiles for the upper case source term. The simulated arsenic Potable Criteria exceedances occur within the Property Boundary, except small isolated areas north of the NAG waste rock stockpile and the topsoil stockpile south of Mud Lake. As discussed in Appendix E.3 (Geochemical Source Terms), the simulated arsenic exceedance is expected to be temporary since arsenic concentrations will decrease as EOM source terms transition to the PC source terms. It should be noted that arsenic is naturally occurring in groundwater at the Beaver Dam Mine Site and is found at concentrations above the Potable Criteria under baseline conditions. Therefore, the potential release of arsenic at concentrations above its Potable Criteria does not represent a significant reduction in the beneficial use of groundwater at the Beaver Dam Mine Site, since groundwater requires treatment for arsenic to meet its Potable Criteria under baseline conditions.

- Manganese (Figure 7.9 in Appendix F.5) is predicted to exceed its Potable Criteria at the till stockpiles for the upper case source term. The simulated manganese Potable Criteria exceedance is located within the Property Boundary and the exceedance is expected to be temporary since the till stockpiles are to be removed during reclamation of the Beaver Dam Mine Site.
- Nitrate (Figures 7.10 and 7.11 in Appendix F.5) is predicted to exceed its Potable Criteria in the vicinity of the NAG waste rock stockpile for both the base case and upper case source terms. The simulated nitrate Potable Criteria exceedance is located within the Property Boundary. Furthermore, nitrate concentrations will decrease as nitrate is leeched from and depleted within NAG waste rock stockpile. Nitrate concentrations are predicted to decrease from the maximum simulated concentrations shown on Figures 7.10 and 7.11 in Appendix F.5 to below the Potable Criteria within approximately 10 years and 25 years for base case and upper case source terms, respectively.
- Uranium (Figures 7.12 and 7.13 in Appendix F.5) is predicted to exceed its Potable Criteria in the vicinity of the NAG waste rock stockpile for both the base case and upper case source terms, and in vicinity of the PAG waste rock stockpile for the upper case source term. The simulated uranium Potable Criteria exceedance is located within the Property Boundary. As discussed in Lorax Environmental (2019a), the simulated uranium exceedance is expected to be temporary since uranium concentrations will decrease as EOM source terms transition to the PC source terms.

Figures 7.14 through 7.28 in Appendix F.5 (Hydrogeologic Modelling Report) present the simulated COC exceedances of the Potable Criteria for base case and upper case source terms under base case conditions for PC, as follows:

- Arsenic (Figure 7.14 in Appendix F.5), cadmium (Figure 7.16 in Appendix F.5), cobalt (Figure 7.18 in Appendix F.5), manganese (Figure 7.20 in Appendix F.5), nickel (Figure 7.22 in Appendix F.5), lead (Figure 7.24 in Appendix F.5), and uranium (Figure 7.26 in Appendix F.5) are predicted to exceed the Potable Criteria in the vicinity of the PAG waste rock stockpile for the base case source term. The predicted exceedances of the Potable Criteria all occur within the Property Boundary.
- Arsenic (Figure 7.15 in Appendix F.5), cadmium (Figure 7.17 in Appendix F.5), cobalt (Figure 7.19 in Appendix F.5), manganese (Figure 7.21 in Appendix F.5), nickel (Figure 7.23 in Appendix F.5), lead (Figure 7.25 in Appendix F.5), uranium (Figure 7.27 in Appendix F.5), and zinc (Figure 7.28 in Appendix F.5) are predicted to exceed the Potable Criteria in the vicinity of the PAG waste rock stockpile for the upper case source term. In all cases the pit lake contains the majority of COCs migrating from the PAG waste rock stockpile, and no predicted exceedances of the Potable Criteria occur beyond the Property Boundary.

Simulated COC exceedances of the Potable Criteria for the base case and upper case source terms for EOM and PC under dry conditions are presented on Figures D.1 to D.22 of Appendix D in Appendix F.5 (Hydrogeologic Modelling Report). Simulated COC exceedances of the Potable Criteria for the base case and upper case source terms for EOM and PC under wet conditions are presented on Figures E.1 to E.22 of Appendix E in Appendix F.5 (Hydrogeologic Modelling Report). The Appendix D and E in Appendix F.5 (Hydrogeologic Modelling Report) figures show that simulated COC exceedances of the Potable Criteria in groundwater do not change significantly from that predicted under base case conditions.

Figures 7.29 through 7.32 in Appendix F.5 present the simulated COC exceedances of the Tier 2 PSS for the base case and upper case source terms under base case conditions for EOM, as follows:

- Aluminum (Figure 7.29 and Figure 7.30 in Appendix F.5 is predicted to exceed its Tier 2 PSS in the vicinity of the topsoil stockpiles for both the base case and upper case source terms. The predicted exceedance is within the Property Boundary for the base case source terms (Figure 7.29 in Appendix F.5) and extends slightly beyond the Property Boundary for the upper case source terms (Figure 7.30 in Appendix F.5).

- Arsenic (Figure 7.31 in Appendix F.5) and Cadmium (Figure 7.32 in Appendix F.5) are predicted to exceed the Tier 2 PSS in the vicinity of the topsoil stockpiles for the upper case source term. The predicted exceedance is within the Property Boundary for both Arsenic and Cadmium.

Figures 7.33 through 7.47 in Appendix F.5 present simulated COC exceedances of the Tier 2 PSS for base case and upper case source terms under base case conditions for PC, as follows:

- Aluminum (Figure 7.33 in Appendix F.5), cobalt (Figure 7.37 in Appendix F.5), iron (Figure 7.40 in Appendix F.5), nickel (Figure 7.42 in Appendix F.5), lead (Figure 7.44 in Appendix F.5), and zinc (Figure 7.46 in Appendix F.5) are predicted to exceed the Tier 2 PSS in the vicinity of the PAG waste rock stockpile for the base case source terms. The predicted exceedances do not reach nearby surface water features and are within the Property Boundary.
- Cadmium (Figure 7.35 in Appendix F.5) is predicted to exceed the Tier 2 PSS in the vicinity of the PAG waste rock stockpile for the base case source terms. The simulated exceedances encroach on the Property Boundary and/or reach surface water features (either Cameron Flowage to the northeast of the PAG waste rock stockpile or mapped streams to the west of the PAG waste rock stockpile).
- Aluminum (Figure 7.34 in Appendix F.5), cobalt (Figure 7.38 in Appendix F.5), copper (Figure 7.39 in Appendix F.5), iron (Figure 7.41 in Appendix F.5), and zinc (Figure 7.47 in Appendix F.5) are predicted to exceed the Tier 2 PSS in the vicinity of the PAG waste rock stockpile for the upper case source terms. The predicted exceedances do not reach the nearby surface water features and are within the Property Boundary.
- Cadmium (Figure 7.36 in Appendix F.5), nickel (Figure 7.43 in Appendix F.5), and lead (Figure 7.45 in Appendix F.5) are predicted to exceed the Tier 2 PSS in the vicinity of the PAG waste rock stockpile for the upper case source terms. The simulated exceedances encroach on the Property Boundary and/or reach surface water features (either Cameron Flowage to the northeast of the PAG waste rock stockpile or mapped streams to the west of the PAG waste rock stockpile).

Simulated COC exceedances of Tier 2 PSS for the base case and upper case source terms for EOM and PC under dry conditions are presented on Figures F.1 to F.19 of Appendix F in Appendix F.5 (Hydrogeologic Modelling Report). Simulated COC exceedances of Tier 2 PSS for the base case and upper case source terms for EOM and PC under wet conditions are presented on Figures G.1 to G.19 of Appendix G in Appendix F.5 (Hydrogeologic Modelling Report). The Appendix F and G figures in Appendix F.5 (Hydrogeologic Modelling Report) show that simulated COC exceedances of the Tier 2 PSS in groundwater do not change significantly from that predicted under base case conditions.

To further evaluate the potential risk to surface water features as a result of predicted Tier 2 PSS exceedances, GHD incorporated the simulated COC mass loading to surface water features into the Predictive Water Quality Assessment (Appendix D of Appendix P.4 Mine Water Management Plan) to predict COC concentrations in surface water features. The total simulated mass loading for each COC from groundwater discharge to surface water within the Killag River watershed is presented in Table 7.5 for EOM and PC for both the base case and upper case source terms. The predicted COC concentrations in surface water are compared to Canadian Council of Ministers of the Environment (CCME) Guidelines for the Protection of Aquatic Life at the near-field and far-field locations within the Killag River/Cameron Flowage. The Predictive Water Quality Assessment (Appendix D of Appendix P.4 Mine Water Management Plan) addresses any potential need for treatment of the effluent water prior to discharge into the Killag River such that the combined groundwater and surface water discharge into the Killag River will meet CCME Guidelines for the Protection of Aquatic Life. However, potential localized impacts to surface water features located to the west of the potentially acid generating (PAG) waste rock stockpile may not be addressed. Therefore, GHD evaluated the effectiveness of potential mitigation measures that could be applied to address the potential migration of COCs to the west of the PAG waste rock stockpile should

groundwater quality monitoring indicate that there may be potential exceedances of Tier 2 PSS. The evaluation of potential mitigation measures for groundwater migration west of the PAG waste rock stockpile is presented in Section 6.6.8.

It is also recognized that potential uncertainty in the quality or quantity of PAG waste rock deposited in the PAG waste rock stockpile could impact potential COC concentrations. Therefore, monitoring of the PAG waste rock material deposited in the PAG waste rock pile will be addressed through the draft Beaver Dam Mine Metal Leaching Acid Rock Drainage Management Plan (Appendix E.5). A contingency of in-pit disposal will be maintained throughout operation should the Geochemical Characterization Management Plan identify that the quality or quantity of PAG may exceed prediction.

The key sensitive receptor in the area of the Beaver Dam Mine Site is the Beaver Lake IR 17. The Beaver Lake IR 17 is a satellite community of the Millbrook First Nation located approximately 5 km southwest of the Beaver Dam Mine Site and beyond the LAA boundary. No significant impacts to groundwater quality or quantity are predicted outside of LAA boundary, and thus, no impacts are predicted at the Beaver Lake IR 17.

The nearest potable well, Beaver Lake IR 17, is approximately 5 km southwest from the Beaver Dam Mine Site, at a residence along Hwy 224 that is located beyond the LAA boundary (Figure 6.6-8). No significant impacts to groundwater quality or quantity are predicted outside of the LAA boundary, and thus, no impacts are predicted at the potable wells from the Beaver Dam Mine Site.

6.6.7.2 Haul Road

The nearest identified potable water supplies are located at a permanent residence near the intersection of Beaver Dam Mines Road and Hwy 224, at the Beaver Lake IR 17 approximately 3 km from the primary Haul Road. The nearest residents at the intersection of the Haul Road and the Mooseland Road is approximately 1 km.

Clearing, grubbing and grading of the Haul Road surface in preparation for construction has the potential to affect the groundwater flow regime. Also, there will be limited wetland alteration required to facilitate Haul Road construction. In consideration of the overall small linear extent of the disturbed area, this disturbance is a low to negligible potential for interaction and affect to the groundwater flow regime.

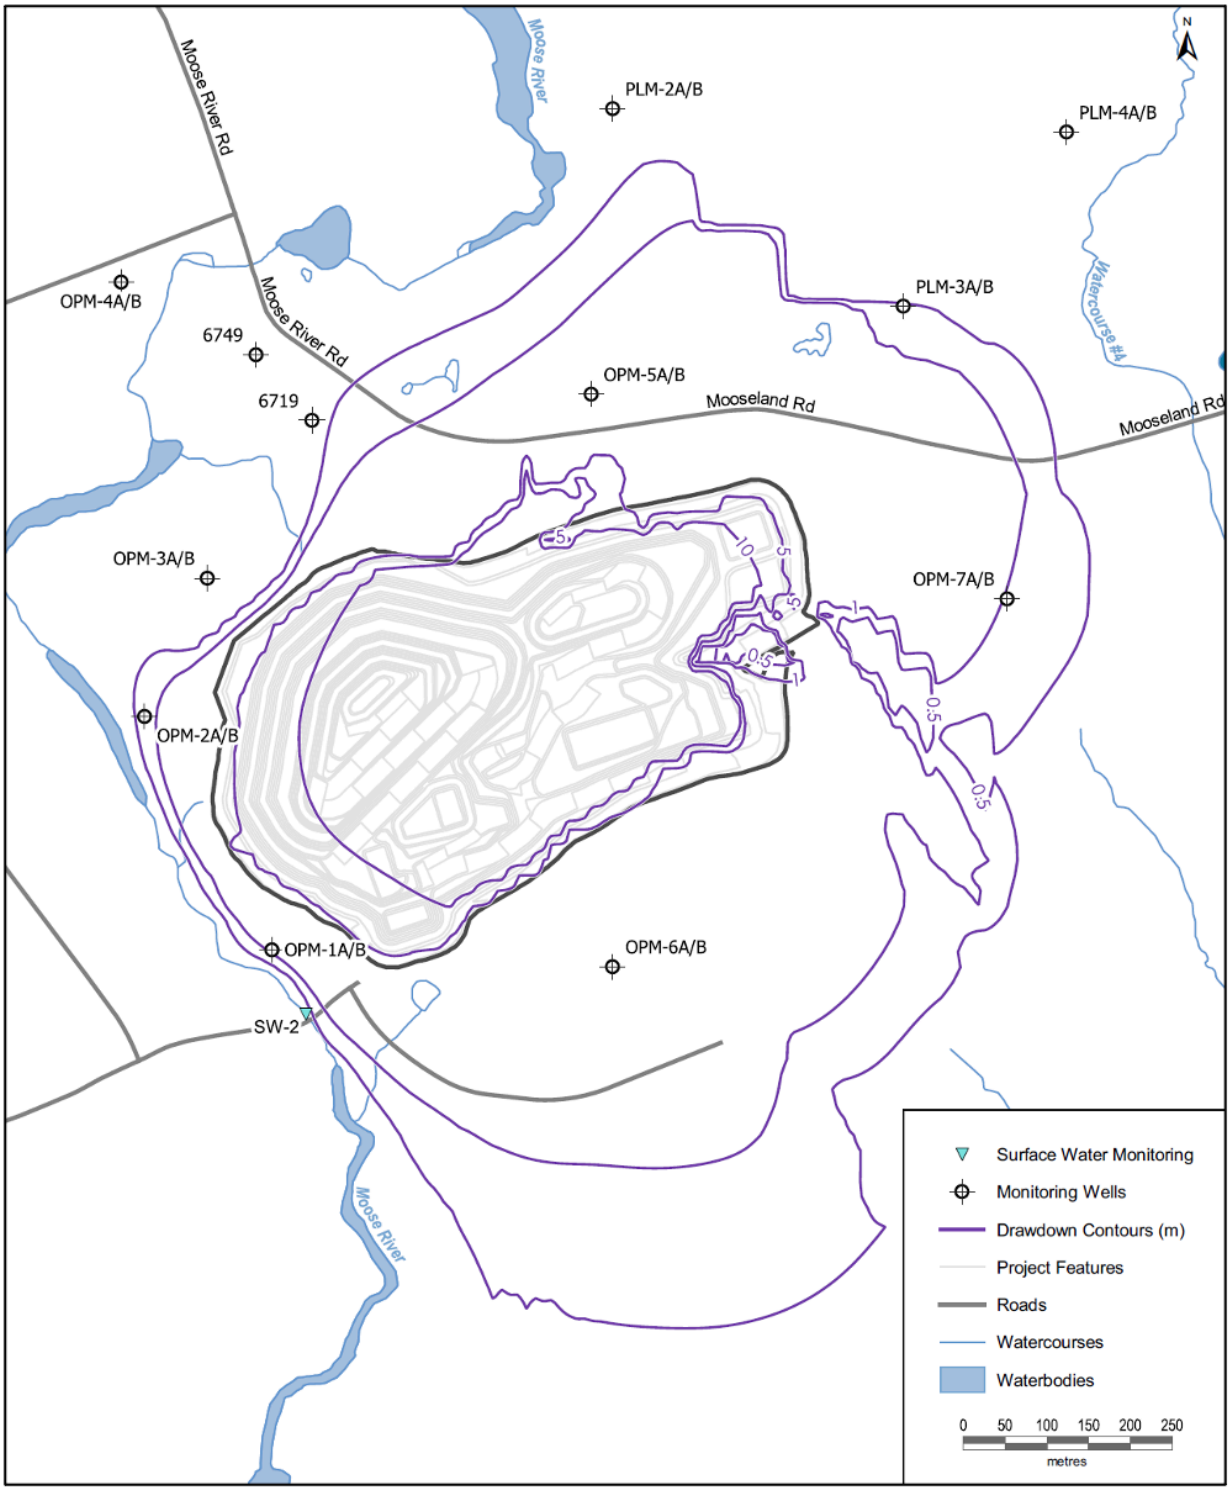
Localized rock blasting will occur along the Haul Road to support construction activities. In general, there is potential to increase fracturing and permeability within 10 m from a well-executed blast. Given the small radius of influence of blasting it is highly unlikely that any nearby shallow potable wells will be impacted by localized changes to the groundwater flow regime. In addition, there is the potential for the release of blasting residues to groundwater via surface water pathways. However, given the small radius of blasting influence and that COC loadings from blast residues will decrease rapidly over time as those COCs are leached from the rock through precipitation infiltration, any potential impacts will be limited in both extent and duration. Therefore, potential impacts to groundwater quantity and groundwater quality would be highly localized and limited in extent.

During operations, there will be maintenance activities that would include grading and repairs to the road as well as the application of a non-toxic biodegradeable dust suppressant. These interactions are predicted to be limited in extent.

During operations, traffic using the Haul Road will generate dust that will be deposited along, and near the Haul Road. A fugitive dust management plan (Appendix C.3) with (i.e., minimum of 80% dust mitigation) will be applied to reduce the amount of dust generated by traffic using the Haul Road. However, there remains the potential for COCs in dust to impact groundwater receptors along the Haul Road through leaching of metals COCs from dust deposited on surficial soil at sensitive receptor locations to precipitation infiltrating through surficial soil and ultimately reaching groundwater.

GHD conducted air dispersion modelling to predict dust deposition rates near the Haul Road and at each sensitive receptor location where there is a potable groundwater resources or could be a potential future potable well source. Dust deposition was predicted based on emissions from the Haul Road while being used for the Project only, and then for cumulative emissions from the Haul Road while being used for the Project combined with the nearby projects. Section 6.2 and Appendix C.1 (Air Emissions Assessment Technical Report) presents the documentation of the air dispersion modelling methodology and results.

Using methods outlined in United States Environmental Protection Agency's (USEPA's) guidance, "*Human Health Risk Assessment Protocol for Hazardous Waste Combustion Facilities*" (USEPA, 2005), GHD applied to the maximum estimated dust deposition rate for the cumulative emissions from the Haul Road while being used for the Project combined with nearby projects (assumed to persist over the entire project lifespan), to estimate the potential metals COCs concentrations in soil leachate that could migrate to groundwater. GHD compared the estimated metals COCs concentration in soil leachate to applicable potable groundwater criteria (NSE Tier 1 EQS for potable groundwater and GCDWQ) (Potable Criteria). There are no predicted exceedances of the applicable groundwater criteria, and therefore, no significant risk to groundwater is predicted to groundwater at the sensitive receptor locations as a result of dust deposition along the Haul Road. The detailed methodology applied to estimate potential metals COCs concentrations in soil leachate is presented in Appendix F.9 (Response to Information Request Nos. CEAA-2-36, CEAA-2-37, and NSE-2-130 - Evaluation of Potential Impacts from Metals COCs to Groundwater and Surface Water from Dust Deposition along the Haul Road).



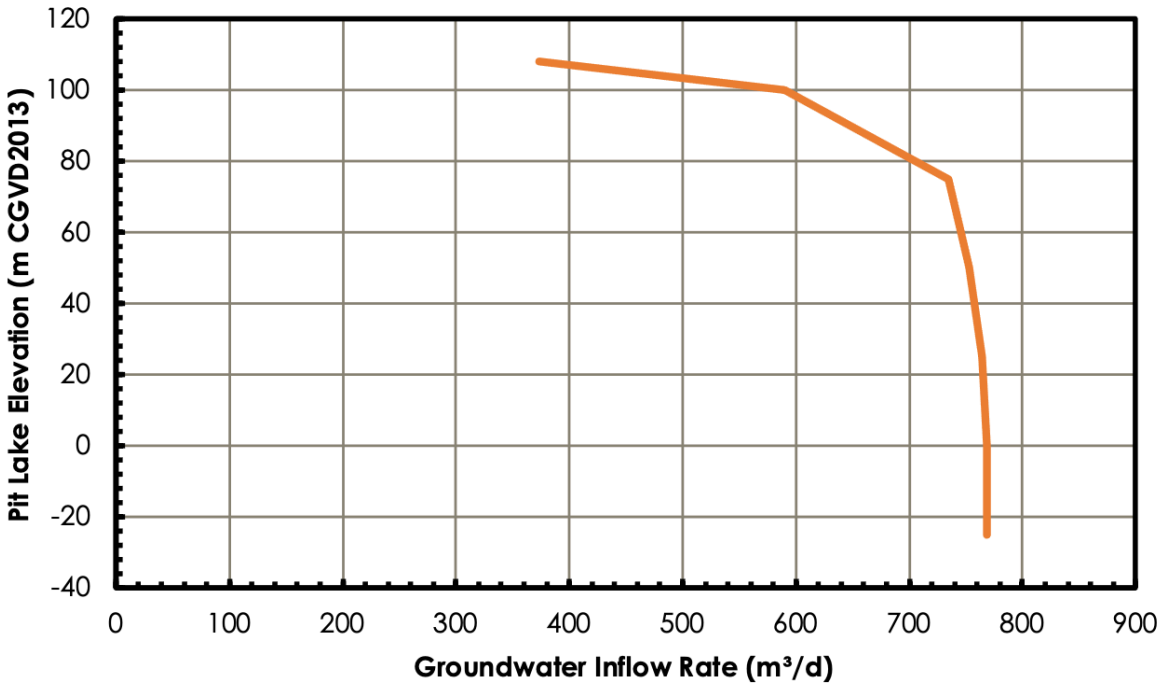
There is the potential for a groundwater interaction from haul road activity in the event of an accident or malfunction (i.e., potential spill). Accidents and Malfunctions are identified and described in Section 6.18.

6.6.7.3 Touquoy Mine Site

The processing of the Beaver Dam ore will result in the generation of tailings (Beaver Dam tailings) that will be deposited into the Touquoy pit. The deposition of tailings into the exhausted pit has the potential to interact with groundwater quality around the Touquoy pit, and the water quality in Moose River from groundwater seepage into the river.

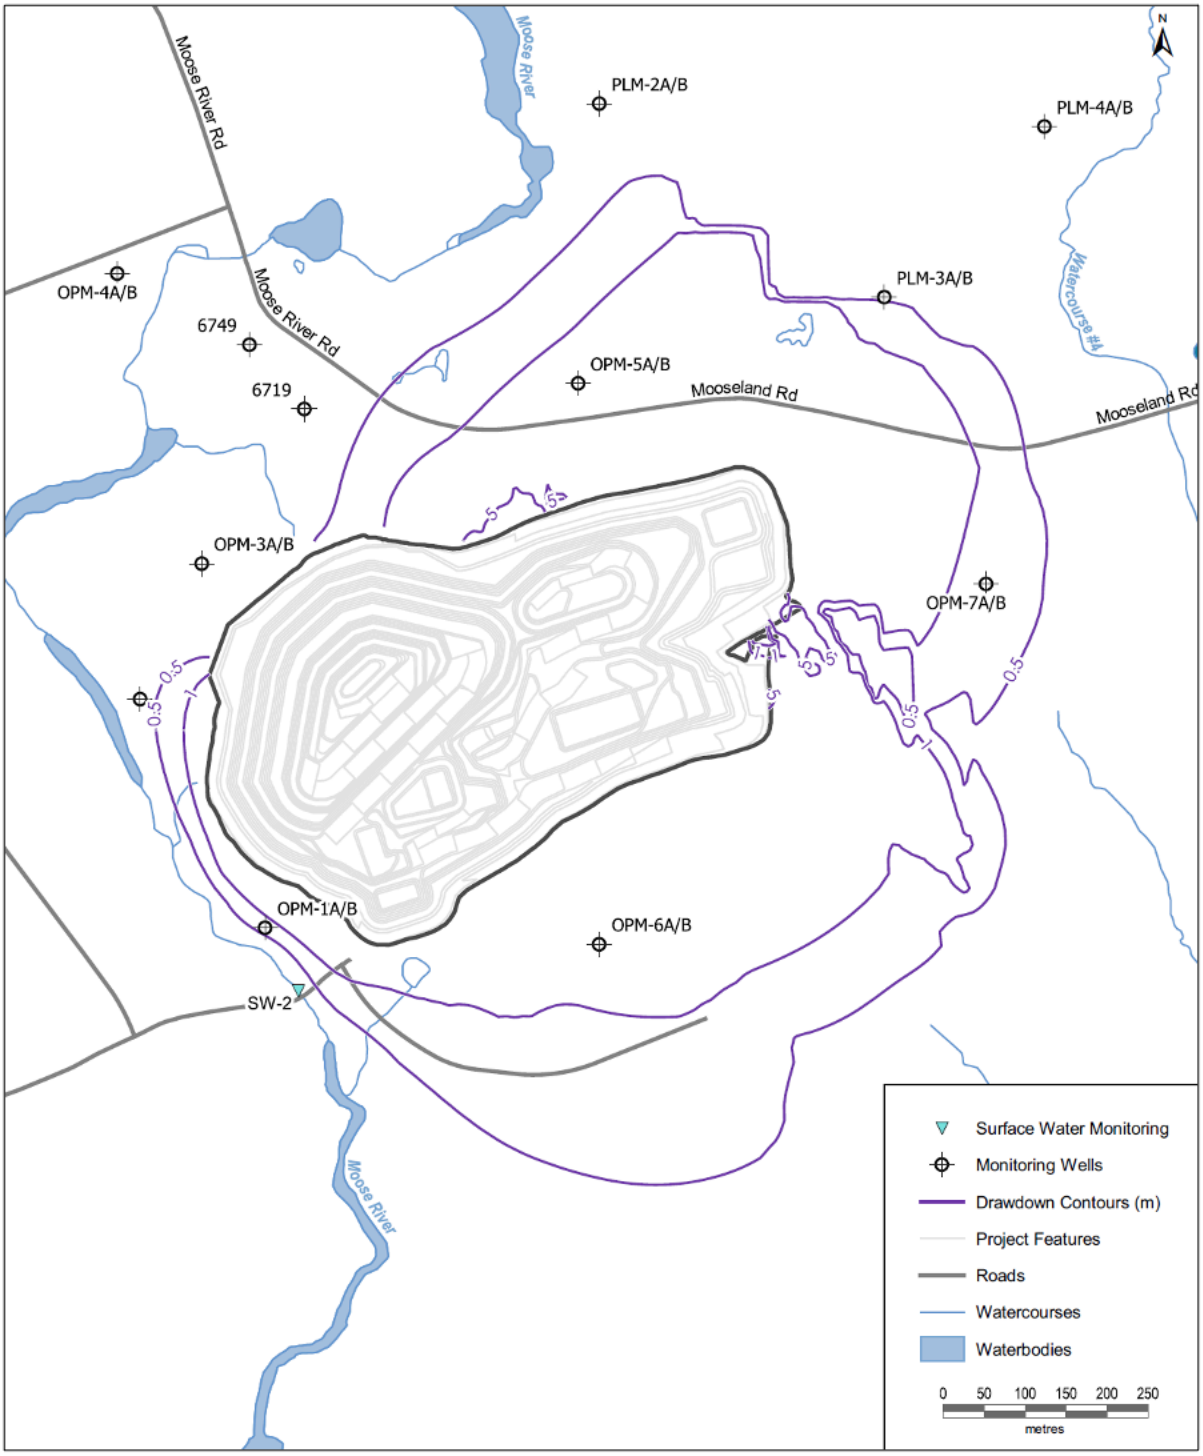
The tailings will be deposited into the exhausted pit, which will have been dewatered as part of the Touquoy Gold Project. Therefore, the dewatering of the open pit will be the initial condition. This condition was simulated during the Touquoy groundwater modelling exercise, as described in Appendix F.6. The dewatering of the Touquoy open pit, prior to tailings deposition, is predicted to occur at a rate of 768 m^3/d, and will result in drawdowns around the open pit, as shown on Figure 6.6-15. The extent of the drawdown cone, as delineated by the 0.5 m drawdown contour, extends approximately 600 m south of the limits of the Touquoy open pit and about 50 m west of the Touquoy open pit toward Moose River.

Figure 6.6-15: Predicted Drawdown Contours from Fully Development Open Pit at Touquoy Mine Site Prior to Deposition of Beaver Dam Mine Tailing



Camp Kidston, which operates only in the summer months, is located 3.5 km northeast of the Touquoy facility. According to the Proponent, the nearest permanent full-time occupied residences are located approximately 5.8 km to the north of the Touquoy open pit along Caribou Road. The next closest permanent residences to the Touquoy Mine Site are approximately 7.4 km to the northwest and 11.7 km to the southeast.

Compared to the existing conditions, the dewatering of the open pit is anticipated to reduce the flow in Moose River by 549 m^3/d. This accounts for approximately 0.6% of the mean annual flow at Moose River, as estimated 99,360 m^3/d (1.15 m^3/s) at SW-2. In the summer months, the dewatering of the Touquoy open pit occurs at a rate of 444 m^3/d, which is anticipated to reduce the flow in Moose River by 339 m^3/d. This accounts for approximately 1.7% of the mean summer flow at Moose River of 18,938 m^3/d at SW-2.



The groundwater inflow rates to the open pit during the filling of the pit were simulated by adding tailings to the model, and then predicting the inflow rates to the pit lake above the tailings over time. The predicted inflow rates compared to the pit lake stage are presented on Figure 6.6-16. As shown, the inflow rates decrease from 768 m^3/d when the pit stage is at -25 m relative to the Canadian Geodetic Vertical Datum of 2013 (CGVD2013), to 373 m^3/d at a pit stage of 108 m CGVD2013, at which point the pit lake will overflow to Moose River through a spillway.

Figure 6.6-16: Groundwater Inflow Rates to the Open Pit During the Filling of the Open Pit

The drawdown at the end of pit filling (i.e., when the pit lake stage is 108 m CGVD2013) was simulated using the Touquoy groundwater model and is shown on Figure 6.6-17. As presented on Figure 6.6-17 the groundwater flow to the open pit remains at 373 m^3/d because the 108 m CCGVD2013 level is below the natural groundwater elevation within the footprint of the open pit. However, at this elevation, there are both groundwater inflows to and outflows from the open pit that are not observed with the fully dewatered open pit where no outflows are observed.

Figure 6.6-17: Predicted Drawdown Contours from Filled Open Pit at Touquoy Mine Site following Deposition of Beaver Dam Tailings

During the Post-Closure period, the deposited Beaver Dam tailings at the Touquoy Mine Site will degrade the water quality in the pit, including the pore water quality in the tailings within the Touquoy open pit. This lower quality water has the potential to migrate toward Moose River via groundwater. The Touquoy groundwater model was used to simulate the migration of solutes from the open pit to Moose River. As described in Appendix F.6, the model simulated the release of water from the pore space in the deposited tailings, and the pit lake quality based on a relative contribution basis. This process simulates the transport of a conservative solute with a concentration of 1 mg/L through the groundwater to the receiving environment over time. The relative concentrations are multiplied by the source term concentrations (refer to Appendix E.3 Geochemical Source Terms) for the parameters of primary concern (POPC) in the open pit to predict the concentrations and mass loadings to the receiving environment over time. The distributions of the concentrations after 50 years are shown on Figure 6.6-18, and after 500 years on Figure 6.6-19. The average concentrations of arsenic discharged to Moose River over the 500-year simulation period are shown on Figure 6.6-20. As shown on Figure 6.6-20, the average concentrations in the discharge to the river stabilize after about 150 years. Refer to Section 6.7 Surface Water Quality and Quantity for a further discussion and effects assessment of the modelled COC in surface water that originates from groundwater seepage. However, the concentration of all parameters at the property line after 500 years of travel are predicted to be less than the CDWG, as shown in Table 6.6-9.

Table 6.6-9: Potential Groundwater Interactions with Project Activities at Touquoy Mine Site

Parameter	Source Term Concentration (mg/L)	Simulated Concentration at South-western Property Line (mg/L)	Canadian Drinking Water Quality Guideline (mg/L)

Figure 6.6-18: Relative Solute Concentrations in Groundwater (mg/L) after 50 Years of Travel Based on Concentrations in Open Pit of 1 mg/L

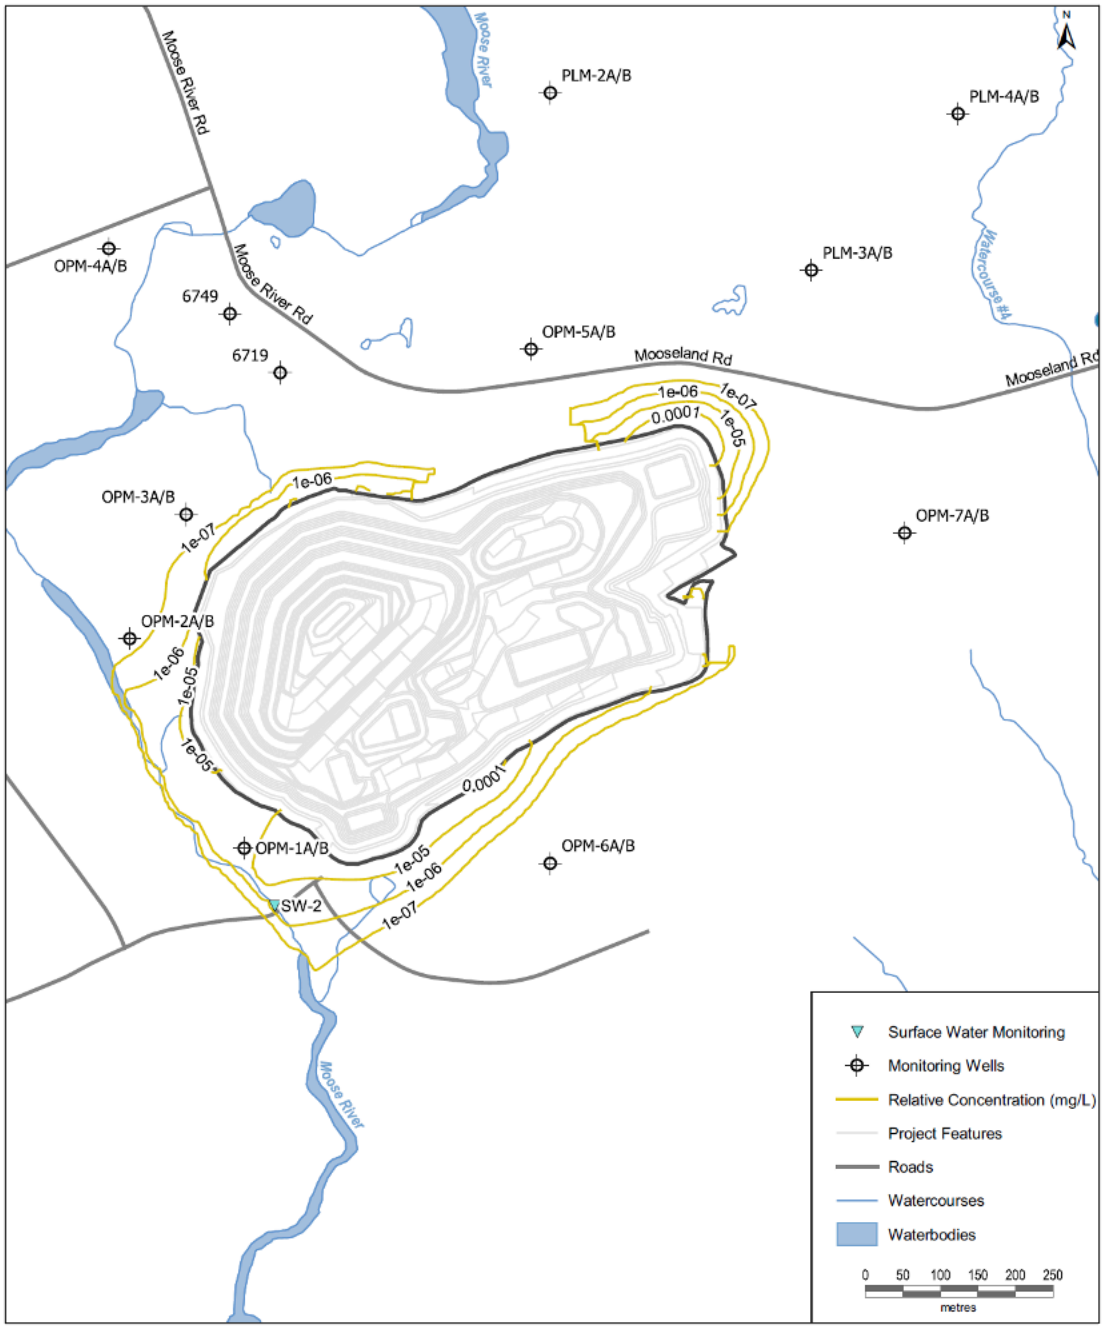

Figure 6.6-19: Relative Solute Concentrations in Groundwater (mg/L) after 500 Years of Travel Based on Concentrations in Open Pit of 1 mg/L

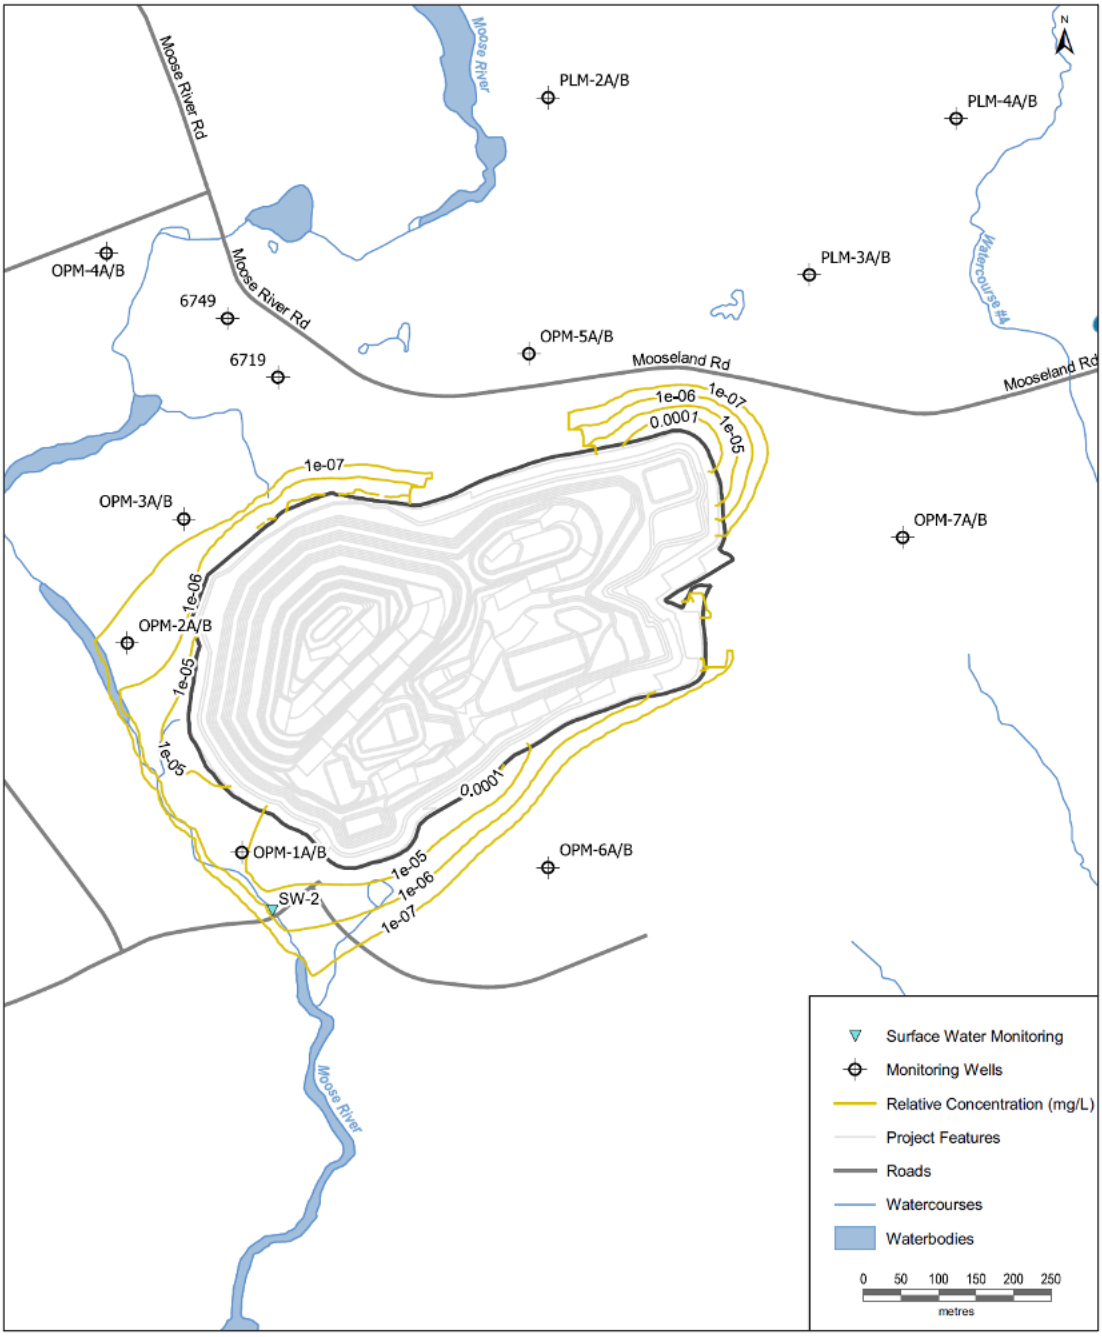

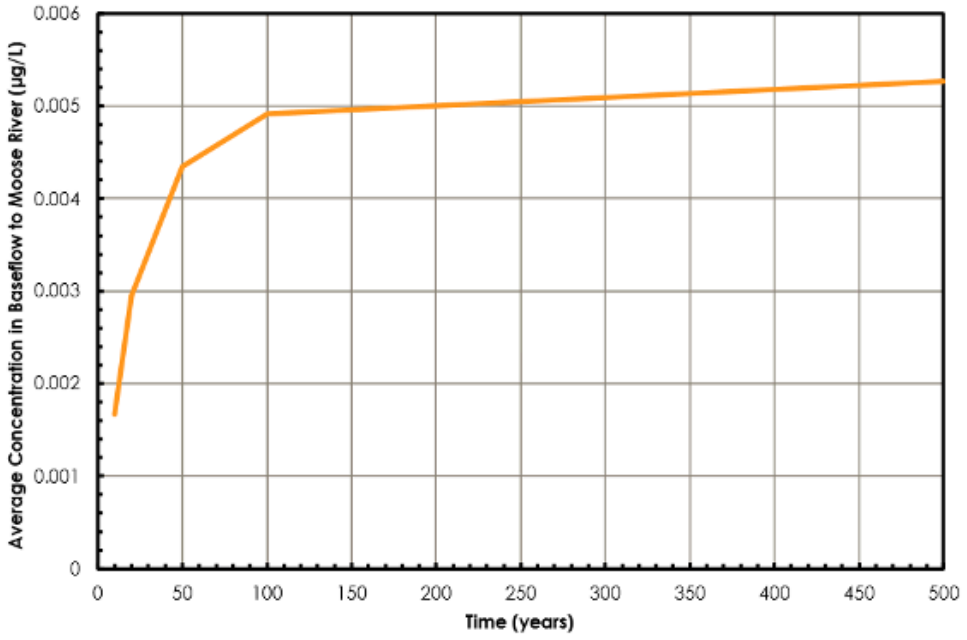

Figure 6.6-20: Simulated Average Concentrations of Arsenic Discharged to Moose River in Groundwater Seepage

A sensitivity analysis of the assumed porosity of the bedrock (Appendix F.6 Groundwater Flow and Solute Transport Modelling to Evaluate Disposal of Tailings in Touquoy Open Pit) was shown to affect the timing of the solute to arrive at Moose River, but did not alter the maximum concentration or underlying groundwater flow rates to the river.

Section 6.7.8.4.2 (Surface Water Quality Modelling Results) provides a discussion and effects assessment of the modelled Parameters of Primary Concern (POPC) in surface water originating from groundwater seepage. This groundwater seepage into the Moose River is an input into the surface water quality modelling and analysis of the assimilative capacity of the Moose River.

6.6.7.4 Groundwater Project Effects Summary

The following summaries are provided for each Mine Site specific to pre-mitigation project interactions, based on results of predictive modelling completed at each Mine Site.

6.6.7.4.1 Beaver Dam Mine Site

The range of potential groundwater inflow rates into the Beaver Dam open pit is approximately 655 to 829 m^3/d.

The maximum radius of groundwater drawdown influence under dry (conservative) conditions has been simulated at 1 km (in a southerly direction) and less than 1 km in all other directions from the Beaver Dam open pit, the impacts from groundwater drawdown is limited to localized drawdown at the surface water management ditches surrounding the Beaver Dam Mine Site infrastructure. Beyond 1 km, simulated drawdown decreases below 10 cm and there is little to no potential impact from the Beaver Dam Mine Site development on groundwater quantity interactions with surface water or potable wells.

The range in **simulated baseflow reduction to the Cameron Flowage watershed is from 2 to 3% of average annual baseflow and is under 1% of total average annual flow**. Potential effects of this baseflow reduction that includes surface water inputs as

well as groundwater on Cameron Flowage/Killag River is assessed in the Surface Water (Section 6.7). In addition, potential impacts wetlands from this localize change in groundwater on Wetlands is discussed in Section 6.8 and on Fish and Fish habitat is assessed in Section 6.9.

At EOM, it was identified that there is potential for arsenic and uranium to exceed the Potable Criteria near the non-potentially acid generating (NAG) waste rock stockpile; however, the impact is expected to be temporary as arsenic and uranium concentrations within the NAG waste rock stockpile are predicted to decrease as the source terms transition from EOM to PC conditions. Furthermore, the predicted exceedance of Potable Criteria for uranium does not extend beyond the Property Boundary, and arsenic is naturally occurring in groundwater at the Beaver Dam Mine Site at concentrations above Potable Criteria. Therefore, at EOM, no significant impact to the reasonable use of groundwater is predicted beyond the Property Boundary.

At PC, using the Base Case (i.e., median) source terms, predicted exceedances of the Potable Criteria for arsenic, cadmium, cobalt, manganese, nickel, lead, and uranium occur in the vicinity of the PAG waste rock stockpile. Using the Upper Case (i.e., 90th percentile) source concentrations, zinc is also predicted to exceed the Potable Criteria in the vicinity of the PAG waste rock stockpile. All predicted long-term PC impacts are contained within the PA boundary.

Simulated COC concentrations for groundwater discharge to surface exceed Tier 2 PSS guidelines under EOM conditions for aluminum for both the base case and upper case source terms and for arsenic and cadmium for the upper case source terms. The predicted exceedances at EOM are related to the topsoil stockpiles which will be removed following operations. For PC, exceedances of Tier 2 PSS were predicted in association with the PAG waste rock stockpile for aluminum, cadmium, cobalt, copper, iron, nickel, lead, and zinc. The predicted exceedances occur either towards Cameron Flowage or towards surface water features west of the PAG waste rock stockpile. To address predicted exceedances of Tier 2 PSS in the vicinity of Cameron Flowage, simulated COC mass loadings to the Killag River watershed were provided as inputs to the Predictive Water Quality Assessment that combined impacts from groundwater discharge and surface water runoff to assess the cumulative impact on the Killag River watershed, as discussed in Section 6.7 Surface Water. To address predicted exceedances of the Tier 2 PSS west of the PAG waste rock stockpile, an interceptor trench was evaluated as a potential mitigation measure. Implementing an interceptor trench is effective for achieving hydraulic containment of potential COC migration west from the PAG waste rock stockpile in the event that groundwater quality monitoring indicates COC concentrations are approaching the Tier 2 PSS in this area.

Potential impacts to groundwater quality and quantity are generally confined to within the PA and LAA. No impacts to groundwater quality and quantity are predicted approaching the RAA or at key receptors including Beaver Lake IR 17 or the nearest potable well located along Hwy 224.

6.6.7.4.2 Touquoy Mine Site

Water levels in the vicinity of the Touquoy Mine Site open pit will be depressed at the beginning of Beaver Dam operations. The Touquoy open pit is forecast to be dewatered at a rate of approximately 768 m^3/d at the end of mining.

Water levels in the vicinity of the Touquoy will recover slightly at the end of Beaver Dam operations but will continue to be depressed relative to existing conditions as the final water level in the Touquoy open pit will be at 108 m CGVD2013. At this stage, there will be both groundwater inflows to and outflows from the filled open pit, with a net groundwater discharge of 251 m^3/d.

Groundwater in the filled Touquoy open pit will seep to Moose River during Post Closure. The total groundwater seepage rate is simulated to contribute approximately 0.6% of the flow in Moose River, therefore the mass loading of the primary compounds of concern are predicted to be low and are not anticipated to adversely affect the water quality in Moose River. These concentrations are considered and evaluated through surface water modelling in Section 6.7.8.4.2.

6.6.7.4.3 Haul Road

No adverse impacts to potable groundwater resources are predicted at sensitive receptor locations along the Haul Road. There is no exceedance of the Potable Criteria.

6.6.8 Mitigation

Groundwater modelling was completed for the Project for potential changes to the quality and quantity of groundwater for the Beaver Dam Mine Site and Haul Road. No current potable groundwater resources for domestic use will be affected by the current Project design as described in Section 2 (Project Description). Potential exceedances of Potable Criteria (i.e., Tier 1 EQS for potable groundwater or GCDWQ) beyond the property boundary are predicted to be short term.

The groundwater quality and quantity effects assessment has been completed and evaluated the effectiveness of mitigation measures that may be included in the design of the Project, and/or as part of adaptive management monitoring, specifically:

- At closure, an engineered cover will be installed over the PAG at closure to reduce infiltration and oxidation, which will reduce the potential acid generation. Runoff from the PAG stockpile will be directed towards the pit.
  - Should monitoring indicate that an interceptor trench is necessary, additional data collected throughout development of the Beaver Dam Mine Site can be applied to refine the design of this potential mitigation measure.
  - An interceptor trench will be constructed to achieving hydraulic containment of potential COC migration west from the NAG and PAG waste rock stockpile.
- During operations and closure at the Beaver Dam Mine Site, water management system collects water from the stockpiles and Waste Rock Storage Area that will be directed towards the north settling pond for treatment at closure the drainage will be directed toward the pit. Water quality will be monitored and if water quality does not exceed predictions and are within water quality guidelines natural drainage will be restored.

The summary of mitigation measures provided in Table 6.6-10 will be implemented where potential direct and indirect impacts to groundwater quality and quantity are possible.

The Touquoy Mine Site is currently operational, mitigation measures for the Touquoy Gold Project can be found in the 2007 Focus Report (CRA 2007b), Industrial Approval and Touquoy Mine Site in annual monitoring reports.

Table 6.6-10: Mitigation for Groundwater Quality and Quantity

Mitigation Category	Project Phase	Mitigation Measure
Quality	C	Conduct pre-construction well survey at Beaver Lake IR 17
	C, O	Use above ground fuel storage tanks that meet applicable regulatory standards
	C, O	Select appropriate type of explosive that will minimize nitrogen release to surface water and groundwater; explosive management plan will be developed before construction and a Nitrogen Management Plan has been developed with site specific adaptive management measures in the event that Nitrogen levels exceed predictions.
	C, O, CL	Sub-aqueous deposition of mine tailings to reduce/prevent oxides and leaching
	CL	In the event of acid rock drainage and metal leaching, implement mitigative measures that will manage the source material and drainage effectively utilizing methods such as an engineered cover to reduce infiltration and oxidation thereby limiting potential acid drainage.
	C, O, CL	Flowage, and existing groundwater wells at Touquoy between the open pit and the Moose River. The purpose of this groundwater treatment is to intersect groundwater seepage impacted with COCs above Tier 2 pathway specific guidelines or groundwater baseline/background prior to seepage discharging into surface water bodies.
Quantity	C, O	Use blasting and pit construction techniques that minimize the potential for negatively interacting the adjacent groundwater table and nearby surface water
	C, O	Implement water conservation program for onsite facilities
	C, O	Recycle site water for reuse wherever practical to reduce water withdrawal from lakes or streams
	C, O	Recycled water must meet acceptable water quality criteria for its intended use

Note: C = construction; O = operations; CL = active closure (decommissioning and reclamation); IR = Indian Reserves; COC = contaminates of concern.

6.6.9 Significance of Residual Effects

The predicted residual environmental effects of Project development on groundwater drawdown are assessed to be adverse, but not significant, beyond the LAA. There is the potential for residual groundwater quality effects within the PA/LAA.

The overall residual effect of the Project on groundwater is assessed as not significant after mitigation measures have been implemented. Effects to groundwater potable resources are not predicted to extend beyond the immediate PA. At the Beaver Dam Mine site changes in potable groundwater resources will likely persist immediately adjacent to the NAG and PAG stockpiles. Groundwater quality will be monitored to determine if an interception trench should be installed to isolate hydraulic connectivity to the surrounding environment.

The reclamation plan for both sites includes a refilling of each pit to attain steady state groundwater flow conditions so that post-mining groundwater conditions are stable (i.e., inflow is equal to outflow).

Interactions or pathways on receptors are assessed in the Surface Water (Section 6.7) Wetlands (Section 6.8) and Fish Habitat (Section 6.9) sections.

A significant adverse environmental effect for Groundwater with respect to potable recourses is not predicted for the Project for the following reasons, with consideration of the ecological and social context of the LAA surrounding the Project:

- During Construction: effects to groundwater potable resources are limited to PA and more specifically the mine site.
- During Operations: Effects are limited to the PA and more specifically the mine site.
- During Closure: Effects are limited to the mine site, and specifically adjacent to the NAG and PAG stockpiles at Beaver Dam Mine.

Table 6.6-11: Residual Environmental Effects for Groundwater

Project - VC Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction – Beaver Dam Mine Site and Haul Road (Surface Water Alteration resulting in reduction of recharge to groundwater, blasting effects on GW, elevated nitrogen in GW from blasting residue)	Sediment and erosion control, pre-blast surveys within 800 m of potable wells, watercourse alteration permitting, inclusion of use of pit dewatering water and collected surface water instead of groundwater for dust control in the project design	M Mitigation strategies and best management practices reduce the magnitude of impact	PA VC confined to the Mine Site	A VC interaction is by timing considerations/during low flows	LT VC interaction effects extend into PCs	R VC interaction will occur regularly during construction phase	PR Mitigation not necessarily return to baseline conditions	Reduction in Water Quantity	Not Significant
Post-Closure – Beaver Dam Mine Site (Groundwater seepage from stockpiles discharge to surface water [Mud Lake, outlet watercourse from Mud Lake, Crusher Lake])	Installation of groundwater wells at the shores of these locations; periodic sampling to evaluate this prediction; modelling updates to include updated source term data/water quality inputs; if necessary groundwater will be intercepted (i.e., interception trench) upstream of wells and treatment will be considered to meet regulatory requirements prior to discharge into receiving environment. Monitoring will determine if additional adaptive management measures will be applied.	L Mitigation strategies and best management practices reduce the magnitude of impact	PA VC confined to the Mine Site	A VC interaction during low flow conditions is assessed	LT VC interaction effects extend into PCs	R Effects will occur at regular intervals during post closure phase of project	PR Mitigation not necessarily return to baseline conditions	Reduction in Water Quality	Not Significant

Notes: See Section 6.6.6.4, Table 6.6-5 for definitions of the below characteristics.

Magnitude

PR	Partially Reversible

6.6.10 Proposed Compliance and Effects Monitoring Program

Groundwater monitoring will be completed to confirm predicted environmental effects and the effectiveness of the mitigation measure groundwater quality. Mitigations are outlined in Table 6.6-10. Groundwater monitoring programs will continue during baseline/pre-construction, to document groundwater baseline conditions. A Proposed Groundwater Monitoring Plan (Appendix G of Appendix P.4 Mine Water Management Plan) has been developed in consideration of wetland and watercourse alteration. The plan provides methods, timing, frequency, and locations for groundwater monitoring. This document will evolve through regulatory permitting, as well as public and Mi'kmaq engagement. Information generated from the groundwater monitoring will be included as part of the Aquatic Effects Monitoring Program that will be developed as part of the permitting process and submitted with the Industrial Approval application.

Groundwater monitoring at Touquoy Mine Site is ongoing and will be expanded before Beaver Dam Mine tailings are deposited in the mined out pit.

6.7 Surface Water Quantity and Quality

6.7.1 Introduction

6.7.1.1 Summary of Surface Water Quality and Quantity Before the Updates

The Beaver Dam Mine (the Project) comprises approximately 592 hectares (ha) of lakes, rivers and forested lands that are in Varying degrees of re-growth due to historical logging. The Project will operate as a satellite surface mine to the existing and fully permitted Touquoy Gold Mine, located nearby in Moose River Gold Mines, Nova Scotia. The ore that is mined from the Beaver Dam Mine Site will be processed at the existing Touquoy Mine.

Prior to updates, Section 6.7 described the methods and results of baseline characterization as well as predictive studies that were undertaken to support characterization of potential Project effects on the Surface Water Quality and Quantity Value Components (VCs). Surface water quality and quantity represent physical components of the natural environment and are protected under both provincial and federal legislation (Canada Water action 1985a, *Fisheries Act* (1985b), *Fisheries Protect Act* (1997), *Nova Scotia Environment Act* (1995)). The regulations help protect ecological components, as well as human health.

Water quality constitutes the physical, chemical, biological, and aesthetic characteristics of water which are, in turn, determined by a variety of regional and local factors including rock weathering, surface transport, biological activity, and anthropogenic influences.

Surface hydrology (used interchangeably with surface water quantity or stream flow) also forms a key component of the aquatic environment, as the magnitude, frequency, duration and timing of stream discharge are directly linked to other components of the aquatic ecosystem. These include groundwater quantity and quality, surface water quality, fish and fish habitat, and aquatic resources.

Prior to updates, the Surface Water Effects Assessment was developed to incorporate quantitative data from baseline reports as well as predictive water quality modelling including sensitivity analyses. The subsequent assessment of residual effects incorporated mitigation and management plans for Project effects and, although residual effects were identified, they were characterized as Not Significant.

6.7.1.2 Summary of Updates to Surface Water Quantity and Quality

The Surface Water Quality and Quantity Effects Assessment (EA) for the Project has been updated to reflect updates of the Project Description (Section 2) and to address Round 2, Information Requests (IR2) issued by the Impact Assessment Agency of Canada (IAAC, formerly the Canadian Environmental Assessment Agency [CEAA 2019]) and Nova Scotia Environment (NSE 2019). This includes:

- Updated description of the existing environment based on ongoing surface water monitoring studies (Section 6.7.4 and Appendix G.1);
- Identification and evaluation of potential water treatment for the Project is described in the Mine Water Management Plan (Appendix P.4) including:
  - Construction Phase (i.e., metals originating from historic mining and tailings Appendix F.1 of Appendix P.4);
  - Operation Phase (i.e., nitrite removal technologies (Appendix F.2 of Appendix P.4); and
  - Post-closure Phase Water treatment Assessment (Appendix F.3 of Appendix P.4).

- Update of the Mine Water Management Plan (Appendix P.4);
- Revised predictive water quality assessment for Construction, End-of-Mine (EOM) and Post-closure phases (Appendix D of Appendix P.4); and
- Assessed the potential effects of Haul Road activities on Surface Water (IR2 responses CEAA-2-36, CEAA-2-37, and NSE-2-130) and included as Appendix F.9 [Evaluation of Potential Impacts from Metals COCs to Groundwater and Surface Water from Dust Deposition along the Haul Road].

Standalone responses to IR2s are provided in AMNS (2021). An outline of updates to the Surface Water Environmental Effects Assessment are summarized in Table 6.7-1.

Table 6.7-1: Updated Subsections from the 2019 Revised Environmental Impact Statement – Surface Water Quantity and Qualtiy

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
-	-	6.7.1 Introduction	• new
6.7.1 Rationale for Valued Component Selection	No	6.7.2 Rationale for Valued Component Selection	• N/A
6.7.2 Baseline Program Methodology	Yes	6.7.3 Baseline Program Methodology	• As a part of this EIS update, the baseline study area was adjusted to allow for the micro-siting of infrastructure, as described in the updated Project Description (Section 2). As a result, targeted surface water surveys were conducted within the modified project area in July and August 2019 to identify and delineate additional surface water features. During the 2019 field evaluations, one new watercourse (WC-AI) and an extension of a previously identified watercourse (WC-O) were delineated along the Haul Road. New watercourses assessed are described in Section 6.7.4.
6.7.3 Baseline Conditions	Yes	6.7.4 Water Quantity Baseline Conditions	• Updated to reflect additional water quality and quantity data collected since the 2019 Revised EIS (AMNS 2019).
-	-	6.7.5 Water Quality Baseline Conditions	• Adjusted heading levels to have Water Quantity and Quality as separated sections. • Updated to reflect additional water quality and quantity data collected since the 2019 Revised EIS (AMNS 2019).
6.7.4 Consideration of Consultation and Engagement Results	No	6.7.6 Consideration of Engagement Results	• Updated to reflect updated engagement with the Public (Section 3), Indigenous Peoples including Mi'kmaq of Nova Scotia (Sections 4 and 6.14).

Table 6.7-1: Updated Subsections from the 2019 Revised Environmental Impact Statement – Surface Water Quantity and Qualtiy (continued)

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
6.7.5 Effects Assessment Methodology – **Boundaries**	Yes	6.7.7 Effects Assessment Methodology – **Boundaries**	• Effects assessment methodology has been updated to reflect updated to models that included additional sampling undertaken since 2018. The additional information has been used either to update the model or calibrate the modelling. The approach for modelling is described is section 6.7.7.3; the associated results are presented in Section 6.7.8.

Notes: PA = Project Area; LAA = Local Assessment Area; RAA = Regional Assessment Area; - = no update; IR2 = Round 2, Information Requests; CEAA = Canadian Environmental Assessment Agency; EIS = environmental impact statement; N/A = not applicable.

6.7.2 Rationale for Valued Component Selection

Surface water (quality and quantity) was selected as a VC for its significance to ecological, and socio-economic systems. Hydrologically and hydrogeologically, surface water consists of stormwater runoff that feeds into various water systems (i.e., rivers, lakes, oceans) including groundwater through recharge.

In summary, Surface Water was selected as a Valued Component for the following reasons:

- Its ecological value in providing habitat for aquatic species;
- The importance of surface water in the daily lives of terrestrial species;
- Its potential to convey stormwater;
- The socio-economic importance of surface water from a recreational and resource perspective; and
- Its potential to interact with Project activities.

The proposed Project has the potential to affect surface water quality during the construction, operations, active closure, and post-closure phases. This effects assessment discretizes Surface Water into two VCs: Surface Water Quality and Quantity, whereby changes to these VCs are, in turn, evaluated using indicators that are relevant, practical, measurable, responsive, accurate and predictable.

The assessment of surface water as individualized VCs, rather than assessing individual physical or chemical constituents, was selected through a review of relevant regulations and guidelines, scientific literature, as well as professional experience and judgement. Indicators, listed in Table 6.7-2, are parameters that allow changes in surface water to be measured. Surface Water Quality and Quantity indicators are assessed quantitatively in predictive modelling, semi-quantitatively using best available data, or qualitatively using professional judgement and experience (Section 6.7.7).

Table 6.7-2: Valued Components Selected for Surface Water Quantity and Quality Assessment

Assessment Pillar	Subject Area	Valued Component	Indicators
Environment	Physical Environment	Surface water quantity	Changes in: • stream volume volumes; and • shifts in seasonal distribution of stream flow.
		Surface water quality	Changes in: • total and dissolved metals; • anions; • nutrients; • TSS; • pH; and • temperature.

Note: TSS = total suspended solids.

6.7.3 Baseline Program Methodology

Surface water monitoring (quality and quantity) for the proposed Project has occurred since 2014; the scope of monitoring programs has varied slightly from year to year to reflect updates to the Project Description (Section 2) as well as to respond to IR2 requests issued by IAAC (CEAA 2019) and Nova Scotia Environment (NSE 2019). However, monitoring has continued to be focused in three geographically distinct areas:

1. Beaver Dam Mine Site;

2. The Haul Road; and

3. The existing Touquoy Mine.

The Killag River, Crusher Lake, Mud Lake, Tent Brook and Cope Brook (Beaver Dam Mine Site area), and Moose River (existing Touquoy Mine) constitute the primary focus of the Project baseline surface water characterization studies, as well as subsequent effects assessment. These watercourses will receive direct discharge and/or their catchment areas have potential to be impacted by Project water management activities, such as non-contact water diversions.

Surface water quality baseline monitoring stations for the Beaver Dam Mine Site, the Haul Road, and the existing Touquoy Mine are presented in Figures 6.7-1, 6.7-2A to 6.7-2D, and 6.7-3, respectively. The baseline program methodology is summarized below, including delineation of the baseline study area and identification of monitoring locations; results of surface water baseline characterization studies are presented in Sections 6.7.4 and 6.7.5.

To identify waterbodies requiring monitoring and characterization, available databases were evaluated to identify mapped waterbodies and watercourses within the Beaver Dam Mine Site and the Haul Road. A field evaluation followed in the spring and summer of 2015 to confirm the presence of the identified water features within and surrounding the site; initially, no mapped waterbodies were identified within the Haul Road. Field evaluation followed in fall 2015 and spring 2016 to confirm the presence of mapped watercourses along the Haul Road and the identification of additional watercourses within the Haul Road corridor; given the linear nature of the Haul Road, mapped watercourses were grouped into watercourse systems 1 to 7 based on their tertiary watershed affiliations to aid in field identification.

As a part of this EIS update, the baseline study area was adjusted to allow for the micro-siting of infrastructure, as described in the Project Description (Section 2). As a result, targeted surface water surveys were conducted within the modified PA in July and August 2019 to identify and delineate additional surface water features. During the 2019 field evaluations, one new watercourse (WC-AI) and an extension of a previously identified watercourse (WC-O) were delineated along the Haul Road. New watercourses are described in Section 6.7.4; summary of physical characterization of watercourses (e.g., wetted widths, average depth, habitat type, etc.) are provided in Appendix G.4 (Physical Characterization of Watercourses).

All open water features identified during the 2019 field evaluations are wetland features, most of which are anthropogenic resulting from historic mine activities that are described in Geology, Soils, and Sediment Quality (Section 6.5, Appendices E.6 to E.9 [i.e., Phase I Environmental Site Assessment (ESA), Limited Phase II ESA, Extended Phase II ESA, and draft Historic Tailings and Waste Rock Management Plan, respectively]). An assessment of historic mining activities and tailings have been updated since the Revised 2019 EIS (AMNS 2019) with more comprehensive sampling program including sediments, which replaces results reported in Appendix E.1 (Sediment Baseline Analytical Results). Open water features associated with wetlands are addressed within the Wetlands Section 6.8.

For the Haul Road, 16 mapped watercourses, including two major rivers, West River Sheet Harbour (WRSH) and Morgan River. Five smaller waterbodies are mapped west of Lake Alma. During field assessments, however, these five waterbodies were confirmed to be wetland habitat. The wetlands are described in Section 6.8.

During field investigations, watercourses were documented using an SXBlue II Global Positioning System (GPS) receiver unit capable of sub-meter accuracy with a handheld SXPad field computer. Blue flagging tape was used to mark the locations of all watercourses. Watercourses were mapped within the Beaver Dam Mine Site and Haul Road and provided a specific watercourse identification number. Each identified watercourse was described for physical parameters, including bank full width, wetted width, water depth, structure (pool, riffle, run, flat, others), littoral zone description, fish habitat potential, overhanging and in-stream vegetation, substrate, potential to support species at risk (SAR) and species of conservation interest (SOCI) and bank stability.

In-stream flow monitoring was conducted at the Beaver Dam Mine Site at two locations, SW-1A and SW-19, in 2018, with four and seven monitoring events completed, respectively. In 2019, a more extensive program was conducted at four locations; SW-1A, SW-2A, SW-6A and SW-19 monthly from April to December. In 2020, three additional baseline flow monitoring locations were established at SW-30, SW-31, and SW-32. These new locations were monitored monthly from April to November 2020. The 2019 and 2020 analysis can be found in IR2 NSE-2-95 response (AMNS 2021). There are a total of seven long-term flow monitoring stations located at the Beaver Dam Mine Site to support the effectiveness of mitigation measures on reducing surface water quantity impacts (Section 6.7.9).

6.7.4 Water Quantity Baseline Conditions

6.7.4.1 Overview

Baseline characterization of Surface Water Quantity (hydrology) conditions at the Project was undertaken to define the existing hydro-climatic regime for the watersheds that could potentially be affected by Project development. The results of these investigations are summarized in the following sections. The primary objectives of the surface hydrology baseline program were to:

- collect stream flow data from a representative suite of Project area watersheds;
- calculate relevant stream flow metrics, including annual runoff, low flows and peak flows, unit yields, etc.; and
- integrate the site-specific data with the available regional hydrometric data to estimate stream flow variability and recurrence intervals for low and peak flows.

The results of baseline characterization studies informed predictive water balance and water quality modelling, informed proposed water mitigation and management activities, and support the effects assessment for the Project (Section 6.7.9 and 6.7.8, respectively).

The proposed Project activities encompass three geographically distinct areas:

- Beaver Dam Mine Site;
- Haul Road; and
- Existing Touquoy Mine.

The Killag River, Crusher Lake, Mud Lake, Tent Brook and Cope Brook (Beaver Dam Mine Site area), and Moose River (existing Touquoy Mine) constitute the primary focus of the Project baseline surface water characterization studies (Appendix G.4), as well as subsequent effects assessment, as these watercourses will receive direct discharge and/or catchment areas have potential to be impacted by Project water management activities.

6.7.4.1.1 Beaver Dam Mine

The Beaver Dam Mine Site lies within the West River Sheet Harbour (WRSH) drainage basin, which is directly east of the Musquodoboit River Valley system. The watershed occupies an area of roughly 576 square kilometers (km^2), a moderately sized watershed in the Province. The area is characterized by rolling till plains, drumlin fields, extensive rockland, and numerous freshwater lakes, streams, bogs and wetlands having relatively low relief, hummocky type terrain. This inland area is somewhat removed from the immediate climatic influence of the Atlantic Ocean and is characterized by warmer summers and cooler winters.

The Killag River and Cameron Flowage is the main mapped linear watercourses of the Beaver Dam Mine Site, and Crusher Lake and Mud Lake are the major mapped lakes. The complex system of streams, lakes, bogs, and wetlands is a direct result of the underlying bedrock geology of greywacke and slate found in the region. The basin ultimately drains to the south via the West River Sheet Harbour, and discharge peaks are likely attenuated to a large extent by the numerous lakes and wetlands through which runoff is routed. The West River Sheet Harbour and Tangier River Secondary boundary runs through the center of the Project Area (Section 6.7.3) along the proposed Haul Road. Elevations within the catchment vary from approximately 135 to 165 meters above sea level (masl) in the headwater areas and gradually decrease to sea level at the final outlet located at Sheet Harbour. The headwaters of the drainage basin are located along the topographic divide separating the Musquodoboit River Valley to the northwest.

An inventory of surface water features was undertaken to identify water features that may be impacted directly or indirectly by the proposed mine and Haul Road construction and operations. Initially three waterbodies (Crusher Lake, Mud Lake, and an unnamed waterbody in the southwest section of the Project Area) were identified through a desktop review of available mapping as requiring characterization of baseline conditions. During the 2019 field evaluations, 10 additional watercourses were identified within the Beaver Dam Mine Site, totaling 24 watercourses within the Beaver Dam Mine Site area. Three additional watercourses outside of the Beaver Dam Mine Site were also delineated (WC23 [Outlet to Cope Brook], WC26 [Outlet to Killag], and WC27 [Outlet of Mud Lake]), due to potential impacts to fish and fish habitat within the LAA (Section 6.9). New watercourses are described in Section 6.7.5 and shown in Figures 6.7-1 and 6.7-2A through 6.7-2D.

Most watercourses within the Beaver Dam Mine Site are first order streams originating within headwater wetland habitat inside of the PA. Many streams across the Beaver Dam Mine Site are generally small with minimal pool/riffle structure and consist of mucky organic substrate. While most are generally perennial in nature, many have intermittent patches, which go dry during prolonged rainless periods when percolation depletes all flow (Alberta Transportation 2009).

Tertiary basins potentially affected by the Project including four within the Beaver Dam Mine Site and six along the Haul Road footprint; were identified as a result of baseline characterizations studies, are listed below and shown on Figure 6.7-4).

The four tertiary basins affected within the Beaver Dam Mine Site:

- Portion of Killag River (1EM-2-D);
- Tent Brook (1EM-2-F);
- Paul Brook (1EM-2-H); and
- Cope Brook (1EM-2-J).

The six tertiary basins affected along the Haul Road:

- Tent Brook (1EM-2-F);
- Keef Brook (1EM-2-G);
- Jack Lowe Brook (1EM-2-N);
- Little River (1EM-2-P);
- Portion of Sandy Pond (1EL-2-C); and
- Portion of Morgan River (1EL-2-H).

McCallum Environmental Ltd.

Document Name: BD_EIS_Figure6-7-1TertWS

6.7.4.1.2 Touquoy Mine Site, Existing Conditions

The Touquoy Mine Site is an active Mine Site that commenced operation on October 11, 2017 and is subject to an Industrial Approval to operate issued by NSE. A Class I Environmental Assessment under the *Nova Scotia Environment Act* and Environmental Assessment Regulations for the Project was reviewed and approved in 2008, subject to Approval conditions. The use of the Touquoy Mine Site for the processing of Beaver Dam Mine ore and deposition of the associated tailings will occur after ore extraction from the Touquoy open pit has ceased. As such, the baseline conditions for the Touquoy Mine Site for the Project operations will be the conditions expected near the end of the Touquoy ore processing operations.

Existing conditions with respect to surface water for the watershed was based on the available data collected as part of the 2007 submission (CRA), 2013 LiDAR (Leading Edge), and Water Management Plan (Stantec 2017a) for operation, the Reclamation Plan (Stantec 2017b) for reclamation and closure, and the 2017 surface water quality/quantity monitoring reports (Stantec 2018b).

The existing Touquoy Mine Site is part of the Moose River drainage basin, which is directly east of the Musquodoboit River Valley system. As described in the Environmental Assessment Registration Document (CRA 2007b), the Moose River watershed can be characterized by rolling till plains, drumlin fields, extensive rock land, and numerous freshwater lakes, streams, bogs and wetlands in the headwaters and the relatively low relief hummocky terrain. Forests are predominantly coniferous of red and black spruce (CRA 2007b). Local ground surface elevations at the Touquoy Mine Site range from 102 to 145 masl. The Touquoy Mine Site is approximately 10 kilometers (km) northwest of the Tangier Grand Lake Wilderness Area. This protected area consists of 16,000 ha of predominantly coniferous forest and has abundant lakes, wetlands, and waterways. The waterbodies within the Wilderness Area are contained within a separate watershed from that of the Touquoy Mine Site, which lies in the Fish River Watershed.

The Moose River drainage basin ultimately drains to the south via Moose River, and runoff through the catchment to Moose River is likely attenuated by the many lakes and wetlands in the catchment thus reducing the peak flow. The catchment area of Moose River is 3,904 ha at surface water monitoring station TQ-SW-2 draining from topographical highs of 180 to 110 masl in elevation (CGVD 2013) at the banks of Moose River. Moose River flows south approximately 2.3 km downstream of SW-2 where it joins the Fish River. Watercourse No. 4 has a catchment area of 136.3 ha at surface water monitoring station TQ-SW-3 and flows south between the existing open pit and Tailings management Facility (TMF) to Moose River and eventually to the Fish River.

6.7.4.2 Monitoring Results

Site-specific baseline results for the effects assessment are presented in this section. The results were calculated for five assessment points selected to assess the hydrologic conditions at the two major mapped lakes (Mud Lake, Crusher Lake) and the main watercourses of the three tertiary basins assessed for the Project including the Killag River, Tent Brook and Cope Brook. The catchment areas were delineated upstream of the assessment points. A summary of baseline catchment areas is provided in Table 6.7-4. Detailed descriptions of the catchment areas are provided in Appendix G.4, Table G.4-1 and presented in Figure 6.7-5. Descriptions and baseline conditions for all 16 assessment points considered in the aquatic effects assessment are provided in Appendix P.4 (Mine Water Management Plan, Appendix A).

6.7.4.2.1 Beaver Dam Mine Site

Climate and Baseline Runoff Estimates

Average daily temperature values and daily precipitation totals were obtained from the Environment Canada Middle Musquodoboit Climate Station (Climate ID 8203535). The station was selected based on its proximity to the Project Site and relatively long, complete and current record. Monthly lake evaporation normal were obtained from the Environment Canada Truro Climate Station (Climate ID 8205990), which is the closest climate station to the site that collects lake evaporation data. Table 6.7-4 summarizes the monthly precipitation totals and average temperatures at the Project Site.

Table 6.7-4: Climate Normals, Hydrological Baseline Conditions Beaver Dam Project

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sept	Oct	Nov	Dec
Average Temperature (°C)	-6.2	-5.3	-1.1	4.3	9.9	15.0	18.5	18.3	13.9	8.3	3.4	-2.5
Precipitation (mm of rain)	128.8	103.3	125.6	105.1	102.6	94.8	97.8	97.7	103.0	123.9	137.1	136.0
Lake Evaporation (mm/day)	0	0	0	0	2.9	3.4	3.8	3.1	2.3	1.3	0	0

Note: Data from Middle Musquodoboit and Truro Environment Climate Stations

To characterize baseline conditions, daily rainfall, snowfall and mean temperature data were obtained from the Environment Canada Middle Musquodoboit Climate Station daily precipitation record for 41 years including 1968 to 2005, 2009, 2014, and 2016. The years that have a significant amount of missing data were excluded from the analysis. The average monthly temperature at the site ranges from a low of -6.2°C in January to a high of 18.5°C in July. The lowest average total monthly precipitation occurs in June (94.8 mm), while the highest occurs in November (137.1 mm). Snowfall was converted to snowmelt using the degree-day method. The rainfall plus snowmelt values were taken from this analysis for use in the water balance and predictive water quality assessments. Rainfall plus snowmelt depths peaked in March due to the rising temperature depleting the snow pack, creating a greater volume of available water for discharge. The lowest rainfall plus snowmelt occurred in June to August.

The catchment areas and assessment points of the Project site under existing (baseline) conditions are presented in Figure 6.7-5 and summarized in Table 6.7-3. The total contributing drainage area to the Killag River downstream of the site, which includes the Project Site and Mud Lake and Crusher Lake, is approximately 3,933.5 ha.

Killag River

Table 6.7-5 presents the monthly baseline metrics (runoff volumes) for the Killag River catchment area. The Killag River catchment was delineated upstream of the Killag River (Killag River DS) assessment point, which is located at the point along the river that fully captures the hydrologic impact of the mine development. The Killag River is one major tributary to the WRSH. The Killag is a long and narrow drainage basin, with a main channel length of approximately 27 km. This system is also organic-acid stained, similar to the WRSH. Land-use within this tertiary watershed is similar to the overall secondary watershed, with sparse development and abundant timber harvesting. The Killag River system has several associated waterbodies. West Lake, Mud Lake and Crusher Lake are associated with sub-tertiary basins that are tributaries to the Killag River. According to local knowledge, most salmon (as well as brook trout, white suckers, American eel and lake chub) spawned in this part of the system. As previously discussed, the Nova Scotia Salmon Federation has installed a second lime dosing station along the Killag River.

Table 6.7-5: Monthly Site Runoff Flow Estimates for the Killag River, Hydrological Baseline Conditions Beaver Dam Project

Month	Average Runoff (m^3)
January	3,644,162
February	3,216,235
March	5,543,553
April	4,107,511
May	2,751,927
June	1,544,772
July	1,159,993
August	1,043,753
September	1,389,421
October	3,139,108
November	4,487,350
December	3,549,515

Note: Estimated for the Killag River DS assessment point (Appendix A Water Balance Analysis of Appendix P.4 Mine Water Management Plan). m^3 = cubic metre.

Monthly runoff values are highest in March due to the combination of rainfall and snowmelt from the snowpack. Monthly runoff values are lowest in July, August, and September due to the lower precipitation and baseflow, and higher evaporation rates.

Mud Lake and Crusher Lake

Tables 6.7-7 and 6.7-8 present the monthly baseline metrics for the Mud Lake and Crusher Lake catchment areas, respectively. The Mud Lake catchment was delineated upstream of the Mud Lake (WC27 US) assessment point at the lake outlet to WC27. The Crusher Lake catchment was delineated upstream of the Crusher Lake (WC5 US) assessment point at the lake outlet to WC5. Monthly runoff volumes are highest in March and lowest in July, August, and September.

Table 6.7-6: Monthly Site Runoff Flow Estimates for Mud Lake, Hydrological Baseline Conditions Beaver Dam Project

Month	Average Runoff (m^3)
January	208,040
February	183,358
March	316,138
April	234,530
May	151,496
June	83,876
July	61,860
August	57,347
September	78,583
October	178,371
November	256,314
December	203,690

Note: Estimated for the WC27 US (Mud Lake outlet) assessment point (Appendix A Water Balance Analysis of Appendix P.4 Mine Water Management Plan). m^3 = cubic metre.

Table 6.7-7: Monthly Site Runoff Flow Estimates for Crusher Lake, Hydrological Baseline Conditions Beaver Dam Project

Month	Average Runoff (m^3)
January	55,154
February	48,542
March	83,721
April	62,188
May	38,628
June	21,056
July	15,240
August	14,666
September	20,557
October	47,031
November	67,983
December	54,289

Note: Estimated for the WC5 US (Crusher Lake outlet) assessment point (Appendix P.4,). m^3 = cubic metre.

Tent Brook

Table 6.7-8 presents the monthly baseline metrics for the Tent Brook catchment area. The Tent Brook assessment point is located immediately downstream of the WC19 confluence to fully capture the hydrologic impact of the Project on Tent Brook. Monthly runoff values are highest in March and lowest in July, August, and September.

Table 6.7-8: Monthly Site Runoff Flow Estimates for Tent Brook, Hydrological Baseline Conditions Beaver Dam Project

Month	Average Runoff (m^3)
January	283,563
February	250,286
March	431,391
April	319,617
May	214,600
June	120,560
July	90,623
August	81,403
September	107,846
October	244,328
November	349,224
December	276,112

Note: Estimated for the Tent Brook assessment point (Appendix A Water Balance Analysis of Appendix P.4 Mine Water Management Plan). m^3 = cubic metre.

Cope Brook

Table 6.7-9 presents the monthly baseline metrics for the Cope Brook catchment area. The Cope Brook catchment was delineated upstream of the Cope Brook (Cope Brook DS#1) assessment point. The Cope Brook assessment point is located immediately downstream of the WC23 confluence to fully capture the impact of the Project on Cope Brook. Monthly runoff values are highest in March and lowest in July, August, and September.

Table 6.7-9: Monthly Site Runoff Flow Estimates for Cope Brook, Hydrological Baseline Conditions Beaver Dam Project

Month	Average Runoff (m^3)
January	445,351
February	393,087
March	677,518
April	501,972
May	337,039
June	189,345
July	142,328
August	127,847
September	169,896
October	383,737
November	548,379
December	433,648

Note: Estimated for the Cope Brook DS#1 assessment point (Appendix A Water Balance Analysis of Appendix P.4 Mine Water Management Plan). m^3 = cubic metre.

Haul Road

During field assessments in spring and summer 2016, 34 watercourses were mapped and evaluated within the Haul Road corridor. These watercourses straddle seven tertiary watersheds, and many are classified as first order streams, in high positions within the tertiary basins. Others, however, are second and third order streams, positioned lower in the tertiary watersheds and broader secondary watersheds, and offer more substantial aquatic and fish habitat.

Main West River, Sheet Harbour (WRSH)

The West River Sheet Harbour (WRSH) commences at headwater lakes including Sand Lake and West Lake just southeast of the community of Pleasant Valley near Upper Musquodoboit and crosses the Haul Road just north of the intersection of the Haul Road with Highway 224. The river drains in the southeast direction, parallel to Highway 224, across the Haul Road and into the Atlantic Ocean at Sheet Harbour, Nova Soctia. The Killag River joins the main West River Sheet Harbour southeast of the Haul Road.

There is a current bridge crossing at this location that will require upgrading to support road widening and increased truck traffic. The Atlantic Salmon Conservation Centre has completed recent liming programs (2009, 2010) on the West River Sheet Harbour with a goal to maintain a pH of 5.5 at the river mouth to support quality salmon habitat in the river (Atlantic Salmon Conservation Foundation: West River Sheet Harbour Project, lime doser support).

The WRSH watershed is largely undeveloped, though extensive timber harvesting is present. Water within the WRSH is naturally high in tannins and flash prone. There are two, large lake-like pools on the system, the uppermost being River Lake at roughly 0.5 km^2 and the lower, Sheet Harbour lake, at roughly 1.2 km^2. A waterfall forms a natural barrier to fish passage approximately 30 km upstream of the head of tide (9.5 km upstream of Beaver Dam Mines Road, where the proposed Haul Road will cross the WRSH).

The Morgan River

The Morgan River is one major tributary to the Tangier River that originates at the headwater lakes (including First and Second Essen Lakes) and south of the community of Pleasant Valley, near Upper Musquodoboit. The river drains south/southeast across the Haul Road and into River Lake, east of the Haul Road, and then joins the main Tangier River to the southeast of the study area. The Tangier River drains from Tangier Grand Lake to the Atlantic Ocean at Tangier, Nova Scotia.

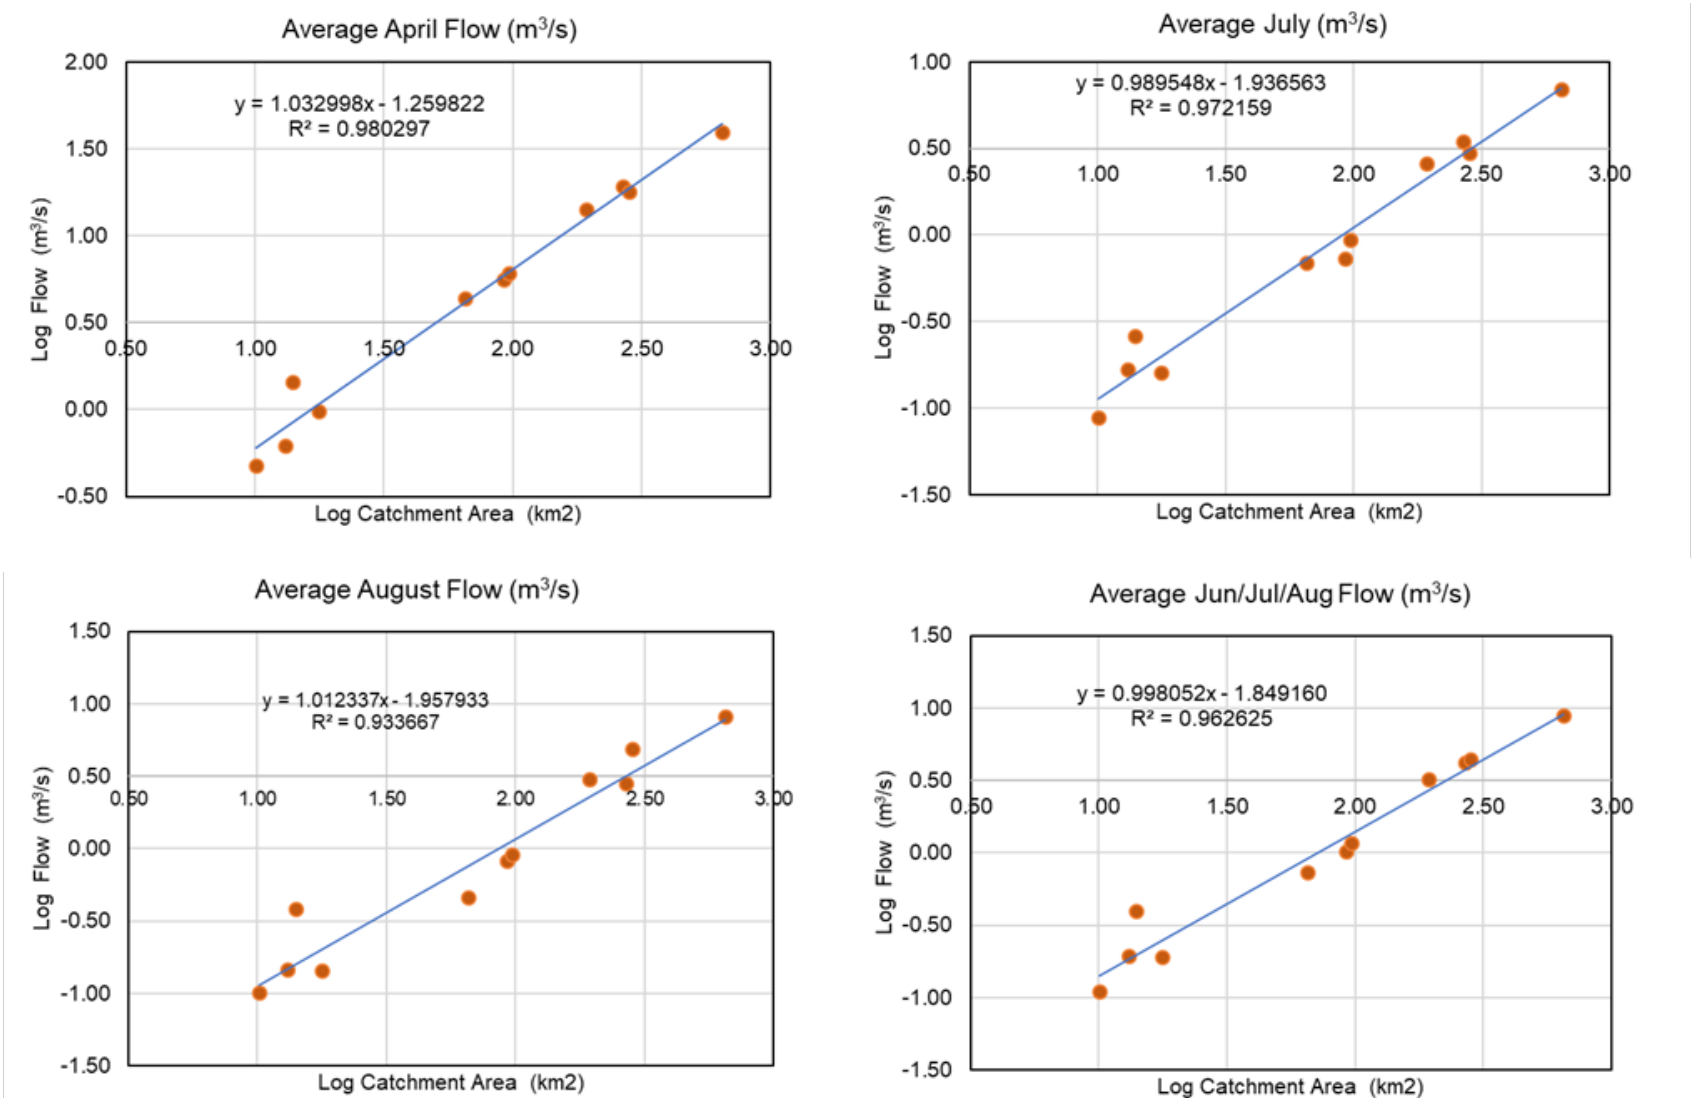
During field assessments in spring and summer 2016, 34 watercourses were mapped and evaluated within the Haul Road corridor. These watercourses straddle seven tertiary watersheds, and many are classified as first order streams, in high positions within the tertiary basins. Others, however, are second and third order streams, positioned lower in the tertiary watersheds and broader secondary watersheds, and offer more substantial aquatic and fish habitat. All watercourses observed within the Haul Road are described in Table 6.7-11 and shown on Figures 6.7-2A to 6.7-2D.

6.7.4.2.2 Touquoy Mine Site

The use of the Touquoy Mine Site for the processing of Beaver Dam ore and deposition of the associated tailings will occur after ore extraction from the Touquoy open pit has ceased. As such, the baseline conditions for the Touquoy Mine Site for the Project operations will be the conditions expected near the end of the Touquoy ore processing operations.

The existing Touquoy open pit is actively dewatered and pumped to the TMF. Based on the groundwater flow model (Appendix F.6), the open pit acts as a groundwater sink resulting in groundwater inflows at an average rate of 450 m^3/d. Water in the TMF is decanted to the effluent treatment plant for treatment. Effluent then drains to the polishing pond through a series of geobags, then

to a constructed wetland where water infiltrates through the berm and finger drains to Scraggy Lake, the receiving water body for the Mine Site. The approved Touquoy Environmental Assessment stated that the exhausted open pit would be allowed to fill naturally with water over a period through the collection of direct precipitation, surface flow and groundwater inflow. No change to this method is planned for the deposition of Beaver Dam tailings, except that the time frame for refilling will be shorter given the decrease in available volume taken by the tailings.



Scraggy Lake is part of the Moose River drainage system. It has an area of 6.4 km^2 (Stantec 2018c) and forms two major basins which are separated by islands and peninsulas. Scraggy Lake is the freshwater make-up supply for the active Touquoy mill process. Water flows into Scraggy Lake from approximately twenty-two inlets consisting of mapped watercourses or adjacent waterbodies. Water flows out of Scraggy Lake over the Fish River Dam and into the Fish River. The Fish River drains Square Lake located north of the existing Touquoy waste rock area to Scraggy Lake. Both lakes are part of the Fish River Watershed which flows west and then south into Lake Charlotte, eventually emptying into the Atlantic Ocean at Ship Harbour.

As per the Reclamation Plan for Touquoy (Stantec 2017b), Moose River is proposed as a second point of final discharge under closure of the exhausted Touquoy open pit. At SW-2, Moose River is a 3rd order watercourse with an approximately 12.5 m bankfull width as measured in the 2017 hydrometric program. The substrate was noted in the 2017 hydrometric monitoring report (Atlantis 2017) as characteristically muddy consisting predominantly of cobbles and small boulders, silt/sand with gravel.

Baseline flow in Moose River and Scraggy Lake at the end of Touquoy operations will be similar to the existing conditions prior to the development of the Touquoy Gold Project. The flow conditions in Moose River are represented by a stage-discharge curve derived based on an annual hydrometric monitoring program at stations SW-2, HM-1, and SW-11. Baseline flow statistics on Moose River were generated based on a regional analysis of thirteen representative ECCC (ECCC 2018) hydrometric stations, prorated to the Moose River catchment area at TQ-SW-2. The record of daily average flow for each station was fitted to the Log Pearson Type III distribution and prorated to the site based on catchment area. The log relationship of catchment area and flow was graphically plotted to establish a relationship between the catchment area and the average spring flow (April), summer flow (June/July/August), and low flow (July).

Surface water in Moose River is based a statistical analysis of regional flow records. As presented on Figure 6.7-6, strong linear trends exist between the average monthly flow rates of the selected monitoring stations and drainage area for April, August, and June to August with a correlation coefficient (R^2) of 0.98, 0.93, and 0.96, respectively. From these regional relationships, the average April and August flows for SW-2 in Moose River (catchment area of 39.03 km^2) are estimated to be 2.42 m^3/s and 0.45 m^3/s, respectively. Results of the analysis indicated that generally the peak and low flow events occur in April and August, respectively.

6.7.5 Water Quality Baseline Conditions

6.7.5.1 Overview

This section describes Surface Water Quality baseline monitoring studies conducted in the Project area. The surface water quality program aimed to provide sufficient data for the Mine Water Management Plan (Appendix P.4), Predictive Water Quality Assessment (Appendix D of Appendix P.4) and Environmental Effects Assessments (Sections 6.6 (Groundwater), 6.7 (Surface Water), 6.8 (Wetlands) and 6.9 (Fish and Fish Habitat)) and an Aquatics Effects Monitoring Program (AEMP), which will be developed as part of the permitting process. The objectives of the baseline program were the following:

- identification of waterbodies that could be directly or indirectly affected by the Project;
- collection of water quality data from potentially affected waterbodies; and
- compilation and presentation of surface water quality data from sampled waterbodies in the PA, LAA, and RAA.

The results of baseline characterization studies informed predictive water balance water quality modelling, performed to support the effects assessment for the Project.

The proposed Project activities encompass three geographically distinct areas:

1. Beaver Dam Mine Site;
2. Haul Road; and
3. Existing Touquoy Mine.

The Killag River, Crusher Lake, Mud Lake, Tent Brook and Cope Brook (Beaver Dam Mine Site area), and Moose River (existing Touquoy Mine) constitute the primary focus of the Project baseline surface water characterization studies, as well as subsequent effects assessment, as these watercourses will receive direct discharge and/or catchment areas have potential to be impacted by Project water management activities.

The Project is in a highly mineralized region and the geology contributes to naturally elevated concentrations of many water quality parameters in the area, including iron, arsenic and aluminum. The occurrence of naturally elevated concentrations in surface waters is commonly observed in regions of planned/proposed mining activities, all over the world (e.g., “Golden Triangle“ of northwestern British Columbia, Canada). In such regions, naturally elevated concentrations of certain water quality parameters generally occur where exposure of rock or other geologic materials to oxygen and water results in natural weathering processes, including chemical oxidation and leaching of solid-phase constituents (e.g., metals), which are then transported to surface waters.

Natural exceedances of water quality guidelines in baseline conditions are not a Project effect and, for these parameters, generic water quality guidelines (WQG) such as Canadian Council of Ministers of the Environment Water Quality Guidelines for the Protection of Freshwater Aquatic life (CCME FAL), do not necessarily apply. That is, WQG generally represent generic criteria that are developed by governments or international organizations to identify the concentrations of parameters in the receiving environment that are not expected to cause an adverse effect on various receptors or uses (e.g., aquatic life, wildlife, livestock/agriculture, drinking water. As WQG are intended to apply universally, they do not necessarily account for site-specific factors including the presence/absence of specific species in the receiving environment, or naturally occurring elevated existing water quality due to mineralization of the watershed.

To support baseline characterization for the Project, and subsequent effects assessment, site-specific water quality objectives (SSWQO) have been developed for arsenic (As). SSWQOs are site-specific criteria developed by proponents as part of ESIAs or permit applications in many jurisdictions, for example Canada, on a site-by-site basis to replace the generic WQG guidelines of the receiving environment; take instead, site-specific water quality. Here, arsenic is naturally elevated in Project area-streams and, in this instance, CCME FAL is not appropriate.

Baseline surface water monitoring was conducted at 19 locations around the Beaver Dam Mine Site and 29 locations along the Haul Road and 13 locations at the Touquoy Mine site, to obtain water quality data. The purpose of this program was to establish a baseline for comparison of surface water quality and quantity before site activities for the Beaver Dam Mine site commence. Key baseline water quality sampling locations are depicted in Figures 6.7-1 though 6.7-3; description of sampling locations is provided in Table 6.7-10 through Table 6.7-12. Baseline samples were collected in 2014, 2015, 2019 and 2020, with sub-samples collected in 2017.

Table 6.7-10: Baseline Surface Water Locations for Beaver Dam Mine Site (2015 to 2020)

Sample ID	Sample Location	Rationale
SW-1	Killag River	Characterize surface water quality downstream and east of mine activities
SW-1A	Killag River	Characterize surface water quality and quantity further downstream and east of mine activities
SW-2A	Killag River upstream of Cameron Flowage	Characterize surface water quantity upstream and north of mine activities
SW-4A	Wetland downstream of Mud Lake (WC27)	Characterize surface water quality and quantity downstream and north of mine activities
SW-5	Historical settling pond outlet (WC13)	Characterize surface water quality exiting the historical settling pond into Cameron Flowage and near mine activities
SW-5A	Killag River downstream of Cameron Flowage	Characterize surface water quality downstream of a proposed site discharge. Located downstream and east of Project activities
SW-6A	Watercourse between Crusher Lake and Mud Lake (WC5)	Characterize surface water quality downstream and west of mine activities
SW-9	West River Sheet Harbour	Characterize surface water quality in a different watershed for reference
SW-10	Upstream of historical settling pond (WC12)	Characterize surface water quality entering the historical settling pond
SW-11	Tent Lake	Characterize surface water quality downstream and south of mine activities
SW-12	Unnamed lake/wetland - headwaters of Paul Brook (WL-29)	Characterize surface water quality downstream and southwest of mine activities
SW-14	Historical settling pond	Characterize surface water quality in the historical settling pond into Cameron Flowage and near mine activities
SW-19	Killag River	Characterize surface water quality and quantity upstream and north of mine activities
SW-26A	Cameron Flowage	Characterize surface water quality in Cameron Flowage downstream of a proposed Site discharge location and north of mine activities
SW-28	Tributary to Tent Brook (WC19)	Characterize surface water quality downstream of proposed Organic Stockpile south of mine activities

Table 6.7-10: Baseline Surface Water Locations for Beaver Dam Mine Site (2015 to 2020) (continued)

Sample ID	Sample Location	Rationale
SW-29	Killag River	Characterize surface water quality upstream of the site northwest of mine activities
SW-30	Killag River	Characterize surface water quality and quantity prior to entering the Killag River, down gradient of the NAG Stockpile northwest of mine activities
SW-31	Tributary of the Cope Brook system (WC23)	Characterize surface water quality and quantity located in a natural watercourse downgradient of the NAG Stockpile, southwest of mine activities
SW-32	Killag River	Characterize surface water quality and quantity downstream of Killag River, located where the NSSA lime doser mixing occurs, southeast of mine activities

Notes: NAG = non-acid generating; NSSA = Nova Scotia Salmon Association.

Table 6.7-11: Baseline Surface Water Locations for Haul Road (2015 to 2020)

Sample ID	Sample Location Description	Rationale
WC2 WC3 WC7 to WC17	Watercourses along Beaver Dam Mines Road portion of the Haul Road	To characterize surface water quality in watercourses upstream of the Beaver Dam Mines Road portion of the Haul Road
SW-41 SW-42	Watercourses along new construction through greenfield environment	To characterize surface water quality in watercourses upstream of the new construction portion of the Haul Road
WC23 to WC 31	Watercourses along Moose River Cross Road portion of Haul Road	To characterize surface water quality in watercourses upstream of Moose River Cross Road portion of the Haul Road
SW-43 to SW-47	Watercourses along the Mooseland Road portion of the Haul Road	To characterize surface water quality in watercourses upstream of the Mooseland Road portion of the Haul Road

Table 6.7-12: Surface Water Monitoring Locations at Touquoy Mine Site

Sample ID	Sample Location	Location Description	Rationale
TQ-SW1	504325E, 4981604N	Moose River - adjacent to site and upstream of Moose River road culvert and open pit	Background
TQ-SW2	504378E, 4980703N	Moose River - downstream of Facility and upstream of Bridge, just below the open pit	Downstream - Near- field

6.7.5.2 Baseline Results

Site-specific baseline results most salient to the effects assessment are presented in this section; results are summarized by Project Area and catchment; surface water monitoring locations are presented in Figures 6.7-1 through 6.7-3. Physical characteristics of water courses are appended as Appendix G.4.

Seventeen water quality sampling events were completed between 2014 to 2015 and 2019 to 2020 with an additional standalone event occurring in 2017. From these 18 samples, eight of these were collected during baseflow conditions, with the remaining 10 being collected during precipitation events. However, during this time frame, only four of the sample locations collected 18 sampling events. Two locations collected 13 events, two locations collected nine events, one location collected seven events, nine locations collected four events and one location only had two sample events. In response to IR2 response NSE-2-90 (AMNS 2021). Table 6.7-13 presents water quality sample date, precipitation amount, and whether it was a baseflow or precipitation event.

Surface water quality results are compared to Nova Scotia Environment Contaminated Sites Regulation 2013 Tier 1 Environmental Quality Standards (EQS) as per a requirement of the Industrial Approval to operate (NSE 2017), in addition to the CCME FAL.

Weather Stations

8203405 MALAY FALLS – 21.17 km

8204193 UPPER STEWIACKE RCS – 31.68 km

8203535 MIDDLE MUSQUODOBOIT – 29.80 km

8200051 HALIFAX STANFIELD INT'L A – 65.57 km (Dec. 1 and 2, 2019 ONLY)

Notes:

(a) Only two monitoring locations were sampled during this event.

(b) 2020 surface water samples were collected over a 2-day period, specific sample date/time not provided. Only one event was counted.

(c) This event was classified as a precipitation event based on recorded continuous flow monitoring from McCallum Environmental Ltd.

6.7.5.2.1 Beaver Dam Mine Site

Generally, water quality at the Beaver Dam Mine Site is characterized as having been affected somewhat from the influence of past mining activities, local industry, road salting, or local residents. Some localized influences from road work (culverts, ditching) or forestry use would have occurred historically (total suspended solids for example), but these would be localized and short-term variations. Portions of the Haul Road where Nova Scotia Department of Transportation and Infrastructure Renewal (NSTIR) had a role in winter maintenance may have experienced salt and/or sanding, but there is little publicly available information on these activities or potential influence on surface waters.

Monitoring results for the Killag River (identified receiving water for the Project) are presented in Table 6.7-14 and a summary of baseline exceedances for all sampling locations is presented in Table 6.7-15. Detailed surface water baseline analytical results and guideline exceedance comparison, specifically for total metals are presented in Appendix G.1, Table G.1-3.

Data in Table 6.7-14 is for station SW1, the most relevant station to characterize the receiving environment. The baseline summary statistics water quality results for all stations are presented in Appendix G.1 (Surface Water Baseline Analytical Results). Metal concentrations were typically below detectable levels. Three of the baseline water quality locations (i.e., SW-5, SW-10 and SW-14A) located either within, or directly downstream of historic tailings, show metal concentrations exceeding guideline concentrations. During Construction, water impacted by historic activities will be treated as described in Section 6.7.9 and Appendix P.4 (Mine Water Management Plan, Appendix F.1 [Water Treatment Assessment - Construction Phase]).

Most nutrients were below or slightly above detectable concentrations, but below available water quality guidelines, indicating little to no influence from agricultural operations in the area. The watersheds have been logged extensively, yet turbidity is low, indicating generally little long-term impacts and a lack of silt in the soils and/or little erosion from logging practices. The existing Haul Roads at the in and around the Beaver Dam Mine Site have been used to haul timber as well; however, measured TSS levels were low, which may be attributable to limited use, existing road conditions and allowable speeds.

Table 6.7-14: Baseline Surface Water Concentrations Collected from Killag River, Station SW1 (Total Metals; µg/L; N = 7-15)[(a)]

Parameter	Min	Max	Mean	75th Percentile	90th Percentile	Number of Non-Detects	CCME (µg/L)	Nova Scotia Tier 1 (µg/L)
Silver	<1.0	<1.0	0.05	0.05	0.05	20/20	0.25	0.1
Aluminum	20	400	206	280	334	0/20	5	5

Thallium	0.05	0.05	0.05	0.05	0.05	20/20	0.8	0.8

Table 6.7-14: Baseline Surface Water Concentrations Collected from Killag River, Station SW1 (continued)

Parameter	Min	Max	Mean	75th Percentile	90th Percentile	Number of Non-Detects	CCME (µg/L)	Nova Scotia Tier 1 (µg/L)
Uranium	0.05	0.05	0.05	0.05	0.05	20/20	15	300
Zinc	0.15	7.8	3.1	2.5	5.3	15/20	7[e]	30
Nitrate	0.025	0.096	0.044	0.061	0.081	11/20	13,000	NV
Nitrite	0.005	0.01	0.0053	0.005	0.005	20/20	60	NV
Ammonia	0.025	0.1	0.029	0.025	0.025	19/20	27,550[f]	NC
pH	2.63	6.48	5.1	5.8	5.9	-	6 to 9.5	6 to 9.5
Hardness (mg/L as $CaCO_3$)	1.6	16	4.9	4.8	8.3	-	NV	NV
TOC (mg/L)	2	20	10	12	18	-	NV	NV

Notes: NV indicates no value provided; reported pH is based on lab analysis, as field measurements were unusually low (range of 2.63 to 6.48); less than indicates that the concentration reported is the analytical detection limit (value was not detected).

[a] Summary statistics were calculated using the maximum value between duplicate samples and half the detection limit value when a chemical was not detected in a sample.

[b] Concentrations are in µg/L unless noted otherwise.

[c] For parameters measured below the detection limit, half of the detection limit was used when calculating this metric.

[d] Selected guideline represents Environment Canada (2017) FEQG for the protection of aquatic life at water hardness of 52 mg/L, which is the lowest hardness level cited for the FWQG equation. Site specific hardness falls below the accepted range of values for the equation.

[e] Selected guideline represents the Long-term CWQG, SSD 5th percentile at water hardness of 50 mg·L-1, pH of 7.5 and DOC of 0.5 mg·L-1. The CCME equation is valid between hardness of 23.4 and 399 mg $CaCO_3$/L, pH of 6.5 to 8.13, and DOC of 0.3 to 22.9 mg/L. The site-specific hardness and pH values in the Killag are slightly below the accepted ranges for these parameters. For screening purposes, the guideline of 7 was used, as site specific DOC will increase the guideline beyond 7 ug/L.

[f] Selected guideline represents the ammonia (total) CCME guideline value at pH 6.0 and temperature of 25ºC, multiplied by 0.8224 (for the conversion of NH_3 to total ammonia-N).

At the Beaver Dam Mine Site, the following baseline observations include:

- **Aluminum and iron:** exceeded the CCME FWAL guidelines and NSEQSs at all sampling locations during most sampling events; however, this is a common feature of surface water in Nova Scotia (Dalhousie Hydrology Group 2018). Further, as described above, the Project is in a highly mineralized region; the geology will contribute to naturally elevated concentrations of many water quality parameters in the area, including aluminum. This is indicated here by elevated aluminum and iron concentrations recorded at both upstream (i.e., background) and downstream monitoring locations (Table 6.7-15). Detailed surface water baseline analytical results and guideline exceedance comparison, specifically for total metals are presented in Appendix G.1, Table G.1-3.
- **Mercury**: exceeded the CCME FWAL guidelines and NSEQSs at all sampling locations during the August 2015 sampling event; there were no mercury exceedances in recent sampling events (2018/2019).
- **Arsenic**: exceeded the CCME FWAL guidelines and NSEQSs at SW-4A, SW-5, SW-6A, SW-10, SW-14, SW-26, and SW-30. Arsenic concentrations were variable at all sampling locations but were generally elevated in the summer months. As described above, the Project is in a highly mineralized region; the geology will contribute to naturally elevated concentrations of many water quality parameters in the area, including arsenic (Section 6.5 Geology, Soils, and Sediment). This is indicated here by elevated arsenic concentrations recorded at both upstream and downstream monitoring locations (Table 6.7-15). Here, sulphide minerals (Section 6.5), such as myrrhotitie and arsenopyrite (an iron arsenic sulfide) are common in the surficial and bedrock geology in the Project area, and is the likely source of natural/background arsenic loadings. Detailed surface water

baseline analytical results and guideline exceedance comparison, specifically for total metals are presented in Appendix G.1, Table G.1-3.

- **Lead**: fluctuates in surface water at most sampling locations and at times slightly exceeded the CCME FWAL guidelines and NSEQSs at SW-1A, SW-5, SW-10, and SW-32.
- **Copper**: fluctuates in surface water at most sampling locations and at times slightly exceeded the CCME FWAL guidelines and NSEQSs at SW-6A and SW-10.
- **Cadmium**: The NSEQS for cadmium, which is lower than the CCME FWAL guideline, was exceeded at most sampling locations during most sampling events. The CCME FWAL guideline for cadmium was only exceeded at five sampling locations, SW-4A, SW-6A, SW-10, SW-11, and SW-12, throughout the sampling program.
- **TSS**: levels were sampled during the 2019 to 2020 monitoring program, and exceeded the CCME FQAL guideline at SW-1A, SW-26A and SW-32.

Opportunities for improvement of the existing surface water conditions through proper sediment and erosion control measures during construction and maintenance and properly designed and installed culverts (Section 6.7.9). Similarly, proposed water treatment technologies (WTP) indicate that for some parameters (e.g., aluminum, arsenic) concentrations will be lower in Project discharges than baseline conditions of the receiving environment. In these instances, there is potential to reduce in-stream concentrations for these parameters, relative to existing conditions.

Table 6.7-15: Summary of Baseline Surface Water Quality for Beaver Dam Mine Site, All Stations

Sample ID	Sample Location	Parameters Exceeding CCME FWAL	Parameters Exceeding NS Tier 1 EQS for Freshwater
SW-1	Killag River	pH, DO, Aluminum, Iron, Mercury	pH. Aluminum, Iron, Mercury
SW-1A	Killag River	pH, DO, TSS, Aluminum, Iron, Lead	Aluminum, Iron, Lead
SW-2A	Killag River upstream of Cameron Flowage	pH, DO, Aluminum, Iron, Mercury	Aluminum, Iron, Mercury
SW-4A	Wetland downstream of Mud Lake (WC27)	pH, DO, Aluminum, Arsenic, Cadmium, Iron, Mercury	Aluminum, Arsenic, Cadmium, Iron, Mercury
SW-5	Historical settling pond outlet (WC13)	pH, DO, Aluminum, Arsenic, Iron, Lead, Mercury	Aluminum, Arsenic, Iron, Lead, Mercury
SW-5A	Killag River	pH, DO, Aluminum, Iron	Aluminum, Iron
SW-6A	Watercourse between Crusher Lake and Mud Lake (WC5)	pH, DO, Aluminum, Arsenic, Cadmium, Copper, Iron, Mercury	Aluminum, Arsenic, Cadmium, Copper, Iron, Mercury
SW-9	West River Sheet Harbour	pH, DO, Aluminum, Iron, Mercury	Aluminum, Iron, Mercury
SW-10	Upstream of historical settling pond (WC12)	pH, DO, Aluminum, Arsenic, Cadmium, Copper, Iron, Lead, Mercury	Aluminum, Arsenic, Cadmium, Copper, Iron, Lead, Mercury
SW-11	Tent Lake	pH, DO, Aluminum, Iron	Aluminum, Iron
SW-12	Unnamed lake/wetland - headwaters of Paul Brook	pH, DO, Turbidity, Aluminum, Iron	Aluminum, Iron
SW-14	Historical settling pond	pH, DO, Aluminum, Arsenic, Iron	Aluminum, Arsenic, Iron
SW-19	Killag River	pH, DO, Aluminum, Iron	Aluminum, Iron
SW-26A	Cameron Flowage	pH, DO, TSS, Turbidity, Aluminum, Arsenic, Iron	Aluminum, Arsenic, Iron
SW-28	Tributary to Tent Brook (WC19)	pH, DO, Aluminum, Iron	Aluminum, Iron
SW-29	Killag River	pH, DO, Aluminum, Iron	Aluminum, Iron
SW-30	Killag River	pH, DO, Aluminum, Arsenic, Iron	Aluminum, Arsenic, Iron
SW-31	Tributary to Cope Brook (WC23)	pH, DO, Aluminum, Iron	Aluminum, Iron
SW-32	Killag River	pH, DO, TSS, Aluminum, Iron, Lead	Aluminum, Iron, Lead

Notes: CCME FWAL = Canadian Council of Ministers of the Environment Freshwater Aquatic Life; NSEQS = Nova Scotia Environmental Quality Standards; DO = dissolved oxygen; TSS = total suspended solids.

6.7.5.2.2 Haul Road

Monitoring results for the proposed haul road area are presented in Table 6.7-16; a summary of baseline exceedances are presented in Table 6.7-16. Similar to as described for the Beaver Dam Mine Site Area, most nutrients were below or slightly above detectable concentrations, but below available water quality guidelines, indicating little to no influence from agricultural operations in the area. The watersheds have been logged extensively, yet turbidity is low, indicating generally little long-term impacts and a lack of silt in the soils and/or little erosion from logging practices. Detailed haul route surface water baseline analytical results and guideline exceedance comparison, specifically Appendix G.1, Table G.1-5.

Metal concentrations were typically below detectable levels and/or available water quality guidelines. At the Haul Road the following baseline. Baseline observations include:

- **Aluminum and iron:** aluminum exceeded the CCME FWAL guideline and NSEQS at all sampling locations, and iron exceeded both guidelines at all but three sampling locations.
- **Arsenic, copper, and lead:** concentrations were identified to exceed the CCME FWAL guidelines and NSEQSs at several sampling locations (SW-43, SW-45, and/or SW-47).
- **Cadmium**: The NSEQS for cadmium, which is lower than the CCME FWAL guideline, was exceeded at most sampling locations during most sampling events. The CCME FWAL guideline for cadmium was not exceeded.

Note, there is also an opportunity for improvement of the existing surface water conditions through proper sediment and erosion control measures during construction and operation including maintenance and properly designed installed culverts (Section 6.7.9 and Appendix C [draft Erosion and Sediment Control Plan] of Appendix P.4 [Mine Water Management Plan]).

Table 6.7-16: Summary of Baseline Surface Water Quality along the Haul Road

Sample ID	Sample Location Description	Parameters Exceeding CCME FWAL	Parameters Exceeding NSEQS for Freshwater
WC2, WC7 to WC17	Watercourses along Beaver Dam Mines Road portion of the Haul Road	Aluminum, iron, pH	Aluminum, cadmium, iron
WC3	Watercourses along Beaver Dam Mines Road portion of the Haul Road	Aluminum, iron, pH	Aluminum, iron
SW-41	Watercourse along new construction through greenfield environment	Aluminum, pH	Aluminum, cadmium, iron
SW-42	Watercourse along new construction through greenfield environment	Aluminum, iron, pH	Aluminum, cadmium, iron
WC23 to WC28	Watercourses along the Moose River Cross Road portion of Haul Road	Aluminum, iron, pH	Aluminum, cadmium, iron
WC29	Watercourse along the Moose River Cross Road portion of Haul Road	Aluminum, pH	Aluminum, cadmium
WC30, WC31	Watercourses along the Moose River Cross Road portion of Haul Road	Aluminum, iron, pH	Aluminum, cadmium, iron
SW-43	Watercourse along the Mooseland Road portion of the Haul Road	Aluminum, copper, iron, lead, pH	Aluminum, cadmium, copper, iron, lead
SW-44	Watercourse along the Mooseland Road portion of the Haul Road	Aluminum, iron, pH	Aluminum, cadmium, iron
SW-45	Watercourse along the Mooseland Road portion of the Haul Road	Aluminum, arsenic, iron, pH	Aluminum, arsenic, cadmium, iron

Table 6.7-16: Summary of Baseline Surface Water Quality along the Haul Road (continued)

Sample ID	Sample Location Description	Parameters Exceeding CCME FWAL	Parameters Exceeding NSEQS for Freshwater
SW-46	Watercourse along the Mooseland Road portion of the Haul Road	Aluminum, iron, pH	Aluminum, cadmium, iron
SW-47	Watercourse along the Mooseland Road portion of the Haul Road	Aluminum, iron, lead, pH	Aluminum, cadmium, iron, lead

Notes: CCME FWAL = Canadian Council of Ministers of the Environment Freshwater Aquatic Life; MDMER = Metals and Diamonds Effluent Regulations; NSEQS = Nova Scotia Environmental Quality Standards.

6.7.5.2.3 Touquoy Mine Site

The Touquoy Mine Site is currently in operation and will be used for the processing of Beaver Dam Mine ore and deposition of the associated tailings. As such, the baseline conditions for the Touquoy Mine Site for the Project operations will be the conditions expected near the end of the Touquoy ore processing operations. However, the surface water quality in Moose River is not anticipated to be adversely affected by the operation of the Touquoy Mine Site. Therefore, the baseline conditions in Moose River for the Project at the Touquoy Mine Site are anticipated to be similar to the existing conditions.

As required under the Industrial Approval for operation of the Touquoy Mine Site, surface water quality monitoring is conducted at thirteen surface water monitoring locations applicable to the Beaver Dam Mine ore processing and tailings deposition (exhausted Touquoy pit), as shown in Figure 6.7-3. Existing surface water quality monitoring locations at the Touquoy Mine Site are shown in Figure 6.7-3 and summarized in Table 6.7-12. Surface water monitoring locations TQ-SW-1, TQ-SW-11, and TQ-SW-2 are located on Moose River. TQ-SW-1 and TQ-SW-11 are identified as “background” as they are located upstream from the Touquoy Mine Site and are not expected to be affected by the Touquoy Gold Project or the Project. Surface water quality monitoring station TQ SW-2 is located downstream of the project on Moose River and is used to identify potential impacts from the Project by comparison to the upstream monitoring stations. Surface water quality results both in 2016 and 2017 are used to represent the baseline conditions at these monitoring locations.

A baseline environmental effects monitoring program was conducted in 2017 and 2018 to establish existing conditions in what was designed to be the future aquatic receiving environment for effluent in Scraggy Lake. The program was designed to meet the MDMER. Near surface and near bottom surface water quality samples were collected at each location on Scraggy Lake (SGL-001, -002, -003, -004 and -008) for laboratory analysis which included general chemistry, dissolved metals, total metals, strong acid dissociated cyanide and chlorophyll a. Results are provided in the Baseline Environmental Effects Monitoring Program (Stantec 2018c).

Based on a review of the 2017 baseline surface water quality results (Stantec 2018a), surface water at the monitoring stations upstream and downstream of the Touquoy Mine Site had elevated baseline concentrations of arsenic, aluminum, iron, cadmium, copper, lead, zinc, and manganese that exceeded Nova Scotia Environment Tier 1 EQS. Table 6.7-17 summarizes parameter exceedances by monitoring locations. In addition, cobalt, manganese, silver and mercury exceeded the Canadian Council of Ministers of the Environment (CCME 2018) guideline for the protection of freshwater aquatic life. These exceedances are considered to be naturally occurring, or the result of historical anthropogenic (i.e., non- Project related) activities, varying seasonally and representing baseline conditions at the Touquoy Mine Site. Site-specific standards have been developed for both the Beaver Dam Mine and the Touquoy Mine Site to establish thresholds for surface water quality that include the elevated concentrations of parameters under baseline conditions (Appendix G.2 Beaver Dam Mine: Killag River and Moose River Water Quality Predictions and Aquatic Effects Assessment – Reassessment of Killag River based on February 2021 Update [GHD modelling Provided

February 12, 2021]; Reassessment of Moose River based on March 2021 Update [Stantec modelling of March 11, 2021]). Surface water quality in Watercourse #4 and Scraggy Lake are predicted to have different water quality at the end of Touquoy operations (Appendix G.5a [Assessment of Water Quality Downstream of Railings Management Facility, Touquoy Gold Project]). These predictions are used as the baseline conditions for the Project at the Touquoy Mine Site in these watercourses. Surface water locations TQ-SW-12 located at the outlet of Square Lake, and TQ-SW-23 located on TQ-WC4 are identified as "background" as they are located upstream from the Touquoy Mine Site and are not expected to be affected by the Touquoy Gold Project or the Project. Water quality predictions are made at downstream locations TQ-SW-3 on TQ-WC4, and TQ-SW-13 on Scraggy Lake (Figure 6.7-3 and Table 6.7-12).

As reported in the 2017 groundwater and surface water monitoring report (Stantec 2018b), spatial trends were not apparent between conductivity and the observed Tier 1 EQS exceedances, or between background and downstream monitoring locations to indicate an effect of a specific mine facility (i.e., TMF, waste rock pile, open pit) on surface water resources during construction. Arsenic was noted to consistently exceed the Tier 1 EQS at TQ-SW-2 downstream of the open pit in both 2016 and 2017. As no trends in water quantity or quality were identified between baseline and operation, these elevated arsenic concentrations are not attributed to operation and may be from historical tailing piles and/or the Touquoy ore body itself. A remedial action plan is currently underway by AMNS that involves the delineation, removal, and management of these historical tailings piles around the open pit area (Appendix E.9 [draft Historic Tailings and Waste Rock Management Plan]) .

Table 6.7-17: Summary of Baseline 2016 and 2017 Surface Water Quality for Touquoy Mine Site Parameter Exceedance

Water Quality Parameter	TQ-SW-1	TQ-SW-2	TQ-SW-3	TQ-SW-11	TQ-SW-12	TQ-SW-13	TQ-SW-15	TQ-SW-18	TQ-SW-19	TQ-SW-20	TQ-SW-21	TQ-SW-23	No. of Stations with Parameter Exceedance
Exceedance of Tier 1 EQS

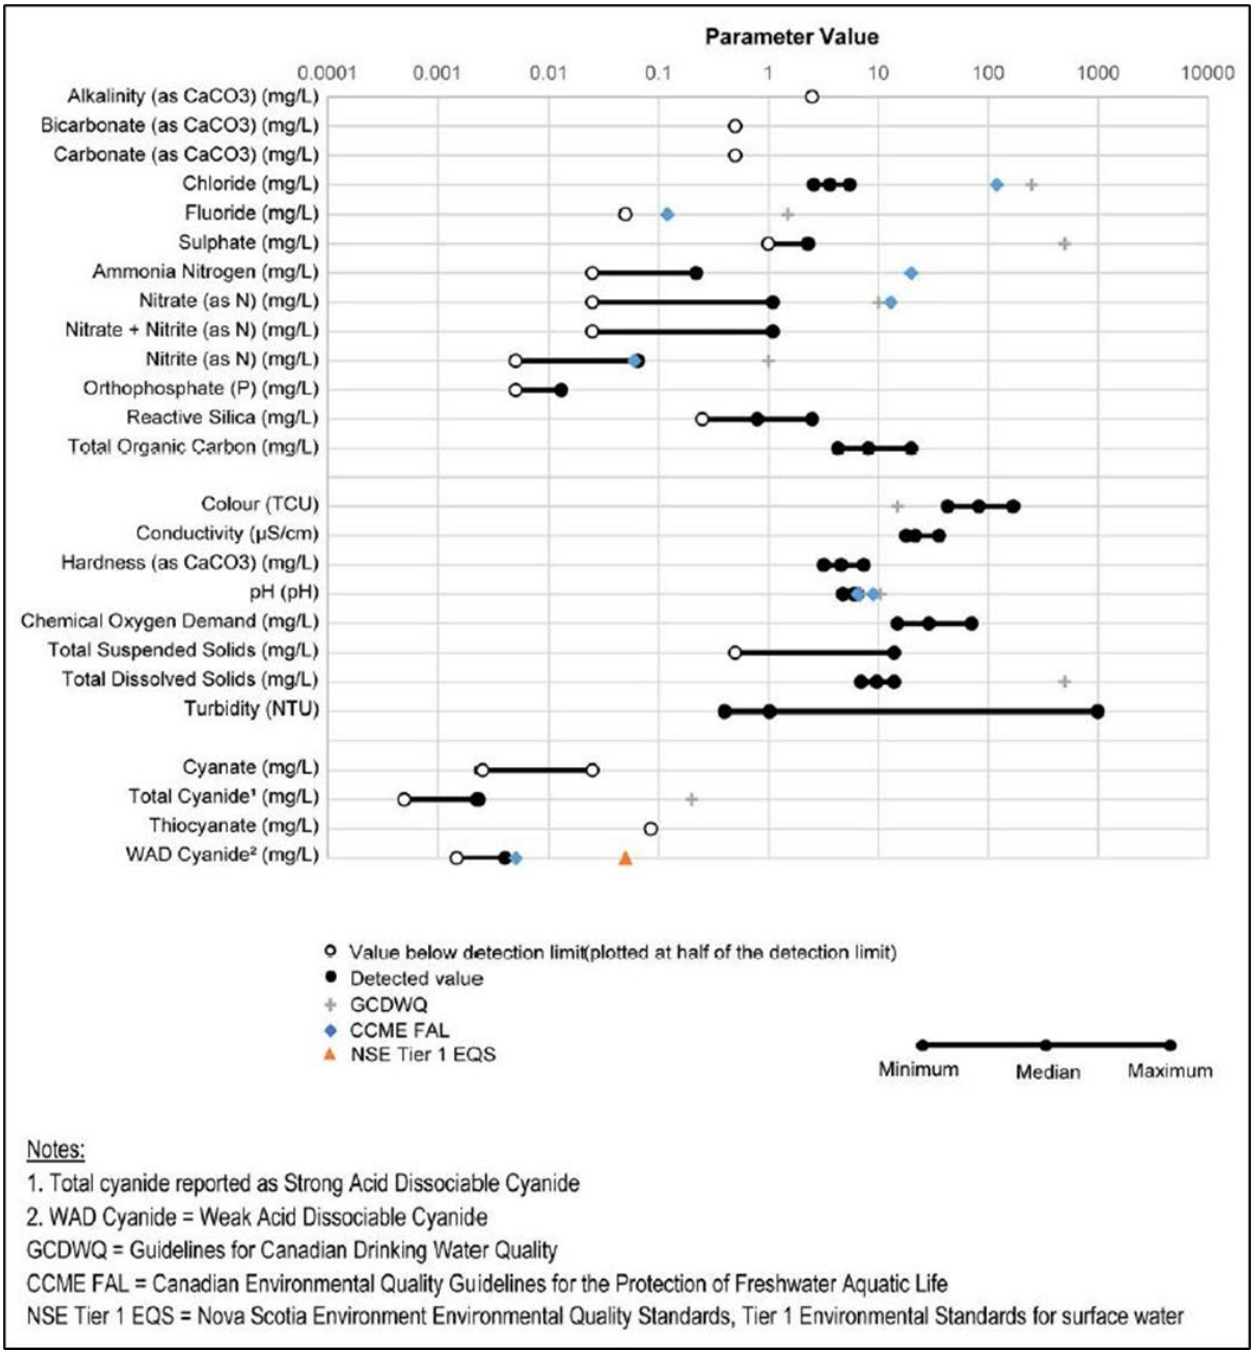
Source: Stantec 2018a.

Note: Surface water quality parameter is listed if there is at least 1 exceedance in 2016/2017 monitoring. MDMER = Metal and Dimond Mining Effluent Regulations; Tier 1 EQS = Nova Scotia Tier 1 (Contaminated Sites) Environmental Quality Standards for Surface Water (Fresh Water).

[(a)] Indicates exceedance of CCME guideline.



Figures 6.7-7 to 6.7-10 present box plots that summarize the surface water quality for both the background and downstream locations at the Touquoy Mine Site. These represent the baseline conditions for the use of the Touquoy Mine Site for the processing of the ore for the Beaver Dam Mine Project. The minimum, mean, and maximum concentration or value for the parameters are presented on a logarithmic scale. Values below the detection limits are flagged in the plots, as are the relevant guidelines or discharge limits. For example, in Figure 6.7-9, all values for total bismuth in the background data set (i.e., TQ-SW-1, TQ-SW-11 TQ-SW-12, and TQ-SW-23) are below the detection limit. In Figure 6.7-9 for the background data set, the minimum cadmium value is below the detection limit, the mean and maximum value is above Tier 1 EQS and CCME FWAL guideline.

Source: Stantec (2017a).

Overall, the water quality is similar between background and downstream surface water quality presented in the 2017 monitoring report (Stantec 2018b). All applicable parameters meet MDMER discharge limits, with the exception of pH which is slightly acidic in background water quality conditions. Organic sampling parameters related to hydrocarbons as well as cyanide related parameters were all below the detection limits for all 2016/2017 sampling locations, thus no exceedances are reported under the Tier 1 EQS for freshwater. There were no detections of radium 226 at the locations sampled (i.e., TQ-SW-2, TQ-SW-21).

Conductivity is generally stable at each location by month in 2016 and 2017 and is generally low (<43 microSiemens per centimeter [µS/cm]) at most sampling locations. The pH in surface water was noted to be slightly acidic and generally at or below 6.0 at both background and downstream locations with the exception of TQ-SW-3 where more neutral values (i.e., pH generally between 6 and 7) were observed. Total suspended solids (TSS) were generally less than 10 mg/L. Turbidity was generally low at less than 5.5 NTU at background locations but were slightly elevated in downstream locations at the site. Ammonia nitrogen concentrations were typically not detected or were less than 0.1 mg/L. There were no Tier 1 EQS surface water guideline exceedances noted for antimony, barium, beryllium, boron, molybdenum, mercury, nickel, selenium, strontium, thallium, uranium, benzene, toluene, ethylbenzene, total xylenes and total cyanide (i.e., strong acid dissociated cyanide). The surface water sampling locations are presented in Figures 6.7-1 through 6.7-3. Complete water quality results are presented in the 2017 Annual Report - Surface Water & Groundwater Monitoring (Stantec 2018b).

6.7.6 Consideration of Engagement Results

Key issues raised during public consultation and Mi'kmaq engagement relating to surface water quality and quantity include potential effect from acid rock drainage, suspended solids and leached metals from the Beaver Dam Mine Site activities. Potential effects on the quantity of surface water near the Beaver Dam pit were noted, specifically potential effects on water levels in Cameron Flowage. Concerns were identified related to effects on surface waters along the Haul Road, specifically during construction activities, including River Lake, a segment of the West River Sheet Harbour, near the Beaver Lake Indian Reserve (IR) 17. At the Touquoy Mine Site, questions arose about potential effects on Moose River from placement of tailings in the mined-out pit.

Questions were identified on potential effects on receiving waters in the event of unplanned releases due to accidents and malfunctions, specifically during operations. Potential effects on traditional uses of land and resources by the Mi'kmaq were noted, including importance of clean water to support the natural environment, including fish, flora, fauna, and drinking water.

The results of the public consultation and Mi'kmaq engagement have been considered in the environmental effects assessment, including AMNS's commitments to mitigation and monitoring measures and proposed compliance and effects monitoring programs, as well as AMNS's broader commitment to ongoing public consultation and Mi'kmaq engagement. Specific to evaluating the effect on surface water quality and quantity, these commitments are described within the following environmental effects assessment.

6.7.7 Effects Assessment Methodology

The Project is part of the Moose River Consolidated (MRC) Project, which includes the existing and fully permitted Touquoy Gold Project, located in Moose River Gold Mines, Nova Scotia. The Project will operate as a satellite surface mine to the MRC Project, and the ore that is mined from the Project Site will be processed at the existing Touquoy plant.

This section describes the boundaries of the effects assessment including the quantitative modelling methods for surface water quality and quantity, and the thresholds for determination of significance for both surface water quality potential effects and surface water quantity potential effects of the Project.

6.7.7.1 Boundaries

6.7.7.1.1 Spatial Boundaries

Assessment boundaries define the maximum limit within which the effects assessment and supporting studies (e.g., predictive models) are conducted. Boundaries encompass where and when the Project is expected to interact with identified VCs as well as constraints that may be placed on the assessment of those interactions due to political, social, and economic realities (administrative boundaries), and limitations in predicting or measuring changes (technical boundaries). The definition of these assessment boundaries is an integral part of the assessment process of surface water quality, and encompasses possible direct, indirect, and induced Project effects, as well as the trends in processes that may be relevant.

The spatial boundaries used for the assessment of Project effects to surface water quality and quantity are the Project Area (PA), the Local Assessment Area (LAA), and the Regional Assessment Area (RAA). These are defined below and shown in Figure 6.7-11:

- The Project Area (PA) (Figure 6.7-11) consists of the three project components; Beaver Dam Mine Site, Touquoy Mine Site, and the Haul Road, which extends from Marinette to Moose River Gold Mines, Halifax County, Nova Scotia. The Beaver Dam Mine Site is located at the eastern end of the Beaver Dam Mines Road. The Haul Road spans from the Beaver Dam Mine Site to Moose River Gold Mines, where the Touquoy Mine Site [processing and exhausted pit (to be used to dispose Beaver Dam tailings) is located. The PA has changed as a result of the expansion of the Beaver Dam Mine Site to accommodate micro-siting of mine infrastructure and ongoing modifications to the Haul Road design, as described in Project Description (Section 2). These changes have been captured under the existing and additional desktop and field evaluations.
- The Local Assessment Area (LAA) includes the Project Area and further encompasses watersheds that could be potentially directly affected by mine construction and operation phases. Water quality will be assessed at release points (e.g., end-of-pipe) and receiving environment locations in the LAA. Figure 6.7-12 presents the location of mine discharge relative to proposed Project infrastructure and water assessment points.

GIS File: Q:\GIS\PROJECTS\88000s\88664\Layouts\011\088664-27(011)GIS-WA004.mxd

The LAA boundaries were defined considering the maximum expected extent of direct and indirect impacts to the aquatic environment as well as the location of Project activities across all PA components. The LAA surrounding the Touquoy Mine Site incorporates the Moose River to the west, and only includes the portion of the Square Lake watershed which interacts with the PA. No Project related aquatic effects are expected in the headwater portions of these watersheds. The lakes and watercourses that are included as part of the baseline programs and/or predictions of effects are located within the LAA boundary. The list below identifies tertiary watershed boundaries intersected by each component of the Project. The LAA is defined as the collection of all tertiary watersheds listed below:

- Beaver Dam Mine Site:
  - Portion of Killag River (1EM-2-D);
  - Tent Brook (1EM-2-F);
  - Paul Brook (1EM-2-H); and
  - Cope Brook (1EM-2-J).
- Haul Road:
  - Tent Brook (1EM-2-F);
  - Keef Brook (1EM-2-G);
  - Jack Lowe Brook (1EM-2-N);
  - Little River (1EM-2-P);
  - Portion of Sandy Pond (1EL-2-C); and
  - Portion of Morgan River (1EL-2-H).
- Touquoy Mine Site:
  - Portion of Moose River (1EL-P-5);
  - Portion of Square Lake (1EL-5-M); and
  - Portion of Scraggy Lake (1EL-5-N).

The RAA encompasses the three secondary watersheds that the PA is located within. These watersheds are:

- West River Sheet Harbour secondary watershed (1EM-2, incorporating the Beaver Dam Mine Site and Haul Road);
- Tangier River secondary watershed (1EL-2, incorporating the Haul Road); and
- Fish River-Lake Charlotte secondary watershed (1EL-5, which incorporates the Touquoy Mine Site).

The RAA is broader than expected Project impacts and considers other project boundaries as per the cumulative effects assessment methodology. As the Project has the potential to cause direct and indirect effects to fish and fish habitat outside of the PA, the LAA is the appropriate boundary for evaluation of this VC.

6.7.7.1.2 Temporal Boundaries

Temporal boundaries reflect those periods during which planned Project activities are reasonably expected to potentially affect a VC. The temporal boundaries used for the assessment of effects to Surface Water are the Construction phase, Operational phase, and Active Closure and Post-closure

To support the effects assessment for the operations phase, predictive models were developed for the end of operations (EOM) model (i.e., max build out) as well as Post-closure. EOM represents the Project stage with the highest potential for significant effects to the receiving environment and thus the prediction and assessment of potential effects at EOM, and applying to the whole of operations, is a conservative approach.

6.7.7.1.3 Technical Boundaries

The surface water effects assessment was developed to incorporate quantitative data from baseline reports as well as predictive water modelling including sensitivity analyses; the modelling domains of predictive models represent a technical boundary for the effects assessment.

Effects on indicators of Surface Water Quantity (e.g., base flow, L/s) and Surface Water Quality (total and dissolved metals, anions, and nutrients; mg/L) were either assessed quantitatively by predictive water modelling or qualitatively based on geochemical characterization studies and professional judgement and experience (e.g., pH, TSS). The goals were to remove as much subjectivity as possible from the assessment and to increase certainty in the predictions of alteration of the Surface Water VC, residual effects, and the determination of significance to ensure a robust, transparent, and defensible approach to the effects assessment.

The effects assessment for Surface Water Quality VC further considers several different pathways through which surface water quality indicators can be affected by Project activities and components, many of which overlap in terms of definition and scope. These include:

- discharges, including direct discharge to the receiving environment and management of contact water;
- groundwater seepage from Project components to receiving environment;
- metal leaching and acid rock drainage (ML/ARD) generated from excavating or exposing material with the potential for ML/ARD, or in runoff from stockpiles;
- erosion and sedimentation during site clearing, construction, maintenance activities, and reclamation efforts; and
- dust deposition along the Haul Road route (CEAA-2-37 [AMNS 2021]).

6.7.7.1.4 Administrative Boundaries

The Project is subject to the MDMER criteria at the point(s) of discharge. Three discharge points are planned that are expected to be subject to MDMER:

- **Construction:** discharge from the north settling pond following treatment of historic tailings may be subject to MDMER and will be confirmed during the permitting phase.
- **Operations:** discharge from the north, east, and south settling ponds to the Cameron Flowage (Killag River) and WC19 of the Tent Brook system at the Beaver Dam Mine Site;
- **Closure:** discharge from the pit to the Cameron Flowage (Killag River) at the Beaver Dam Mine Site; and
- **Closure:** discharge from the pit to the Moose River at the existing Touquoy Mine Site.

CCME FWAL guidelines, NSE Tier 1 criteria and established background concentrations for each river will be applied in the receiving environment to support the effects assessment are presented in Table 6.7-18. A site-specific water quality objective was developed for arsenic in the receiving environment, following CCME (2007) protocols, using a species sensitivity distribution (SSD) approach. The resultant Site-Specific Water Quality Objective (SSWQO) can be found in Appendix G.2. This the site-specific criteria established by Intrinsik and included in Appendix G.2 will be requested arsenic in both the Killag and Moose Rivers, which is anticipated to be consistent with current site-specific criteria (CRA 2007b).

Table 6.7-18: Selected Receiving Environment Guidelines Informing the Effects Assessment to Surface Water Quality Valued Component

Chemical	CCME (µg/L)	Nova Scotia Tier 1 (µg/L)	Selected Guideline	Regulation
Silver	0.25	0.25	0.25	Nova Scotia Tier 1
Aluminium	5/100[(a)]	5	5	Nova Scotia Tier 1
Antimony	NV	20	20	Nova Scotia Tier 1
Arsenic	5	5	5	Nova Scotia Tier 1
Cadmium	0.04/0.09[(b)]	0.04	0.04	Nova Scotia Tier 1
Chromium	8.9[(c)]	1[(d)]	8.9	CCME
Cobalt	NV	10	10	Nova Scotia Tier 1
Copper	2/4[(e)]	2	2	Nova Scotia Tier 1
Iron	300	300	300	Nova Scotia Tier 1
Mercury	0.026	0.026	0.026	Nova Scotia Tier 1
Manganese	NV	820	820	Nova Scotia Tier 1
Molybdenum	73	73	73	Nova Scotia Tier 1

Thallium	0.8	0.8	0.8	Nova Scotia Tier 1
Uranium	15	300	15	CCME
Zinc	7	30	7	CCME
WAD Cyanide	5	5	5	Nova Scotia Tier 1
Total Cyanide (based on Strong Acid Dissociated)	NG	NG	5[(h)]	CCME
Nitrite (as N)	NG	60	60	CCME
Total Ammonia - N	NG	Varies with pH and temperature	Varies with pH and temperature	CCME

Notes: NG = No guideline available from that agency

(a) The CCME water quality guideline for aluminum of 5 µg/L is for pH<6.5, and 100 µg/L is for pH 26.5. The background pH of the Killag River is 4.59 and 6; and mean pH of Moose River is 6.05; therefore, the guideline of 5 µg/L is appropriate for use at both sites.

(b) The CCME water quality guideline for cadmium of 0.04 µg/L is for water hardness >0 to <17 mg/L, and 0.09 µg/L is for water of 50 mg/L hardness. The background water hardness of the Killag River is between 1.6 and 5.5 mg/L $CaCO_3$; and the mean hardness of Moose River is 5.0 mg/L; therefore, the guideline of 0.04 µg/L is appropriate for use at both sites.

(c) Based on Cr6+; this value was selected to be conservative and that is assumed that Cr will exist in the oxidized state under oxygenated conditions characteristic of fast-moving streams/rivers as well as epilimnetic environments.

(e) The CCME water quality guideline for copper of 2 µg/L is for water hardness of 0 to <82 mg/L or when the hardness is unknown.

When the hardness is >82 to :5180 mg/L, the following equation is used to calculate the guideline: CWQG (µg/L) = 0.2 * e{0.8545[ln(hardness)]-1.465}, and at a hardness >180 mg/L, the guideline is 4 µg/L. The background water hardness of the Killag River is between 1.6 and 5.5 mg/L $CaCO_3$ and the mean hardness of Moose River is 5.0 mg/L; therefore, the guideline of 2 µg/L is appropriate for use at both sites.

(f) The CCME water quality guideline for lead of 1 µg/L is for water hardness of 0 to :560 mg/L or when the hardness is unknown.

When the hardness is >60 to :5180 mg/L, the following equation is used to calculate the guideline: CWQG (µg/L) = e{1.273[ln(hardness)]-4.705}, and at a hardness >180 mg/L, the guideline is 7 µg/L. The background water hardness of the Killag River is between 1.6 and 5.5 mg/L $CaCO_3$ and the mean hardness in Moose River is 5.0 mg/L; therefore, the guideline of 1 µg/L is appropriate for use at both sites.

(g) No CCME or NS Tier 1 guideline is available; therefore, a guideline from BC Moe was used (https://www2.gov.bc.ca/assets/gov/environment/air-land-water/water/waterquality/wqgs-wqos/approved- wqgs/wqg_summary_aquaticlife_wildlife_agri.pdf).

(h) This guideline is for free CN, and hence does not apply to Total CN. It is used to provide perspective only in the effects assessment.

6.7.7.2 Thresholds for Determination of Significance

6.7.7.2.1 Surface Water Quantity

Residual effects of the Project on Surface Water Quantity VC identified are characterized using standard criteria, including magnitude, geographical extent, duration, frequency, reversibility, and context of the effect (Table 6.7-19). The residual effects assessment concludes with a determination of Significance. The screening of project effects, mitigation measures, and the subsequent water balance model results are assessed in aggregate to determine whether the residual impacts are "Not Significant" or "Significant" according to the following definitions:

- **Significant Residual Effect:** residual effects have high magnitude, be of potential regional geographic extent and of medium to long term duration, occur at any frequency and only be partially reversible to irreversible.
- **Not Significant Residual Effect:** to Surface Water Quality VC is defined as: negligible to moderate magnitude, are restricted to the PA or near-field receiving environment, are of sporadic or short-term duration, occur at any frequency and are reversible to partially reversible.

6.7.7.2.2 Surface Water Quality

Residual effects of the Project on Surface Water Quality VC identified are characterized using standard criteria, including magnitude, geographical extent, duration, frequency, reversibility, and context of the effect (Table 6.7-20). The residual effects assessment concludes with a determination of Significance. The screening of project effects, mitigation measures, and the subsequent water quality model results are assessed in aggregate to determine whether the residual impacts are "Not Significant" or "Significant" according to the following definitions:

- **Significant Residual Effect:** residual effects have high magnitude, be of potential regional geographic extent and of medium to long term duration, occur at any frequency and only be partially reversible to irreversible.
- **Not Significant Residual Effect:** to Surface Water Quality VC is defined as: negligible to moderate magnitude, are restricted to the PA or near-field receiving environment, are of sporadic or short-term duration, occur at any frequency and are reversible to partially reversible.

Table 6.7-19: Definitions of Characterization Criteria for Residual Effects on Surface Water Quantity

Criteria	Description of Ratings
Magnitude	• **Negligible:** change to surface water flow or catchment area indicator is less than 1% of background conditions, (i.e., no measurable change of state of indicator from background conditions) • **Low:** change to surface water flow or catchment area is detectable, but less than 10% over baseline levels • **Medium:** change to surface water flow or catchment area is detectable, but less than 15% over baseline levels • **High:** change to surface water flow or catchment area is detectable, and differ substantially from baseline conditions (greater than 15%)
Geographical Extent	• **Discrete:** effect is limited to receiving environments in the immediate footprint or Project Area (PA) • **Local:** effect is limited to the near-filed Local Assessment Area • **Potential** Regional: effect persists to the far-field Local Assessment Area
Timing	• Timing represents seasonal occurrence of the effect (e.g., spring vs winter; high flows vs. low flows) and represents effect criteria for designated water users (aquatic resources, human health). The characterization of effect of changes to surface water on designated water resources is assessed in their respective; for surface water quality timing is considered redundant to duration and frequency criteria and is not further considered here

Table 6.7-19: Definitions of Characterization Criteria for Residual Effects on Surface Water Quantity (continued)

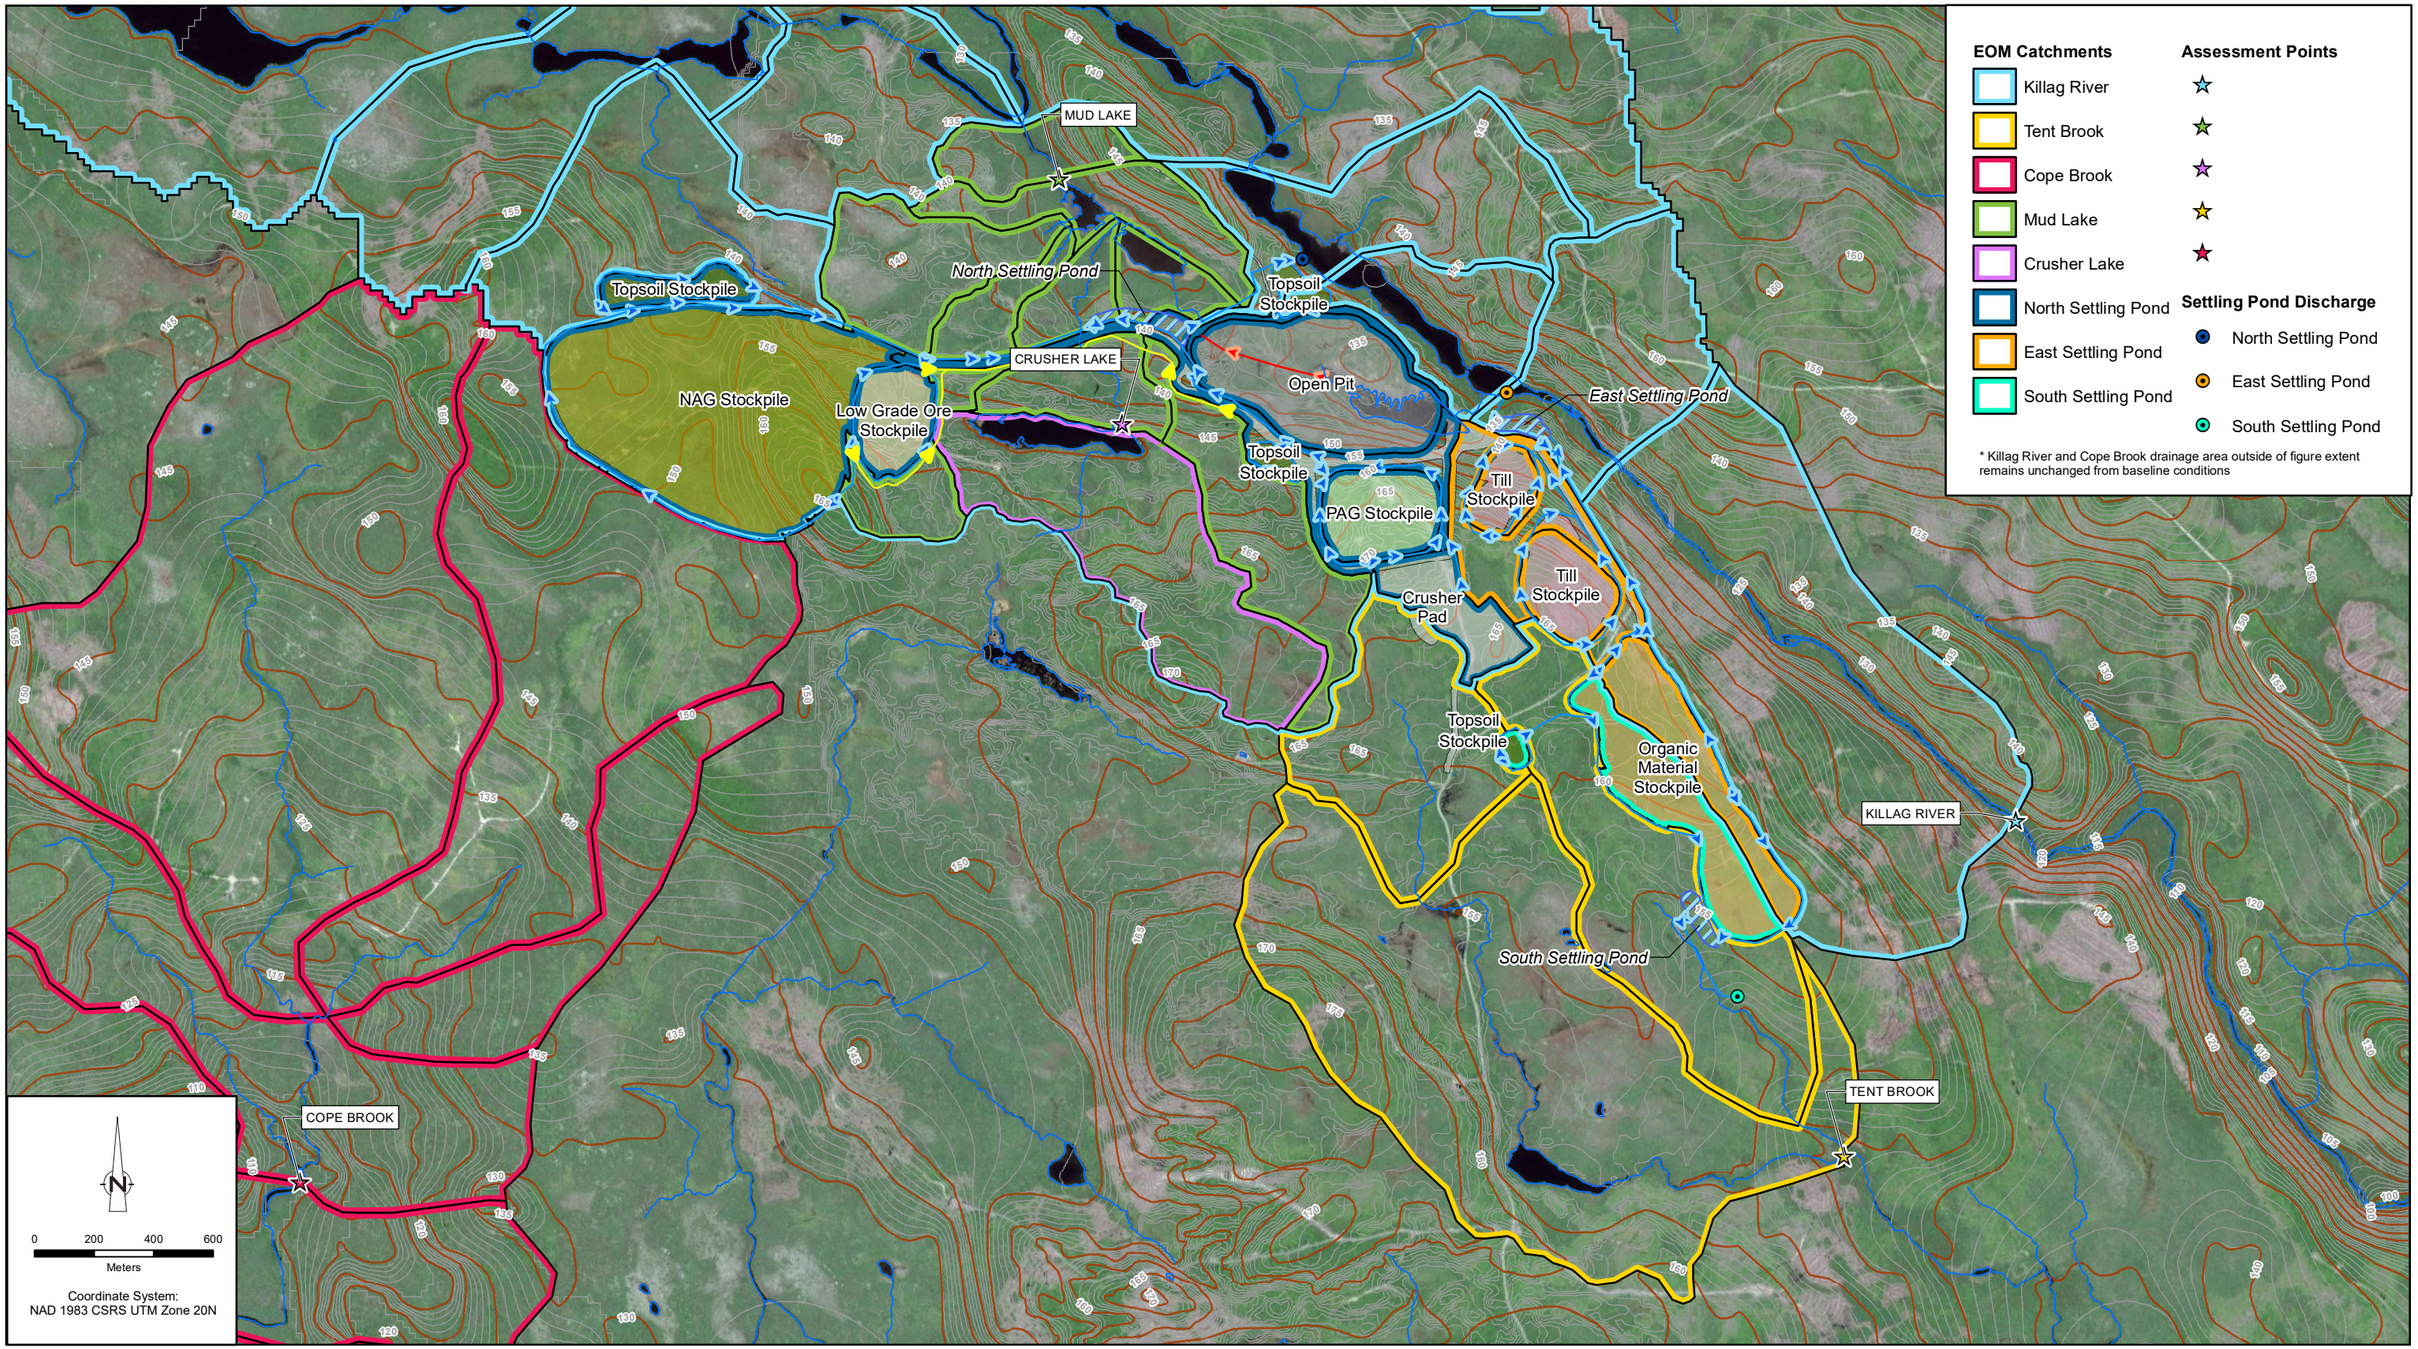
Criteria	Description of Ratings
Duration	• **Short term:** effect is restricted to Construction Phase and/or EOM modelling. • **Medium term:** effect occurs in Construction Phase and EOM Phase • **Long term:** Effect occurs in Construction Phase and EOM Phase and/or persists in PC
Frequency	• **Sporadic:** VC interaction or effect will occur at irregular intervals throughout any Project Phase • **Regular:** effect occurs on a regular basis but not continuous basis • **Continuous:** effect occurs constantly (e.g., every model timestep in a given Project Phase)
Reversibility	• **Reversible:** effect can be reversed • **Partially reversible:** effect can be partially reversed • **Irreversible:** effect cannot be reversed, is of permanent duration

Table 6.7-20: Definitions of Characterization Criteria for Residual Effects on Surface Water Quality

Criteria	Description of Ratings
Magnitude	• **Negligible:** predicted change of surface water quality indicator is less than 10% of background conditions, (i.e., no measurable change of state of indicator from background conditions). • **Low:** indicator is predicted to be greater than guidelines **and** increase by greater than 10% over baseline levels but remains well within the observed range of natural variation (defined as 25th to 75th percentile baseline water quality). • **Medium:** indicator is predicted to be greater than guidelines and differ substantially from baseline levels and approaches upper observed limits of natural variation (defined as percentile baseline water quality). • **High:** indicator is predicted to be greater than guidelines and differ substantially from baseline water quality (outside of 75th to 95th baseline water quality), resulting in a detectable change beyond the range of natural variation.
Geographical Extent	• **Discrete:** effect is limited to receiving environments in the immediate footprint or Project Area (PA). • **Local:** effect is limited to the near-field Local Assessment Area. • **Potential Regional:** effect persists to the far-field Local Assessment Area.
Timing	• Timing represents seasonal occurrence of the effect (e.g., spring vs winter; high flows vs. low flows), and represents characterization criteria for designated water users (i.e., to aquatic resources, fish, and human health). The characterization of effect of changes to surface water on designated water resources is assessed in their respective sections; for Surface Water Quantity timing is considered redundant criteria to duration and frequency characterizations (see below) and is not further considered.
Duration	• **Short term:** effect is restricted to Construction Phase and/or EOM modelling. • **Medium term:** effect occurs in Construction Phase and EOM Phase • **Long term:** Effect occurs in Construction Phase and EOM Phase and persists in PC
Frequency	• **Sporadic:** VC interaction or effect will occur at irregular intervals throughout any Project Phase. • **Regular:** effect occurs on a regular basis but not continuous basis. • **Continuous:** effect occurs constantly (e.g., every model timestep in a given Project Phase).
Reversibility	• **Reversible:** effect can be reversed. • **Partially reversible:** effect can be partially reversed. • **Irreversible:** effect cannot be reversed, is of permanent duration.

6.7.7.3 Surface Water Modelling: Methodology

In support of the environmental assessment, water quality and quantity predictions for the Project were produced through the development of deterministic mass and water balance modelling for both the Beaver Dam Mine Site and Touquoy Mine. Summaries of model approaches, assumptions, and sensitivity analyses as they relate to surface water predictive efforts are provided in the following sections. Full details and results of surface water studies conducted to support the environmental assessment for the Project are appended here as:



- Appendix P.4 Mine Water Management Plan:
  - Appendix A Water Balance Analysis, GHD (2021); and
  - Appendix D Predictive Water Quality Assessment, GHD (2021).
- Appendix G.2 Beaver Dam Mine: Killag River and Moose River Water Quality Predictions and Aquatic Effects Assessment – Reassessment of Killag River based on February 2021 Update (GHD modelling Provided February 12, 2021); Reassessment of Moose River based on March 2021 Update (Stantec modelling of March 11, 2021), Intrinsik (2021);
- Appendix F.8 Beaver Dam Gold Project Assimilative Capacity Study of Moose River – Touquoy Pit Discharge, Stantec (2021);
- Appendix G.10 Additional Water Quality Modelling, GHD (2021); and
- Appendix F.9 Response to IR2s CEAA-2-36, CEAA-2-37, and NSE-2-130 Evaluation of Potential Impacts from Metals COCs to Groundwater and Surface Water from Dust Deposition along the Haul Road, Beaver Dam Mine Project, GHD (2021).

The overall objective of the surface water modelling (quantity and quality) is to predict discharge water quality and quantity, identify potential needs for water treatment (Section 6.7.9) and assess the short and long-term impacts of the Project on the receiving environment. As such, model predictions herein presented do not include effects of planned water treatment.

Surface Water Model Results for the receiving environment informing the effects assessment are presented in Section 6.7.8; predictions for mine site contact water and effluent quality informing the effects assessment are presented in Appendix P.4 (Mine Water Management Plan, Appendix D).

Predictions are compared between the three mine life-cycle stages (baseline, EOM and PC) at three discharge points including Mud Lake, Tent Lake, and the Killag River.

Figures 6.7-13 and 6.7-14 depict the catchment areas contributing drainage area to the Killag River at the proposed receiving waterbody for the Project.

6.7.7.3.1 Beaver Dam Mine Site

Surface Water Quantity Modelling

A water balance analysis was conducted for three stages of mine development including baseline, EOM, and PC conditions. An objective of the water balance analysis was to assess the impacts of the proposed mine development on drainage patterns in surrounding watercourses. Monthly and annual runoff (streamflow) volumes were compared between baseline and EOM/PC conditions at five assessment points where the site will discharge or impact flows in the natural environment.

The water balance model (WBM) was developed using the GoldSim software. GoldSim is a highly graphical program used for carrying out dynamic simulations to support decision making. GoldSim is particularly well-suited to simulating dynamic, computationally intensive, but well-defined network models such as a water balance. GoldSim can perform Monte Carlo simulations, tracks outputs from those simulations, and provides a graphic interface to facilitate the review and identification of interactions between system components.

Hydrologic processes in the predictive model include evaporation, infiltration, direct runoff, and seepage from the stockpile areas. These processes were modelled using coefficients of the rainfall and snowmelt. The coefficients were determined from a combination of literature and observations at the existing Touquoy Mine Site. A runoff coefficient of 1.0 was applied to impervious surfaces, including the site roads, crusher pad, and administrative building areas based on the assumption that all rainfall and snowmelt that occurs on impervious surfaces will generate surface runoff. Baseflow volume variations due to the influence of the mine development (particularly the pit development) on groundwater flow patterns were determined using the groundwater model (Appendix F.5 Hydrogeologic Modelling Report [GHD, 2021h]).

Baseflow impacts were incorporated into the WBM as percent changes from baseline conditions at the five assessment points or included as an input (groundwater inflow rate) to the open pit. Pit dewatering was included as an input to the Killag River streamflow volume based on the assumption that the pit water will be continuously pumped to the north settling pond, which will discharge to the Killag River, and the pit itself will be kept dry during operating conditions.

Surface Water Quality Modelling

The overall objective of the surface water modelling quality modelling is to predict discharge water quality, identify potential needs for water treatment (Section 6.7.9) and assess the short and long-term impacts of the Project on the receiving environment. As such, model predictions herein presented to not include effects of planned water treatment.

A predictive water quality assessment model was developed for two life cycle stages of the Beaver Dam Mine Site development, including EOM and PC. To support the effects assessment for the operations phase, predictive models were developed for the end of operations (EOM) model (i.e., max build out). This represents the Project stage with the highest potential for significant effects to the receiving environment; the prediction and assessment of potential effects at EOM is a conservative approach.

The predictive water quality assessment model was calculated monthly for the average year climatic conditions. Performing the water quality assessment monthly allows for the prediction of the seasonality characteristics of water quality in the Killag River. This allows for the assessment of the average wet and dry months to determine the month with the highest potential impacts on the water quality in the Killag River and will assist with the design of water quality treatment options at the site. A detailed summary of the predictive water quality assessment is provided in Appendix P.4 (Mine Water Management Plan, Appendix D).

To determine the concentration of each constituent of concern in the site effluent, the geochemistry of each stockpile (till, non-acid generating (NAG) waste rock, potentially acid generating (PAG) waste rock, low grade ore (LGO), topsoil), and the pit wall rock

were assessed individually by Lorax Environmental (Appendix E.3 Beaver Dam Project - Geochemical Source Term Update). This assessment established both the base case and the upper-case scenarios of constituent concentrations for EOM and PC mine life cycle conditions. Base case conditions represent the most likely concentration scenario (median) while upper case conditions represent the likely worst-case loadings (90th percentile) concentration scenario.

For the EOM conditions, the water quality model assumed the following:

- NAG and PAG waste rock stockpiles have reached their maximum height but remain uncovered and unrestored.
- The LGO stockpiles have an area of 86,000 m^2 (8.6 ha) and remain uncovered and unrestored.
- The pit is constantly being dewatered and discharged into the north settling pond.
- Standard best practice erosion and sediment control measures have been implemented on the soil and till piles.

For the PC conditions, the water quality model assumed the following:

- The NAG waste rock stockpile has been covered and seeded.
  - The PAG waste rock stockpile has been covered with a High-Density Polyethylene (HDPE) liner allowing for an estimated infiltration rate of 3% of total precipitation through the liner. The cap is covered with soil and re-vegetated.
- The LGO stockpile has been removed from the site and processed at the Touquoy Mine Site. Surface water from this restored stockpile area is diverted to Mud Lake.
  - The till and topsoil stockpiles have been removed and restored.
- The pit has been allowed to naturally fill with water to an elevation of 127 masl.
- All site water will drain to the pit prior to discharge into the Killag River.
- Other than what is mentioned above no other reclamation activities have been incorporated into the predictive water quality modelling of the site.

The predictive water quality assessment incorporated mine impacted groundwater recharge into the surface water ditches and the Killag River. Concentrations of constituents of concern and discharge volumes were taken from GHD's groundwater model for the Beaver Dam Mine Site (Appendix F.5 Hydrogeologic Modelling Report for Beaver Dam Mine Site).

During the operational phase of the open pit, dewatering will have to occur since the natural groundwater table is above the mining elevation. During EOM conditions, the precipitation that fell into the pit was assumed to contact the freshly exposed pit walls causing the release of the weathering products, in particular those related to sulphide oxidation (Lorax Environmental, 2018). Groundwater inflows are expected to contain constituents of concern equal to the background groundwater monitoring concentration levels. Average measured groundwater concentrations were used for the base case scenario while maximum measured groundwater concentrations were used for the upper-case scenario. During PC conditions, the direct precipitation into the pit is assumed clean as it will fall directly onto the lake, which has formed in the pit.

Mine rock materials are not expected to turn acidic during the mine operational phase. Based on the geochemical and modelling completed to date (Appendices E.3 [Beaver Dam Project - Geochemical Source Term Update] and E.4 [Beaver Dam Project: 2020 Kinetic Test Update (IR NSE 2-74) – DRAFT], respectively), which was based on conservative assumptions, there is a potential for some of the mine rock to turn acidic over the long term during the post-closure phase. This effect is mitigated naturally due to the alkaline groundwater inflows into the open pit and, as required, by the adoption of closure measures such as water treatment and/or the installation of a cover on the waste rock pile. All mine contact water released from the site must meet the stringent

MDMER limits for pH which ranges from 6.0 to 9.5. If deviation from modelling detected through monitoring, system will be adapted to meet discharge criteria (i.e., water treatment).

6.7.7.3.2 Haul Road

Sedimentation/Erosion and dust deposition represent the primary pathways of interaction for the Project to Surface Water along the Haul Road.

Potential effects on surface water quality from increased erosion and sedimentation are qualitatively assessed (Section 6.7.8).

Potential effects on surface water quality from dust deposition were quantitively assessed by air dispersion modelling. Appendix F.9 (Evaluation of Potential Impacts from Metal Contaminates of Concern to Groundwater and Surface Water from Dust Deposition along the Haul Road) presents the air dispersion model and associated results, including the quantitative evaluation of potential impacts to surface water from metals found in dust that may be deposited on surficial soil and surface water along the Haul Road for the Project. Air dispersion modelling was performed to predict dust deposition rates in the immediate vicinity of the Haul Road and at each sensitive receptor location (Section 6.2) where there is a domestic water source (groundwater or surface water) or where it was identified there could be a potential future domestic water source. Dust deposition was predicted based on emissions from the Haul Road while being used for the Project only, and then for cumulative emissions from the Haul Road while being used for the Project combined with the nearby projects. Appendix F.9 presents the documentation of the air dispersion modelling methodology and results; results of modelling informed the effects assessment for the Haul Road (Section 6.7.8.3).

6.7.7.3.3 Touquoy Mine

Overview

Predictive modelling at the Touquoy Mine has been updated to reflect updates of the Project Description (Section 2) and to address IR2 issued by IAAC (CEAA 2019) and Nova Scotia Environment (NSE 2019). The water balance model of the Touquoy Mine Site has been updated to available to simulate the quantity of runoff at the Touquoy Mine Site under existing conditions. The water balance model development includes multiple revisions to reflect the changes to the mine site during design, construction, commissioning, and operation of the Touquoy Gold Project that have improved the accuracy of the model. Inputs to the model include groundwater inflows, surface runoff, direct precipitation, and Touquoy pit dewatering for Touquoy ore processing. Precipitation in the water balance model was based on the Environment and Climate Change Canada Middle Musquodoboit climate station (ID 8205990) and evaporation based on the Truro climate station (ID 8205990). The proportion of the precipitation that contributes to runoff collected in the Touquoy pit was estimated in the model through a runoff coefficient, with 100% of direct precipitation on the pond and 85% of precipitation as runoff on natural ground. Runoff from the WRSA captured in the collection ponds is assumed to increase from 5 to 30% of precipitation by the end of Touquoy Gold Project mine life.

Water management at the currently operating Touquoy Mine Site includes directing all wastewater and surface runoff that comes in contact with the ore to the existing tailings management facility (TMF) for treatment. Treatment includes the addition of ferric sulphate to the effluent to precipitate arsenic, hydrated lime to adjust pH, and coagulant polymer to facilitate the removal of colloidal sized suspended matter. The treated effluent is then directed into the polishing pond where additional settling will occur before being released into a constructed wetland for subsequent discharge into the northwestern end of Scraggy Lake. At the point of final discharge, the effluent meets MDMER water quality criteria.

Surface Water Quantity

A water balance model has been developed to simulate the quantity of runoff at the existing mine facilities under existing conditions, and for future conditions (i.e., influence of Beaver Dam Mine activities) and various climate scenarios. The water balance model was developed through multiple iteration and revisions during design, construction, commissioning, and operation of the Touquoy Gold Project to improve accuracy. Model inputs accounted for groundwater inflows, surface runoff, direct precipitation, and Touquoy pit dewatering for Touquoy ore processing.

Results of the monthly water balance model at the end of processing of Touquoy ore is used to represent the baseline conditions for the use of the Touquoy Mine Site for the Beaver Dam Mine Project. Details of the modelling are presented in the Touquoy Integrated Water and Tailings Management Plan included in Appendix F.7.

As described in more detail the technical report (Stantec, 2018d), the water balance was refined to simulate the existing conditions (water quantity and water quality) at the end of Touquoy mine life and the start of processing Beaver dam ore. The Touquoy Mine Site was divided into five sub-catchment areas based on the available LiDAR topography (Leading Edge 2013) and the water management at the site. The catchment areas for each of the mine facilities include the mill site (13.8 ha), TMF (94.0 ha), open pit (40.4 ha), waste rock area (55.1 ha), and polishing pond (16.9 ha). Other model assumptions include:

- at the start of the mode, the TMF dam is at the maximum elevation of 130 m with an emergency spillway at 128.5 m in elevation;
- the maximum tailings capacity in the Touquoy TMF is reached in April/May 2022 and the pond water level is at normal operating water level;
- at the start of the model, the Touquoy waste rock storage area is fully developed and reached the maximum capacity;
- at the start of the model, the Touquoy open pit is exhausted and empty; the exhausted open pit used as a tailing's management facility assuming an average deposited dry density of 1.3 t/m^3 for subaqueous tailings deposition;
- processing Beaver Dam Mine ore occurs at the existing Touquoy mill;
- process water decant from the existing Touquoy TMF during start-up until pond volumes are depleted;
- existing decant barge relocated to exhausted open pit for reclaim throughout the remainder of operation;
- natural filling of the open pit over time to create a pit lake overtop of the tailings;
- groundwater inflow to the pit varying from 768 m^3/d when the pit is completely dewatering, and decreasing to 363 m^3/d when the pit lake water elevation reaches 108 m CGVD2013;
- an emergency spillway in the open pit with an invert elevation of 108 m to prevent overtopping and a conveyance channel to Moose River;
- effluent treatment as a batch reactor in the open pit; and
- effluent further treated or pumped and treated at the existing effluent treatment plant for treatment and discharged to the downstream treatment facilities and Scraggy Lake receiving environment.

Surface Water Quality Modelling

The prediction of surface water quantity effects was completed for the operations and closure phases of the Project at the Touquoy Mine Site using qualitative and numerical modelling to simulate the water and tailings management at the Touquoy Mine Site during and after the processing of the Beaver Dan Mine ore.

Water quality in Scraggy Lake and WC4 were evaluated qualitatively, as the Beaver Dam Mine ore processing and deposition to the exhausted pit are not expected to change the water quality in the TMF, nor downstream.

Numerical modelling was conducted to assess the water quality effects in Moose River. A water quality model was prepared from the water balance model described in Section 6.7.5.3. Flow terms in the water balance were assigned water quality source terms (Appendix F.6 Groundwater Flow and Solute Transport Modelling to Evaluate Disposal of Beaver Dam Tailings in Touquoy Open Pit) to simulate the overall water quality of metal parameters and nitrogen species including cyanide, ammonia, nitrate, and nitrite in the Touquoy pit during operation and post closure. Mixing of the discharge from the Touquoy pit through the spillway at SW-2 at post-closure with Moose River was conducted using an assimilative capacity model (Appendix F.8 Project Assimilative Capacity Study of Moose River – Touquoy Pit Discharge).

The objectives of numerical modelling are to predict the period of time that water treatment will be required prior to the pit water effluent discharge to Moose River, and the water quality of effluent discharge to Moose River at biological monitoring stations in place to assess environmental effects.

Water quality modelling considered the pore water quality in the tailings and the groundwater inflow quality in the pit floor/ walls, dilution from surface runoff, direct precipitation, and process water surplus, and the geochemistry of the individual water quality parameters. As discussed in source terms memo (Appendix E.3 Beaver Dam Project - Geochemical Source Term Update), the pore water quality in the tailings and pit walls/floor was based on geochemical source term predictions that were derived from upscaling of kinetic tests and Touquoy monitoring data. The kinetic test and Touquoy monitoring data are considered representative for Beaver Dam ore processing as the Beaver Dam and Touquoy pits mine ore from the same geologic formation with similar sulphur content and Beaver Dam ore processing and cyanide detoxification in the Touquoy mill will follow the same general approach as the Touquoy ore processing. These source terms were coupled with the inflow rates for the various components of inflow to the Touquoy pit and mixed to predict the water quality in the pit over time. The volume in the pit increased until discharge was predicted to occur in Beaver Dam Mine Year 12. Further details of the modelling can be found in the Touquoy Integrated Water and Tailings Management Plan (Appendix F.7).

As summarized in the assimilative capacity study of Moose River (Appendix F.8 Project Assimilative Capacity Study of Moose River – Touquoy Pit Discharge), a CORMIX mixing zone model (Doneker and Jirka 2017) was run in to predict the distance in Moose River downstream of the open pit spillway where full mixing is achieved. Based on mass balance, water quality in Moose River is a result of the climate- driven effluent discharge and the continuous seepage input from the pit lake at the post closure phase. Several climate statistics were run to identify the worst-case dilution ratio between effluent discharge and flow volume in Moose River that would result in the highest metal and nitrogen species concentrations at the MDMER biological monitoring stations located at 100 m and 200 m downstream of the effluent discharge point. Full mixing of discharge effluent in Moose River is achieved 120 m downstream of the discharge point, and water quality was predicted for 100 m, and 120 m downstream, with areas more of 120 m downstream will have similar or better water quality due to Project related effects. Effluent discharge water quality from the pit lake was assumed to meet MDMER discharge criteria for an existing mine in 2021 prior to discharge to Moose River. Operational plans are in place so that effluent not meeting criteria would either be further treated or pumped to the existing Touquoy effluent treatment plant for treatment prior to discharge to the downstream Touquoy discharge facilities and finally Scraggy Lake.

6.7.8 Project Activities/Interactions with Surface Water Quantity and Quality

6.7.8.1 Overview of Potential Surface Water Interactions

The purpose of this section is to identify how the Surface Water VCs may be affected by interactions with the Project's components and activities (Tables 6.7-21 to 6.7-23). The Project is part of the Moose River Consolidated (MRC) Project, which includes the existing and fully permitted Touquoy Gold Project, located in Moose River Gold Mines, Nova Scotia. The Project will operate as a satellite surface mine to the MRC Project, and crushed ore from the will be transported by truck via the Haul Road to the existing and fully permitted Touquoy Mine.

Table 6.7-21: Potential Project Activities/Interactions with Surface Water Quantity and Quality at the Beaver Dam Mine Site

Project Phase	Duration	Project Interaction
Construction	1 year (monitoring and adaptive management)	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of construction • Till and waste rock from site preparation transport and storage • Historical settling pond dewatering in preparation of construction • Watercourse and wetland alteration in preparation of construction • Mine Site road construction • Surface infrastructure installation and construction • Collection and settling pond construction • Dewatering pf historical tailings facility and associated discharge to the receiving environment
Operation and Maintenance	5 years (monitoring and adaptive management)	• Rock blasting to access and extract ore • Surface mine dewatering to facilitate access to and extraction of ore • Management of waste rock produced from crushing and preparing ore for transport • Treatment of site surface water runoff and surface mine pumped water. • Discharge to Killag River from North Settling Pond • Petroleum products management • Site maintenance and repairs
Active Closure	2 years (monitoring and adaptive management)	• Infrastructure demolition, Earthworks, Revegetation, and other site reclamation activities
Post-closure	+10 years (monitoring, adaptive management)	• Discharges from Open Pit lake to Killag River

Table 6.7-22: Potential Project Activities/Interactions with Surface Water Quantity and Quality along Haul Road

Project Phase	Duration	Project Interaction
Construction	1 year (monitoring and adaptive management)	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of construction • Till and waste rock from site preparation transport and storage • Watercourse and wetland alteration in preparation of construction • Haul road construction and upgrades
Operation and Maintenance	5 years (monitoring and adaptive management)	• Ore transport • Haul road maintenance and repairs
Active Closure[(a)]	2 years (monitoring and adaptive management)	• An inventory of the condition of culverts and bridges will be undertaken once the Haul Road is not longer used for ore transport.
Post-closure	+10 years (monitoring, adaptive management)	• Not anticipated since Project related activities will be no longer occurring and no reclamation is planned.

Notes: [(a)] Decommissioning and Reclamation of the Haul Road is not expected. The Haul Road will be returned to owner for forestry industry. N/A = not applicable.

Table 6.7-23: Potential Project Activities/Interactions with Surface Water Quantity and Quality at Touquoy Mine Site

Project Phase	Duration	Project Interaction
Construction	1 year (monitoring and adaptive management)	• Tailings pipeline, make-up water pipeline alteration, and relocation of reclaim infrastructure
Operation and Maintenance	5 years (monitoring and adaptive management)	• Ore management (drilling, blasting, loading and hauling of ore and waste rock) • Ore processing (ore crushing and conveyance, ore milling) • Management of tailings produced from processing ore (Sub-aqueous deposition in Touquoy open pit) • Environmental monitoring of surface water • General management of waste derived from processing activities • Water treatment as a batch reactor as pit is filling
Active Closure	2 years (monitoring and adaptive management)	• Water treatment of Touquoy pit lake surplus at water treatment plan until water quality meets MDMER criteria • Effluent Discharge from Touquoy pit lake to Moose River
Post-closure	+10 years (monitoring, adaptive management)	• Monitoring is expected to occur until the Touquoy pit is refilled and groundwater depressurization zone achieves stability. • Discharge from Touquoy pit lake to Moose River

Notes: MDMER = Metal and Diamond Mining Effluent Regulations.

In general, the Project has the potential to change Surface Water by:

- discharges, including direct discharge to the receiving environment and management of contact water;
- water management activities, including diversions of contact and non-contact water;
- groundwater seepage from Project components to receiving environment;
- ML/ARD generated from excavating or exposing material with the potential for ML/ARD, or in runoff from temporary stockpile or road cuts;
- erosion and sedimentation during site clearing, construction, and maintenance activities; and
- dust deposition along the Haul Road Corridor (CEAA-2-37).

Project components/activities are not expected to interact with the Surface Water VCs, these components and activities are considered to have no potential effects and are not considered further in the assessment. These include interactions between the Project and surface water quality and quantity resulting from hazardous waste materials and potential spills well as potential failures of water management structures (e.g., failure settling pond); these are related to occurrences of low likelihood outside of normal operating conditions. These potential effects are addressed in Section 6.18, Accidents and Malfunctions, as well as the Spill Contingency Plan (Appendix A of Appendix P.1), which is included as part of the Emergency Response Plan (Appendix P.1).

Effects on indicators of Surface Water Quantity (e.g., base flow, L/s) and Surface Water Quality (total and dissolved metals, anions, and nutrients; mg/L) were either assessed quantitatively by predictive water modelling or qualitatively based on geochemical characterization studies and professional judgement and experience (e.g., pH, TSS). The goals were to remove as much subjectivity as possible from the assessment and to increase certainty in the predictions of alteration of the Surface Water VC, residual effects, and the determination of significance to ensure a robust, transparent, and defensible approach to the effects assessment.

6.7.8.2 Surface Water Effects: Beaver Dam Mine

In support of the environmental assessment, Surface Water Quantity predictions for the Project were produced through the development of deterministic water -balance modelling for both the Beaver Dam Mine Site and the existing Touquoy Mine. Summaries of model approaches, assumptions, and sensitivity analyses as they relate to surface water predictive efforts are provided in Section 6.7.7.3; a summary of model results is provided in the following Sections.

Full details and results of surface water studies conducted to support the environmental assessment for the Project are appended here as:

- Appendix D (Predictive Water Quality Assessment) of Appendix P.4 Mine Water Management Plan;
- Appendix A (Water Balance Analyses) of Appendix P.4 Mine Water Management Plan;
- Appendix F.8 Beaver Dam Gold Project Assimilative Capacity Study of Moose River – Touquoy Pit Discharge; and
- Appendix G.3 Additional Water Quality Modelling to Support the Mine Site Water Management Plan.

6.7.8.2.1 Surface Water Quantity Modelling Results

A water balance analysis was conducted to assess the hydrologic impact of mine development on the surrounding water features. The water balance was calculated for five assessment points where the site will discharge or impact flows in the natural environment, including the Killag River, Mud Lake (outlet to WC27), Crusher Lake (outlet to WC5), Tent Brook and Cope Brook systems.

A summary of catchment areas at EOM condition and change relative to baseline are presented in Table 6.7-24. Table 6.7-25 through Table 6.7-29 present the monthly and annual metrics for identified assessment points in the receiving environment relative to baseline conditions. Mine site development will increase the Killag River catchment area, and decrease the Mud Lake, Tent Brook and Cope Brook catchments due to the placement of mine features in their baseline drainage areas. Surface runoff from mine features will be directed to settling ponds for treatment prior to being released into the Killag River and Tent Brook systems. The north settling pond will receive and treat runoff from the waste rock, low-grade ore and topsoil stockpiles, the crusher pad, administrative building area and site roads. Surface water and groundwater collected in the pit sump will also be dewatered to the north settling pond. The east settling pond will receive runoff from the till stockpiles, part of the organic stockpile and site roads.

The north and east settling ponds discharge to the Killag River. The south settling pond will receive runoff from another other part of the organic stockpile and a topsoil stockpile. The south settling pond discharges to WC19 of the Tent Brook system.

Table 6.7-24: Summary of Catchment Areas under Baseline, End-of-Mine and Post-closure Conditions

Assessment Point	Catchment Area for Water Balance Assessment Points (ha)			Change from Baseline Condition (%)	
	Baseline	EOM	PC	EOM	PC
Killag River	3,933.5	3,974.5	3,974.5	1.0	1.0
Crusher Lake	58.8	58.8	58.8	0	0
Mud Lake	223.2	184.0	192.6	-17.6	-13.7
Tent Brook	306.2	301.6	301.6	-1.5	-1.5
Cope Brook	481.0	444.8	444.8	-7.5	-7.5

Source: Appendix P.4 Mine Water Management Plan, Appendix A Water Balance Analysis.

Notes: ha = hectares; EOM = end-of-mine; PC = Post-closure; % = percent; < = less than.

As part of the site reclamation plan, the pit will be filled with water from groundwater inflows, direct precipitation, and site contact water. Water will no longer be pumped from the pit to the north settling pond, and the north settling pond discharge will be re-directed into the pit. Once the pit is filled, the north settling pond will be decommissioned and site runoff will be diverted directly into the pit (Figure 6.7-14). Overflow from the pit will be directed to the Killag River through an engineered outfall in the east pit wall and existing outlet channel (WC13). The capacity of the pit is approximately 16,000,000 m^3. During PC conditions an additional 8.6 ha will be routed to Mud Lake, reducing the impact to the Mud Lake drainage area to from a 18.3% decrease between baseline and EOM conditions to a 13.7% decrease between baseline and PC conditions. The impact to the drainage area of the Tent Brook and Cope Brook assessment points remain the same as in EOM conditions.

Killag River

The WBM output shows there is a 1.7% decrease in baseflow and a 2.2% increase in total annual streamflow at the Killag River assessment point between baseline and EOM conditions. The increase in streamflow is due to the proposed site development and increase in impervious area. The reduction in baseflow is due to the formation of the open pit, which draws water from the local aquifer (refer to Section 6.6 for discussion on groundwater quality and quantity).

The WBM simulates a 1.3% decrease in baseflow and a 1.1% increase in total annual streamflow at the Killag River assessment point between baseline and PC conditions after the pit is filled with water. The reduced impact to surface runoff and baseflow to the Killag River between EOM and PC conditions can be explained by the proposed site modifications as part of the reclamation plan. These modifications include vegetating or removing stockpiles and filling the open pit with water to reduce its capacity to draw groundwater from the local aquifer compared to EOM conditions.

The impacts to the Killag River while the open pit fills with water were also assessed. The WBM simulates a 1.7% decrease in baseflow and 2.2% decrease in annual streamflow between baseline and PC conditions at the Killag River assessment point during this period. The decrease in streamflow is caused by the reduction in drainage area as a large portion of the site that drains to the Killag River under baseline conditions will be directed to the open pit to reduce the pit filling time. The pit filling time is estimated to be approximately 13 years. Contingency measures will be in place to mitigate baseflow reduction in the Killag River during dry months of the pit filling period as described in Appendix P.4 (Mine Water Management Plan, Appendix H Baseflow Mitigation Assessment).

There is a low probability of detectable impacts to ecosystems that support fisheries, when the alterations are less than 10% of the natural flow regime. Further there is unlikely to be negative effects on these systems for a flow reduction up to 15%. The predicted impacts in the Killag River from alteration of surface runoff from the Project during construction, operation and closure is below 10% , which results in a low probability of detectable impact to ecosystems that support fish. This is detailed and discussed in the Fish and Fish Habitat effects assessment (Section 6.9).

Crusher Lake

Crusher Lake is part of the Mud Lake catchment. Its drainage area remains unchanged from baseline conditions throughout the mine development stages; however, the groundwater modelling results show a small increase in baseflow contributions to the lake in the order of 2 to 3% annually. The small gain in baseflow is likely attributed to the placement of waste rock and low-grade ore stockpiles overtop of a watercourse in a neighbouring watershed. Under baseline conditions the watercourse would have collected baseflow prior to reaching the Crusher Lake catchment. Under EOM and PC conditions this portion of the baseflow emerges in the Crusher Lake catchment. In addition, during operations, water will be extracted from the lake at a rate of 3 m^3/hour to meet the domestic and truck wash water demands. The combined impact is a 4.4% decrease in annual lake discharge. In PC conditions, the Project impact is reversed as water extraction from the lake is discontinued. The WBM simulates a 0.6% increase in annual lake discharge.

Mud Lake

The WBM simulates a 18.1% decrease in annual total inflow and 18.3% decrease in annual discharge at Mud Lake between baseline and EOM conditions. These results are attributed to a 4.4% decrease in annual Crusher Lake discharge through WC5 a 24.5% decrease in annual surface runoff and a 21.9% decrease in annual baseflow. The decrease in surface runoff volume is proportional to the reduction in drainage area due to stockpile and road development within the baseline Mud Lake catchment. The decrease in baseflow is caused by the impact of the open pit on groundwater patterns in the Mud Lake catchment.

The WBM simulates a 13.6% decrease in annual total inflow and 13.7% decrease in annual discharge at Mud Lake between baseline and PC conditions. The impact to surface runoff in the Mud Lake catchment is reduced from EOM to PC conditions, because the low-grade ore stockpile will be removed and the area where the pile once was will be directed to Mud Lake. The impact to baseflow will be reduced between EOM and PC conditions because of the change in drainage area and because the pit will be filled with water, reducing its capacity to draw water from the local aquifer.

The predicted impacts to Mud Lake water levels are highest in wet periods and lowest in dry periods of the year. The results from the WBM indicated that Mud Lake has a surplus of water throughout all periods of the year. Therefore, it is predicted that the discharge channel from Mud Lake to the Killag River will not run dry as a result of the mine development (i.e., extreme long-term drought can lead to dry conditions, which are out of the control of site development).

Tent Brook

The WBM predicts a 0.4% decrease in baseflow, and 1.1 to 1.2% decrease in annual streamflow at the Tent Brook assessment point between baseline and EOM/PC conditions. The decrease in streamflow is caused by the diversion of runoff from the crusher pad and administrative building areas, which are partially located in the baseline Tent Brook catchment, toward the Killag River system.

The annual impact to the streamflow components at the Tent Brook assessment point are the same between EOM and PC conditions; however, the monthly variation of impacts is reduced. This is due to the removal of the organic material and topsoil stockpiles, and restoration of these areas to baseline conditions. The water balance analysis (Appendix P.4 Mine Water Management, Appendix A) details the monthly impacts to all assessment points for EOM and PC development stages. The predicted impacts from alteration of surface runoff from the Project during construction, operation and closure is below 10%, which results in a low probability of detectable impact to ecosystems that support fish. This is discussed in the Fish and Fish Habitat effects assessment (Section 6.9).

Cope Brook

The WBM simulates a decrease in surface runoff contributing to the Cope Brook system under EOM and PC conditions due to the placement of the waste rock stockpile in its baseline catchment, and the diversion of stockpile runoff to the north settling pond for treatment. The hydrologic impacts to Cope Brook are predicted to be consistent between EOM and PC conditions. The WBM simulates a 0.5% decrease in baseflow, and 5.7% decrease in annual streamflow at the Cope Brook assessment point between baseline and EOM/PC conditions. The predicted impacts from alteration of surface runoff from the Project during construction, operation and closure is below 10%, which results in a low probability of detectable impact to ecosystems that support fish. This is discussed in the Fish and Fish Habitat effects assessment (Section 6.9).

Table 6.7-25: Summary Monthly and Annual Water Balance Results for End-of-Mine and Post-closure Conditions, Killag River

Water Balance Components	Baseline Monthly and Annual Water Balance Volumes for the Killage River (m^3)												
	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sept	Oct	Nov	Dec	Annual

6.7.8.2.2 Surface Water Quality Results: Mine Site Water

Surface water runoff from the surrounding area of the Mine Site, waste rock, till, topsoil and organic material stockpiles, and site roads will be managed with the aid of berms and newly constructed channels, which will discharge into settling ponds. Surface runoff that falls directly into the pit will be dewatered to the north settling pond during operations. Further details on the surface water management during EOM and PC conditions, including the settling pond design criteria and surface water management infrastructure layout, are provided in the Stormwater Management Assessment - Hydrologic Modelling Technical Memorandum (Appendix P.4 Mine Water Management Plan, Appendix B).

Contact/Mine Site water quality predictions (Appendix P.4 Mine Water Management Plan, Appendix D [Predictive Water Quality Assessment]) were generated for:

1. North Settling Pond and Discharges (EOM, PC); and

2. Open Pit Water Discharges (PC).

The constituent concentrations entering the North Settling Pond during EOM conditions for base case and upper-case scenarios are presented in Appendix P.4 (Mine Water Management Plan, Appendix D, Tables 3-2 and 3-3). The pond will likely be decommissioned for PC conditions.

Water quality predictions for contact water quality, prior to water treatment, are presented in Appendix P.4 (Appendix D [Predicted Water Quality] and Appendix F [Mine Water Treatment Assessments). In summary results indicate:

- North Settling Pond: MDMER objectives are not exceeded in the during either base case or uppercase scenarios for EOM and PC;

- Open Pit Water Discharges: Under PC conditions, all site contact water will be routed through the pit prior to discharge into the Killag River. Arsenic exceeds MDMER objectives for most of the year in the pit during the base case scenario, indicating a need for water treatment. Water treatability studies for pit water quality are presented in Appendix P.4 (Appendix F Mine Water Treatment Assessments).

In response to IR2 issued by IAAC (CEAA 2019) and Nova Scotia Environment (NSE 2019), and as a result of ongoing water quality, water quantity and geochemical studies for the Project, water treatment for both EOM and PC is planned for the Project. Details for water management and planned water treatments are summarized in Section 6.7.9 and presented in Appendix P.4 Mine Water Management Plan, Appendix F.2 Mine Water Treatment Assessment Operations. The treatment system will be designed to ensure that all site effluent water meets MDMER and will reflect assimilation capacity of the receiving environment, such that any potential effects to the Surface Water Quality VC, and downstream water users, will be fully mitigated.

6.7.8.2.3 Surface Water Quality Results: Receiving Environment

During EOM conditions, site water from the waste rock, LGO stockpiles, crusher pad and the pit will be routed through the north settling pond prior to discharge into the Killag River. There will also be runoff from the till and organic material stockpiles to the east settling pond prior to discharge into the Killag River and from the organic material stockpiles south to the south settling pond prior to discharge to WC19. During PC conditions, site water from the waste rock stockpiles will be routed through the pit prior to discharge directly from the pit into the Killag River.

The only discharge points with potential for discharge of impacted mine effluent into the Killag River system are the north settling pond (EOM) and the pit (PC). There are three discharge points proposed during EOM conditions and PC conditions (Figure 6.7-13 and 6.7-14).

Receiving water quality predictions were generated for:

1. EOM: near-field mixing zone (100 m downstream of each discharge point with the potential for constituent transport);

2. PC: near-field mixing Zone on Killag River for the Pit; and

3. EOM and PC: far-field mixing zone (approximately 1 km downstream of Near Field - Pit - PC discharge point in the Killag River).

The predictive water quality assessment was calculated on a monthly basis for the average year climatic conditions. Performing the water quality assessment on a monthly basis allows for the prediction of the seasonality characteristics of water quality in the Killag River. This allows for the assessment of the wet and dry months to determine the month with the highest effect on the water quality in the Killag River and will assist with the design of water quality treatment options at the Project Site.

Cormix modelling was also performed for protect discharges; modelling details are included in Appendix P.4 Mine Water Management Plan, Appendix F (Water Treatment Assessments). Results indicate that full mixing would occur in a relatively short distance from the discharge point in Cameron Flowage.

Note, as limited information was available for the Construction Phase, the water quality of a similar site (i.e., Touquoy) was used as an indication of water quality for the Project (Appendix P.4 Mine Water Management Plan [Appendix F.1 Water Treatment Assessment –Construction]), rather than mass and water balance modelling.

Surface Water Quality predictions are presented in Table 6.7-30 through 6.7-38.

Source, with minor revisions from: Appendix G.2 Beaver Dam Mine: Killag River and Moose River Water Quality Predictions and Aquatic Effects Assessment – Reassessment of Killag River based on February 2021 Update (GHD modelling Provided February 12, 2021); Reassessment of Moose River based on March 2021 Update (Stantec modelling of March 11, 2021) (Intrinsik 2021).

Notes: All values are presented as µg/L. For the purposes of summary here, **bolded** predicted values are greater than applicable water quality criteria; grey shaded values are greater than 75th percentile baseline values. Results indicate that while concentrations are predicted to increase relative to baseline conditions for some parameters, no values are predicted to be greater than applicable water quality criteria (i.e., selected benchmark concentrations). As water quality criteria are defined by national and international entities as protective of the receiving environment and all water users, there are no anticipated effects to surface waters are a result of discharges from the Project to the Killag River in this scenario.

(a) Selected benchmarks represent Nova Scotia Tier 1 guidelines unless specified otherwise.

(b) Adopted from CCME.

(c) Based on baseline concentration in the Killag River (75th percentile).

(d) Site-specific water quality guideline.

(e) Selected guideline represents Environment Canada (2017) FEQG for the protection of aquatic life at water hardness of 52 mg/L.

(f) Selected guideline represents the Long-term CWQG, SSD 5th percentile at water hardness of 50 mg·L-1, pH of 7.5 and DOC of 0.5 mg·L-1.

(g) Selected guideline represents the ammonia (total) CCME guideline value at pH 6.0 and temperature of 25ºC, multiplied by 0.8224 (for the conversion of NH_3 to total ammonia-N).

(b) Adopted from CCME.

(c) Based on baseline concentration in the Killag River (75th percentile).

(d) Site-specific water quality guideline.

(e) Selected guideline represents Environment Canada (2017) FEQG for the protection of aquatic life at water hardness of 52 mg/L.

(f) Selected guideline represents the Long-term CWQG, SSD 5th percentile at water hardness of 50 mg·L-1, pH of 7.5 and DOC of 0.5 mg·L-1.

(g) Selected guideline represents the ammonia (total) CCME guideline value at pH 6.0 and temperature of 25ºC, multiplied by 0.8224 (for the conversion of NH_3 to total ammonia-N).

Sourced with minor revisions from: Appendix G.2 Beaver Dam Mine: Killag River and Moose River Water Quality Predictions and Aquatic Effects Assessment – Reassessment of Killag River based on February 2021 Update (GHD modelling Provided February 12, 2021); Reassessment of Moose River based on March 2021 Update (Stantec modelling of March 11, 2021) (Intrinsik 2021).

Notes: All values are presented as µg/L. For the purposes of summary here, **bolded** predicted values are greater than applicable water quality criteria; grey shaded values are greater than 75th percentile baseline values. Results indicate that while concentrations are predicted to increase relative to baseline conditions for some parameters, no values are predicted to be greater than applicable water quality criteria (i.e., selected benchmark). As water quality criteria are defined by national and international entities as protective of the receiving environment and all water users, there are no anticipated effects to surface waters are a result of discharges from the Project to the Killag River in this scenario.

(a) Selected benchmarks represent Nova Scotia Tier 1 guidelines unless specified otherwise.

(b) Adopted from CCME.

(c) Based on baseline concentration in the Killag River (75th percentile).

(d) Site-specific water quality guideline.

(e) Selected guideline represents Environment Canada (2017) FEQG for the protection of aquatic life at water hardness of 52 mg/L.

(f) Selected guideline represents the Long-term CWQG, SSD 5th percentile at water hardness of 50 mg·L-1, pH of 7.5 and DOC of 0.5 mg·L-1.

(g) Selected guideline represents the ammonia (total) CCME guideline value at pH 6.0 and temperature of 25ºC, multiplied by 0.8224 (for the conversion of NH_3 to total ammonia-N).

(d) Site-specific water quality guideline.

(e) Selected guideline represents Environment Canada (2017) FEQG for the protection of aquatic life at water hardness of 52 mg/L.

(f) Selected guideline represents the Long-term CWQG, SSD 5th percentile at water hardness of 50 mg·L-1, pH of 7.5 and DOC of 0.5 mg·L-1.

(g) Selected guideline represents the ammonia (total) CCME guideline value at pH 6.0 and temperature of 25ºC, multiplied by 0.8224 (for the conversion of NH_3 to total ammonia-N).

Source: Appendix G.2 Beaver Dam Mine: Killag River and Moose River Water Quality Predictions and Aquatic Effects Assessment – Reassessment of Killag River based on February 2021 Update (GHD modelling Provided February 12, 2021); Reassessment of Moose River based on March 2021 Update (Stantec modelling of March 11, 2021) (Intrinsik 2021).

Notes: All values are presented as µg/L. For the purposes of summary here, **bolded** predicted values are greater than applicable water quality criteria; grey shaded values are greater than 75th percentile baseline values. Results indicate that while concentrations are predicted to increase relative to baseline conditions for some parameters, no values are predicted to be greater than applicable water quality criteria (i.e., selected benchmark). As water quality criteria are defined by national and international entities as protective of the receiving environment and all water users, there are no anticipated effects to surface waters are a result of discharges from the Project to the Killag River in this scenario.

(a) Selected benchmarks represent Nova Scotia Tier 1 guidelines unless specified otherwise.

(b) Adopted from CCME.

(c) Based on baseline concentration in the Killag River (75th percentile).

(d) Site-specific water quality guideline.

(e) Selected guideline represents Environment Canada (2017) FEQG for the protection of aquatic life at water hardness of 52 mg/L.

(f) Selected guideline represents the Long-term CWQG, SSD 5th percentile at water hardness of 50 mg·L-1, pH of 7.5 and DOC of 0.5 mg·L-1.

(g) Selected guideline represents the ammonia (total) CCME guideline value at pH 6.0 and temperature of 25ºC, multiplied by 0.8224 (for the conversion of NH_3 to total ammonia-N).

Source: Appendix G.2 Beaver Dam Mine: Killag River and Moose River Water Quality Predictions and Aquatic Effects Assessment – Reassessment of Killag River based on February 2021 Update (GHD modelling Provided February 12, 2021); Reassessment of Moose River based on March 2021 Update (Stantec modelling of March 11, 2021) (Intrinsik 2021).

Notes: All values are presented as µg/L. For the purposes of summary here, **bolded** predicted values are greater than applicable water quality criteria; grey shaded values are greater than 75th percentile baseline values. No values are predicted to be greater than selected benchmarks. Results indicate that cobalt and zinc concentrations are greater than baseline and water quality criteria in some months in this scenario. As a result of these predictions, Atlantic Mining has committed to implementation of a water treatment system to ensure that all site effluent water meets MDMER and will reflect assimilation capacity of the receiving environment, such that any potential effects to the Surface Water Quality VC, and downstream water users, will be fully mitigated.

(a) Selected benchmarks represent Nova Scotia Tier 1 guidelines unless specified otherwise.

(b) Adopted from CCME.

(c) Based on baseline concentration in the Killag River (75th percentile).

(d) Site-specific water quality guideline.

(e) Selected guideline represents Environment Canada (2017) FEQG for the protection of aquatic life at water hardness of 52 mg/L.

(f) Selected guideline represents the Long-term CWQG, SSD 5th percentile at water hardness of 50 mg·L-1, pH of 7.5 and DOC of 0.5 mg·L-1.

(g) Selected guideline represents the ammonia (total) CCME guideline value at pH 6.0 and temperature of 25ºC, multiplied by 0.8224 (for the conversion of NH_3 to total ammonia-N).

Construction Predictions-Killag River

As limited information was available for the Construction Phase, the water quality of a similar site (i.e., Touquoy) was used as an indication of water quality for the Project (Appendix P.4 Mine Water Management Plan, Appendix F.1 [Water Treatment Assessment Construction]), rather than mass and water balance modelling. There will be three main sources of impacted water that may need treatment before discharge during the construction phase. The first source will be the existing body of water in the open pit area which is expected to require minimal to no treatment. The second source of water would be impacted water which is in contact with historical tailings and is expected to have a high concentration of metals such aluminum, arsenic, cadmium, cobalt, copper, iron, manganese, mercury, lead, and zinc. This source of water will include any leachate that will be generated as the result of historical sediment removal. The third source of water that will need treatment during the construction phase would be precipitated water which comes in contact with impacted material.

To support assessment of effects during the Construction Phase, analysis results of two samples from the historical tailing water (HT-EXW-01 and HT-EXW-02) and one sample from the pit sump were provided by AMNS from the Touquoy site. Results of this evaluation indicate that aluminum, arsenic, cadmium, cobalt, copper, iron, manganese, mercury, lead, and zinc are among exceeded parameters and likely will require treatment (Appendix P.4 Mine Water Management Plan, Appendix F.1 [Water Treatment Assessment Construction]). The same results show that polyaromatic hydrocarbons such as anthracene, benzo(a)anthracene, benzo(a)pyrene, fluoranthene, and pyrene also exceeded Nova Scotia Environment (NSE) Tier 1 Environmental Quality Guidelines (EQS) for Surface Water in the historical tailing water. The concentrations of polyaromatic hydrocarbons were below the detection limit for the pit sump water. The complete water quality analytical report is presented in Appendix P.4, Appendix F.

In response to IR2 issued by IAAC (CEAA 2019) and Nova Scotia Environment (NSE 2019), and as a result of ongoing water quality and quantity and geochemical studies for the Project, water treatment for Construction is planned for the Project. Details for water management and evaluation of alternative water treatments are presented in Appendix F in Appendix P.4. Note, the treatment system will be designed to ensure that all site effluent water meets MDMER and will reflect assimilation capacity of the receiving environment, such that any potential effects to the Surface Water Quality VC, and downstream water users, will be fully mitigated.

EOM Predictions- Killag River

During EOM conditions site water from the waste rock, low grade ore stockpiles and the pit will be routed through the North Settling Pond prior to discharge into the Killag River. Additionally, clean water from the site will be diverted and discharged directly to Mud Lake. There will also be clean discharge from the eastern till stockpiles to the Killag River. During PC conditions, site water from the waste rock stockpiles will be routed through the pit prior to discharge into the Killag River.

In summary, under the EOM scenarios, predicted mass balance near-field mixing zone and far-field mixing zone chemical concentrations in the base case are consistently below selected water quality benchmarks. The initial analysis assumed no treatment of mine contact water in the north settling pond and only analyzed the results from a mass balance (dilution) calculation at the extent of the predicted mixing zone. The results indicated that, while concentrations for some parameters are anticipated to increase above baseline levels, at the near-field mixing zone there are no exceedances of either CCME, NSE Tier 1 criteria. As water quality criteria are defined by national and international entities as protective of the receiving environment and all water users, there are no anticipated effects to surface waters are a result of discharges from the Project to the Killag River.

However, in the EOM upper case scenario, nitrite is predicted to exceed CCME regulatory guidelines in three months of the year. Note, modelling for the Project is conservative, and based on the principles of mass balance. That is, while mass and water balance models (including GoldSim) provide capabilities for simulating mass and water balances, these processes do not represent complete reaction paths and water quality predictions are expected to be further governed by in situ processes. This included equilibrium reactions, sorption reactions and solubility limits which, together, would generally service to reduce concentrations of many quality parameters predicted by the mass balance. In particular, nitrite is known to be unstable in oxygenated environments (such as the Killag River), oxidizing to Nitrate and/or bio-assimilated. Thus, it is likely that nitrite concentrations have been overestimated for the Killag River, in both base case and upper-case scenarios. However, in response to IR2, potential nitrite removal technologies have been identified and evaluated for the Project (Appendix P.4 Mine Water Management Plan, Appendix F.2 [Water Treatment Assessment – Operations).

Similarly, in response to IR2 issued by Canadian Environmental Assessment Agency and Nova Scotia Environment, and as a result of ongoing water quality and quantity and geochemical studies for the Project, water treatment for both EOM and PC is planned for the Project. Details for water management and evaluation of alternative water treatments are presented in Appendix F.3 (Post-Closure Water Treatment Assessment) in Appendix P.4 (Mine Water Management Plan). Note, the treatment system will be designed to ensure that all site effluent water meets MDMER and will reflect assimilation capacity of the receiving environment, such that any potential effects to the Surface Water Quality VC, and downstream water users, will be fully mitigated (Section 6.7.9).

PC Predictions- Killag River

During PC conditions the pit lake discharges into the Killag River directly. Predictions were generated for the PC at near-field mixing zone assessment point and PC far-field mixing zone assessment point. The initial analysis assumed no treatment of mine contact water in the pit lake and only analyzed the results from a mass balance (dilution) calculation at the extent of the predicted mixing zone. There is contingency for an interception trench during PC if there are potential impacts from the PAG pile on groundwater. Water from the interception trench will be directed to the pit and/or treated.

At the near-field and far field mixing zones the results from the analysis concluded that during base case scenario, while concentrations for some parameters are anticipated to increase above baseline levels, there are no exceedances of either CCME, NSE Tier 1 criteria. As water quality criteria are defined by national and international entities as protective of the receiving environment and all water users, there are no anticipated effects to surface waters are a result of discharges from the Project to the Killag River. However, results from the upper-case scenario suggest there is potential for a slight exceedance of the CCME guideline for cobalt and zinc in July and August, which is within range of natural variability. If monitoring data deviates from impact predictions, then water treatment will be undertaken.

Under the PC scenarios, there is little difference between predicted chemical concentrations at near-field mixing zone (pit lake discharge) and far-field mixing zone locations for each assessment each case. The results for the mass balance assessment during the base case PC scenarios the chemical concentrations are consistently below selected water quality benchmarks. In upper case PC scenarios, cobalt and zinc concentrations are predicted to exceed selected water quality benchmarks at both locations without during the months of July and August. An aquatic ecological risk assessment is provided in (Appendix G.2). If monitoring data deviates from impact predictions, then water treatment will be undertaken. Results for cobalt and zinc, are further discussed below:

- **Cobalt**, the predicted PC cobalt concentration at the near-field location marginally exceeds the Federal Environmental Quality Guideline (FEQG; 0.78 µg/L) in the upper case (0.8 and 0.85 µg/L in July and August; Table 6.7-35). The concentrations are up to 1.1 times the FEQG. A similar situation occurs with the PC far field location, wherein cobalt

concentrations are predicted to range between 0.8 to 0.84 µg/L in July and August (upper case; Table 6.7-39). Additional water quality modelling was conducted to confirm hardness levels in the receiving environment, following effluent release. his modelling indicates that hardness in the near field receiving environment is predicted to increase to 11.4 mg/L $CaCO_3$ in the PC upper case. These hardness levels are also predicted for the far field location. The FEQG considers hardness as a modifying factor, and was derived for water hardness values ranging between 52 to 396 mg/L. The FEQG of 0.78 µg/L represents the guideline value using a water hardness of 52 mg/L. Given that the water hardness in the near field receiving environment is predicted to be below this range, there is some uncertainty associated with the use of this guideline value. However, the SSD model developed by Environment Canada in this guideline setting approach is very conservative, and the data used in the assessment do not fit the selected model of the SSD in the lower quartile of the dataset well (see Figure 1; ECCC, 2017). This results in the estimated HC5 value being considerably lower than it should be, relative to the toxicity dataset. This indicates that the selected guideline is over predicting toxicity of cobalt, and hence, the marginal exceedances predicted are unlikely to pose a risk in the receiving environment. In addition, Dissolved Organic Carbon (DOC) is an additional modifying factor for cobalt toxicity (Stubblefield et al., 2020). This factor was not considered in the development of the FEQG, and would assist in mitigating potential for toxicity, based values that cobalt is largely non-detect in the baseline data, at a detection limit of 0.4 µg/L (Table 6.7-12). The predicted concentrations have been added to a mean value which may be biased high due to the non-detect samples. For additional context, it is interesting to note that Stubblefield et al. (2020) published two water quality guidelines for cobalt recently as follows:

- European-based approach and EC_{10} values and a species sensitivity distribution (SSD), yielding a median hazardous concentration for 5% of the organisms (HC5, 50%) of 1.8 µg/L; and
- A US EPA-style approach, using EC_{20} values in a SSD to derive a final chronic value (FCV) of 7.13 µg/L (note: this approach is more relaxed than typical Canadian approaches for deriving water quality standards, and hence, it is not recommended to use this value).

Neither of these approaches used hardness, or other water quality factors as modifiers. Based on the marginal degree of exceedance, the presence of elevated DOC concentrations, and increased hardness levels associated with the release of effluent, cobalt is considered unlikely to pose a risk to aquatic life:

- **Zinc**: The predicted concentrations do not exceed the new CCME guideline for zinc (7 µg/L) in the EOM scenarios for near field or far field. Additionally, predicted concentrations do not exceed the CCME guideline for zinc in the PC scenarios for near or far field in the base case, but do in the upper case. In the near field PC scenario, upper case predicted exceedances from the pit are 7.09 and 7.39 µg/L in July and August, respectively (Table 6.7-35). In the far field PC scenario, upper case predicted exceedances are 7.05 and 7.35 µg/L in July and August, respectively (Table 6.7-39). The Lowest observed effect concentration (LOEC) listed in the CCME (2018) fact sheet is 9.89 µg/L (11-week study; development; Chironomid sp.; normalized to 50 mg/L $CaCO_3$ and Dissolved Organic Carbon (DOC) of 0.5 mg/L). The predicted concentrations are within the range of background (<5 to 7.8 µg/L; based on sample size N=15). The waters of the Killag River are soft (<10 mg/L $CaCO_3$), but the DOC is reasonably high (ranging from 7 to 20 mg/L; mean of 12.2 mg/L, based on 2019 and 2020 data), and would be expected to provide adequate protection, for several of the months where predictions indicate elevated levels. Additional water quality modelling was conducted to confirm hardness levels in the receiving environment, following effluent release. This modelling indicates in the PC base case, hardness in the near field receiving environment is predicted to increase to 11.4 mg/L $CaCO_3$ in the PC upper case. These hardness levels are also predicted for the far field location. Based on these hardness levels, and accounting for site specific pH and DOC, the zinc guideline changes to 33 µg/L (based on an assumed mean hardness: 11.4 mg/L; mean pH: 5.43; mean DOC: 12.2 mg/L). None of the predicted concentrations exceed this guideline value, and hence, predicted zinc concentrations are considered to have a low potential for toxicity.

The site will be monitored during construction and operations. The outcomes from the modelling will inform updates to water quality model to refine PC predictions. The principals of adaptive management will be applied if the outcomes from modelling differ from those predicted.

In response to IR2 issued by Canadian Environmental Assessment Agency and Nova Scotia Environment, and as a result of ongoing water quality, water quantity and geochemical studies for the Project, water treatment for both EOM and PC is planned for the Project. Details for water management and evaluation of water treatment alternatives are presented (Appendix P.4 Mine Water Management Plan, Appendix F [Water Treatment Assessments]). Note, the treatment system will be designed to ensure that all site effluent water meets MDMER and will reflect assimilation capacity of the receiving environment, such that any potential effects to the Surface Water Quality VC, and downstream water users, will be fully mitigated.

Sedimentation and Erosion Effects to the Receiving Environment

Sedimentation/Erosion and dust deposition represent the primary pathways of interaction for the Project to Surface Water. Surface disturbance during Project activities has the potential to increase sedimentation and erosion of soils and overburden materials.

The potential effects on surface water quality from increased erosion and sedimentation are qualitatively assessed; erosion and sedimentation effects on surface water quality can be indicated primarily by changes in turbidity and total suspended solids (TSS) in surface water bodies. However, for the Project there is generally minimal risk of effects from erosion and sedimentation on surface water quality due to the limited extent of planned surface disturbances and the proposed use of pre-existing infrastructure such as roads, camp, and the processing facility

Mitigation and management strategies for erosion and sediment control will follow best management practices (BMPs). General strategies for erosion prevention are described in Section 6.7.9; specific details of mitigation and management strategies for the minimization of erosion and control of sediment, including specific BMPs to be applied during Project Construction, Operations, and Closure, are discussed primarily in the Erosion and Sediment Control Plan (Appendix P.4 Mine Water Management Plan, Appendix C). Where soil erosion may still occur despite preventative measures, sediment control strategies may be implemented to capture sediments before they are released to the receiving environment. The success of erosion management and sediment control measures would be monitored by regular inspection and maintenance of all water management and sediment control structures, which will include prompt attention to potential erosion sites, ditch or culvert failure and blockage, or outside seepage. Accumulated sediment would also be routinely removed from ditches and retention structures.

Potential residual effects from sedimentation and erosion are most likely to occur during the Construction and (active) Closure phases, when surface materials will likely be disturbed during construction or reclamation activities. As TSS loads are generally low in Project are streams, any additional sediment loading has the potential to increase TSS and turbidity in the receiving environment. Potential residual effects due to sedimentation and erosion have the greatest potential to occur during periods of significant overland flow, such as freshet and rainfall events. However, planned disturbances in the Project Area are limited, and implementation of BMPs and mitigation measures as summarized in Section 6.7.9 and detailed in the Mine Water Management Plan (Appendix P.4), and will prevent substantial change of surface water quality near the proposed access corridor and other planned site upgrades. Further, water quality responses to run-off include increased concentrations of TSS but tend to be temporary and localized (Forman 1998).

pH Effects to the Receiving Environment

Effects on indicators of Surface Water Quality (total and dissolved metals, anions, and nutrients; mg/L) were either assessed quantitatively by predictive water modelling, as describe above, or qualitatively based on geochemical characterization studies and professional judgement and experience (e.g., pH and TSS). pH cannot be predicted with certainty by mass-balance models as used here. That is, while modelling for the Project is conservative, mass balances modelling processes/predictions do not represent complete reaction paths and thus for non-conservative parameters (such as pH) water quality predictions are expected to be further governed by in situ processes. Note, discharges from the project will be subject to the MDMER such that effluent concentrations must be within pH range of 6.0 to 9.5, which is protective of aquatic life. Therefore, there are no effects to Surface Water Quality as a result of Project effluent discharges.

6.7.8.3 Surface Water Quality Effects: Haul Road

6.7.8.3.1 Sedimentation and Erosion Effects

Sedimentation/Erosion and dust deposition represent the primary pathways of interaction for the Project to Surface Water. Surface disturbance during Project activities has the potential to increase sedimentation and erosion of soils and overburden materials. As described above for the Beaver Dam Mine Site, potential effects on surface water quality from increased erosion and sedimentation are qualitatively assessed; erosion and sedimentation effects on surface water quality can be indicated primarily by changes in turbidity and total suspended solids (TSS) in surface water bodies. However, for the Project there is generally minimal risk of effects from erosion and sedimentation on surface water quality due to the limited extent of planned surface disturbances and the proposed use of pre-existing infrastructure such as roads, camp, and the processing facility.

At the Haul Road, portion of the road will have to be widened to accommodate two-way traffic. However, some deviations in the existing route may be required as described in the Project Description (Section 2). Water courses potentially affected by development and use of the Haul Road are identified in Table 6.7-40.

Table 6.7-40: Watercourses Directly Impacted by Beaver Dam Mine Site Infrastructure and Haul Road

Watercourse ID	Total Delineated Watercourse Length (m)	Estimated Direct Impact Length (m)	Estimated Direct Impact Area (m^2)[a]	Infrastructure	Fish Habitat Potential?

Notes: [(a)] Average wetted width used to calculate estimated impact area. m = meter; m^2 = square meter.

The Haul Road crosses three watercourses, which are between 6 and 13 m wide, via single lane timber bridges. These bridges will be replaced with dual lane, clear-span, pre-engineered, single arch modular bridges designed to not result in any impediment on water flow and fish passage. The road also crosses several smaller watercourses. Detailed discussion on current condition of culverts including recommendation on culvert replacements in provided in Fish and Fish Habitat effects assessment (Section 6.9 in Table 6.9-17 Potential Direct Fish Habitat Impacts within the Haul Road).

Water quality effects due to erosion and sedimentation will be mitigated by implementation of the draft Erosion and Sediment Control Plan (Appendix P.4 Mine Water Management Plan, Appendix C); mitigation and management strategies for erosion and sediment control will follow best management practices (BMPs); general strategies for erosion prevention are summarized in Section 6.7.9.

The success of erosion management and sediment control measures would be monitored by regular inspection and maintenance of all water management and sediment control structures, which will include prompt attention to potential erosion sites, ditch or culvert failure and blockage, or outside seepage. Accumulated sediment would also be routinely removed from ditches and retention structures.

At the Haul Road, potential residual effects from sedimentation and erosion are most likely to occur during the Construction and (active) Closure phases, when surface materials will likely be disturbed during construction or reclamation activities. As TSS loads are generally low in Project area streams, any additional sediment loading has the potential to increase TSS and turbidity in the receiving environment. Potential residual effects due to sedimentation and erosion have the greatest potential to occur during

periods of significant overland flow, such as freshet and rainfall events. However, planned disturbances in the Project Area are limited, and implementation of BMPs and mitigation measures as summarized in Section 6.7.9 and detailed in Environmental Management and Monitoring Plans; these , and will prevent substantial change of surface water quality near the proposed access corridor and other planned site upgrades. Further, water quality responses to run-off include increased concentrations of TSS but tend to be temporary and localized (Forman 1998).

6.7.8.3.2 Dust Deposition

Sedimentation/Erosion and dust deposition represent the primary pathways of interaction for the Project to Surface Water. In response to CEAA-2-36, CEAA-2-37 and NSE-2-130 (AMNS 2021) and included in Appendix F.9 (Evaluation of Potential Impacts from Metals COCs to Groundwater and Surface Water from Dust Deposition along the Haul Road), potential effects on surface water quality (and groundwater) from dust deposition were quantitively assessed by air dispersion modelling. Appendix F.9 presents the air dispersion model and associated results, including the quantitative evaluation of potential impacts to surface water from metals found in dust that may be deposited on surficial soil and surface water along the Haul Road for the Project. Table 6.7-41 summarizes the results of the air dispersion modelling relative to maximum annual dust deposition rates, in terms of total particulate, at the sensitive receptor locations and Haul Road sections where maximum dust deposition occurs.

Table 6.7-41: Maximum Predicted Annual Deposition Rates for Total Particulate, Haul Road

Sensitive Receptor ID and Description	Project Alone[(a)] (g/m^2-yr)	Cumulative Project and Nearby Projects[(a)] (g/m^2-yr)
R1 9 Beaver Dam Mine Road (Marlborough Property)	27.9	31.5
R2 4112 Highway 224 (Beaver Lake IR 17)	0.3	0.3
R3 4115 Highway 224 (Cottage on Crown land)	0.8	0.9
R4 3492 Highway 224 (Hobbs Property)	45.1	50.9
R5 3379 Highway 224 (McLeod Property)	6.0	6.7
R6 3373 Highway 224 (Smith Property)	5.0	5.6
R7 Tangier River (Deepwood Estates Property)	82.4	93.1
R8 Tangier River (Musqudoboit Lumber Co Ltd. Property/John Dickson Lease)	11.7	13.2
R9 5579 Mooseland Road (Lloy Property)	36.5	41.2
Road Section R1	227.6	257.2
Road Section R9	194.4	219.7
Road Section STP	224.5	253.7
Road Section East Corner	210.2	237.5

Notes: [(a)] Annual dust deposition rates correspond to 80% dust suppression. g/m^2-yr = grams per squared metres per year.

Modelling results indicated that highest maximum annual deposition rate along the Haul Road occurs at Road Section R1, and the maximum annual deposition rate for a sensitive receptor occurs at Sensitive Receptor R7, both of which correspond to the cumulative condition where the Haul Road is utilized for the Project as well as the nearby projects.

To assess the impact of dust deposition on downstream surface water bodies through surface water runoff, the maximum dust deposition rate at Road Section R1 for the cumulative condition (i.e., the Project as well as the nearby projects) also is assumed to occur over all 9 years of Haul Road use and is applied to estimate metals COCs concentrations in surface water runoff; complete details of modelling methodologies, including estimate of metal concentrations in soil leachate and surface water runoff, are

provided in Appendix F.9 (Evaluation of Potential Impacts from Metal Contaminants of Concern to Groundwater and Surface Water from Dust Deposition along the Haul Road).

Summary findings of dust deposition effects are presented in Table 6.7-42 and Table 6.7-43 and provide the estimated metals concentrations in in surface water runoff from Road Section R1, and in Ferry Lake surface water. Ferry Lake is located approximately 1.5 km southeast of the Haul Road and is the only surface waterbody that was identified as a potable water supply in the vicinity of the Haul road. Results indicate that concentrations are below applicable surface water quality guidelines/criteria.

b) CCME, 2020: Water Quality Guidelines for the Protection of Aquatic Life

g/yr = grams per year; COC = contaminant of concern; µg/L= micrograms per litre.

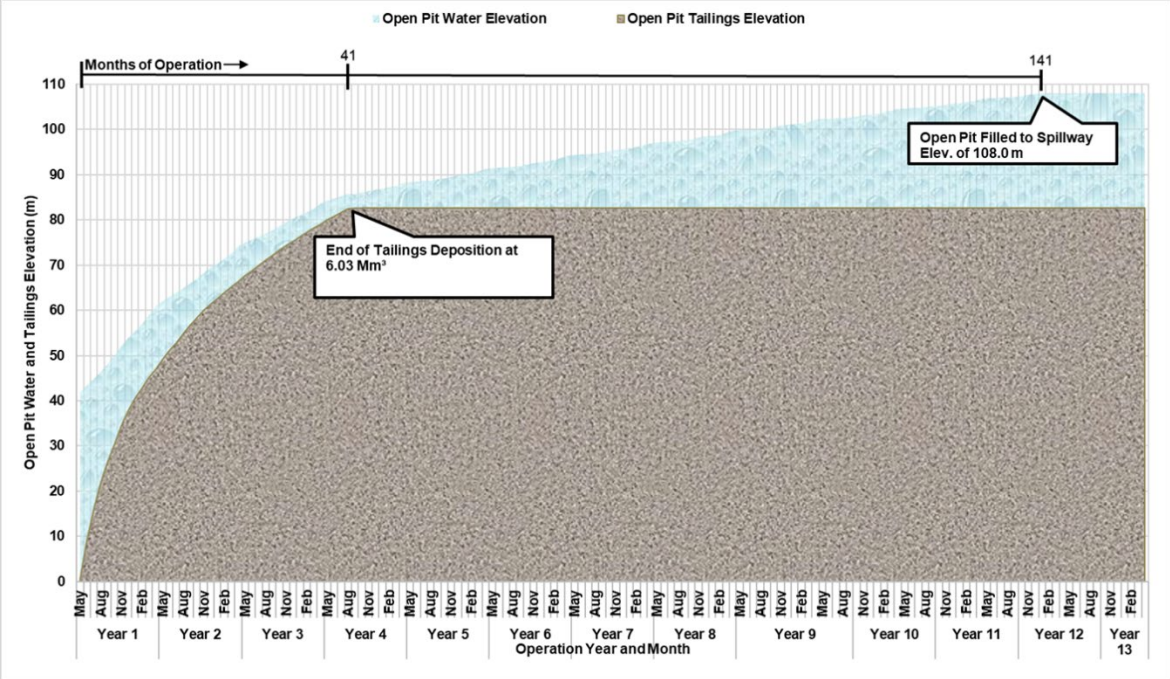
Results indicate that the estimated metals COCs concentrations in at Sensitive Receptor R7, in surface water runoff from Road Section R1, and in Ferry Lake surface water are below the respective water quality criteria. As water quality criteria are defined by national and international entities as protective of the receiving environment and all water users, there are no anticipated effects to surface waters are a result of dusting and emission along the Haul Road.

6.7.8.4 Surface Water Effects: Touquoy Mine Site

The primary potential effect of the continued use of the Touquoy facility on surface water quality is the use of the exhausted open pit for tailings storage with possible seepage degrading surface water quality in receiving environments and the potential for accidents and malfunctions as described in Section 6.18.

Deposition of Beaver Dam Mine tailings in the exhausted Touquoy open pit will accelerate the time to naturally fill the pit and create a pit lake during reclamation. However, this does not change the environmental effects predicted for the reclamation and closure plans for the existing Touquoy Mine Site as it simply changes the total time for the pit to fill. Project effects are discussed further in the sections below.

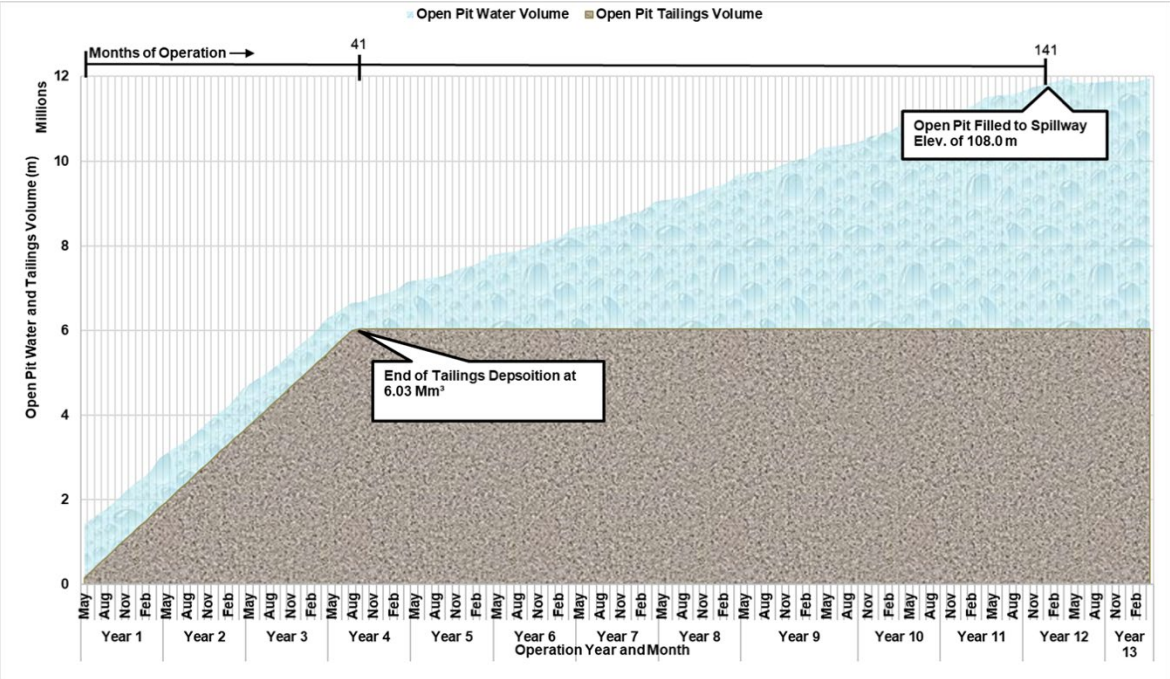
6.7.8.4.1 Surface Water Quantity Modelling Results



Accelerated Filling of the Pit

As originally planned in the approved Touquoy Gold Mine Project Reclamation Plan (Stantec 2017b), the inflow of groundwater, surface flow and precipitation into the pit will naturally create a lake upon closure of the site. No change to this method is planned to follow the deposition of Beaver Dam tailings, except that the time to fill the pond is accelerated given the decrease in available volume taken by the tailings.

Based on a three-dimensional model of the Touquoy ore body presented in the water and tailings management plan (Appendix F.7 [Touquoy Integrated Water and Tailings Management Plan]), the total storage capacity of the exhausted open pit at the maximum surface water elevation of 108 m CGVD2013 is estimated at 8.962 Mm^3. The water balance model predicted the amount of water and tailings stored in the pit until the pit was filled to 108 m CGVD2013. Based on results of the water balance model and the derived elevation storage relationship, tailings will be deposited in the open pit for a total of 41 months reaching an elevation in the pit of 93.2 m CGVD2013. This amounts to approximately 14.8 m of water cover above the tailings, assuming the spillway invert elevation of 108 m CGVD2013. The water balance model simulated that it would take an additional 100 months or a total of 141 months from commencement of operation to fill the pit to the spillway invert elevation. Figures 6.7-15 and 6.7-16 illustrate the predicted elevation and storage of tailings and water in the exhausted Touquoy open pit over the simulation period.



Initially, process water will be reclaimed at a rate of 8,960 m^3/d from the existing Touquoy TMF until surplus water storage in the pond is depleted. Based on results of the water balance model under climate normal conditions, three to five months of process water surplus will be available depending on the month of start-up. Subsequently, process water will be reclaimed from the exhausted Touquoy open pit at the same rate, recirculated as a closed loop through the mill facility during the remaining period of processing Beaver Dam ore at the Touquoy facility. As the current practice at Touquoy, this water management strategy reduces the quantity of mine contact water or the at the site and a lower demand on freshwater supplies.

Figure 6.7-15: Tailings and Water Elevation in the Exhausted Touquoy Open Pit

Source: Stantec 2021.

Figure 6.7-16: Tailings and Water Storage in the Exhausted Touquoy Open Pit

Source: Stantec 2021.

Extended Withdrawal from Scraggy Lake

As discussed above, process freshwater make-up requirements for Beaver Dam ore processing are similar to existing Touquoy operation. Freshwater make-up for the process is sourced from Scraggy Lake, as conducted under existing operations associated with processing the Touquoy ore. Additional make-up process water required in a dry year or to build a reservoir in case of a dry year will be sourced from effluent from the TMF treatment plant or Scraggy Lake, subject to NSE approval. Incremental effects to surface water quantity at Scraggy Lake is not expected, in the event water withdrawal is necessary.

Water Management in Open Pit

A spillway is proposed to be installed to prevent the pit lake from overtopping during refilling (NSE-2-197). The capacity of the spillway will be sized to accommodate the Canadian Dam Association inflow design flood and associated freeboard requirements for wind run-up and wave set-up and in consideration of DFO requirements. The spillway will discharge to a conveyance channel that outlets to Moose River, approximately 70 m downstream of the surface water monitoring station SW-2. As the predevelopment and post development catchment areas draining to the discharge location at Moose River are similar, Moose River is capable of handling the resultant flows.

A geotechnical investigation will be completed prior to the detailed design of the spillway to identify the overburden and bedrock materials that may be encountered during construction of the spillway. Any required erosion and scour protection of Moose River at the discharge location will be considered in design, as well as the roadway crossing. There are no changes in surface water management of the Touquoy pit catchment from tailings deposition in the TMF to tailings deposition in the open pit, with the exception of the timing to discharge to Moose River.

The footprint of the proposed spillway overlaps with an area of delineated historical tailings. The historical tailings encountered within the construction footprint for the spillway will be relocated to an historical tailings containment cell in the existing Touquoy TMF along with other excavated historical tailings prior to the closure of the containment cells. Blasting may be required to construct the proposed spillway. Blasting would be conducted in accordance with DFO guidelines for blasting near a watercourse. A culvert will be installed to facilitate the spillway under the road present in the proposed location of the spillway.

6.7.8.4.2 Surface Water Quality Modelling Results

Mill Process to Reduce Cyanide Concentrations in Tailings Slurry

Tailings will be subject to cyanide destruction at the process plant before flowing to the exhausted Touquoy pit. Based on water quality monitoring results at the Touquoy Mine Site for existing operation, cyanide destruction to cyanate is 99.5% effective (Lorax, 2018). Cyanate decomposes harmlessly. The majority of the residual cyanide reagent introduced to the tailings during ore processing will be degraded and hydrolyzed to carbon dioxide and ammonium during storage in the tailings pond. Similarly, this will be expected to occur for the tailings being stored in the Touquoy pit. Based on the efficiencies of cyanide destruction to cyanate (i.e., cyanide recovery) in the existing Touquoy TMF of 99.5%, there is no expectation that cyanide recovery will be an issue in processing of Beaver Dam ore. Potential failures related to cyanide recovery and proposed Touquoy pit disposal will be addressed in the Touquoy groundwater contingency plan as required in the Industrial Approval.

Degraded Pit Water Quality due to Tailings Deposition

Mill operation for Beaver Dam ore processing is planned to be consistent with Touquoy ore processing. A total of 7.84 Mt Beaver Dam ore will be processed at the existing Touquoy mill facility, extending operation at the Touquoy Mine Site for approximately an additional 41 months. Beaver Dam ore processing amounts to approximately 6.03 Mm^3 of tailings deposited sub-aqueously in the exhausted open pit. Deposition of tailings in the exhausted open pit is simulated to degrade the water quality in the pit compared to naturally filling of the pit as per the Touquoy reclamation plan (Stantec 2017b).

As presented in the technical report (Appendix F.8 Project Assimilative Capacity Study of Moose River - Touquoy Open Pit Discharge), the water quality model characterized this change in pit water quality in operation and reclamation. As described in the Geochemical Source Terms Update (Lorax, 2018) in Appendix E.3, water quality modelling considered the pore water quality in the tailings and the pit floor/ walls, the dilution from surface runoff and direct precipitation in the pit and the water quality of the mixture based on the geochemistry of the individual water quality parameters. For Beaver Dam, geochemical source term predictions were derived from upscaling of kinetic tests and Touquoy monitoring data, to represent the pore water quality of pit walls/floor in the water quality model. Pore water is expected to have elevated metal (e.g., arsenic, cobalt, copper), ammonia, nitrate and cyanide concentrations thus reducing pit lake water quality at the time of discharge. Results of the water quality model in the exhausted open pit over time for metals, ammonia, and cyanide parameters are presented in the technical report provided in Appendix F.8.

Based on the water balance model results (Appendix F.8), no water will be discharged from the exhausted Touquoy open pit until the pit reaches the spillway elevation in Year 12. This allows for many years of water treatment in the pit as a batch reactor with the objective of adjusting the pH to precipitate metals, potentially improving discharge criteria toward MDMER discharge criteria. As an additional benefit of the slow filling of the pit over time, the residence time and exposure to the atmosphere will increase, thus enhancing the natural UV degradation of cyanide and improving water quality in the pit lake.

The water quality in the Touquoy open pit will be monitored during the pit filling and as the pit level approaches the spillway elevation. The water quality will be compared to the MDMER discharge limits and will be treated as required to meet these limits. The MDMER discharge limits will decrease from the existing limits to those presented in Table 6.7-15 effective June 2, 2021. The discharge from the Touquoy Mine Site is anticipated to occur after this period, and therefore the lower MDMER limits will apply.

Change to Moose River Water Quality from Effluent Discharge and Groundwater Seepage

The water quality model of Moose River predicts the effluent concentrations under normal discharge from the Touquoy open pit combined with the groundwater seepage contributions in Moose River under the same climate conditions. Moose River will primarily be driven by climatic conditions, and April flows were selected in the modelling to represent a worst-case dilution ratio between the effluent discharge from the Touquoy open pit and Moose River. This results in conservatively higher estimates of mass loadings to the receiving environment from the Project.

It is important to note that the NS Tier 1 guideline of 5 µg/L (which is based on the CCME guideline), is for free cyanide. This guideline is not a relevant guideline to compare Total cyanide, SAD or even WAD forms of cyanide to, as it is based on the free ion, as opposed to bound forms of cyanide, which have far lower toxic potential. Based on the receiving environment predictions, WAD cyanide is approximately half of the Total Cyanide predicted concentration (0.0032 mg/L WAD, compared to 0.0074 mg/L Total). This implies that the half of the Total Cyanide prediction would be SAD, and hence, less likely to dissociate in the receiving environment (mean pH in receiving environment is 6.05). Predicted WAD concentrations in the receiving environment are below the NS Tier 1 guideline, indicating acceptable levels of risk to aquatic life. Based on this, risk to aquatic life are predicted to be low.

Predicted cobalt levels in the receiving environment (0.0011 mg/L) marginally exceed the new FEQG for cobalt (0.00078 mg/L), but are less than the NS Tier 1 cobalt value of 0.01 mg/L. The FEQG considers hardness as a modifying factor, but the SSD model developed by Environment Canada in this guideline setting approach is very conservative, and the data used in the assessment do not fit the selected model of the SSD in the lower quartile of the dataset well (Figure 1; ECCC, 2017). This results in the estimated HC5 value being considerably lower than it should be, relative to the toxicity dataset. This indicates that the selected guideline is over predicting toxicity of cobalt, and hence, the marginal exceedance is not considered to represent a concern, with respect to toxicity to aquatic species. Cobalt concentrations are predicted to decrease to 0.0010 mg/L by 120 m from the effluent discharge point (Appendix F.8, Table 10 [Project Assimilative Capacity Study of Moose River - Touquoy Open Pit Discharge]), which is 0.1 ppb above the guideline. Risks to aquatic life at this concentration are anticipated to be low (Appendix G.2).

If required during the Closure Phase, the water level in the Touquoy pit will be maintained through pumping to a water treatment plant at or beneath the permeable bedrock layer at 104 m elev. until water quality improves to meet discharge criteria. This low pit water level will provide more than adequate storage of the inflow design flood and freeboard as the lowest Touquoy pit level at surface is at 108 m elevation. As the Touquoy pit has approximately 14.8 m of water cover assuming a spillway invert of 108 m, the potential for settled tailings to be resuspended due to wind or wave action is unlikely with little potential of tailings deposited in the exhausted Touquoy pit to migrate to Moose River. This water cover over the deposited tailings will limit oxygen thus reducing metal leaching conditions and further improving water quality in the pit.

Based on the predictive modelling conducted, only Total cyanide and cobalt were predicted to exceed the selected benchmarks. For Total cyanide, the selected benchmark was the NS Tier 1 guideline, which is based on free cyanide, and hence not a relevant benchmark for comparison purposes. Based on the available toxicity data and predictions, Total cyanide is unlikely to be present in concentrations of concern to aquatic life. Cobalt predictions marginally exceed the new FEQG for cobalt (ECCC, 2017a), but do not exceed the NS Tier 1 guideline. The conservative nature of the SSD calculation within the FEQG for cobalt is potentially resulting in a biased low guideline, and based on comparisons to available toxicity data, cobalt at the predicted concentrations is not expected to result in adverse effects in aquatic life in the receiving environment.

As the pit water is planned to be treated to MDMER and any regulatory closure criteria or site-specific guidelines prior to discharge, the magnitude of the effect is expected to be negligible on Moose River quality and downstream tributaries. Discharge and seepage flow from the pit to Moose River during closure will be permanent and will occur regularly based on climate conditions. The change

on water quality of Moose River will be irreversible. The environmental effect is considered not significant after mitigation measures have been implemented.

Dilution of Pit Lake from Freshwater Make-up

Process freshwater make-up water requirements of approximately 5.8% of production or 503 m^3/d will be sourced from Scraggy Lake as per the existing NSE approval for Touquoy ore processing or other sources as directed in the NSE approval for Beaver Dam. Should additional process make-up water be required in a water reclaim deficit scenario than the Scraggy Lake supply will be supplemented with treated effluent from the existing Touquoy polishing pond. As surface water quality in the polishing pond meets effluent discharge criteria based on surface water quality results for Touquoy, the make-up water pumped to the open pit is not expected to degrade the pit lake quality and may benefit water quality through dilution.

6.7.9 Mitigation

Design and operation of surface water management infrastructure represents a key aspect of planned mitigation and management activities; surface water management infrastructure at the existing Touquoy mine and the proposed Beaver Dam Project have been developed to attain the following performance objectives:

1. minimize the amount of precipitation and runoff that comes into contact with potential contaminant sources during mine operations through surface water diversions;

2. avoid effects to surface water and downstream water users by collecting and capturing all potentially contaminated water for mine reuse (reclaim water) or directing to water treatment prior to offsite discharge; and

3. manage and control other non-contaminated surface water on the Project site.

A summary of planned mitigation and management measures are provided in Table 6.7-44 and the underlying sections. Complete details are presented in the Mine Water Management Plan, presented in Appendix P.4.

6.7.9.1 Water Treatment and Project Discharges

Predictive modelling for the Project (Section 6.7.8.2) indicated that, while concentrations for some parameters are anticipated to increase above baseline levels there are no exceedances of either CCME, NSE Tier 1 criteria. As water quality criteria are defined by national and international entities as protective of the receiving environment and all water users, there are no anticipated effects to surface waters are a result of discharges from the Project to the Killag River and so Water Treatment is not likely to be required.

However, in uppercase scenarios and predictions, modelling for the Project is suggestive of a need for water treatment for some parameters under these conditions. In response to IR2 issued by Canadian Environmental Assessment Agency and Nova Scotia Environment, water treatment for both EOM and PC is planned for the Project as a means to plan for and mitigate water quality if uppercase predictions were realized. Details for water management and planned water treatments are presented in the Mine Water Management Plan (Appendix P.4).

6.7.9.2 Sedimentation and Erosion

A draft Erosion and Sediment Control Plan (Appendix P.4 Mine Water Management Plan, Appendix C) will be implemented during construction and operation to mitigate the release of sediment from the mine site to the receiving surface water systems. A draft Erosion and Sediment Plan is included in Appendix P.4, Appendix C.

General strategies for erosion prevention are:

- minimizing clearing and grubbing dimensions during construction activities;
- controlling and directing runoff from disturbed areas by grading slopes and ditching;
- re-vegetating disturbed areas;
- limiting the length and steepness of bare, exposed slopes to minimize runoff energy;
- applying appropriate surface drainage techniques (e.g., ditch blocks, ditch surface lining, and rip-rap);
- stabilizing water diversion channels and ditches and protecting channel banks with rocks, gabions, or fibre mats; and
- protecting disturbed areas from water erosion and collecting surface water from disturbed areas for treatment, if required, to meet discharge standards prior to release.

Where soil erosion may still occur despite preventative measures, sediment control strategies may be implemented to capture sediments before they are released to the receiving environment. Sediment control measures may include installation of, for example:

- silt fences;
- weed-free straw bales;
- check dams;
- fabric-covered triangular dikes;
- gravel or sand-filled burlap bags;
- sedimentation ponds; and
- rip-rap along channels and ditches

Table 6.7-44: Mitigation Program for Surface Water Quantity and Quality

Mitigation Category	Project Phase	Mitigation Measure
Quality	C, O, CL	• Use of the following structures, as needed: • Silt fences • Silt curtains • Riprap • Check dams
	C, O, CL	• Limit exposed soil
	C, O	• Implement Erosion and Sediment Control Plan

Table 6.7-44: Mitigation Program for Surface Water Quality and Quantity (continued)

Mitigation Category	Project Phase	Mitigation Measure
	O, CL	• Segregate and manage waste rock with the potential for acid generation
	O	• Use adequately sized settling and containment ponds as required
	O	• Use flocculants and coagulants as required
	C, O	• Install perimeter ditches around site infrastructure
	O	• Provide appropriate settling time for suspended solids prior to discharge
	O	• Ensure pit water meets applicable regulatory quality criteria for discharge – otherwise treat water prior to discharge
	O	• Direct drainage ditches to designated settling ponds or other locations
	C, O	• Use above ground fuel storage tanks that meet applicable regulatory standards
	C, O	• Select appropriate type of explosive that will minimize nitrogen release to surface water and groundwater
	C, O	• Implement Surface Water Management Plan
	C, O	• Develop and implement an Emergency Response Spill Contingency Plan
	C, O	• Use clean, non-ore-bearing, non-watercourse derived and non-toxic materials for erosion control methods
	C, O, CL	• Sub-aqueous deposition of mine tailings to reduce/prevent oxides and leaching
	CL	• In the event of the potential for acid rock drainage and metal leaching, implement additional studies required to assess to actual risk and, as warranted, implement mitigative measures that will manage the source material and drainage effectively utilizing methods such as segregation and encapsulation
	C, O, CL, PC	• Minimize snow deposition into watercourses during snow removal activities
Quantity	C	• Construct drainage ditches and ponds to maintain natural flow directions when practical
	O	• Control release of settling ponds to mimic natural hydrograph, where practicable
	O	• Recycle site water for reuse wherever practical to reduce water withdrawal from lakes or streams
	O	• Recycled water must meet acceptable water quality criteria for its intended use

Notes: C = Construction; O – Operations; CL = Active Closure; m = metre; PA = Project Area.

6.7.10 Residual Effects and Significance

Table 6.7-45 presents a summary of the assessment of potential environmental effects on surface water quality. The assessment of residual effects incorporated mitigation and management plans for Project effects as included in the proposed Project design and described in Appendix P.4 (Mine Water Management Plan). However, the proposed mitigation cannot eliminate the Project-related residual effect on water quality, and the following residual effects were identified:

- change in concentrations of total and dissolved metals, anions, and nutrients, and conductivity in the receiving environment due to direct discharge, groundwater interactions and seepage, and ML/ARD;
- change in nutrient concentrations in the receiving environment due to nitrogen loading from explosives; and
- change in turbidity and TSS in the receiving environment due to erosion and sedimentation.

The following sections summarize the effects assessment for each project area (Section 6.7.8) and present the residual effect characterization as per the methodology outlined in Section 6.7.7.

6.7.10.1 Beaver Dam Mine

A summary of the predicted surface water quantity impacts, detailed above, of the mine are provided below:

- The potential effects on surface water quality from increased erosion and sedimentation are qualitatively assessed; potential residual effects from sedimentation and erosion are most likely to occur during the Construction and (active) Closure phases, when surface materials will likely be disturbed during construction or reclamation activities. As TSS loads are generally low in Project area streams, any additional sediment loading has the potential to increase TSS and turbidity in the receiving environment. Potential residual effects due to sedimentation and erosion have the greatest potential to occur during periods of significant overland flow, such as freshet and rainfall events. However, planned disturbances in the Project Area are limited, and implementation of BMPs and mitigation measures as summarized in Section 6.7.9 and detailed in Environmental Management and Monitoring Plans, and will prevent substantial change of surface water quality near the proposed access corridor and other planned site upgrades. Further, water quality responses to run-off include increased concentrations of TSS but tend to be temporary and localized (Forman 1998).
- The proposed development of the Beaver Dam Mine Site results in small increases in streamflow volume at the Killag River assessment point defined in the water balance analysis (Appendix A [Water Balance Analysis] of Appendix P.4 Mine Water Management Plan). The predicted increase in annual streamflow is 2.2% in EOM conditions and 1.1% in PC conditions. The small increases are a result of the change in land cover and the diversion away from the adjacent watersheds to the Killag River.
- There will be a 4.4% decrease in annual discharge from Crusher Lake due to the proposed water extraction to meet the domestic water demand. The proposed development results in a <1% increase in Crusher Lake discharge in PC conditions, and 18.3% and 13.7% decreases in Mud Lake discharge in EOM and PC conditions, respectively. The hydrologic impacts to Mud Lake are due to the placement stockpiles and influence of the open pit on groundwater flow patterns in the catchment.
- The proposed development results in a 1.1 to 1.2% and 5.7% reduction in annual streamflow volume at the Tent Brook and Cope Brook assessment points, respectively, in both EOM and PC conditions. The impacts to the Tent Brook system are considered to be minor. The impacts to the Cope Brook system are due to the placement of the waste rock stockpile in its baseline catchment.

A summary of the predicted surface water quality impacts of the mine are provided below:

- The results of the predictive water quality assessment demonstrate the need for treatment of the mine effluent water prior to discharge to the Killag River.
  - Nitrite (EOM) and cobalt and zinc (PC) have the potential to exceed CCME, background or site-specific guidelines within the Killag River at the near-field mixing zone locations and far-field mixing zone location.
- Treatment will occur, as required, prior to discharge into the receiving environment to ensure discharge meets MDMER regulations and concentrations in the Killag River do not exceed CCME or site-specific guidelines.
- It is unlikely ARD onset will occur during the operations phase (5 years). An engineered will be placed immediately following operations during active closure.
- At closure, the pit will be filled by diverting all surface site water to the pit, therefore submerging most of the exposed pit walls with water. This should eliminate most of the risk associated with pit wall runoff.
- Initial predictions indicate that it will take 20 to 30 years for half of the Beaver Dam Mine PAG waste rock to turn acidic.
- As part of the final closure plan, AMNS will develop and implement a Beaver Dam Mine draft ML/ARD Management Plan (draft plan is provided in Appendix E.5). This plan will determine the path forward for continued kinetic test work for Beaver Dam waste rock samples during operations and monitoring to determine if mitigation is required to manage potentially long-term acidic conditions associated with PAG waste rock at the Beaver Dam Mine Site.
- If this Plan confirms that acidic conditions are predicted during the closure phase, appropriate mitigation will be applied (refer to Section 6.7.9 for mitigation measures).

6.7.10.2 Haul Road

At the Haul Road, potential residual effects from sedimentation and erosion, as well as dusting/air deposition, are most likely to occur during the Construction and (active) Closure phases, when surface materials will likely be disturbed during construction or reclamation activities. As TSS loads are generally low in Project are streams, any additional sediment loading has the potential to increase TSS and turbidity in the receiving environment. Potential residual effects due to sedimentation and erosion have the greatest potential to occur during periods of significant overland flow, such as freshet and rainfall events. However, planned disturbances in the Project Area are limited, and implementation of BMPs and mitigation measures, summarized in Section 6.7.9 and detailed in Environmental Management and Monitoring Plans, will prevent substantial change of surface water quality near the proposed access corridor and other planned site upgrades. Further, water quality responses to run-off include increased concentrations of TSS but tend to be temporary and localized (Forman 1998).

6.7.10.3 Touquoy Mine Site

A summary of the predicted surface water quantity impacts, detailed above, of the mine are provided below:

The use of the exhausted Touquoy pit for tailings storages will result in the accelerated filling of the pit from that of the Touquoy reclamation plan.

- Tailings will be deposited in the open pit for a total of 37 months reaching an elevation in the pit of 90.5 m (CGVD 2013). This amounts to approximately 17.5 m of water cover over the deposited tailings based on a spillway elevation of 108 m CGVD 2013 and will limit oxygen, reduce metal leaching conditions and further improved water quality.
- No water will be discharged from the exhausted Touquoy open pit until the pit reaches the spillway elevation in Year 9.
- Water withdrawal from Scraggy Lake will require to be extended for an additional three years for processing Beaver Dam ore.

The use of the exhausted Touquoy pit for tailings storage of Beaver Dam tailings effect the receiving environment of Moose River through seepage and effluent discharge. As the pit lake is planned to be treated to MDMER limits and any regulatory closure criteria or site-specific guidelines prior to discharge, the magnitude of the effect is expected to be low to negligible on Moose River quality and downstream tributaries.

- The predicted receiving environment concentration of arsenic of 0.023 mg/L; risks to aquatic life associated with predicted arsenic concentrations are anticipated to be low.
- The aluminum concentration of 0.184 mg/L for aluminum is well with the natural variation of existing conditions of the Moose River; i.e., predicted below the 75th percentile receiver quality in Moose River.
- Concentrations of key parameters of interest (arsenic, cobalt, copper and nitrite) in groundwater were predicted in the model to meet CCME FAL/NSE EQS after mixing with Moose River 100 m downstream of the discharge point.

There are no further effects to surface water quality or quantity anticipated to be caused by the processing of ore and the management of tailings (exhausted pit) from the Beaver Dam Mine. Surface water quality and quantity will continue to be monitored over the life of the Touquoy facility as part of existing approval for the Touquoy mine life and the revised approval for the proposed extended life of the Touquoy site associated with processing of Beaver Dam ore.

The overall residual effect of the Project on surface water is assessed as not significant after mitigation measures have been implemented (Table 6.7-45). The moose river will be monitored as part of the EEM program to confirm impact predictions and if necessary adaptive management will be applied to the operation.

Table 6.7-45: Residual Environmental Effects for Surface Water Quantity and Surface Water Quality

Value Component (VC)	Project - VC Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
			Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Surface Water Quantity	Construction – Beaver Dam Mine Site and Haul Road	Project Design to evaluate hydrology patterns. Erosion and Sediment Control Measures	Low Minor changes from baseline conditions	Discrete Effects are confined to the PA (Beaver Dam Mine Site and Haul Road)	N/A	Short-Term	S VC interaction will occur at irregular intervals throughout construction phase	Reversible to Partially Reversible	Change in Water Quantity (baseflow, stream flow in Mud Lake and WC23, WC26 due to project development/construction of water management diversions etc.)	Not Significant
Surface Water Quality	Construction – Beaver Dam Mine Site and Haul Road (TSS and Dust Deposition)	Project Design to evaluate hydrology patterns. Erosion and Sediment Control Measures	Low Minor changes from baseline conditions	Discrete Effects are confined to the PA (Beaver Dam Mine Site and Haul Road)	N/A	Short-Term Effects can occur beyond 12 months and up to three years	S VC interaction will occur at irregular intervals throughout construction phase	R VC will recover to baseline conditions	Change in Water Quality Disturbance	Not Significant
Surface Water Quantity	Beaver Dam Mine Site (Crusher Lake, Killag River, Tent Brook)	Surface water from pit dewatering activities will be designed to discharge back into Cameron Flowage/Killag River at rates to mimic seasonal flows, where practicable.	Negligible to Low Minor changes from baseline conditions	Local Effect are confined to the near-field assessment area	N/A	Short-Term to Medium Term	R Effects will occur at regular intervals throughout operations	Reversible VC will recover to baseline conditions once project activities have been completed	Change in hydrology in Cameron Flowage/Killag River	Not Significant
	Beaver Dam Mine Site (Reduction in base flow to WC26 and WC23)	Predicted flow reduction. Monitoring to confirm, watercourse alteration permitting, fisheries authorization, if required	Low to High VC interaction Causes reduction in surface flow	Discrete Effects are confined to the Beaver Dam Mine Site	N/A	P VC interaction is permanent	C VC interaction will occur continuously	Irreversible While effect is reduced in PC, it is still measurable/ medium to high magnetite	Disturbance; impacts are due to the placement of stockpiles catchment	Not Significant
	Beaver Dam Mine Site (Mud Lake)	Predicted flow reduction. Monitoring to confirm.	Medium to High Resultant change is outside natural variations from baseline conditions	Discrete Effects are confined to the PA (Beaver Dam Mine Site)	N/A	Long Term	C VC interaction will occur continuously	Partially Reversible Effect decreases in PC phases	Disturbance	Not significant
Surface Water Quality	**Operations** – Beaver Dam Mine Site (Surface water quality of Killag River from effluent discharge through north settling pond and groundwater seepage)	Water Treatment at discharge (as required)	Low to Negligible Negligible change in water quality	Local Effect are confined to the near-field assessment area	N/A	Short-Term to medium term	R VC interaction will occur regularly	IR VC will not return to baseline condition	Change in water quality in the Killag	Not significant
	Operations Beaver Dam Mine Site and Haul Road (Release of non-mine-contact surface water to receiving waters resulting in reduction in water quality)	Erosion and Sediment Control Measures	Low to Negligible Minor change from baseline conditions	Local Effect are confined to the near-field assessment area	N/A	Short-Term to medium term	S VC interaction will occur sporadically	R VC will return to baseline conditions	Disturbance	Not Significant
	Closure – Beaver Dam Mine Site (Surface water quality of Killag River from pit from effluent discharge)	Water Treatment at discharge (as required)	Low to Negligible Negligible change in water quality	Local Effect are confined to the near-field assessment area	N/A	Short-Term to medium term	R VC interaction will occur regularly	Partially Reversible Effect decreases in PC phases	Disturbance	Not Significant
	Closure – Touquoy Mine Site (Storage of Beaver Dam tailings in the Touquoy open pit mine and surface water quality of Moose River from effluent discharge and groundwater seepage)	Treatment of water quality in pit as tailings are disposed in the open pit Water Treatment at discharge (as required) Continuation of the monitoring program that is currently underway at Touquoy since 2016	Low to Negligible Negligible change in water quality	Local Effect are confined to the near-field assessment area	N/A	Short-Term to medium term	R VC interaction will occur regularly	IR VC remains at the end of the activity	Disturbance	Not significant

Notes: See Section 6.7.7.2, Tables 6.7-19 and 6.7-20for definitions of the below characteristics.

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	IR	Irreversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	PR	Partially Reversible
H	High					P	Permanent	C	Continuous		

6.7.11 Proposed Compliance and Effects Monitoring Program

Surface water monitoring will be completed to verify the predicted environmental effects and the effectiveness of the mitigation measures for the surface water environment. Surface water monitoring will be completed to verify the predicted environmental effects and the effectiveness of the mitigation measures for the surface water environment. A draft Aquatic Effects Monitoring Program that includes Environmental Effects Monitoring (EEM) as defined under MDMER will be developed as part of the permitting process and submitted as part of the Industrial Approval application. The mitigations are outlined in Table 6.7-44.

This document will evolve through regulatory liaison, as well as public and Mi'kmaq of Nova Scotia engagement.

6.7.12 Summary of Residual Effects to Surface Water Quantity and Quality

Residual effects of the Project on Surface Water Quantity VC identified are characterized using standard criteria, including magnitude, geographical extent, duration, frequency, reversibility, and context of the effect (Table 6.7-45). Changes are assessed as Not Significant (Section 6.7.10).

Under the EOM scenarios, predicted near-field (North and East pond discharge) and far-field chemical concentrations in the base case and upper case are consistently below selected water quality benchmarks without water treatment, with the exception of nitrite, which exceeds the guideline only in the upper-case scenarios in three months/year. Under the PC scenarios, there is little difference between predicted chemical concentrations at near-field (pit lake discharge) and far-field locations for each assessment each case. In base case PC scenarios, all predicted constituent concentrations were consistently below selected water quality benchmarks. In the upper-case PC scenarios, both cobalt and zinc are predicted to exceed their respective guidelines in two months/year. Note, uppercase modelling scenarios are, by definition, of low likelihood. Thus, as water quality criteria are defined by national and international entities as protective of the receiving environment and all water users, there are no anticipated effects to surface waters as a result of discharges from the Project to the Killag River and water treatment during operations and posit closure phases is likely not required.

However, in response to IR2 issued by IAAC (CEAA 2019) and Nova Scotia Environment (NSE 2019), and as a result of ongoing water quality, water quantity and geochemical studies for the Project, water treatment for both EOM and PC is planned for the Project. Details for water management and evaluation of alternative water treatments are presented in Appendix P.4 Mine Water Management Plan (Appendix F.3 Water Treatment Assessment Post-closure). Note, the treatment system will be designed to ensure that all site effluent water meets MDMER and will reflect assimilation capacity of the receiving environment, such that any potential effects to the Surface Water Quality VC, and downstream water users, will be fully mitigated (Section 6.7.9).

Further details regarding characterization of Residual Effects as non-significant are summarized below by Project phase.

- During Construction:
  - Linear watercourses within the PA at the Beaver Dam Mine Site will be altered to support Project development.
  - Micro-sighting of infrastructure will reduce interactions with surface water features wherever possible.
  - Systems that will be altered to support Project construction are first order streams with limited fish habitat potential and low pH.
  - Haul Road upgrade and construction, with appropriate mitigation measures including proper culvert installation and erosion and sediment control measures, will have limited residual impact to linear watercourses along this route.

- During Operations:
  - With appropriate treatment of effluent discharge, the magnitude of the residual effect to the Killag River at the Beaver Dam Mine Site is considered negligible (within established criteria or background concentrations at the 100 m compliance point).
  - Effluent is predicted to be of neutral pH, limiting potential impact to Killag River.
  - Changes in flow to the Killag River from pit operations and dewatering have been predicted to be minimal.
  - There is a predicted alteration to WC5 relating to the operational water balance of the Beaver Dam Mine Site. Permitting is expected to be required to support this alteration.
  - Mud Lake will experience reductions in flow, which have been predicted to result in minimal impacts to fish.
- During Closure:
  - With appropriate treatment of effluent discharge, the magnitude of the residual effect to the Killag River at the Beaver Dam Mine Site is considered negligible (within established criteria or background concentrations at the 100 m compliance point).
  - Effluent is predicted to be of neutral pH, limiting potential impact to Killag River, a low pH river with current efforts to increase pH to support salmon restoration.
  - Considering water treatment, as required, for effluent discharge, the magnitude of the residual effect to the Moose River at the Touquoy Mine Site is considered negligible (within established criteria or background concentrations at the 100 m mixing zone).

Surface water monitoring will be completed to verify the predicted environmental effects and the effectiveness of the mitigation measures for the surface water environment. A draft Aquatic Effects Monitoring Program that includes Environmental Effects Monitoring (EEM) as defined under MDMER will be developed as part of the permitting process and submitted with the Industrial Approval application. The mitigations are outlined in Table 6.7-44.

This document will evolve through regulatory liaison, as well as public and Mi'kmaq of Nova Scotia engagement.

6.8 Wetlands

6.8.1 Introduction

6.8.1.1 Summary of Wetlands Before the Updates

In the 2019 Revised EIS (AMNS 2019), there were a total of 197 wetlands identified within the Beaver Dam Mine Site (n=81) and Haul Road (n=116), occupying a total of 123.2 hectares (ha). The identified wetlands were dominated by swamps, representing 65% of all wetland types within both the Beaver Dam Mine Site and Haul Road. Bog, fens, and marshes accounted for 6%, 3% and 3% of wetland habitat within the Bever Dam Mine Site and Haul Road, respectively. Thirteen percent of identified wetlands were complexes, largely composed of swamp, bog and fen habitat. Species at Risk (SAR) and Species of Conservation Interest (SOCI), evidence of or potential habitat were observed within identified wetlands and one WSS was identified (WL 29) through field assessments. Many wetlands were noted to have previously undergone direct or indirect disturbance as a result of timber harvesting, historic mining and/or road and trail networks.

Of the 123.2 ha of delineated wetland habitat, 22.1 ha within the Bever Dam Mine Site and 2.4 ha within the Haul Road was expected to be directly impacted by Project development. This impact area represents 18% of the identified wetland area. In total, 21 wetlands were proposed for complete alteration and 86 wetlands were proposed for partial alteration within the Beaver Dam Mine Site and Haul Road. Project development was anticipated to indirectly impact wetlands through groundwater drawdown and changes to catchment area hydrology.

6.8.1.2 Summary of Updates to Wetlands

As a result of Project Area (PA) modifications and continued infrastructure micro-siting since the Revised 2019 EIS (AMNS 2019), additional wetland habitat was delineated during the supplementary surveys. In addition, this section has been updated to reflect responses to Round 2, Information Requests (IR2) from Impact Assessment Agency of Canada (IAAC formerly the Canadian Assessment Agency of Canada [CEAA]) (CEAA 2019) and Nova Scotia Environment (NSE 20219).

A total of 236 wetlands (166.3 ha) were identified within the Beaver Dam Mine Site and Haul Road in the Updated 2021 EIS (AMNS 2021), which is an additional 43.1 ha of wetland habitat in comparison to the Revised 2019 EIS (AMNS 2019). The following wetlands are no longer located within the PA, due to Haul Road realignments and have been removed from the 2021 Updated EIS (i.e., WL130, 131, 132 and 180-199). There is no proportional change to wetland types observed within he Beaver Dam Mine Site and Haul Road, which continue to be dominated by swamps (67%). The Updated 2021 EIS (AMNS 2021) includes an expanded evaluation and discussion of wetlands with significant functions (IR2 NSE-2-178). Based on new assessment criteria and baseline surveys, six wetlands were identified as confirmed or possible Wetland of Special Significance (WSS) based on field evaluations.

Of the 166.3 ha of delineated wetland habitat, it is anticipated that 31.5 ha of wetland area will be directly impacted by the Project. This impact area represents 18% of the identified wetland area within the Beaver Dam Mine Site and Haul Road. A total of 108 wetlands are expected to be directly impacted, 34 of which are expected to be completely altered, and 74 of which are expected to be partially altered. The remaining 128 wetlands (54%) will not be directly altered. In comparison to the Revised 2019 EIS, the total area of direct wetland impact has increased by 30% (31.5 ha, previously 22.1 ha). This increase has occurred as the result of necessary Project changes to micro-site infrastructure away from fish bearing watercourses and the addition of an organics material stockpile that will be used for reclamation at closure. Modifications to the Haul Road alignment has resulted in a decrease in the total direct wetland impact area by 33%, 2.4 ha (AMNS 2019) to 1.6 ha (AMNS 2021). The updates assessment also includes an

expanded evaluation and discussion of indirect impacts to wetlands, through a revised assessment of groundwater interactions and changes to local catchment areas. Expected indirect wetland impact areas have been quantified (4.56 ha).

Project mitigation measures have been reassessed based on the new design, additional baseline surveys and updated effects assessment. A preliminary wetland monitoring plan is presented, along with a revised Preliminary Wetland Compensation Plan (Appendix H.3), which includes consideration of conservation allowances for observed SAR in response to IR2 CEAA-2-24 and CEAA-2-26.

Table 6.8-1: Updated Subsections from the 2019 Revised Environmental Impact Statement – Wetlands

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
-	-	6.8.1 Introduction	• New
6.8.1 Rationale for Valued Component Selection	No	6.8.2 Rationale for Valued Component Selection	-
6.8.2 Baseline Program Methodology	Yes	6.8.3 Baseline Program Methodology	• Addition of 2019/2020/2021 field surveys. • Additional survey areas as a result of PA modification for infrastructure micro-sitting. • Expanded discussion on WSS and wetlands with significant functions (IR2 NSE-2-178) • Response to IR2 NSE-2-01, NSE-2-174
6.8.3 Baseline Conditions	Yes	6.8.4 Baseline Conditions	• Present results from additional field surveys: • Additional survey areas as a result of PA modification for infrastructure micro-sitting. • Response to IR2 NSE-2-175, NSE-2-176, NSE-2-177, NSE-2-178
6.8.4 Consideration of Consultation and Engagement Results	No	6.8.5 Consideration of Engagement Results	-
6.8.5 Effects Assessment Methodology – **Boundaries**	Yes	6.8.6 Effects Assessment Methodology – **Boundaries**	• Adjusted PA description. • PA modification for infrastructure micro-sitting. • LAA was modified due to modified PA and improved interactions analysis
6.8.5 Effects Assessment Methodology – **Wetland Cumulative Effects Modeling**	Yes	6.8.6 Effects Assessment Methodology – **Wetland Cumulative Effects Modeling**	• Updated based on PA modification
6.8.5 Effects Assessment Methodology – **Thresholds for Determination of Significance**	Yes	6.8.6 Effects Assessment Methodology – **Thresholds for Determination of Significance**	• Updated significance threshold and magnitude assessment: • Reflect changes in VC baseline conditions and improve significance assessment criteria • Response to IR2 CEAA 2-02, NSE-2-09

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
6.8.6 Project Activities and Wetlands Interactions and Effects	Yes	6.8.7 Project Activities/Interactions with Wetlands	• Bolster discussion of direct and indirect impacts to fauna. Incorporated changes to assessment level and RAA. • Changes to project timelines • Updated results of Wetland CEA • Response to IR NSE-2-03, NSE-2-05, NSE-2-07, NSE-2-176, NSE-2-180, NSE-2-182a
6.8.7 Preferred Alternative Haul Road	Yes	Section removed	• The Preferred Alternative Haul Road is no longer being considered and has been removed from the Project Description (Section 2) and EIS
6.8.8 Mitigation and Monitoring	Yes	6.8.8 Avoidance and Mitigation	• Updated based on field survey results and changes to effects assessment • Response to IR2 NSE-2-06, NSE-2-181
6.8.9 Residual Effects and Significance	Yes	6.8.9 Residual Effects and Significance	• Updated based on field survey results and changes to significance threshold determination. • Change to magnitude determination • Reflect changes to significance threshold and magnitude assessment.
6.8.10 Proposed Compliance and Effects Monitoring Program	No	6.8.10 Proposed Compliance and Effects Monitoring Program	• Presents preliminary wetland monitoring plan • Revised Preliminary Wetland Compensation Plan (IR2 CEAA-2-24, CEAA-2-26) • Response to IR2 NSE-2-02, NSE-2-13

Notes: PA = Project Area; LAA = Local Assessment Area; RAA = Regional Assessment Area- = no update; IR2 = Round 2, Information Requests; CEAA = Canadian Environmental Assessment Agency; EIS = environmental impact statement; WSS = Wetland of Special Significance.

6.8.2 Rationale for Valued Component Selection

Wetlands were selected as a valued component due to their ecological value in providing habitat for aquatic species and rare plants, the importance of wetlands in the daily lives of terrestrial species, their capacity to store water, managing downstream flooding, improving water quality, and the recharge/discharge of groundwater aquifers. The socio-economic importance of wetlands from a recreational and resource perspective is also noted in the selection of wetlands as a valued component (Section 6.1.4 of the EIS Guidelines [CEAA 2016] and its potential interactions with Project activities).

In Nova Scotia, Wetlands are protected under the *Environment Act* and the Wetland Conservation Policy. The Nova Scotia. *Environment Act* defines a wetland as "*Land referred to as a marsh, swamp, fen, or bog that either periodically or permanently has water table at, near, or above the land surface or that is saturated with water, and sustains aquatic processes as indicated by the presence of poorly drained soils, hydrophytic vegetation, and biological activities adapted to wet conditions*".

6.8.3 Baseline Program Methodology

Methodology of wetland surveys within the Beaver Dam Mine Site and Haul Road are discussed below. Information pertaining to Touquoy Mine Site has been brought forward from the Environmental Assessment Registration Document (EARD) and Focus Report. Methods and results are summarized in subheadings within the applicable sections; however, the data is not being revaluated. For further information regarding Touquoy Mine Site, refer to the EARD (CRA 2007a) and Focus Report (CRA 2007b).

In the Revised 2019 EIS, the PA was modified to allow for the micro-siting of infrastructure, as described in the Project Description (Section 2). As a result, targeted wetland surveys were conducted within the modified portions of the Beaver Dam Mine Site and Haul Road in July/August 2019 and December 2020 to confirm and delineate additional wetland habitat. Additional wetland surveys were also conducted in January 2021 along the Haul Road where minor PA modifications were made to accommodate the detailed road design. Where wetland surveys were complete outside the growing season, this has been noted within the following Sections where appropriate.

6.8.3.1 Desktop Evaluation

A desktop review of available topographic maps, provincial databases, and aerial photography was completed to aid in the determination of wetland habitat in the PA. Mapped wetland areas were identified from the NSE Wetland Inventory Database. The Nova Scotia Topographic Database and the Nova Scotia Wet Areas Mapping (WAM) database were reviewed to identify potential un-mapped wetlands. The Wetland of Special Significance (WSS) geographic information system (GIS) predictive layer provided by NSE was consulted for the presence of expected and potential WSS within the PA.

6.8.3.2 Field Delineation

Following the initial desktop review, field surveys were completed within the Beaver Dam Mine Site from June to August 2015 and September 2018, and within the Haul Road from June to July 2016 (excluding the existing Mooseland Road portion). As a result of PA modifications, additional wetland surveys were conducted in the western and southeastern expansions of the Beaver Dam Mine Site and along modified portions of the Haul Road in July and August 2019. Further small adjustments to the PA resulted in three wetlands which were delineated and assessed outside of the growing season (December/January 2020/2021; noted in Appendix H.1). No impacts are expected to these wetlands. The remaining wetlands were delineations and assessments took place within the growing season (June 1 to September 30). Wetland characteristics and functional assessments can be completed sufficiently during any time of the growing season, as per consultation with NSE. Distribution and identification for priority species and accessibility for fish are considered and targeted species surveys were completed within identified wetland habitat to further support functional assessment. Seasonal considerations for each species assemblage within wetlands are described in their respective sections of this EIS (i.e., flow regimes and seasonality of fish movement in Section 6.9, seasonal avian surveys in Section 6.12). Targeted surveys were completed within the Beaver Dam Mine Site and Haul Road where mapped systems were present to confirm and delineate wetland habitat. Meandering transects were also completed across the Beaver Dam Mine Site and Haul Road to support efforts to delineate all wetlands present within the PA, beyond those identified in the available database resources.

Trained wetland delineators and evaluators completed all field surveys. Isolated wetlands that were obviously identified as <100 m^2 in the field were not delineated due to the minimum size requirement of a provincially regulated wetland (NSE 2011). However, if a wetland was near 100 m^2, or if the delineators were unsure of the size in the field, the wetland was delineated. Wetlands determined to be smaller than 100 m^2 post field evaluation were not included on figures nor were these small wetland areas considered for the effects' assessment.

Delineated wetlands that extended outside of the PA (for both the Beaver Dam Mine Site and the Haul Road) were only delineated to the PA boundary. Wetland habitat extending beyond the PA was evaluated through desktop resources to estimate wetland type, size, and broad wetland function, including provincial topographic datasets and aerial imagery. Details related to functional assessment methods for wetlands which extend outside of the PA boundary are described in Section 6.8.3.4.

Wetland delineation was conducted in accordance with the Corps of Engineers Wetland Delineation Manual (Environmental Laboratory, 1987) and the Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Northcentral and Northeast Region (United States Army Corps of Engineers, 2011). In each wetland, vegetation, hydrology, and soils data were recorded at both wetland and upland data points on either side of the wetland boundary in accordance with the Corps of Engineers Wetland Delineation Manual (Environmental Laboratory, 1987). Wetland types were determined using the Canadian Wetland Classification System (NWWG,1997).

Wetland boundaries were documented using an SXBlue II Global Positioning System (GPS) receiver unit capable of sub-metre accuracy with a handheld SXPad field computer. Any inlet and outlet streams or other features associated with each wetland present within the PA were marked during the delineation processes, as well as mapped within the boundaries of the wetland. Pink flagging tape was used to mark the boundaries of wetlands and blue flagging tape was used to mark the locations of associated watercourses.

In keeping with the Army Corps of Engineers methodologies for wetland delineation, three criteria are required in order for a wetland determination to be made:

- Presence of hydrophytic (water loving) vegetation;
- Presence of hydrologic conditions that result in periods of flooding, ponding, or saturation during the growing season; and
- Presence of hydric soils.

Hydrophytic vegetation is defined as the sum total of macrophytic plant life that occurs in areas where the frequency and duration of inundation or soil saturation produce permanent or periodically saturated soils of sufficient duration to exert a controlling influence on the plant species present (Environmental Laboratory, 1987). Hydrophytic vegetation should be the dominant plant type in wetland habitat (Environmental Laboratory, 1987).

Dominant plant species observed at each data point were classified according to their indicator status (probability of occurrence in wetlands) in accordance with the Nova Scotia Wetland Indicator Plant List (NSE 2011c). Further relevant information was reviewed in Flora of Nova Scotia (Roland, 1998).

If the majority (greater than 50%) of the dominant vegetation at a data point is classified as obligate (OBL), facultative wetland (FACW), or facultative (FAC) (excluding FAC-), then the location of the data point is considered to be dominated by hydrophytic vegetation. Wetland vegetation compositions for wetland types identified within the Beaver Dam Mine Site and Haul Road during field surveys have been described in Section 6.8.4.1.

A hydric soil is defined as a soil that formed under conditions of saturation, flooding, or ponding long enough during the growing season to develop anaerobic conditions in the upper part (United States Department of Agriculture, 2003). Indicators that a hydric soil is present include soil colour (gleyed soils and soils with bright mottles and/or low matrix chroma), aquic or preaquic moisture regime, reducing soil conditions, sulfidic material (odour), soils listed on the hydric soils list, iron and manganese concretions, organic soils (histosols), histic epipedon, high organic content in surface layer in sandy soils, and organic streaking in sandy soils.

A soil pit was completed at each data point. These pits were excavated to a maximum depth of 50 cm or refusal. The soil in each pit was then examined for hydric soil indicators. The matrix colour and mottle colour (if present) of the soil were determined using the Munsell Soil Colour Charts.

Wetland habitat, by definition, either periodically or permanently, has a water table at, near, or above the land surface or is saturated with water. To be classified as a wetland, a site should have at least one primary indicator or two secondary indicators of wetland hydrology. Examples of primary indicators of wetland hydrology include watermarks, drift lines, sediment deposition, and water stained leaves. Examples of secondary indicators of wetland hydrology include oxidized root channels, dry season water table, and stunted or stressed plants.

Each area of expected wetland habitat was assessed for signs of hydrology through observations across the area and assessment of soil pits at each data point.

Further baseline field surveys were conducted in the Beaver Dam Mine Site and Haul Road to assess the suitability of wetland habitat for wetland specific species, especially SAR/SOCI. All surveys conducted for SAR and SOCI were completed in suitable habitat in the Beaver Dam Mine Site and Haul Road according to species-specific methodologies. Survey effort to support wetland identification and functional assessment was extensive and results in significant time on the landscape from early spring (high flow conditions to evaluate fish habitat and connectivity) to late fall across multiple years, in key habitat where presence of SAR and SOCI would be expected. This included, for instance, both early and late season botany surveys, and avian migration, breeding and overwintering surveys. Priority species were noted during the field programs and therefore, were assessed during all surveys conducted on the landscape. A summary of the biophysical surveys including, location, date, frequency and time of day (where applicable), is presented in IR2 NSE 2-01 (AMNS 2021). Further information on these baseline survey methods, and species observed, including date and time, can be found in Section 6.13 and Appendix K.1 (Master Species List [includes priority species]). Priority species were assessed in the Beaver Dam Mine Site and Haul Road, and wetland specific species lists will be generated if necessary, at the permitting phase. It should be noted that, while it was not possible to confirm a species' absence from the landscape, all care was taken to identify the presence of preferred habitat in the Beaver Dam Mine Site and Haul Road (Section 6.13 for further information). Where suitable habitat was observed for a SAR (particularly SAR fish and turtles), it was presumed to potentially be present, even if presence was not confirmed via observation of that species (or evidence thereof).

6.8.3.3 Wetlands of Special Significance

The Wetland Conservation Policy was developed by Nova Scotia Environment in 2011 and amended in 2019 (NSE 2019). Its mandate is to provide a framework for the conservation of wetlands. Furthermore, it provides a framework for the identification of Wetlands of Special Significance. According to NSE (2019, p.11-12), the following criteria define Wetlands of Special Significance:

- All salt marshes;
- Wetlands that are within or partially within a designated Ramsar site, Provincial Wildlife Management Area (Crown and Provincial lands only), Provincial Park, Nature Reserve, Wilderness Areas or lands owned or legally protected by non-government charitable conservation land trusts;
- Intact or restored wetlands that are project sites under the North American Waterfowl Management Plan and secured for conservation through the NS-EHJV;
- Wetlands known to support at-risk species as designated under the federal *Species at Risk Act* or the *Nova Scotia Endangered Species Act*; and
- etlands in designated protected water areas as described within Section 106 of the *Environment Act*.

The presence of a sessile or non-mobile (primarily flora) SAR within a delineated wetland triggers the determination of that wetland as a WSS. Mobile SAR have home ranges that may include wetlands within and beyond the PA, which may be used at various times of the year (i.e., used during the breeding season, but not at other times). Given the mobility of some species, an observation of a mobile SAR has not immediately designated these wetlands as WSS. The determination of WSS based on the observation a mobile species is determined on a species-specific and site-specific basis, considering the following factors:

- whether the species was observed within the wetland, and weather it was a current or historic observation (i.e., Atlantic Canada Conservation Data Centre [ACCDC]);
- whether suitable habitat is present within the wetland;
- what is the wetland habitat used for (i.e., does the habitat provided within the wetland provide necessary life functions (i.e., nesting or overwintering habitat); and
- the discreteness or specificity of habitat use by the mobile species (i.e., wood turtles have specific and discrete nest beach requirements, compared with the in-discrete and non-specific foraging habitat usage by mainland moose, for example).

Furthermore, the NS Wetland Conservation Policy states that the Province is in the process of developing a system for classifying additional wetlands or wetland types as WSS (NSE 2019). Among the wetland characteristics, functions and services to be considered during the process are whether the area:

- Supports a significant species or species assemblages (e.g., coastal plain flora);
- Supports high wildlife biodiversity;
- Has significant hydrologic value; or
- Has high social or cultural importance.

Currently, a province-wide framework for determination of WSS using Wetland Ecosystem Services Protocol - Atlantic Canada (WESP-AC) has not been developed. Current understanding is that the Province is in the process of identifying parameters for WSS within the WESP-AC framework. Through final implementation of WESP-AC, parameters may be established to help identify significance thresholds for functions listed above (i.e., significant hydrologic value).

NSE developed a WSS predictive GIS layer (September 2020, pers. comm., Ian Bryson, NSE Wetland Specialist), which overlies mapped wetlands with protected areas layers, and priority species observations from ACCDC, among other attributes. According to NSE, this WSS GIS layer is intended to be used as a planning tool, and its contents should be interpreted as potential WSS. The actual determination of WSS status is based on field verification of the parameters or considerations listed above.

This predictive layer was consulted during the desktop evaluation for wetlands prior to initial wetland delineations in 2016, and reconfirmed with the latest WSS layer, provided to MEL by Ian Bryson in September 2020. This predictive layer incorporates all rare species observations, regardless of the species' ranking, accuracy of the data points, observation date, and mobility of species. As such, it is used as a predictive tool only to support WSS determination.

Final determination of WSS will be completed at the permitting phase with guidance from NSE when the framework for determination of WSS has been developed or as directed by the regulator. Until the framework for WSS determination is available, AMNS will continue to engage with NSE and NSL&F to discuss WSS designation on a site-specific basis.

6.8.3.4 Wetland Functional Assessment

Wetland functional assessments were completed for each wetland using the NSE NovaWET 3.0 (2011d) wetland evaluation technique. At the time of baseline data collection, NovaWET was the primary functional assessment tool recommended for use in Nova Scotia by NSE. The WESP-AC method for functional assessment of wetland habitats was not calibrated for use in Nova Scotia. In 2016, a calibration study was completed to support NSE in the implementation of WESP-AC as the preferred functional assessment technique was completed. To date, WESP-AC has not been fully implemented as the preferred technique, and NovaWET is still recognized as an appropriate method for assessing wetland functions (NSE 2011d).

Field observations were made on wetland types, water flow path, dominant vegetation communities (and SAR/SOCI, if present), fish habitat potential and characterization, and wetland function. The evaluation of wetland function included gathering field and desktop information to support conclusions relating to wetland characteristics, condition and integrity of adjacent lands, identification of exceptional features, hydrologic condition and integrity, water quality, groundwater interactions, shoreline stabilization, plant community, fish and wildlife habitat and habitat integrity, and community use and value.

Where wetland habitat extended beyond the PA, a functional assessment is based on observations made within the PA, landscape position and connectivity observed via desktop review in portions of the wetland that extend beyond the PA boundary. Connectivity to other aquatic habitats (i.e., wetlands, watercourses, lakes and ponds) are an important component of any functional assessment. Where a wetland extended beyond the PA boundary but did not coincide with an NSE mapped wetland, provincial topographic datasets (i.e., NSE wetland inventory, local topography, Wet Area Mapping, flow accumulation, watercourses and waterbodies) and aerial imagery interpretation were used to identify the likely extents of wetland boundaries to support functional assessment conclusions. Approximate wetland area beyond the PA, estimated through this exercise, is presented in Table 6.8-2. Functional assessments are based on field observations within a defined study area, supplemented by desktop resources where appropriate.

Results of the NovaWET functional assessment are provided in Section 6.8.4.1. In addition, summaries specific to the Guidelines for Preparation of an Environmental Impact Statement, Beaver Dam Mine (CEAA 2016) specific to wetlands are discussed in this section.

6.8.3.5 Touquoy Mine Site

Wetlands were identified within Touquoy Mine Site as part of the EARD process via the NSL&F Wetlands Database and air photo interpretation. These wetlands were assessed in September 2006 and in the spring of 2007 (CRA 2007).

From 2015 to 2017 MEL biologists conducted further wetland surveys by delineating and completing functional assessments on additional wetlands within the Touquoy Mine Site as part of the wetland permitting process.

Additional wetland surveys were conducted along the Moose River, downstream of the proposed spillway, in October 2020 in response to IR2 NSE 2-176 (AMNS 2021). Results of these surveys are presented in Section 6.8.4.2.

6.8.4 Baseline Conditions

Updates to wetlands (total number, individual areas, etc.) reflected within this section are a result of additional surveys required by changes to the Beaver Dam Mine Site to incorporate the micro-siting of Project infrastructure (e.g., western waste rock stockpile and organic materials stockpile) and modifications to the Haul Road design, including the addition of a multiuse bypass road and the removal of the preferred alternative haul road option as described in the updated Project Description (Section 2).

Including the additional wetland habitat delineated during the supplementary surveys, a total of 236 freshwater wetlands were identified within the Beaver Dam Mine Site and Haul Road (excluding the existing Mooseland Road portion). Within the Beaver Dam Mine Site 117 wetlands were identified, and 121 wetlands were identified along the current Haul Road layout, with 2 wetlands (WL64 and WL66) located partially within each component. As a result of Haul Road modifications, the following wetlands are no longer located within the PA and have been removed from the EIS: WL130, 131, 132 and 180-199. A summary of wetland numbers, types, areas within the Beaver Dam Mine Site and Haul Road, and tertiary watershed locations are described in Table 6.8-2 and presented on Figures 6.8-1A to 6.8-1O.

Table 6.8-2: Wetland Delineation Summary Results

Total Haul Road Wetland Area		**250,930 m^2 (25.1 ha)**		
Total Wetland Area		**1,662,496 m^2 (166.3 ha)**		
% Total Beaver Dam Mine Site Area (592 ha)		**24%**		
% Total Haul Road Area (189 ha)		**13%**		

Notes: [a] Approximate wetland area that extends beyond the PA, were applicable. Area is estimated through desktop review.

[b] Wetland area is partially within the Beaver Dam Mine Site and Haul Road.

[c] Wetland extends beyond the PA boundaries. Total size is estimated. m^2 = squared metre.

McCallum Environmental Ltd.

Document Name: BD_EIS_Figure6-8-XBD and HR Wetlands

In total the 236 delineated wetlands occupy 166 ha and represent 24% and 13% of the Beaver Dam Mine Site and Haul Road (excluding Mooseland Road) areas, respectively (Table 6.8-2). It is important to note that open water within delineated wetland boundaries that could not be classified as an open water wetland as per the Canadian Wetland Classification System definition (NWWG 1997) has been removed from the calculation of wetland area (i.e., anthropogenically created waterbodies from historic mining operations (WL59)). This habitat is discussed specifically relating to watercourses and fish habitat (Section 6.9).

In the Beaver Dam Mine Site, hydrologic flow within wetlands is generally divided north and south where the Killag River tertiary watershed abuts the Cope Brook, Paul Brook and Tent Brook tertiary watersheds (Section 6.7.4 Water Quantity Baseline Conditions, Figure 6.7-4 and Appendix G.4 Physical Characterization of Watercourses). Larger wetland complexes straddle watershed boundaries (notably WL1, 2, 29, 35, 57, 222 and 247) and act as primary water sources for downgradient wetlands, watercourses and waterbodies. Wetlands 1 and 2 exist as bog complexes, which intercept and store precipitation and small scale water seepage from surrounding land prior to draining via additional aquatic features to the north and south. As is typical of these habitats in Nova Scotia, bogs located at higher elevation have the ability to source water to more than one tertiary watershed. In this case, water flows northward into the Killag River watershed and southward to the Tent Brook watershed. The same can be said for Wetlands 29 and 57, which also exist as complexes (albeit with a larger swamp component) and outflow northward toward into the Killag River watershed and southward into Paul Brook and Tent Brook tertiary watersheds, respectively.

As water drains northward through the Beaver Dam Mine Site, it does so via predominantly swamp habitat, often associated with watercourses or small-scale surface channelization (i.e., throughflow function). While intermixed with a scattering of isolated wetlands, swamps dominate the central portions the Killag River tertiary watershed and act as either mechanisms to drain water northward from the larger wetland complexes in the south, or in the case of isolated wetlands, form in small topographically defined basin formations. The major receptors of water within the Beaver Dam Mine Site are initially Crusher Lake, with Mud Lake and Cameron Flowage ultimately receiving most water prior to it draining offsite to the southeast. Larger riparian swamp wetlands (e.g., WL17 and 61) border Mud Lake and Cameron Flowage, intercepting water prior to releasing it into the water bodies.

Wetlands located in the headwaters of the Cope Brook, Paul Brook, and Tent Brook watersheds supply water to a lesser extent and shuttle water out of the Beaver Dam Mine Site more rapidly, whereby Wetlands 205, 29 and 66 are the primary outflows for the Cope Brook, Paul Brook, and Tent Brook watersheds, respectively. The remaining wetlands identified within these watersheds are primarily isolated in nature or support throughflow. Many provide groundwater recharge capacities rather than act as a source of surface water discharge to lower lying features.

Due to its length and intersection with six separate tertiary watersheds, wetlands along the Haul Road vary between outflow wetlands located at headwater locations, throughflow wetlands that drain water toward lower reaches of the watersheds, or receiving water wetlands in lower portions of the watershed. As is typical of the Nova Scotia landscape, however, smaller isolated wetlands were also identified along the length of the Haul Road, in all watersheds.

6.8.4.1 Functional Assessment Results

The NovaWET functional evaluation technique consists of 11 major sections associated with key wetland functions as listed below:

- Watershed Characteristics;
- Wetland Characterization;
- Condition and Integrity of Adjacent Land;
- Identification of Exceptional Features;

- Hydrologic Condition and Integrity;
- Water Quality;
- Groundwater Interactions;
- Shoreline Stabilization and Integrity;
- Plant Community;
- Fish and Wildlife Habitat and Integrity; and
- Community Use/Value

Each section contains questions specific to a function that supports the assessor in determining to what degree the wetland provides significant functions (SF). NovaWET continues to identify critical wetland functions that are often unique or rare or associated with higher risk to the watershed if lost. The Wetland Functional Assessment Summary Table included in Appendix H.1 provides the results of the SF determination for all wetlands within the Beaver Dam Mine Site and Haul Road. Critical SF functions are highlighted red.

Additional details for each wetland, including functional summary sheets, plant lists, photographs, and data sheets were recorded during field evaluations, but have not been included in this document due to the volume of data (236 wetlands within the Beaver Dam Mine Site and the Haul Road). These data are available upon request.

The following sections provide results of the NovaWET functional assessment.

6.8.4.1.1 Watershed Characteristics

The functional assessments conducted for the 236 wetlands located within the Beaver Dam Mine Site and the Haul Road determined that the overall watershed condition of the nine relevant tertiary watersheds is in a relatively unaltered state. Urban/commercial development is not present within the watersheds and, therefore, existing roads account for the impervious surfaces calculated within the watershed evaluation, resulting in a range of 0% to 0.62%, with the higher percentages being along the existing Haul Road. Therefore, condition is classified as low. Wetland habitat cover ranges from 3.40% to 22.19% of the total land area of the watersheds. Four of the watersheds provide a high ability to contribute to floodwater protection (<10% wetland cover), three of which comprise the Haul Road and one comprised the Beaver Dam Mine Site. Moderate floodwater protection (10% to 20% wetland cover) is afforded by four watersheds, of which two comprise the Beaver Dam Mine Site and two comprise the Haul Road. One watershed provides low floodwater protection (>20% wetland cover) and comprises the Beaver Dam Mine Site. Watershed evaluation results are presented in Table 6.8-3.

Most buffer areas surrounding the wetlands are highly vegetated. These wetlands and buffers generally offer high quality wildlife habitat and good water quality functions. Forestry activity was documented in habitat along the Haul Road and is also present surrounding the Beaver Dam Mine Site. Ninety-five percent of all wetlands assessed were determined to provide moderate-high plant community integrity with a diversity of species generally composed primarily of native species characteristic of the wetland type.

Table 6.8-3: Detailed Watershed Evaluation Results

Tertiary Watershed	Watershed Number	Project Area Component	Describe Watershed Condition (% impervious surface)	Percent Wetland Cover (%)	Total Watershed Area (ha)	Total Wetland Area (ha)	Road Surface Length (m)	Road Area (ha) (6.5 m wide)
Killag River	1EM-2-D	Beaver Dam Mine Site	0.00	12.52	6,727.78	842.11	0	0

Notes: % = percent; ha = hectares; m = meters.

6.8.4.1.2 Wetland Characteristics

The majority of individual wetlands (not including multi-wetland complexes) identified within the Beaver Dam Mine Site and Haul Road were classified as swamps and account for 68% and 64% of all wetlands, respectively. Swamps identified in the PA are consistent with swamp habitats observed throughout the province and are predominantly coniferous or mixed-wood treed swamps. A smaller proportion of shrub swamps were observed. Collectively swamps account for 22% of the total wetland area. Seventy-eight percent of delineated swamps are isolated, 14% support throughflow, 8% are in a headwater or outflow position and 1% receives inflow but lack a clear outflow. Some swamps may be classified into multiple hydrologic flow paths due to their size or position on the landscape.

The vegetation communities of swamps within the Beaver Dam Mine Site and Haul Road are coniferous dominated and characterized by a diverse herbaceous layer, with a variety of graminoids, ferns, and forbs. The most common herbaceous species in swamps are three-seeded sedge (*Carex trisperma),* cinnamon fern (*Osmundastrum cinnamomeum)*, and sheep laurel (*Kalmia angustifolia)*. Coniferous treed swamps are characterized by a prominent tree layer which is largely composed of black spruce (*Picea mariana*), tamarack (*Larix laricina*), and balsam fir (*Abies balsamea*). Mixed-wood treed swamps within the Beaver Dam Mine Site and Haul Road are also characterized by these species, and additionally include deciduous species, frequently red maple (*Acer rubrum)* and yellow birch (*Betula alleghaniensis)*. Shrub swamps are typically dominated by speckled alder (*Alnus incana)* and common softwood and hardwood species less than 8 cm diameter at breast height. The tree layer in shrub swamps is considerably reduced from those of treed swamps, while in some shrub swamps, particularly alder-dominated shrub swamps, the tree layer is completely absent.

Bogs, not including complexes with multiple wetland types, account for 15% of all wetlands within the Beaver Dam Mine Site and Haul Road, and 19% of the total wetland area. The largest wetland delineated within the Beaver Dam Mine Site or Haul Road is Wetland 2, a 20 ha bog complex within the south-central portion of the Beaver Dam Mine Site. Treed bogs are typically dominated by coniferous species, namely black spruce and tamarack. Low shrub bogs, whose tree layers are sparse or absent, are characterized by ericaceous shrubs like leatherleaf (*Chamaedaphne calyculata*), sheep laurel, and Labrador tea (*Rhododendron groenlandicum),* which are adapted to the acidic and nutrient poor soils indicative of bogs. Herbaceous layer diversity within bogs is greatly reduced from that of swamps.

Three percent of the identified wetlands within the Beaver Dam Mine Site and Haul Road are fens, not including complexes with multiple wetland types, and account for 3% of the total wetland area. This is likely an under-representative proportion, however, as many of the large wetland complexes are dominated by fen wetland types. Fens within the Beaver Dam Mine Site and Haul Road include graminoid, shrub, and to a lesser extent, treed fens. Graminoid fens tend to establish where the water table within the wetland is at or above the surface. The most commonly observed, dominant graminoid species in fens were tussock sedge (Carex stricta), leather leaf (*Chamaedaphne calyculata*) and bluejoint reed grass (Calamagrostis canadensis). Shrubs, in the form of speckled alder, black spruce, tamarack, and sweet gale (Myrica gale) are the dominant stratum in drier fens with a lower water table. Trees, when present, include black spruce, tamarack, balsam fir and red maple.

Marshes account for 2% of all wetlands within the Beaver Dam Mine Site and Haul Road (not including multi-wetland complexes), but only 0.2% of the total wetland area. Marsh vegetation predominantly comprises emergent aquatic macrophytes; these are plants that are rooted in shallow water but emerge above the water's surface. Common emergent vegetation includes bluejoint reed grass, woolgrass (*Scirpus cyperinus*), American manna grass (*Glyceria grandis*),and northern long sedge (*Carex folliculata*). The marsh shrub layer has a similar species composition to that of fens, though this stratum, along with the tree layer, are typically restricted to the edges of wetland. Tree species in marshes are limited and similar to those found in fens.

There are 30 wetland complexes (13% of all wetlands) that account for 56% of the total wetland area within the Beaver Dam Mine Site and Haul Road. These complexes comprise of a combination of swamp, bog, fen and, to a lesser extent, marsh wetland types, many of which extended beyond the PA boundaries.

Table 6.9-4 outlines the wetland types identified throughout the Beaver Dam Mine Site and Haul Road, including those identified during additional surveys.

Table 6.8-4: Summary of Wetland Types and Aerial Extent within the Beaver Dam Mine Site and Haul Road

Wetland Type	Beaver Dam Mine Site	Haul Road
Wetland Complex		
Number of Wetlands	18	13
Wetland Area	82.4 ha	10.1 ha
% of total wetlands identified within each PA component	15%	11%
Treed or Shrub Swamps		
Number of Wetlands	81	78
Wetland Area	27.1 ha	10.0 ha
% of total wetlands identified within each PA component	69%	64%
Bogs		
Number of Wetlands	12	23
Wetland Area	26.9 ha	4.5 ha
% of total wetlands identified within each PA component	10%	19%
Fens		
Number of Wetlands	4	4
Wetland Area	4.6 ha	0.4 ha
% of total wetlands identified within each PA component	3%	3%
Marshes		
Number of Wetlands	2	3
Wetland Area	0.2 ha	0.2 ha
% of total wetlands identified within each PA component	2%	2%
Total Number of Wetlands[(a)]	**117**	**121**

Note: [(a)] WL64 and WL66 are partially located within the Beaver Dam Mine Site and Haul Road. % = percent; PA = Project Area.

The average size of wetlands within the Beaver Dam Mine Site is approximately 1 ha. The wetlands identified in southern portions of the Beaver Dam Mine Site are in headwater positions within their respective tertiary watersheds, which are all within the West River Sheet Harbour Secondary Watershed. Many of these wetlands are sources of surface water for first order stream formation within their respective tertiary watersheds. Wetlands within the northern half of the Beaver Dam Mine Site, however, are centrally located within the Killag River tertiary watershed and therefore, predominantly act as throughflow features.

The vast majority of wetland habitat identified within the Haul Road was partially delineated, with wetland habitat extending beyond the PA boundaries. Wetlands within the Haul Road are located within six tertiary watersheds and range from wetlands in headwater positions to wetlands near, or at the bottom of watersheds. Detailed biophysical wetland information for each delineated wetland including wetland type, dominant vegetation, soil and hydrological conditions is provided in a Wetland Characterization Table in Appendix H.2.

Table 6.8-5 summarizes functional wetland information used as part of the functional assessment analysis throughout this chapter, including those identified during the 2019 surveys. Table 6.8-5 also presents baseline wetland conditions and stressors (e.g., altered hydrology, forestry impacts, historic tailings). Tailings from historic mining operations were assessed and mapped within the Beaver Dam Mine Site, through soil test pit and water quality analysis, as part of the surveys that have been undertaken to document the geochemistry at the Beaver Dam mine site in areas that indicated historic mining activity (Appendix E.6 [Phase I - Environmental Site Assessment], Appendix E.7 [Limited Phase II - Environmental Site Assessment] and Appendix E.8 [Extended Phase II - Environmental Site Assessment]). This assessment noted elevated levels of arsenic, exceeding NSE Tier 1 Environmental Quality Standards. An assessment of impacts from historic tailings is provided in Section 6.5. These reports were reviewed with consideration of wetland interactions. Where applicable, historical tailings with arsenic impacted soil have been included as a potential stressor. Wetlands within or near mapped areas of historic tailings with arsenic impacted soil are identified in Table 6.8-5. There are a total eight wetlands (WL8, 14, 56, 59, 60, 61, 210 and 216) that occur in areas where historic tailings or tailings that have been reworked into soils. During construction and dewatering stage of the project water will be directed towards the north settling pond for treatment prior to discharge, which is described in the Project Description (Section 2) and in the Mine Water Management Plan (Appendix P.4). Historic tailings impacted soils will be temporarily stored on site before being moved off-site to the Touquoy Mine Site Tailings Management Facility (TMF). The management of historic tailings is described in Appendix E.9 (draft Historic Tailings and Waste Rock Management Plan).

6.8.4.1.3 Identification of Exceptional Features

NovaWET 3.0 defines Expectational Features as a potential WSS, significant fish habitat, federally or provincially listed species in or near the wetland, restored or protected wetlands, calcareous fens, cedar, black ash or large floodplain swamps, wetlands in a public water supply, floodplains upstream/within a populated area or wetlands within a Federal/Provincial/Municipal Area of Interest.

The NSE predictive WSS GIS layer was consulted during the desktop evaluation for wetlands prior to initial wetland delineations in 2016, and reconfirmed with the latest WSS layer, provided to MEL by Ian Bryson (Wetland Specialist, NSE) in September 2020. As part of the wetland functional assessment, along with a review of the predictive WSS layer, each wetland in the Beaver Dam Mine Site and Haul Road was reviewed to determine its potential as a WSS. The WSS qualifications are defined and described (Section 6.8.3.3).

Figures 6.8-1A to 6.8-1O indicate the proximity of the wetlands identified within the Beaver Dam Mine Site and Haul Road to: Ramsar Sites; Provincial Wildlife Management Areas (Crown and Provincial lands only); Provincial Parks; Nature Reserves; Wilderness Areas; Lands owned or legally protected by non-governmental charitable conservation land trusts; intact or restored wetlands under the North American Waterfowl Management Plan; and protected water areas. No wetlands within the Beaver Dam Mine Site and Haul Road are present within any of these special habitats, shown on the above-noted figures.

Nova Scotia Environment Predicted Wetlands of Special Significance

A review of the NSE predictive WSS layer identified seven potential WSS within the Beaver Dam Mine Site and Haul Road, Wetlands 1, 29, 61, 64, 178, 205 and 220. Wetlands 205 and 220 were delineated during 2019 wetland surveys.

The predictive WSS layer does not consider the temporal scale of the observation, or the mobility of the species documented. As such, this layer is to be used as a predictive tool. Where predicted due to the presence of a priority species, the WSS designation may be dependent on the mobility of the species, it's confirmed or historic presence (i.e., ACCDC) and the presence of habitat to support critical life functions of that species. Sessile or non-mobile priority species (i.e., lichen or vascular flora) may trigger WSS designation. This may include species without legal protection under SARA or NSESA (i.e., designation of Special Concern or Vulnerable, respectively), such as blue felt lichen (SARA/COSEWIC Special Concern, NSESA Vulnerable). WSS evaluation criteria are presented in Section 6.8.3.3. Additional consultation with NSE will occur during the permitting process to confirm WSS designation.

Wetland 1 is identified as a potential WSS by NSE due to a blue felt lichen observation in 2015 (ACCDC, 2021), which was confirmed by the Project Team. This observation was located within the NSE mapped wetland, however; upon field delineation of the wetland, it was determined that the observation is located outside of the wetland area. No blue felt lichen has been observed within Wetland 1 and was therefore not determined a WSS.

Wetland 29 is identified as a potential WSS by NSE due to the historic presence of multiple observations of boreal felt lichen (*Erioderma pedicellatum)* (listed as Endangered by SARA/COSEWIC/NSESA) in 2013 (ACCDC, 2021; pers.comm. Charles Sangster, NSE). Three locations of boreal felt lichen were confirmed during field surveys within Wetland 29 on May 8, 2015, as discussed in Section 6.13.4.3 and shown on Figure 6.13-2. However, its location is beyond the PA and as such, impacts are not expected as a result of the Project. A follow up survey conducted in the fall of 2016 determined that all three thalli were no longer present. This absence was reconfirmed on December 4, 2017. Infrastructure micro-siting has increased the distance between Project infrastructure and Wetland 29 (wetland and phorophyte critical function zone) as per the Amended Recovery Strategy for

boreal felt lichen (ECCC, 2018). Wetland 29 was identified as a WSS based on historical presence of boreal felt lichen discussed above under Identification of Exceptional Features.

Wetland 61, located within the Beaver Dam Mie Site along the Cameron Flowage, is identified as a potential WSS by NSE due to the presence of lichen SOCI (e.g., blistered jellyskin lichen) and blue felt lichen within proximity to, but not within, the wetland boundary (within 100 m; pers. comm. Kimberley George, NSLF). Upon field delineation of the wetland, it was confirmed that there were no observations of lichen SAR within the wetland. As a result, Wetland 61 was not determined a WSS.

Wetland 64, which exists where the proposed Haul Road meets the Beaver Dam Mine Site, is identified as a potential WSS by NSE due to the historical presence of Canada warbler (pers.comm. Kimberley George, NSLF; ACCDC, 2021). ACCDC also notes observations of olive-sided flycatcher and rusty blackbird within the wetland. Possible breeding/nesting by an olive-sided flycatcher was noted in 2009 (pers. comm. Charles Sangster, NSE). Although suitable breeding habitat for the olive-sided flycatcher is present within Wetland 64, neither this species nor rusty blackbird or Canada warbler were observed during the breeding bird surveys completed during appropriate breeding periods (i.e., June 13 and 25, 2016 and July 3 and 13, 2019). As a result, Wetland 64 was not determined a WSS.

While the aforementioned species were not observed in Wetland 64, a pair of greater yellowlegs and possible breeding activity was observed (pair and probable nesting displayed). Species-specific mitigation measures for greater yellowlegs are presented within Section 6.8.9.

Wetland 178 is located along the Haul Road, where the proposed new road meets Mooseland Road. It is identified as a potential WSS by NSE due to the historic presence of Canada warbler, observed in 2015 (ACCDC, 2021). While Canada warbler habitat is present in Wetland 178, the historic observations lays beyond the field delineated wetland extent and Canada warbler were not observed during the breeding bird surveys within this area, completed during appropriate breeding periods (i.e., June 13 and 25, 2016). As a result, Wetland 178 was not determined a WSS.

Both Wetlands 205 and WL 220 are identified as potential WSS due to the historical presence of rusty blackbird (*Euphagus carolinus*). The ACCDC (2021) identifies the observation of a rusty blackbird along the road in between these two wetlands on June 15, 2010 (Appendix I.1), which are located under the proposed non-acid generating (NAG) waste rock stockpile. The observation notes that two juvenile birds were observed, which confirms that breeding occurred in that location in 2010. The point represents the location from which the birds were recorded and not necessarily the precise location. One rusty blackbird was observed incidentally in Fall 2014 near an avian point count location to the north of the Beaver Dam Mine Site (BD-PC15). No rusty blackbirds were observed within the Beaver Dam Mine Site or Haul Road since this survey. Detailed avifauna SAR and SOCI data are presented in Section 6.13. Rusty blackbirds build nests within 3 m of the ground in short conifer trees near or over water (Landbird SAR, 2018). Portions of Wetlands 205 and 220 contain potential rusty blackbird breeding habitat, both of which contain discontinuous patches of open water. Given the high site fidelity of this species, returning to the same breeding location year after year (Landbird SAR, 2018), and ongoing fieldwork within the area since 2010, it is unlikely that the presence of rusty blackbirds in and around Wetlands 205 and 220 would not have been detected. Extensive field work was conducted in these wetlands in July 2019 and within Watercourse 21, which runs between the two wetlands, in August, November and December 2019 as a result of fish and fish habitat surveys (Section 6.9). Neither rusty blackbird nor sign of the species was observed in any of these surveys. It is possible that breeding rusty blackbirds have relocated. As a result, Wetlands 205 and 220 were not determined a WSS.

Wetlands with Observed Species at Risk

Wetlands with observed SAR and the presence of suitable species-specific habitat are indicated in Table 6.8-6. Species in bold have legal protection under SARA or the NSESA (Endangered or Threatened), while others do not have legal protection but are listed as species of Special Concern or Vulnerable).

Table 6.8-6: Wetlands with Observed Species at Risk

Wetland ID and Type	Observed SAR and Ranks	Direct Wetland Alteration Proposed and Type of Alteration?	Suitable Habitat Present (Y/N)
WL4 - complex: treed swamp/ treed fen, mixed wood treed swamp	Blue Felt Lichen (SARA/COSEWIC SC, NSESA V, S3)	No	Y
WL8-complex: coniferous treed swamp, graminoid fen, low shrub fen, shrub swamp	**Olive-sided flycatcher** (SARA/COSEWIC T, NSESA T, S2B)	No	Y
WL14-complex: shrub bog, mixed wood treed swamp, low shrub fen	**Olive-sided flycatcher** (SARA/COSEWIC T, NSESA T, S2B)	Yes, Partial	Y
	Blue Felt Lichen (SARA/COSEWIC SC, NSESA V, S3)	Yes, Partial	Y
WL17-complex: tall shrub swamp, coniferous treed bog	Blue Felt Lichen (SARA/COSEWIC SC, NSESA V, S3)	Yes, Partial	Y
WL29-complex: mixed wood treed swamp, low shrub fen, open bog, coniferous treed swamp, coniferous raised bog, graminoid fen	**Canada warbler** (SARA/COSEWIC T, NSESA E, S3B)	No	Y
	Boreal Felt Lichen[(a)] (SARA/COSEWIC E, NSESA E, S1)	No	Y
WL51-mixed wood treed swamp	**Olive-sided flycatcher** (SARA/COSEWIC T, NSESA T, S2B)	No	Y
WL53-low shrub swamp	**Chimney swift** (SARA/COSEWIC T, NSESA E, S2B S1M)	No	N
WL56-complex: coniferous treed swamp, tall shrub swamp, low shrub bog	**Mainland Moose** (NSESA E, S1)	Yes, Complete	Y
WL57-complex: coniferous treed swamp, deciduous treed swamp	**Canada warbler** (SARA/COSEWIC T, NSESA E, S3B)	Yes, Partial	Y
WL59- complex: coniferous treed swamp, emergent marsh, open water	Snapping Turtle (SARA/COSEWIC SC, NSESA V, S3)	Yes, Complete	Y (nesting specific habitat is outside wetland)
WL66-complex: graminoid fen, mixed wood treed swamp, high shrub fen	**Canada warbler** (SARA/COSEWIC T, NSESA E, S3B)	Yes, Partial	Y
WL71-deciduous treed swamp	**Canada warbler** (SARA/COSEWIC T, NSESA E, S3B)	No	Y
WL72-deciduous treed swamp	**Canada warbler** (SARA/COSEWIC T, NSESA E, S3B)	No	Y
WL76-complex: mixed wood treed swamp, open graminoid fen	**Canada warbler** (SARA/COSEWIC T, NSESA E, S3B)	Yes, Partial	Y
WL89-treed swamp	**Barn swallow** (SARA/COSEWIC T, NSESA E, S2S3B)	Yes, Partial	N
WL148-low shrub bog	**Canada warbler** (SARA/COSEWIC T, NSESA E, S3B)	Yes, Partial	Y

Table 6.8-6: Wetlands with Observed Species at Risk (continued)

Wetland ID and Type	Observed SAR and Ranks	Direct Wetland Alteration Proposed and Type of Alteration?	Suitable Habitat Present (Y/N)
WL156-shrub bog	**Olive-sided flycatcher** (SARA/COSEWIC T, NSESA T, S2B)	Yes, Partial	N
WL157-complex: shrub fen, shrub swamp	**Olive-sided flycatcher** (SARA/COSEWIC T, NSESA T, S2B)	Yes, Partial	N
WL173-mixed wood treed swamp	**Canada warbler** (SARA/COSEWIC T, NSESA E, S3B)	Yes, Partial	Y
WL 205-complex: fen, soft wood treed swamp	**Canada warbler** (SARA/COSEWIC T, NSESA E, S3B)	Yes, Partial	Y
	Blue Felt Lichen (SARA/COSEWIC SC, NSESA V, S3)	Yes, Partial	Y
WL206-shrub swamp	**Mainland Moose**[(b)] (NSESA E, S1)	No	N
WL210-coniferous bog	**Mainland Moose** (NSESA E, S1)	No	N
WL219-complex: fen, mixed wood treed swamp	**Canada warbler** (SARA/COSEWIC T, NSESA E, S3B)	Yes, Partial	Y
WL229-swamp	**Olive-sided flycatcher** (SARA/COSEWIC T, NSESA T, S2B)	Yes, Complete	Y

Notes: [(a)] Boreal felt lichen observed in portion of Wetland 29 beyond the PA. Wetland 29 is part of the defined boreal felt lichen critical habitat area.

[(b)] Mainland moose tracks observed adjacent to WL206 beyond the PA.

SAR = Species at Risk; Y/N = Yes/No; WL = wetland; WSS = wetlands of special significance; ID = identification; SARA = *Species at Risk Act*; COSEWIC = Committee on the Status of Endangered Wildlife in Canada (SC = special concern; T = threatened; E = endangered); NSESA = *Nova Scotia Endangered Species Act* (E = endangered; T = threatened; V = vulnerable); S = s-rank (sub-national); S1 = critically imperilled; S2 = imperilled; S3 = vulnerable; S4 = apparently secure; S5 = secure; S#S# = range rank; S2B = Imperilled breeding; S3B = vulnerable breeding; S5B = secure breeding; S3N = vulnerable nonbreeding; S3S4M = vulnerable/apparently secure migrant; S3S4B = vulnerable/apparently secure breeding.

Blue felt lichen (SARA/COSEWIC Special Concern, NSESA Vulnerable) is the only SAR flora species observed within wetlands in the PA. Blue felt lichen was observed in four wetlands (WL 4, 14, 17 and 205) and is typically found in swamps or on the edges of wetland complexes growing on mature red maple. Suitable habitat for blue felt lichen within wetlands is scattered throughout the Beaver Dam Mine Site and Haul Road. Wetland 29, which contains occurrences of boreal felt lichen (SARA/COSEWIC/NSESA Endangered) beyond the PA. As such, Wetlands 4, 14, 17, 29 and 205 are identified as a WSS.

One female snapping turtle and nest was observed on June 27, 2019 on a berm adjacent to Wetland 59 within the Beaver Dam Mine Site. Snapping turtles are ranked as Special Concern by SARA and COSEWIC and Vulnerable by the NSESA. This anthropogenic feature (gravel berm created during historic mining operations) provides suitable nesting habitat for this species. Due to the mobility of the species, Wetland 59 was evaluated as a possible WSS.

Mainland moose tracks were observed in Wetland 210, adjacent to Wetland 206 (beyond the PA) and approximately 20 m north of Wetland 56, during dedicated moose surveys (May 24, 2015) and incidentally (September 9, 2014). These wetlands are located at the northern extent of the Beaver Dam Mine Site. Mainland moose are ranked as Endangered by the NSESA (no SARA/COSEWIC designation). Mainland moose forage for aquatic vegetation within wetlands during the summer. Wetland 56 was the only observation location assessed to have suitable habitat for foraging activities (i.e., anthropogenic open water features). It should be noted that a local Mooseland resident that frequents areas in and around the haul road had indicated that they had

observed mainland moose in the area in previous years (Appendix A.4a and A.5). Considering to the mobility of mainland moose and the presence of other unimpacted foraging habitat within the Beaver Dam Mine Site and Haul Road (e.g., wetlands surrounding Crusher Lake and Mud Lake), and Local Assessment Area (LAA) and Regional Assessment Area (RAA) (Section 6.8.7.2). Wetlands 56, 206 and 210 were not determined to be WSS.

Considering the above determinations, Figure 6.8-2A (Section 6.8.4.1.11) shows the location of field identified and potential WSS in relation to proposed infrastructure. Habitat quality present within the above identified wetlands is presented in Section 6.8.4.1.7. Priority species are discussed further in Section 6.13.

6.8.4.1.4 Hydrologic Condition and Integrity

The significance of this wetland function is determined by evaluating a wetlands' ability to manage water. Landscape and wetland characteristics, such as position in the landscape, connectivity to watercourses, evidence of water detention in the wetland, and vegetation composition and density, combine to determine the capacity of the wetlands to hold water, retard flows and hence maintain downstream flood potential.

The vast majority of all wetlands in the Beaver Dam Mine Site and Haul Road are either natural, or have been somewhat modified by historical timber harvesting, access roads, or lie adjacent to the existing roads. The NovaWET evaluation determined that the majority of assessed wetlands (80 within the Beaver Dam Mine Site (68%) and 91 within the Haul Road (75%)) provide a high ability to detain surface water, reducing downstream peak flows and aiding in flood mitigation. To a lesser extent, some wetlands has been determined important for maintaining stream flows (19 within the Beaver Dam Mine Site (19%) and 18 within the Haul Road (15%)).

6.8.4.1.5 Water Quality

The surrounding landscape condition, as well as wetland characteristics determine a wetland's ability to provide water quality functions. The NovaWET evaluation technique ranks wetlands whose source water contains sediment or contamination as higher than wetlands whose source water is pristine. Vegetative density and the position of the wetland on the landscape also help to determine how a wetland ranks in this category.

The NovaWET evaluation determined that 108 wetlands within the Beaver Dam Mine Site (92%) and 103 wetlands within the Haul Road (85%) contribute to water quality in downstream resources.

6.8.4.1.6 Groundwater Interactions

The NovaWET evaluation technique includes groundwater recharge/discharge determination. While this is difficult to determine by visual inspection alone, it has been included in this section and is further discussed in the Groundwater Quality and Quantity (Section 6.6).

Within a groundwater discharge wetland, the hydraulic gradient is upwards, receiving groundwater inputs from underlying soils. A recharge wetland has a downward hydraulic gradient, supplying water from the surface to underlying soils. Typically, groundwater discharge maintains high water tables within the wetland, whereas recharge sites replenish aquifers (Siegela 1988).

Landscape characteristics that are likely to indicate recharge wetlands include (NovaWET 3.0):

- Geographically isolated wetlands that contain all water entering them;

- Mineral soils and/or a lack of restrictive sub-surface components that may prevent the downward movement of water and recharge potential;
- Surrounding upland soils that prevent the downward movement of water (e.g., clays, shallow bedrock);
- Lack of outlet or restricted outlets, inflow wetlands, and lentic wetlands; and
- Land sloped away from a wetland (e.g., wetlands that are elevated in the watershed or near a watershed divide).

Within the Beaver Dam Mine Site and Haul Road, approximately 70% of wetlands are isolated or inflow wetlands, which provide potential groundwater recharge. Other wetlands contain watercourses or drainage channels that drain water toward the various waterbodies within and surrounding the Beaver Dam Mine Site and Haul Road. Outflow and throughflow wetlands (approximately 30%) are more likely to act as groundwater discharge sites. As discussed in Section 6.5.4 (Geology, Soil, and Sediment Qualty Baseline Conditions) underlying bedrock l conditions within the Beaver Dam Mine Site (and the general region) are comprised of greywacke and slate, and as a result of their impermeability and poorly jointed rocks, act as a confining layer. As a result, water sources to these wetlands are primarily via precipitation, snow melt, and surface water inputs (i.e., watercourses, runoff/sheet flow).

The relative percentage of recharge and discharge wetlands along the Haul Road and within the Beaver Dam Mine Site are similar. There is a slightly greater proportion of throughflow and outflow wetlands along the Haul Road.

6.8.4.1.7 Fish and Wildlife Habitat Integrity

Results of the NovaWET evaluation determined that nine wetlands within the Beaver Dam Mine (8%) and 10 within the Haul Road (8%) provide high functional significance for wildlife and fish habitat. The determination of high significance was afforded to these wetlands as a result of the wetlands' association with potential fish passage via connected watercourses, provision of fish habitat, and access to open water habitat for migratory birds.

Mainland moose (NSESA Endangered) tracks were observed in Wetland 210, adjacent to Wetland 206 (beyond the PA) and approximately 20 m north of Wetland 56, during dedicated moose surveys (May 24, 2015) and incidentally (September 9, 2014; Figure 6.13-1A). Mainland moose use wetlands to access submerged and emergent aquatic vegetation during summer and often seek out streams, ponds, and shorelines of lakes to escape heat and insects (e.g., wetlands surrounding Crusher Lake and Mud Lake) (NSDNR, 2007). Although not directly observed, wetlands identified within the Beaver Dam Mine Site and Haul Road provide potential habitat for priority wildlife species (e.g., Maritime shrew (S3) and the rock vole (S2)) which have been documented within 5 km of the PA). The fisher (*Martes pennanti* (S2)) is a largely nocturnal hunter with large home ranges and elusive behavior.

One female snapping turtle (SARA/COSEWIC Special Concern, NSESA Vulnerable), and nest was observed on June 27, 2019 on a berm adjacent to Wetland 59 within the Beaver Dam Mine Site. (Figure 6.13-1A). Previously, there was one incidental observation, outside field surveys, of this species along the Mooseland Road section of the Haul Road and two observations within the vicinity of the Touquoy Mine Site (Figure 6.13-1G). This species requires wetland habitat as part of its life cycle activities, specifically for overwintering. Wetlands within the Beaver Dam Mine Site and Haul Road which provide suitable habitat for snapping turtle include Wetlands 8, 10, 14, 17, 29, 44, 56, 59, 61, 64, 66, 68, 69, 159, 168, 171, and 207. These wetlands provide standing water to a depth exceeding 0.5 m and muddy substrate (e.g., lentic and lotic wetlands and wetlands with open water features), which provide potential overwintering habitat.

Twenty-nine of the wetlands in the Beaver Dam Mine Site (25%) have been determined to provide life cycle supporting habitat for fish species or provide other habitat support to fish (e.g., riparian vegetation, water quality, buffer functions) as a result of their

association with watercourses. Twenty-five of the wetlands identified in the Haul Road (20%) provide these functions. Priority fish species (American eel and brook trout) or their habitat were identified within Wetlands 8, 10, 17, 44 and 59. Details on fish species observed and their use of wetland habitat is described in Section 6.9 (Fish and Fish Habitat).

Multiple priority avifauna species were identified within and in close proximity to wetlands during dedicated avifauna surveys and via incidental sightings during field assessments completed throughout the Beaver Dam Mine Site and Haul Road. In addition, focused avifauna surveys were completed in many other habitat types and locations that do not constitute wetland habitat. A full list of priority avifauna species observed within the Beaver Dam Mine Site and Haul Road is provided in Section 6.13.5.4 The list was narrowed down to priority avifauna species that were identified at survey locations within, and directly adjacent to, wetland habitat, and that use wetlands as part of their preferred breeding habitat. These species are listed in Table 6.8-7, together with the preferred wetland habitat.

Priority species are discussed further in Section 6.13.

Table 6.8-7: Observed Bird Priority Species and Wetland Habitat Association

Bird Species	Preferred Wetland Habitat
Eastern wood-pewee	Wooded habitat, in riverside habitat
Canada warbler	Wet forests, riparian shrub forests
Rusty blackbird	Wet forests including fens, bogs, swamps and beaver pond
Spotted sandpiper	Semi-open area near shoreline of ponds, lakes, river and streams
Greater yellowlegs	Muskeg, wet bogs, marshes
Wilson's snipe	Wet, marsh, bogs, fens alder and willow swamps, wet meadows
Northern harrier	Nest on ground in grassland and wetland vegetation- marshes
Yellow-bellied flycatcher	Boreal coniferous forests and peatlands, bogs, swamps and muskeg
Tennessee warbler	Bogs, swamps and forests
Olive-sided flycatcher	Conifer forests near meadows and ponds

The NovaWET evaluation determined that at least one SAR bird was identified at point count locations within or directly adjacent to seven wetlands in the Beaver Dam Mine Site and 12 wetlands within the Haul Road. At least one SOCI bird was identified at point count locations within or directly adjacent to 13 wetlands in the Beaver Dam Mine Site and 25 wetlands within or adjacent to wetlands within the Haul Road. It should be noted, however, that these observations are based on detection points (e.g., point count locations) and do not specify whether the bird identified is using, or how it might be using, the wetland habitat as its preferred habitat.

6.8.4.1.8 Shoreline Stabilization and Integrity

The NovaWET evaluation technique ranks wetlands based on their ability to stabilize and provide stabilizing support to shorelines via their association with a watercourse (stream, lake, pond, etc.) or tidal feature (estuary, ocean). Other factors that determine the significance a wetland may play in providing these functions include vegetation characteristics (e.g., density, widths, species type, streambank colonization), but also the characteristics of the waterbody to which the wetland is adjacent (e.g., subjected to wave action, high flows, and other erosive forces).

Ten wetlands within the Beaver Dam Mine Site (9%) and seven within the Haul Road (6%) were determined to provide a high functional significance to shoreline stabilization.

6.8.4.1.9 Plant Community

None of the plant communities found in these wetlands were found to be regionally or provincially rare in either the Beaver Dam Mine Site or the Haul Road. As discussed in previous sections, wetlands present within the Beaver Dam Mine Site and Haul Road include treed and shrub swamps, bog, fen, marsh, and complexes of these wetland types. Wetland vegetation composition within all wetland habitats is typical to those existing in similar habitat throughout the province. Treed and shrub swamps are predominantly coniferous or mixed wood, with lesser amounts of deciduous swamp occurring. Bog habitats vary between low and high shrub bogs to treed bogs. Fen habitat predominantly comprises low shrubs or exist entirely as graminoid features. The few marsh habitats identified consist entirely of graminoid vegetation.

Table 6.8-8 provides the dominant species supported by each wetland habitat type found within the Beaver Dam Mine Site and Haul Road. Dominant vegetation per wetland is provided in the Wetland Characterization Table (Appendix H.2).

Table 6.8-8: Dominant Vegetation Supported by Wetland Habitat within the Project Area

Wetland Habitat Type	Dominant Species Supported
Treed and Shrub Swamps	Balsam fir, black and red spruce, red maple, yellow birch, mountain holly, cinnamon fern, three-seeded sedge, Canada bunchberry, bristly dewberry.
Shrub and Treed Bogs	Tamarack, black spruce, balsam fir, speckled alder, balsam fir, sheep laurel, Labrador tea, leatherleaf, cinnamon fern, bog fern, three-seeded sedge.
Graminoid and shrub Fen	Red maple, black spruce, tamarack, wild raisin, common winterberry, Atlantic sedge, bog cranberry, royal fern.
Graminoid Marsh	Bluejoint reed grass, harlequin blue flag, tussock's sedge, Common woolly bulrush, Canada manna grass.

Overall plant integrity within wetlands was determined via the NovaWET process by evaluating specific vegetative characteristics within wetlands identified during the study. Characteristics include presence of invasive or exotic species, extent of disturbances, vegetative density, and the presence of rare or endangered species (priority species).

The evaluation concluded that 34 wetlands within Beaver Dam Mine Site (29%) wetlands and 25 wetlands within the Haul Road (21%) were rated as comprising a highly significant diversity of species, whereas are also rated as such.

Six wetlands (WL 4, 12, 14, 17, 29, and 33) comprise at least one priority plant species (vascular and non-vascular) within the Beaver Dam Mine Site and eight wetlands (WL 80, 115, 129, 135, 137, 147, 157 and 161) comprise priority plant species in the Haul Road. Wetland 29, which contains boreal felt lichen (SARA/COSEWIC/NSESA Endangered), is the only wetland with a federally listed SAR observation. While the historical boreal felt lichen observations were not observed in most recent surveys in 2016 and 2017 (Section 6.13.4.3) and were located beyond the PA boundary, the wetland extends into the Beaver Dam Mine Site and is identified as critical/core habitat (NSE, 2020; ECCC, 2018). As such, Wetland 29 is identified as a WSS (Section 6.8.4.1.3). As per the ECCC Amended Recovery Strategy (2018) and NSE Adopted Recovery Plan (2020) for boreal felt lichen, the micro-siting and division of the waste rock stockpile has removed Project infrastructure from WL29 and the larger defined boreal felt lichen critical habitat area. Therefore, impacts to this species as a result of Project activities are not expected.

The overall integrity and quality of plants has been determined to be high in 46 of the wetlands identified in the Beaver Dam Mine Site (39%) and in 58 within the Haul Road (48%). Vegetation and habitat integrity remain moderate to high in the majority of wetlands despite disturbances in land surrounding the wetlands within Beaver Dam Mine Site and Haul Road (i.e., historic mining, timber harvesting, trail/road networks).

Priority species are discussed further in Section 6.13.

6.8.4.1.10 Community Use/Value

Community use and value of wetlands include, among others, access and visibility for humans to complete activities such as hunting, recreational, wildlife viewing, plant and berry gathering, fishing, etc.

The NovaWET evaluation determined that the majority of wetlands identified in the Beaver Dam Mine Site and Haul Road provide a low functional significance for community use and value, largely as a result of their inaccessibility. None of the wetlands have been determined to provide high value for community use in either the Beaver Dam Mine Site or the Haul Road.

6.8.4.1.11 Summary of Functional Assessment

Table 6.8-9 presents a summary of wetlands assessed to support critical functions (highlighted red in Appendix H.1) or contain a significant attribute, based on NovaWet SF groups. Specific SFs which identify unique or rare qualities described in Section 6.8.4.1.3 were selected to narrow the scope to wetlands observed to support significant functions or SAR/SOCI. Bolded wetlands provide multiple significant functions and are shown on Figures 6.8-2A to 6.8-2E.

Table 6.8-9: Summary of Wetlands with High Functional Significance

Significant Function (NovaWet SF)	Wetlands with High Functional Significance	
	Beaver Dam Mine Site	Haul Road
Floodplain Association (SF11)	WL **217**	n/a
Drinking Water Protected Area (SF10)	n/a	n/a

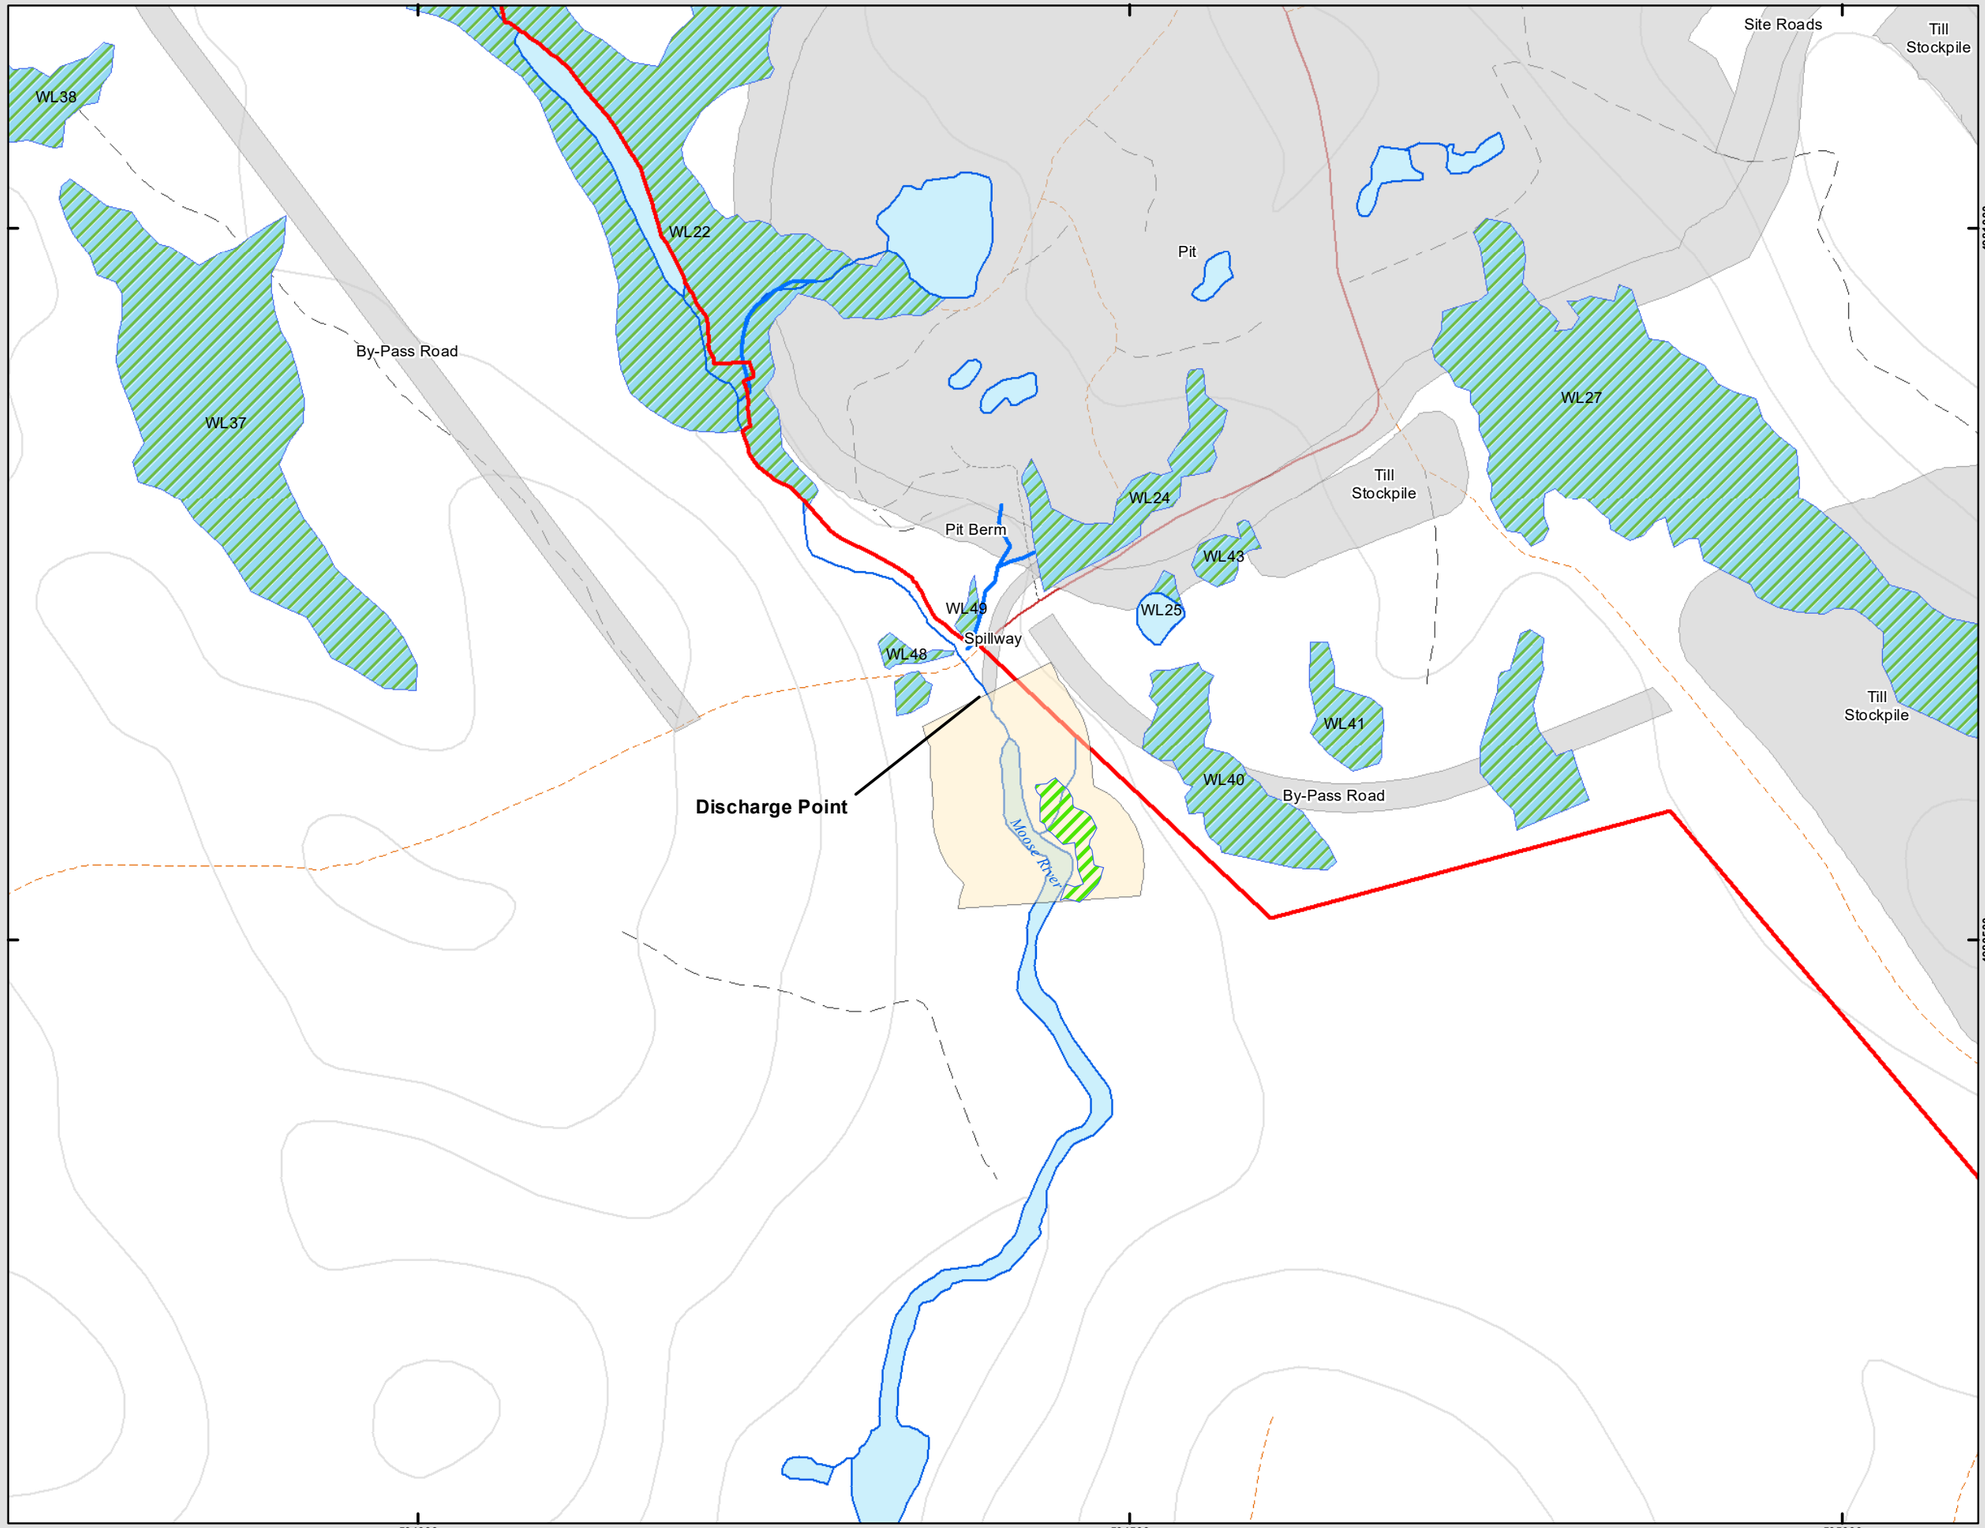
6.8.4.2 Touquoy Mine Site

Six wetlands were identified within the Touquoy Mine Site in 2006 as part of the EARD process, five of which were assessed. One of these wetlands was deemed to not be affected from Project development and therefore was not evaluated (CRA 2007a).



A total of 52 wetlands were identified within the Touquoy Mine Site (including the western bypass road) during field studies by MEL biologists from 2015 to 2017. These wetlands were identified for wetland permitting process and functional assessments were completed to support permitting. Evaluation will be limited to riparian wetlands along Moose River, downstream of the discharge location, to confirm potential indirect impacts from the Beaver Dam Mine Project during pit filling and deposition of tailings, and during the post closure phase when the pit is full, and a surface water connection is re-established to the Moose River. The baseline condition of the pit for the purpose of this assessment is considered at full draw down, at the time when Beaver Dam Mine Project tailings would commence deposition into the pit. Potential impacts to wetlands associated with pit drawn down during Touquoy operations and closure are considered as part of the Touquoy Gold Project EARD and subsequent permitting.

The Touquoy Mine Site is currently operational. The use of the Touquoy Mine Site for the processing of Beaver Dam ore and tailings management (exhausted pit) will not involve modification to the current footprint or new disturbances to wetlands during the construction and operations phase.

At post-closure and once water quality in the Touquoy Mine Site open pit meets MDMER discharge criteria, water surplus will be released into Moose River via a spillway. Wetland surveys, in the context of the Beaver Dam Mine Project, were conducted in along the Moose River, in response to IR2 NSE 2-176 (AMNS 2021). Surveys were conducted up to 200 m downstream of the proposed discharge point, considering the predicted mixing zone from the spillway (100 m from discharge location, Appendix F.8 [Beaver Dam Gold Project Assimilative Capacity Study of Moose River – Touquoy Pit Discharge]). The survey was focused to approximately 50 m east and west of the river to capture potential indirect impacts to wetland hydrology adjacent to the Moose River, focusing on riparian wetlands with direct hydrologic connectivity.

One wetland was observed along the eastern side the Moose River (within 20 m), beginning approximately 60 m south of the proposed discharge point (Figure 6.8-3). This wetland was delineated and characterized in October 2020 and again in April 2021, to assess its connectivity with the Moose River. The wetland is a 0.17 ha shrub dominated swamp, generally located at a higher elevation that the adjacent Moose River, separated by an upland berm along the majority of its western boundary. Overland flow from the adjacent upland was observed as the primary hydrologic input. Flow was observed from the wetland through a drainage feature to the Moose River. While no bidirectional flow, from the river to the wetland, was observed during either visit (October or April), it was noted that the southern portion of the wetland may have periodic connectivity with the Moose River, due to elevation and vegetation composition. However, hydrologic connectivity was not observed during high flow in April, which indicates that bidirectional connectivity is limited to extreme high flow events.

Potential bidirectional flow was observed beyond the 100 m mixing zone. As water quality will meet MDMER at discharge, and CCME/NSE Tier I/background concentrations or site-specific water quality objective at the end of the mixing zone in the Moose River, indirect impact analyses for riparian wetlands were limited to water quantity.

6.8.5 Considerations of Engagement Results

Key issues raised during public consultation and Mi'kmaq engagement relating to wetlands include direct impacts during construction activities at the Beaver Dam Mine Site and during Haul Road construction, as well as potential indirect effects from Project activities. Overall potential effects on habitat loss from direct and indirect wetland impacts was cited as a concern, including potential effects to use by Mi'kmaq peoples for hunting, fishing, trapping, and gathering.

The results of the public and Mi'kmaq engagement have been updated and considered in the environmental effects assessment (Section 3 and Section 4), including AMNS's commitments on mitigation and monitoring measures as well as broader commitment for ongoing public and Mi'kmaq engagement (Section 9 and Section 10).

6.8.6 Effects Assessment Methodology

6.8.6.1 Boundaries

6.8.6.1.1 Spatial Boundaries

The spatial boundaries used for the assessment of Project effects to wetlands is described below.

The PA (Section 5.5, Figure 5.5-1) consists of the three project components; Beaver Dam Mine Site, Touquoy Mine Site, and the Haul Road and extends from Marinette to Moose River Gold Mines, Halifax County, NS. The Beaver Dam Mine Site is located at the eastern end of the Beaver Dam Mines Road. The Haul Road spans from the Beaver Dam Mine Site to Moose River Gold Mines, where the Touquoy Mine Site [processing and exhausted pit (to be used to dispose Beaver Dam tailings)] is located. The PA has changed as a result of the expansion of the Beaver Dam Mine Site to accommodate micro-siting of mine infrastructure and ongoing modifications to the Haul Road design, as described in Section 2 (Project Description). These changes have been captured under the existing and additional desktop and field evaluations.

The LAA consists tertiary watersheds which intersect each component of the Project (Section 6.7, Figures 6.7-4 and 6.7-11). The LAA boundaries were defined considering the maximum expected extent of direct and indirect impacts to the aquatic environment as well as the location of Project activities across all PA components. The LAA surrounding the Touquoy Mine Site incorporates the Moose River to the west, and only includes the portion of the Square Lake watershed which interacts with the PA. No Project related aquatic effects are expected in the headwater portions of these watersheds. The lakes and watercourses that are included as part of the baseline programs and/or predictions of effects are located within the LAA boundary. The list below identifies tertiary watershed boundaries intersected by each component of the Project. The LAA is defined as the collection of all tertiary watersheds listed below:

- Beaver Dam Mine Site:
  - Portion of Killag River (1EM-2-D);
  - Tent Brook (1EM-2-F);
  - Paul Brook (1EM-2-H); and
  - Cope Brook (1EM-2-J).

- Haul Road:
  - Tent Brook (1EM-2-F);
  - Keef Brook (1EM-2-G);
  - Jack Lowe Brook (1EM-2-N);
  - Little River (1EM-2-P);
  - Portion of Sandy Pond (1EL-2-C), downstream of Otter Lake Brook and upstream of Ferry Lake; and
  - Portion of Morgan River (1EL-2-H), downstream of Morgan River.
- Touquoy Mine Site:
  - Portion of Moose River (1EL-5-P), upstream od the Moose River;
  - Westernmost portion of Square Lake (1EL-5-M); and
  - Portion of Scraggy Lake (1EL-5-N), upstream of Rocky Lake.

The RAA (Section 6.7, Figures 6.7-4 and 6.7-11) encompasses the three secondary watersheds that the PA is located within. These watersheds are:

- West River Sheet Harbour secondary watershed (1EM-2, incorporating the Beaver Dam Mine Site and Haul Road);
- Tangier River secondary watershed (1EL-2, incorporating the Haul Road); and
- Fish River-Lake Charlotte secondary watershed (1EL-5, which incorporates the Touquoy Mine Site).

The RAA is broader than expected Project impacts and considers other project boundaries as per the cumulative effects assessment methodology. As the Project has the potential to cause direct and indirect effects to fish and fish habitat outside of the PA, the LAA is the appropriate boundary for evaluation of this VC.

Assessment of wetlands will be completed in consideration of the LAA as the primary spatial boundary. All spatial boundaries will help to identify the direct or indirect impacts to flora and habitat and the effects of the Project on distribution and abundance of these species.

The PA, LAA and RAA were refined for the wetland cumulative effects assessment modelling exercise as discussed in Section 6.8.7.2.

6.8.6.1.2 Temporal Boundaries

The temporal boundaries used for the assessment of effects to wetlands are the construction phase, operational phase, active closure phase, and post-closure phase.

6.8.6.1.3 Technical Boundaries

No technical boundaries were identified for the effects assessment of wetlands.

6.8.6.1.4 Administrative Boundaries

Administrative boundaries for the protection and conservation of wetland habitat in Nova Scotia include the Nova Scotia Wetland Conservation Policy (2011b), the *Environmental Goals and Sustainable Prosperity Act* (EGSPA 2007) and the *Environment Act* (1994) and its' Activities Designation Regulations (1995).

Further wetland protection is provided on a federal level by the Federal Policy of Wetland Conservation (1991).

6.8.6.2 Wetland Cumulative Effects Modeling

A wetland cumulative effects modelling assessment was completed for wetlands losses associated with the Beaver Dam Mine Site. The modelling exercise was updated in order to capture modifications in the PA, LAA and proposed infrastructure footprints.

As stated in Section 6.8.4.1, wetland functional assessment was completed for each observed wetland within the Beaver Dam Mine Site and Haul Road using the NSE NovaWET 3.0 wetland evaluation technique. NovaWET 3.0 is a tool to evaluate individual wetland functions only and does not evaluate wetland functional loss, either individually or cumulative loss of multiple wetlands within any spatial watershed boundary (sub-drainage basin, tertiary or larger watershed). As such, the purpose of the wetland cumulative effects assessment is to evaluate the spatial cumulative effects associated with the loss of wetlands as a result of developing the Beaver Dam Mine Site.

Through completion of a modelling exercise, wetland loss (including loss of wetland function metrics) has been extrapolated to examine potential cumulative effects spatially.

The wetland cumulative effects modelling assessment was completed by establishing individual wetland function "metrics" and evaluating them as indicators of potential wetland function loss. The following metrics were established based on species observations within Beaver Dam Mine Site and Haul Road and known species use of wetland habitat, in alignment with IR2 CEAA-2-24 (AMNS 2021):

- Wetland Area;
- Loss of Wetland Habitat Function including:
  - Moose: mainland moose;
  - Turtles: snapping turtle; and
  - Birds: Canada warbler, olive-sided flycatcher, and rusty blackbird.

Spatial Boundaries

The spatial boundaries used for the assessment of cumulative effects of wetland loss (area and habitat function metrics) vary depending on the wetland function metric being evaluated. Table 6.8-10 provides the spatial boundaries evaluated as part of the wetland cumulative effects modelling:

Table 6.8-10: Wetland Cumulative Effects Spatial Boundaries

Function Metric	Spatial Boundary Assessed	Spatial Boundary Description
Wetland Area	PA	Beaver Dam Mine Site
	LAA	The LAA for wetlands, as described in Section 6.8.6.1. Portions of downstream aquatic habitats and headwaters where appropriate, depending on project activities, up to the maximum size of the tertiary watershed(s)
	RAA	The secondary watershed that the PA is located within (i.e., the West River Sheet Harbour secondary watershed)
Mainland Moose, Snapping Turtle, Rusty Blackbird, Canada Warbler, Olive-sided Flycatcher	PA	Beaver Dam Mine Site
	LAA	The LAA for wetlands, as described in Section 6.8.6.1. Portions of downstream aquatic habitats and headwaters where appropriate, depending on project activities, up to the maximum size of the tertiary watershed(s)
	RAA	Not assessed

6.8.6.2.1 Methods

Wetlands play countless roles in the maintenance of a healthy ecosystem. Among other functions, wetlands improve water quality, control floods, regulate water temperature, retain nutrients, and provide habitat for aquatic and terrestrial species. In order to evaluate the cumulative effects of wetland loss and their associated functions, modelling was completed based on the development of the following wetland function metrics:

- Wetland Area: A larger wetland, or larger frequency of wetlands and area in a given spatial boundary is likely to provide more wetland functions than a smaller wetland, or lesser frequency of wetlands and area in a given spatial boundary. Therefore, for the purposes of the wetland cumulative effects modelling assessment, wetland area has been analyzed as an indicator of potential wetland function loss. In order to effectively determine the loss of wetland area (and potential wetland function loss) the modelling quantified the area of wetland habitat directly impacted by mine development and its associated infrastructure, and compared it to predicted wetland area present in the LAA and RAA. This analysis enabled the potential wetland functions loss (based on the wetland area metric), to be made within the spatial boundaries assessed.
- Loss of Wetland Habitat Function: loss of wetland habitat function was evaluated by considering the loss of habitat provision for specific wildlife species that typically use wetlands for their survival and lifecycle tendencies. The three habitat metrics used were: moose habitat, turtle habitat, and bird habitat. These were evaluated using the following species and their requirements:
  - Moose: mainland moose;
  - Turtles: snapping turtle; and
  - Birds: Canada warbler, olive-sided flycatcher, and rusty blackbird.

These species chosen are SAR (mainland moose, NSESA Endangered; olive-sided flycatcher, SARA Threatened; Canada warbler, SARA Threatened, NSESA Endangered; rusty blackbird, SARA Special Concern, NSESA Endangered and snapping turtle, SARA Special Concern, NSESA Vulnerable) that are known to use a variety of wetland habitat types for critical biological functions, and had either been identified within the Beaver Dam Mine Site and Haul Road during field surveys or have potential to be present in the Beaver Dam Mine Site and Haul Road based on habitat provision or confirmed observations of the species in close proximity to the Beaver Dam Mine Site.

It should be noted that while the DNR forestry GIS layer does contain information on Canada warbler habitat (i.e., dense, deciduous shrub), it is derived from 1:12,500 aerial photographs and lacks the ability to appropriately distinguish suitable habitat for this species. Therefore, modeling was not possible for Canada warbler within the LAA. As such, Canada warbler was removed from the model exercise associated with the LAA so as not to bias the outcome. Canada warbler habitat was however determined for the Beaver Dam Mine Site based on data collected during field programs in combination with desktop resources.

The wetland function metrics were assessed within the spatial and temporal boundaries outlined in Table 6.8-11. In addition, the method of analysis performed on each wetland function metric is provided. For the purposes of this evaluation, Year 0 is considered "prior to any mine development activities" and Year 5 is considered "the completion of mine development" (i.e., complete wetland alteration and at maximum operational footprint/activity).

Table 6.8-11: Wetland Cumulative Effects Temporal Boundaries

Function Metric	Spatial Boundary Assessed	Temporal Boundary Assessed	Method of Data Analysis
Wetland Area	PA	Between Year 0 and Year 5	A comparison between wetland area prior to mine development within the Beaver Dam Mine Site, and wetland area at completion of mine development within the Beaver Dam Mine Site.
	LAA	Year 0	Wetland area within LAA and RAA is not expected to change as a result of the Beaver Dam Mine Site; therefore, a comparison of wetland area at Year 5 within the Beaver Dam Mine Site, to predicted wetland area within the LAA and RA at Year 0 will be made.
	RAA	Year 0	
Mainland Moose, Snapping Turtle, Rusty Blackbird, Canada Warbler, Olive-sided Flycatcher	PA	Between Year 0 and Year 5	A comparison between predicted species' wetland habitat prior to mine development within the Beaver Dam Mine Site, and predicted species' wetland habitat at completion of mine development within the Beaver Dam Mine Site.
	LAA	Year 0	A comparison of predicted species' wetland habitat at Year 5 within the Beaver Dam Mine Site, to predicted species' wetland habitat within the LAA at Year 0 will be made. Canada warbler comparison not possible due to insufficient GIS data.
	RAA	Year 0	Impact at RAA extent not considered likely.

Although not considered a quantifiable determination of potential wetland functional loss as a result of the Project, the analysis described in Table 6.8-12 and 6.8-13, provides the ability to extrapolate important wetland functional metrics, and assess their potential loss as a result of developing the Beaver Dam Mine Site.

It is recognized that wetlands play important water quality and purification functions, however, as a result of the general water management measures being implemented for the mine development, water quality has not been included in this analysis. Refer to Section 6.7, for a detailed description of the potential effects to water quality as a result of mine development, and methods that will be employed to ensure environmental standards are met.

Table 6.8-12: Metrics and Associated GIS Layers used in the Cumulative Effects Assessment – Wetlands Loss

Wetland Loss

Notes: RAA = Regional Assessment Area; LAA = Local Assessment Area; GIS = geographic information system.

Each of the wetland function metrics being evaluated in the cumulative effects wetland modelling exercise required the gathering of datasets which could be used digitally to compare to each other. The metric "Wetland Area" involved the combined collection of desktop and field wetland data. Conversely, the wetland function metrics for Moose, Turtle and Birds wetland habitats required a comprehensive desktop review to identify predicted important habitats for each of the species being evaluated, as well as habitat data collected during field surveys. Based on scientific literature, important wetland habitats were defined as those that support biological requirements for species survival. Determination of these important habitats supported the development of the datasets required for the cumulative effects model. The datasets used for the metrics being evaluated in the model within each spatial boundary are provided in Tables 6.8-12 and 6.8-13.

Once compiled, the datasets listed in Table 6.8-13 were arithmetically overlaid for each wetland function metric using ArcGIS (ArcMap version 10.4.1) at each geographic scale to create a habitat suitability layer at Year 0. The Beaver Dam Mine Site was also analyzed at Year 5. Interactions between wetlands generally, and the predicted suitable habitats created to model loss of wetland function metrics was achieved by overlaying the Beaver Dam Mine and its associated infrastructure footprint with the developed layers. Direct impacts to the developed layers were clipped out to calculate the predicted losses.

By modeling the impact of the Beaver Dam Mine Site and its associated infrastructure on wetland area and the predicted suitable wetland habitat for moose, turtles, and birds, the extent of impact was determined and potential loss of these wetland function metrics could be assessed.

Results of this process are provided in Section 6.8.4.1.

6.8.6.2.2 Modelling Limitations and Assumptions

The wetland cumulative effects modelling was developed to better understand the potential cumulative effect of wetland area and wetland function metric loss geographically, and over time. In order to produce a reasonable method to address this issue that falls within the realistic parameters of evaluating potential effects associated with the Beaver Dam Mine Project, there were multiple limitations and assumptions built into the modelling process. The following information provides a discussion of these limitations and assumptions, and their impact on the outcome of the assessment.

Certain assumptions were made in the selection of the four wetland function metrics. Initially, they were chosen to represent various wetland characteristics that can play an important role in determining a wetland's function. Wetlands play numerous roles in an ecosystem, and it is difficult to narrow those functions down for the purposes of a modelling exercise. However, for the purpose of this modelling exercise it was necessary to do so. The four wetland function metrics were assessed using available data layers. The biological requirements, habitat descriptions, and representative data layers were chosen using scientific information from peer-reviewed papers, government documents and/or conversations with specialists. To the best of our knowledge, they depict an accurate snapshot of the wetland habitat used by each species modelled. Limitations were observed when it came to compiling available data, for example, Canada Warbler, which use a dense, deciduous shrub layer, was not able to be modeled given the lack of available data. When creating this layer, it was determined that the available GIS datasets narrowed the search too much, resulting in an overly conservative selection of suitable wetland habitat. Furthermore, all GIS layers used are limited by the accuracy and precision of the publicly available data from which they came. For all metrics, field assessments and ground truthing in the PA resulted in more accurate data. When comparing this level of detail to the LAA and RAA, where data is far less accurate and less precise, the analysis is underestimated at these larger geographic scales. The analysis performed at the LAA and RAA levels underrepresent predicted suitable wetland habitat, making the comparative area of impacted suitable wetland habitat in the Beaver Dam Mine Site less than the results of the modelling exercise suggests.

In the context of meeting the objectives of the wetland cumulative effects modelling exercise, the modeling methods were developed to get the best possible analysis of cumulative effects. However, given the current resources and limitations in available data, a protracted model was not able to be produced. Instead, the study aimed to qualitatively show the cumulative effects of the project footprint on wetlands and metrics of their function within the LAA/RAA and over the life of the active mine (5 years) where possible within the Beaver Dam Mine Site. The mine footprint was used in the model to show area of impact. There are certain limitations around this, as it does not accurately show the potential indirect impacts to upgradient and downgradient wetland habitats. The impacted area assessed only includes the portion of the wetland directly beneath the Beaver Dam Mine infrastructure footprint, when in reality there could be impacts to other extents of the remaining wetland.

Lastly, for the purposes of this modeling exercise the study was not able to predict the future changes within the LAA and RAA and how those changes may affect wetland habitat and functions.

6.8.6.3 Thresholds for Determination of Significance

A significant adverse effect from the Project on wetlands is defined as:

- an effect that results in an unmitigated or uncompensated net loss of wetland habitat as defined under the NSE Wetland Conservation Policy, and its associated no-net loss policy; or
- an effect to wetlands that is likely to cause a permanent loss of >10% wetland habitat for a SAR species identified in the PA within the LAA, which is defined by the tertiary watershed boundary.

The area of wetland loss within the PA relative to the area of all NSE mapped wetland habitat available within the LAA was used to determine magnitude. This assessment is completed recognizing the fact that wetland habitat outside of the PA is underrepresented by provincial wetland databases. **Given this assumption, the percent of wetland alteration within the Beaver Dam Mine Site and Haul Road is conservatively high, as these area calculations are based on field verified wetland boundaries.**

The following logic was applied to assess the magnitude of a predicted change in wetland habitat as it relates to the cumulative effects methodology and conclusions:

- Negligible – loss of <1% of NSE mapped wetlands in the LAA;
- Low – loss of 1 to 10% of NSE mapped wetlands in the LAA, and no direct or indirect impact to an identified WSS;
- Moderate – loss of 1 to 10% of NSE mapped wetlands in the LAA and direct or indirect impact to an identified WSS; and
- High – greater than 10% loss of NSE mapped wetlands in the LAA.

The timing of residual effects for wetland habitats considers when the residual environmental effect is expected to occur, considering seasonal aspects. The duration of residual effects considers the time frame over which the effects are likely to last, ranging from short-term to permanent. The frequency of residual effects considers the rate of recurrence of the effects, ranging from once to continuous. The reversibility of residual effects considers the time required for wetland habitat to recover to baseline conditions, or whether the changes to wetland habitat, if identified, are permanent.

6.8.7 Project Activities/Interactions with Wetlands

During review of Project activities and their expected direct and potential indirect effects to wetlands, it was determined that wetland alteration authorization would be required to allow for development of the Project. Alternative locations for Project infrastructure were considered, where practicable, focusing specifically on reducing impacts to wetland habitat. The effects of the Project on wetlands were determined considering the effects of the project on groundwater and surface water.

Potential interaction between Project activities and wetland habitat within the Beaver Dam Mine Site and Haul Road are outlined in Tables 6.8-14 and 6.8-15 below.

Table 6.8-14: Potential Project Activities/Interactions with Wetlands at Beaver Dam Mine Site

Project Phase	Duration	Project Interactions
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of construction (e.g., pre-stripping) • Topsoil, till and waste rock from site preparation transport and storage • Watercourse and wetland alteration in preparation of construction, including open pit dewatering • Surface infrastructure installation and construction • General waste management • Collection ditches and settling pond construction • Local traffic bypass road construction • Mine Site road construction • Culvert and bridge upgrades and construction • Invasive species introduction or spread • Environmental monitoring;
Operation	5 years	Drilling and rock blasting to access and extract ore • Management of waste rock produced from crushing and preparing ore for transport • Till and waste rock from site preparation transport and storage • Open pit dewatering, interaction between groundwater drawdown and wetlands; • Alteration of surface water hydrology (i.e. ditching of site surface water runoff and surface mine pumped water) and surface water management; • Site maintenance • Treatment of site surface water runoff and surface mine pumped water • General waste management • Petroleum products management • Dust management • Culvert and bridge maintenance • Invasive species introduction or spread • Environmental monitoring
Active Closure	2 years	• Site reclamation • General waste management • Water treatment and management • Environmental monitoring
Post-closure	10+ years (monitoring)[(a)]	• Water treatment and management • Environmental monitoring

Note: [(a)] Post-closure wetlands monitoring will be determined based on monitoring and discussions with regulators.

Table 6.8-15: Potential Project Activities/Interactions with Wetlands along the Haul Road

Project Phase	Duration	Project Interactions
Construction	1 year	• Clearing, grubbing, and grading in preparation of construction • Rock blasting in preparation of construction • Watercourse and wetland alteration in preparation of construction • Haul Road construction and upgrades • Auxiliary infrastructure installation and construction • Local traffic bypass road construction • Culvert and bridge upgrades and construction • Environmental monitoring • Invasive species introduction or spread • General waste management
Operation	5 years	• Haul Road maintenance and repairs; • Dust management • Petroleum products management; • Environmental monitoring • Invasive species introduction or spread • General waste management.
Active Closure	2 years	• N/A[a]
Post-closure	10+ years (monitoring)[b]	• N/A

Notes: [a] Decommissioning and Reclamation of the Haul Road is not expected. The Haul Road will be returned to owner for forestry industry.
[b] Post-closure wetlands monitoring will be determined based on monitoring and discussions with regulators.
N/A = not applicable.

6.8.7.1 Beaver Dam Mine Site and Haul Road Wetland Impacts

Development of the Beaver Dam Mine Site and Haul Road will cause direct and indirect impacts to wetlands mostly during the construction phase of the Project. Direct impacts will be associated with clearing, grubbing, infilling, and development of the Project and its associated infrastructure. Development of the Beaver Dam Mine Site will account for the greatest direct impact to wetland habitat. Direct impacts along the Haul Road, will include upgrading of the road (e.g., widening) and new construction of a 4 km road section (Section 2, Figure 2.3-1). Indirect impacts are a by-product of direct impacts associated with construction activities, as well as potential indirect impacts to wetlands from mine operations (dewatering, blasting, and accidents). Table 6.8-16 provides general impact types and a description of various direct and indirect examples by which these may occur as a result of Project activities. No direct wetland impacts are proposed outside of the PA.

In 2019, the PA was modified to allow for the micro-siting of infrastructure, as described in Section 2. The waste rock stockpiles have been relocated twice to avoid impacts to fish and wetland habitat. There continues to be ongoing refinement of the Project design to avoid direct and indirect impacts to wetlands. During the wetland alteration permitting phase, additional micro-siting of infrastructure (i.e., road alignment and other supporting infrastructure) will occur where practicable to avoid wetland impacts, and infrastructure-specific buffers will be added to wetland impact areas where necessary.

Table 6.8-16: Direct and Indirect Wetland Impacts

Impact Type	Direct Impact	Project Phase	Indirect Impact	Project Phase
Alteration of Wetland Hydrology: If the hydrological regime of a wetland is altered, the vegetation, character, and function of the wetland also have potential to change.	Complete dewatering (removing wetland), infilling or flooding of a wetland to facilitate Project development resulting in conversion from wetland to upland habitat.	C	Hydrologically connected upstream wetlands may also be at risk of indirect impacts as a result of downstream alteration activities (e.g., water outflow changes, land elevation changes, blasting, etc. causing dewatering). Inadvertent damming of up-gradient wetlands from construction related infrastructure (e.g., roads with lack of flow through infrastructure).	C, CL
	Alteration of hydrological inputs and outputs into partially altered wetlands has the potential to alter remaining (undeveloped) wetland habitat.	C, O, CL	Removal of on-site outflow and throughflow wetland habitat has the potential to alter the localized hydrology in downgradient wetlands.	C
			Hydrological changes can affect the use of the wetland by wildlife as habitat.	C
			Blasting adjacent to wetlands has the potential to alter subsurface water flows, especially in fractured rock. This activity has the potential to increase or decrease subsurface hydrological flow to adjacent wetland habitats and can precipitate drier (dewatering) or wetter conditions in those habitats.	C, O
			Groundwater drawdown will reduce groundwater inputs to specific wetlands causing dryer conditions (14 intact wetlands within the predicted radius of influence).	O, CL
			Changes to catchment areas and resultant flow reduction will reduce water inputs to specific wetlands causing dryer conditions.	C, O, CL
Alteration of Water Quality:	Removal (alteration) of wetland from the landscape leading to reduced or no water supply to downgradient aquatic receivers (e.g., streams, additional wetlands, and lakes).	C, O, CL	Alteration of the wetlands increases the risk of downgradient sedimentation.	C, O, CL
			The effects of increased sedimentation as a result of up-gradient activities (e.g., earth moving, removal of vegetation, soil stockpiling) has the capacity to suffocate existing plant life and increase nutrient levels in downgradient wetlands. Dust created as a result of construction activities can have a similar impact.	C, O, CL
			Runoff from acid producing rock exposed during construction and operations activities has the potential for negatively altering water quality within downgradient wetland habitat.	C, O, CL
Vegetative and Habitat Integrity:	Extensive ground works, including activities such as blasting in and adjacent to wetlands has the potential to destabilize land surfaces and the root zone of vegetative areas, including wetland buffers.	C, CL	Introduction of invasive species can occur indirectly into wetlands when equipment or people enter the wetlands or via runoff or dust from the roads. Introduction of mine and Haul Road traffic during construction and operation can elevate this risk. Invasive species, such as purple loosestrife (*Lythrum salicaria*), can severely degrade wetland habitat and function. No purple loosestrife was noted during field surveys in the Beaver Dam Mine Site or Haul Road.	C, O, CL
	Loss of vegetative cover decreases wildlife habitat availability and also has the potential to reduce natural surface water drainage.	C	Dust accumulation on vegetation can smother and stress the plants. The dust can also provide minerals and nutrients into the wetland habitat.	C, O, CL
	Seeds and roots of invasive species can be transferred from construction equipment, transportation vehicles, or workers into adjacent wetland habitat during construction and operational activities.	C, O, CL		
Malfunctions and Accidents: Accidental spills of contaminants in up-grade work areas has the potential to drain into down-gradient wetlands, and can cause negative impact to wetland function, and potential use of the habitat by wildlife.				C, O, CL

Notes: C = Construction Phase; O = Operation and Maintenance Phase; CL = Active Closure.

6.8.7.1.1 Direct Wetland Impacts

Expected direct impact extent to wetlands, as a result of Project activities during the temporal lifetime of the Project, are presented in Table 6.8-17 for the Beaver Dam Mine Site and Table 6.8-18 for the Haul Road. Indirect hydrological wetland impacts to adjacent wetlands within the PA that may be expected as a result of the Project are discussed separately. Only wetlands where expected direct habitat alteration is expected are included in these tables. All estimated direct impact areas have been updated base on the 2019 PA and infrastructure modifications.

Type of direct impact is categorized as either partial or complete. Where a partial alteration is proposed, in some cases, remaining portions of a wetland may not be maintained in a natural condition or function and is thus considered a complete alteration. Therefore, a wetland is considered completely altered when 100% of the wetland is directly impacted by Project development or the remaining wetland area will not be self-sufficient. It was also determined that if portions of wetland habitat are not likely to maintain a natural condition (i.e., a portion remains between two drainage ditches), the direct alteration area has been expanded to include wetland fragments which lie outside of proposed infrastructure. Each wetland proposed for alteration is assessed on a case-by-case basis. When determining alteration extent, the hydrologic regime, wetland type and morphology, alteration type, indirect effects (e.g., edge effects) and particularly the relative size of the wetland compared to alteration area are considered. Predicted alteration extent will be refined at the permitting stage.

Table 6.8-17: Direct Wetland Impacts (Aerial Extent and % Change) within the Beaver Dam Mine Site

Total	**231,383 m^2 (23.1 ha)**	**15,795 m^2 (1.6 ha)**	**Total complete wetland alterations**		**5**
			Total partial wetland alterations		**53**

Notes: [(a)] Wetland area within the PA.
[(b)] Haul Road upgrade, unless otherwise specified. Includes bypass roads, where applicable.
[(c)] P – Partial habitat loss of wetland. C – Complete habitat loss of wetland.
[(d)] Area is inclusive of both Haul Road and Beaver Dam Mine Site portions of WL64. Both are potentially impacted by Haul Road development.
m^2 = square metre; ha = hectares; NAG = non- acid generating; PAG = potentially acid generating.

As presented in Table 6.8-17, within the Beaver Dam Mine Site, 30 wetlands will be completely altered, and 20 wetlands will be partially altered as a result of Project infrastructure and development. As presented in Table 6.8-18, along the Haul Road, 5 wetlands will be completely altered, and 53 wetlands will be partially altered as a result of new road construction and upgrading activities. Of the 236 wetlands identified within the Beaver Dam Mine Site and Haul Road, a total of 108 wetlands are expected to be directly impacted to support Project development, 35 of which are expected to be completely altered, and 73 of which are expected to be partially altered (Table 6.8-19). The remaining 128 wetlands will not be directly altered.

In total, it is anticipated that 31.8 ha of wetland area will be directly impacted by the Project (Table 6.8-19). Within the Beaver Dam Mine Site and Haul Road, 41% and 7% of the total wetland area, respectively, is expected to be directly impacted (partially or completely). Thirty-three percent of the total wetland area within the Beaver Dam Mine Site and Haul Road is expected to be directly impacted.

Table 6.8-19: Total Expected Direct Wetland Impacts within the Beaver Dam Mine Site and Haul Road

PA Component	Total Wetland Area (m^2)	Total Estimated Direct Impact Area (m^2)	Percent Area Impacted	Complete Alteration	Partial Alteration
Beaver Dam Mine Site	733,997 m^2 (73.4 ha)	302,020 m^2 (30.2 ha)	41%	30	20
Haul Road [(a)]	231,383 m^2 (23.1 ha)	15,795 m^2 (1.6 ha)	7%	5	53
Total	965,380 m^2 (96.5 ha)	**317,815 m^2 (31.8 ha)**	**33%**	**35**	**73**

Notes: [(a)] Haul Road upgrade, unless otherwise specified. Includes bypass roads, where applicable.
m^2 = square metre; ha = hectares; NAG = non- acid generating; PAG = potentially acid generating

Modifications from the original Project design (Beaver Dam Mine Project – EIS, 2017) has maintained a similar total area of direct wetland impact within the Beaver Dam Mine Site and Haul Road (<1% change). However, in comparison to the Beaver Dam Mine Project – Revised EIS (February 2019), the total area of direct wetland impact has increased by 30% (previously 22.1 ha). This increase has occurred as the result of necessary Project changes to micro-site infrastructure off fish bearing watercourses (Section 2) and the addition of the organics material stockpile for reclamation purposes. However, due to further refinement and micro-siting of the Haul Road, the total direct wetland impact area has decreased by 33% from 2.4 ha (Beaver Dam Mine Project – Revised EIS, February 2019) to 1.6 ha. This decrease in Haul Road impact area includes the addition of new proposed bypass roads.

Infrastructure has been planned to avoid wetland impacts wherever practicable and considering other environmental and engineering constrains. During the wetland alteration permitting phase, additional micro-siting of infrastructure (i.e., road alignment and other supporting infrastructure) will occur where practicable to avoid wetland impacts, and infrastructure-specific buffers will be added to wetland impact areas where necessary. The impacts of the Project on fish and fish habitat within wetlands is discussed is Section 6.9.7. Wetland area that is accessible to fish is directly accounted for in the draft Fish Habitat Offset Plan (Appendix J.3).

The Beaver Dam Mine Site and Haul Road are dominated by isolated or inflow wetlands, which provide potential groundwater recharge. Removal of recharge wetlands from the landscape removes the ability for water to be collected, stored, and fed into underlying aquifers. However, once other water loss factors such as evapotranspiration have been accounted for, the loss of smaller recharge wetlands (e.g., isolated features lacking an outlet and/or lentic wetlands located adjacent to lakes) is not expected to affect groundwater levels on a landscape level. Based on the proposed Project design within the Beaver Dam Mine Site, many small, isolated, recharge wetlands will be completely altered as a result of Project infrastructure. Of note, however, is the limited size of these wetlands in comparison with other, non-isolated wetlands present within the Beaver Dam Mine Site. It is not anticipated that alteration of the smaller isolated wetlands will bear critical impact to groundwater recharge capacity, especially at a more regional scale (i.e., secondary watershed level). Existing hydrologic connectivity will be maintained through many throughflow and inflow wetlands, within the Beaver Dam Mine Site and Haul Road. Most large headwater recharge wetlands, such as Wetland 2 and 29, will be avoided by Project development. For these reasons, direct wetland alteration associated with the Project is not expected to alter groundwater recharge capacity.

Direct Impacts to Wetlands of Special Significance

As described in Section 6.8.4.1.3, a total of five wetlands (WL 4, 14, 17, 29 and 205), were identified WSS based on the presence of blue felt lichen (SARA/COSEWIC Special Concern, NSESA Vulnerable) and boreal felt lichen (SARA/COSEWIC/NSESA Endangered). Wetland 59 was assessed as a possible WSS based the presence of a nesting snapping turtle ((SARA/COSEWIC Special Concern, NSESA Vulnerable) and suitable habitat. Wetlands 4 and 29 will be avoided by Project infrastructure completely. Wetland 59 will be completely altered and was unable to be avoided due to the placement of the open pit. Wetlands 14, 17 and 205 will be partially impacted by Beaver Dam Mine Site infrastructure.

The impacted areas of these Wetlands 14 and 17 do not contain occurrences of blue felt lichen. A mine road will bisect the western end of Wetland 14. The blue felt lichen occurrences are within the eastern side of this Wetland 14 and there is no planned development within 100 m of these occurrences. Wetland 205 will be partially directly impacted by the NAG waste rock stockpile, including the area that contains one occurrence of blue felt lichen. As avoidance of this wetland is not practicable (Section 6.8.8.1), translocation of the blue felt lichen (detailed in Appendix P.6 [Preliminary Lichen Mitigation and Monitoring Plan]) is proposed, to mitigate impact to this species.

Measures to avoid, mitigate and compensate effects to WSS are provided in Sections 6.8.8.1 and 6.8.8.2.

As described in Section 6.8.4.1.3, the bolded wetlands in Table 6.9-20 have been assessed to support multiple unique or rare attributes, and therefore, may provide, or have the potential to provide, multiple significant functions. These wetlands, including the field-evaluated identified and potential WSS (bolded), are presented in Table 6.8-20, with expected direct impact area (i.e., direct habitat alteration) as a result of Project activities.

Table 6.8-20: Direct Impacts to Wetlands with Multiple Significant Functions

6.8.7.1.2 Potential Indirect Wetland Impacts

Indirect impacts are described as changes to wetland condition that may occur due to the Project, where wetland habitat is not directly lost, but is changed as the result of the Project (i.e., wetting or drying of wetlands). Indirect impacts may occur as a result of unintended wetting or drying of wetlands due to Project development (such as groundwater drawdown, or loss of surface water flow within local catchment areas). Estimates of potential indirect impacts are provided herein, however it should be noted that these estimates represent the maximum potential impact as a worst-case scenario. Reasonable indirect impacts of the Project will be determined at the permitting phase and through monitoring programs. Mechanisms to reduce the potential for wetland impacts from accidents and malfunctions will be addressed and discussed in Section 6.18.

Groundwater Interactions

Indirect impacts to wetlands by groundwater drawdown near the Beaver Dam Mine open pit is expected to occur. When assessing indirect effects to wetlands from groundwater drawdown, the end of mine (EOM) and post-closure (PC) simulations under the modeled conditions with the greatest drawdown extent to use as a conservative, worse-case approach (Section 6.6.7.1 and Appendix F.5 Hydrogeologic Modelling Report). Modeled groundwater drawdown at EOM ranges from 10 to 15 m closest to the pit to 0.1 m at the extent of the predicted drawdown area (Section 6.6 (Groundwater), Figure 6.6-11 for dry conditions and Figure 6.6-13 for wet conditions). Project related drawdown up to 1 m is expected to extent up to 905 m from the Beaver Dam Mine pit, at EOM and PC. However, isolated pockets of groundwater drawdown between 0.1 to 0.5 m are predicted up to 1,700 m from pit. The drawdown area is presented on Figure 6.6-15 for the Beaver Dam Mine Site.

Wetlands regularly undergo seasonal Relative Groundwater Depth (RGWD) fluctuations in response to variability in annual precipitation (magnitude and frequency), evapotranspiration, and climactic trends. Geographically isolated wetlands have been reported to have seasonal fluctuations ranging as high as ±20 cm (Keddy 2010). Keddy (2010) also found that wetlands associated with lakes and watercourses were found to have seasonal variability as high as ± 1.5 m. The US Army Corp (2009) stipulates that wetland hydrology is defined as saturation of soils 20 cm below the surface or groundwater levels within 30 cm of the surface for a period of two consecutive weeks in the growing season (June through September). Therefore, wetland conditions and functions can persist despite natural RGWD variability.

The stability, size and function of wetlands is primarily controlled by hydrological processes (Carter, 1996; Price, 2005, Tiner 2005). Drawdown caused by mining can affect all wetlands that have direct groundwater connectivity (discharge and recharge wetlands), which generally includes most wetlands with the exception of those systems disconnected from local groundwater flow systems (e.g., perched wetlands, some raised bogs). Drawdown can change the hydroperiod of a wetland and reduce water levels which

can cause an adverse effect on wetland function (Mortellaro et al. 1995). Effects include dryer conditions, change in flow direction (lateral and vertical), changes to vegetation, and changes to wildlife habitat (e.g., fish and amphibians).

Large wetland systems within the groundwater drawdown area around the open pit at the Beaver Dam Mine Site that have large area of standing water (e.g., WL17, riparian wetlands along Cameron Flowage) and defined surface water inputs are less likely to be affected by drawdown. Conversely, the impact to dryer, more marginal wetlands are likely to be more severe. If wetlands become dryer, organic soils can subside, and plants may become stressed. Many wetland plants, however, can survive periodic dry conditions and reproduce under altered hydrologic conditions. Loss of groundwater can also convert discharge wetlands into recharge wetlands which in turn can reduce surface water supplies and levels down gradient (Tiner 2005). Changes in surface water quantity can affect downstream wetlands, watercourses and waterbodies that receive surface water inputs, as discussed above, as well as fish and fish habitat (Section 6.9).

There are 22 wetlands which interact with the operations and post-closure drawdown for dry and wet conditions (Figure 6.8-4A, Figure 6.6-11 for dry conditions and Figure 6.6-13 for wet conditions). Of these 22 wetlands, seven will be completely altered from Project development and were not carried forward in this analysis. The remaining 12 wetlands within the drawdown area may vary from being partially altered to unaltered from direct Project development. A summary of wetlands within the drawdown area is presented in Table 6.8-21 and below:

- Complete direct alterations from infrastructure are proposed for seven wetlands. As these will be completely altered, they have not been considered in the evaluation of indirect effects from groundwater drawdown.
  - WL55, 56, 58, 59, 60, 212 and 245.
- Partial direct alterations are proposed for eight wetlands, with the unaltered portion falling within the drawdown area. The unaltered portion of these wetlands have been considered in the evaluation of indirect effects from groundwater drawdown.
  - WL5, 17, 19, 20, 34, 57, 61, 216, 217.
- These five wetlands are considered in the evaluation as indirect effects from groundwater drawdown.
  - WL62, 238, and 240.

There are 12 intact or partially intact wetlands that may be affected from groundwater drawdown. The likelihood of groundwater interactions within wetland habitat increases with increasing proximity to the pit, wetland type, groundwater connectivity and source and flow direction (i.e., upward (discharge) or downward (recharge) gradient). These functions have been determined through the NovaWet functional assessment, summarized in Table 6.8-5. Intact or partially intact wetlands (or portions of) that are predicted to be affected by groundwater drawdown ranges between 0.1 to 5 m during operations (Figure 6.8-4A and Table 6.8-21). Simulated drawdown is generally less than 10 cm outside of the PA, with the exception of the area between the till stockpiles and Cameron Flowage where the maximum drawdown reaches approximately 1 m beyond the PA (Appendix F.5).

Table 6.8-21: Intact Wetlands within the Simulated Groundwater Drawdown Area

Wetland	Total Wetland Area (m^2)	Groundwater Drawdown Area Effect	Simulated Drawdown (m)	Wetland Groundwater Interaction	Potential for Groundwater Indirect Effects
5	6,202	Partial	0.1 to 0.5	Discharge	No
17	76,341	Partial	0.1 to 2.0	Discharge	Yes
19	11,428	Partial	0.1 to 1.0	No GW Interaction	No
20	101,006	Partial	0.1 to 1.0	Discharge	Yes
34	1,382	Complete	2.0 to 5.0	Recharge	Yes
57	88,717	Partial	0.1 to 1.0	Discharge/Recharge	Yes
61	25,809	Partial	0.1 to 5.0	Discharge	Yes
62	832	Partial	0.1 to 0.5	Discharge	No
216	1,397	Complete	1.0 to 2.0	Recharge	Yes
217	5,230	Complete	0.5 to 1.0	Discharge	Yes
238	4,685	Partial	0.1 to 0.5	Recharge	No
240	21,799	Partial	0.1	Recharge	No

Notes: m^2 = square metre; m = metre.

Based on their overlap with the groundwater drawdown area (PC and EOM) and groundwater interactions (i.e., discharge or recharge) seven of the 12 wetlands are expected to experience potential indirect impacts from groundwater drawdown, through operations and/or at post-closure (Table 6.8-21). While the maximum extent of groundwater drawdown at PC is similar to the EOM simulation, the PC drawdown gradient decreases substantially around the pit following closure (Section 6.6, Figures 6.6-11 to 6.6-14). At PC, intact wetland habitat within the 0.5 m groundwater drawdown may experience indirect groundwater impacts from a permanent hydrologic shift as a result of the Project. While wetland water table fluctuations of 40 cm are naturally observed (Keddy 2010), a permanent water table decrease of 0.5 m.

All wetland habitat within the 0.5 m PC groundwater drawdown area is proposed for either partial or complete direct impact through Project infrastructure. The 0.5 m PC groundwater drawdown area is predicted to interact with intact portions of Wetlands 17, 34, 57, 61, 216 and 217. A 0.5 m groundwater drawdown is only expected to impact portions of Wetland 20 that will already be directly impacted by infrastructure, and therefore no further indirect impacts from groundwater drawdown are expected.

To assess the indirect effects of groundwater level change at PC in intact wetlands, wetlands that have direct interactions with groundwater (i.e., wetlands where groundwater is the primary hydrologic source) were identified. Groundwater inputs to wetlands were determined using their topography, wetland type, absence of inflow/through flow, presence of deep organic soils, and the presence of the water table near the soil surface and surface saturation. Wetlands with known or expected groundwater influence are expected to be impacted to a greater extent by groundwater drawdown (compared with those driven by surface water).

Of the six wetlands expected to experience groundwater impacts, Wetlands 17, 61 and 217 have direct connectivity with surface water features and/or are large wetland complexes with multiple hydrologic inputs, which are anticipated to mitigate adverse effects of groundwater drawdown. Wetlands associated with lakes and watercourses can naturally experience larger seasonal variability in water table levels (± 1.5 m, Keddy 2010). However, intact portions of Wetland 61 (approximately 3%) are expected to experience a groundwater drawdown greater than 2.0 m at EOM. This drawdown will decrease to less than 1.0 m at PC. As Wetland 61 is a riparian system directly connected to Cameron Flowage, which is not expected to experience a flow reduction during operations or at PC (Appendix F.5 Hydrogeologic Modelling Report), groundwater drawdown impacts are predicted to be mitigated by surface

water inputs. Nevertheless, Wetland 61 is proposed for monitoring due to its proximity to the open pit, partial direct impacts and potential groundwater impacts.

While Wetland 57 is a discharge headwater wetland and is more vulnerable to changes in groundwater levels, the majority of the intact portion of Wetland 57 is within the 0.1 m of groundwater drawdown (EOM and PC). As a result, it is anticipated that Project related groundwater impacts within this wetland will be within natural variability. Where drawdown is expected to exceed 0.1 m, monitoring of Wetland 57 is proposed.

Wetlands 34 and 216 were assessed to be the most at risk of indirect groundwater impacts (excluding those that will be completely directly impacted by infrastructure or where groundwater drawdown is limited to the directly impacted portion) and are anticipated to experience indirect effects from groundwater drawdown. Wetlands 34 and 216 are isolated swamps without persistent surface water inputs and are predicted to experience groundwater drawdowns of 1.0 to 5.0 m at PC. Conservatively, it is estimated that the full areas of Wetland 34 and 216 will be potentially impacted from groundwater drawdown (0.28 ha).

Monitoring of potential indirect groundwater impacts will be conducted to verify the accuracy of the predicted environmental effects and the effectiveness of mitigation measures and is described in Section 6.8.10. Wetlands where groundwater drawdown effects are anticipated (i.e., WL34 and 216), or compounded with other direct and indirect effects, will be prioritized during wetland monitoring. Further consultation regarding indirect effects and monitoring with NSE will occur through the wetland permitting process.

Local Catchment Area Flow Reduction

Potential for downgradient, indirect wetland impacts can be expected throughout the Beaver Dam Mine Site and Haul Road as a result of up-gradient hydrological alteration. Primarily, the alteration of hydrological conditions in up-gradient wetlands, watercourses and local watershed catchments to manage site contact water, will affect natural inflows, outflows and hydroperiod characteristics in contiguous wetland systems. In addition, where up-gradient alteration is occurring, but a direct hydrological flow is being maintained, potential exists for indirect impacts to downgradient water quality conditions.

To identify the effects of the Project on local flow regimes and associated habitats, each local catchment area (LCA) in which infrastructure is proposed was assessed within the Beaver Dam Mine Site based on catchment areas presented in Section 6.7.4 and Appendix A (Water Balance Analysis) of Appendix P.4 (Mine Water Management Plan). The construction of site infrastructure will require construction of collector ditches surrounding facilities such as stockpiles. These collector ditches convey all mine site contact water to site water management facilities for treatment prior to release to the environment. The construction of collector ditches surrounding site infrastructure essentially diverts water away from local surface water features within each relevant catchment or diverts water from one catchment to another. This can have an indirect effect on wetland habitat at the local catchment area (LCA). The effects of the Project on surface water quality and quantity at the regional watershed level and the LCA scale are described in detail in Section 6.7.

Alterations of hydrology within each LCA (i.e., changes to surface and baseline flow) may result in indirect impacts to wetlands. Wetlands within each identified LCA were evaluated, excluding those with expected complete direct impact and those that may be entirely influenced by predicted groundwater drawdown (i.e., entirely within the groundwater drawdown area) as described in Section 6.7. A list of all remaining wetland habitats was developed per LCA, to allow for evaluation of potential indirect impacts from flow reduction in each LCA. Table 6.8-22 shows all associated wetlands (or portions of) within the respective LCA. Reduction in flow in each LCA affects each wetland differently, depending on that wetlands' location in the catchment area, and the proposed direct effects of Project infrastructure. Water source, watercourse/waterbody association, magnitude of predicted flow change, and position both in the LCA and relative position to proposed infrastructure were considered to determine wetlands with potential

indirect impacts to reduced flow. Wetlands located upgradient of the proposed infrastructure are not considered for LCA area or flow reductions. Bolded wetlands in Table 6.8-22 have been conservatively assessed for potential indirect impacts based on changes to flow.

Table 6.8-22: Local Catchment Area Decrease from Project Development

Local Catchment Area	Associated Wetlands[(a)]	Percent Change in Annual Flow[(b)]
Cameron Flowage/Killag River	WL57, 61, 238, 240, 241, 242, 243, 244	+2.8% (EOM), -2.2% (PC)
Mud Lake (WC27)	WL14, 16, 17, 204, 206, 207, **210, 215**, 257	-18.1% (EOM), -13.6% (PC)*
Tent Brook	WL57, 64, 66, 218, 219, 237, 258	-1.1% (EOM), -1.2% (PC)
WC26 (north of NAG)	WL207, 228, **231**	-22.2% (EOM), -17.5% (PC)*
WC23 (south of NAG)	WL**205**, 226, 236	-15.2% (EOM and PC)*

Notes: [(a)] Wetlands (or portions of) downgradient of development.

[(b)] Change in total flow (surface runoff and baseflow), based on LCA assessment location (Appendix A [Water Balance Analysis] of Appendix P.4 [Mine Water Management Plan]).

* LCAs with >10% change in flow were assessed for indirect impacts to wetlands. LCAs with <10% change in flow were not expected to impact wetland hydrology.

Mud Lake is expected to experience a reduction in LCA and total flow as a result of Project infrastructure (waste rock stockpiles, open pit, mine roads, surface water management). A maximum 5 cm decrease is lake levels is expected at Mud Lake. Due to PA modifications and micro-siting the waste rock stockpiles, infrastructure has been removed from the headwaters of the Mud Lake LCA. Therefore, downgradient watercourses and wetlands (i.e., WL4, 8, 10, 11, 14, 17 and 20) will no longer be affected by the resultant up-gradient flow reductions. However, there are still wetlands and watercourses downgradient of the current proposed development. Anticipating that hydrologic connectivity is maintained across the mine road between the up and down gradient sides of Watercourse 5 and Wetland 14, indirect impacts of reduced flow are not expected within connected down gradient systems. The up-gradient portion of Wetland 215 is proposed to have partial direct impacts from construction of the NAG waste rock stockpile. Wetland 215 is directly connected to Wetland 210 through Watercourse 15. It is predicted that the anticipated reduced LCA and total flow rate of 14-18% will potentially result in indirect effects to intact portions of Wetlands 210 and 215 from LCA reduction (2.4 ha).

Within the WC26 LCA, Wetlands 207 (in part), 228 and 231 are located downgradient of proposed development (waste rock stockpiles, surface water management). Wetland 207 is a large headwater wetland complex, including bog, partially located within the Mud Lake LCA. Wetland 228 is a hydrologically isolated bog. As such, neither is anticipated to be indirectly impacted by LCA and flow reduction. Wetland 231 is proposed to have partial direct impact from construction of a setting pond and surrounding site ditches. While direct impacts are limited, Wetland 231 is a swamp which receives inflow through up-gradient drainage. As a result of the reduced LCA and total flow rate of 18 to 22%, it is predicted that the intact portions of Wetland 231 will be potentially impacted from LCA reduction (0.48 ha).

The NAG waste rock stockpile impacts the headwater portion of the WC23 LCA. While Wetlands 226 is partially directly impacted by the waste rock stockpile, it is an isolated wetland (a portion of which is bog) with no defined up-gradient surface water connectivity. Wetland 226 is a swamp/bog complex and thus has limited surface water inputs. It is not anticipated either of these wetlands will be indirectly impacted by LCA and flow reduction. The headwater portion of Wetlands 205 is proposed to have partial direct impacts from construction of the NAG waste rock stockpile. The anticipated reduced LCA and total flow rate of 15% could potentially result in indirect effects to these wetlands. As a result, it is conservatively estimated the intact portion of Wetlands 205 will be potentially impacted from LCA reduction (1.4 ha).

The total flow decrease in the Tent Brook LCA is predicted to be <1.5%. As such, not indirect impacts to wetlands within this LCA are expected as a result. Similarly, the small predicted change in streamflow within the Cameron Flowage/Killag River (±2 to 3%) is expected to have negligible impacts to the wetlands within the Killag River LCA.

Potential also exists for up-gradient hydrological alteration as a result of downgradient hydrological alteration. Examples include altered outflow (i.e., faster or slower outflows due to drainage infrastructure), causing either dewatering (drying hydrological trend) or flooding conditions in up-gradient wetlands. Within the Beaver Dam Mine Site, this this is considered a possibility in the southern portions of Wetland 57.

Conservatively, it is estimated that the full areas of Wetland 205, 210, 215 and 231 will be potentially impacted from impacts to LCA and surface flow reduction (4.28 ha).

The potential for indirect wetland impacts as a result of upgrading and new construction of the proposed Haul Road exists. However, due to the limited alteration footprint to up-gradient wetlands from Haul Road infrastructure and standard road construction mitigation methods that will be employed as part of the construction process, downgradient, indirect impacts are not expected. Current culvert placement may support wetlands conditions that were not present prior to road construction. Where road constriction has caused persistent altered hydrology, this may result in permanent changes to wetland function, size and/or type. Ensuring current watercourse crossing standards are met, the Project will endeavor to not draining wetlands that have been established/naturalized based on old culverts. Upgrades to culverts should maintain current wetland hydrology to avoid indirect impacts, while also considering operational requirements, safety, and fish passage. This will be addressed during the detailed design phase.

Monitoring of potential indirect impacts will be conducted to verify the accuracy of the predicted environmental effects and the effectiveness of mitigation measures and is described in Section 6.7. Wetland where flow reduction effects are anticipated (i.e., WL205, 210, 215 and 231), or compounded with other direct and indirect effects, will be prioritized during wetland monitoring. Further consultation regarding indirect effects and monitoring with NSE will occur through the wetland permitting process.

6.8.7.1.3 Summary of Direct and Indirect Impacts to Wetlands

Direct and potentially indirect losses of wetlands will occur as the result of Project development. Project infrastructure development will result in direct loss of wetlands. All wetland losses will require wetland compensation under the Nova Scotia Wetland Conservation Policy. In addition, loss of wetlands accessible to fish are accounted for in the draft Fish Habitat Offset Plan (Appendix J.3) and discussed in Section 6.9.

Overall, changes in hydrology (i.e., reduced flow, groundwater drawdown) due to the placement of Project infrastructure has the potential to affect the functionality of wetlands. On-going detailed infrastructure design will be completed to minimize these impacts. This will be completed at the permitting level. Targeted monitoring for wetlands will also be conducted to verify the accuracy of the predicted environmental effects and the effectiveness of mitigation measures. Refer to Section 6.8.10 for details associated with wetland monitoring, and the Preliminary Wetland Compensation Plan (Appendix H.3) for further information.

As is consistent with alteration to all wetlands associated with the Project, protection and viability of connected, unaltered areas of wetland habitat are considered as part of the provincial wetland alteration process. Design of suitable hydrological connectivity structures (e.g., culverts), implementation of a Project EPP and planned mitigation measures, such as erosion prevention and sediment control, will be employed to ensure that avoidable indirect impacts to upstream or downstream wetlands will not occur as a result of the activities associated with the Project. In addition, post-construction monitoring, including invasive species

monitoring, will be completed as discussed in Section 6.8.10. A comprehensive wetland monitoring program will be developed to meet the requirements of wetland alteration permits issued for direct and indirect wetland alterations associated with the Project.

Furthermore, as part of the design process associated with the new Haul Road, the proponent has committed to identifying culverts that require maintenance and removing or upgrading them where appropriate. As previously discussed, the detailed design phase will consider the established/naturalized wetland conditions, endeavoring to not alter existing hydrology during culvert upgrades.

To support the effects assessment, conservative impact scenarios were employed to determining total direct and potential indirect impacts to wetlands as described in previous sections. Two primary pathways for indirect impacts have been considered in this evaluation of potential indirect effects: groundwater drawdown, and changes to local catchment areas. These have been brought forward and summarized in Table 6.8-23. The maximum extent of potential indirect impact to wetlands as a result of the Project is predicted to be 4.56 ha. As described throughout Section 6.8.7.1.1, these indirect effects are only considered as potential at this point, rather than confirmed alteration areas. During the permitting phase of this Project, a detailed wetland monitoring program will be developed, guided by considerations listed in the table below and the detailed design of the Project infrastructure and water management systems, to verify and confirm the extent of any indirect impacts to wetlands.

Table 6.8-23: Summary of Potential Indirect Impacts of the Project on Wetlands

Indirect Impact Pathway	Considerations	Reasonable Worst-cast Scenario Impact Area
Groundwater drawdown	Simulated groundwater drawdown used to assess potential indirect impacts to wetlands based on predicted permanent changes to groundwater levels post-closure. Wetlands included: WL34 and 216	0.28 ha
Reduction in flow based on infrastructure construction in the LCAs	The reduction in flow per LCA was considered, along with the relative positioning of wetlands, watercourses and surface flow pathways. Wetlands included: WL205, 210, 215 and 231	4.28 ha
Maximum extent of potential indirect effects to wetlands:		**4.56 ha**

Notes: LCA = local catchment area; ha = hectares.

In summary, the proposed direct alteration area to wetlands in the Beaver Dam Mine Site and Haul Road is 31.8 ha, representing 33% of the delineated wetland area in these PA components, and 4% of the wetland area in the LAA. The maximum potential indirect impacts of the project on wetlands, considering groundwater drawdown and LCA flow reduction, is predicted to be 4.56 ha, representing 5% of the delineated wetland area in the Beaver Dam Mine Site and Haul Road, and 0.6% of the wetlands in the LAA. The combined expected direct impact and potential indirect impact wetland area is 36.4 ha, 38% of delineated wetlands in the Beaver Dam Mine Site and Haul Road (Figures 6.8-4A to 6.8-4O). It is anticipated that the actual indirect impacts to wetlands will be substantially lower, given the conservative assessment approach and suite of mitigation measures proposed.

6.8.7.1.4 Touquoy Mine Site

The Touquoy Mine Site is currently operational. The use of the Touquoy Mine Site for the processing of Beaver Dam ore and tailings management (exhausted pit) will not involve modification to the current footprint or further impacts to wetlands. No discharge events to the wetlands in the receiving environment, are planned during operations. The exhausted pit has the capacity to store all mine tailings until scheduled release post-closure. Moving the existing tailings pipeline from the permitted TMF to direct water to the exhausted pit will occur within the disturbed footprint of the permitted Touquoy Project and will not result in additional impacts to wetlands. Potential interaction between Project activities and wetland habitat within the Touquoy Mine Site are outlined in Table 6.8-24 below.

Table 6.8-24: Potential Project Activities/Interactions with Wetlands at the Touquoy Mine Site

Project Phase	Duration	Project Interactions
Construction	1 year	• N/A
Operation	5 years	• General waste management • Invasive species introduction or spread • Environmental monitoring
Active Closure	2 years	• Environmental monitoring
Post-closure	10+ years (monitoring)[(a)]	• Post closure interaction with discharge from Touquoy Mine Site pit to Moose River riparian wetlands (IR2 NSE 2-176)

Note: [(a)] Post-closure wetlands monitoring will be determined based on monitoring and discussions with regulators.
N/A = not applicable.

At post closure and once water quality in the Touquoy Mine Site open pit meets MDMER discharge criteria, water surplus will be released into Moose River via a spillway. The spillway is proposed to be installed at elevation of 108 m to prevent the pit from overtopping. The spillway will discharge to a conveyance channel that outlets to Moose River. With the addition of Beaver Mine Site deposits, under climate normal conditions the average predicted monthly open pit overflow into Moose River varies seasonally from 0.9 L/s in July to 44.2 L/s in April. The average effluent flow rate is 13.9 L/s (Appendix F.8 Beaver Dam Gold Project Assimilative Capacity Study of Moose River – Touquoy Pit Discharge). Additionally, through the completion of a groundwater model it was determined that, under full pit conditions, the average daily seepage from the Touquoy Mine Site open pit to the Moose River is predicted to be 258 m^3/day, or 3.0 L/s (Appendix F.8 Beaver Dam Gold Project Assimilative Capacity Study of Moose River – Touquoy Pit Discharge).

The average monthly flow of the Moose River, in August when flows are lowest, is 38,880 m^3/day, or 450 L/s (Appendix F.8 Beaver Dam Gold Project Assimilative Capacity Study of Moose River – Touquoy Pit Discharge). The predicted increase in flow from both open pit overflow and groundwater seepage is 3.76% of the average August Moose River flow (when flows are lowest). Due to the topographic setting and limited bi-directional hydrological connectivity of the assessed wetland adjacent to the Moose River (Section 6.8.3.5), no indirect impacts to wetlands are expected from this minor increase in flow.

Project operations and trucking of ore from the Beaver Dam Mine Site to the Touquoy Mine Site, along the Haul Road, has the potential to spread invasive species. Invasive species are currently monitored at the Touquoy Mine Site during the existing wetland monitoring program (IR2 NSE 2-181).

Therefore, with the exception of the above and continued potential for accidents and malfunctions and environmental monitoring, there are no direct or indirect effects to wetlands anticipated from the Project at the Touquoy Mine Site during the construction and operations phases. For further information regarding Touquoy Mine Site and wetland interactions, refer to the EARD (CRA 2007a)

and Focus Report (CRA 2007b). Wetland mitigations and monitoring are presented in Sections 6.8.8.1 and 6.8.8.2 and will be further addressed as part of the permitting process.

6.8.7.2 Wetland Cumulative Effects Modelling Results

The Wetland Cumulative Effects Modelling exercise was completed to support the determination of wetland effects associated with the Beaver Dam Mine Site and its associated infrastructure. The modeling exercise was completed across the three spatial boundaries noted in Section 6.8.6. Results presented herein reflected updates to the modeling exercise in order to capture changes in the PA, LAA and proposed infrastructure footprints.

The modelling has enabled a determination of the following to be made:

- The extent of wetland area loss at the PA (i.e., Beaver Dam Mine Site), LAA, and RAA at Year 0 (i.e., prior to any mine development activities) and Year 5 (i.e., completion of mine development /complete wetland alteration).
- The extent of predicted mainland moose, snapping turtle, olive-sided flycatcher and rusty blackbird wetland habitat within the PA (i.e., Beaver Dam Mine Site) and LAA at Year 0.
- The extent of Canada warbler habitat loss within the PA (i.e., Beaver Dam Mine Site) between Year 0 and Year 5.
- The extent of predicted mainland moose, snapping turtle, olive-sided flycatcher and rusty blackbird loss in the PA (i.e., Beaver Dam Mine Site) between Year 0 and Year 5.

When reviewing the results of the modelling in the following tables, the reader is reminded of the limitations associated with the modelling completed in the LAA and RAA. The analysis performed within the LAA and RAA spatial boundaries underrepresent predicted suitable wetland habitat. As such, the comparative area of impacted suitable wetland habitat in the Beaver Dam Mine Site is expected to be less than the results of the modelling exercise suggest.

6.8.7.2.1 Modeling Results

Results of the modelling exercise are provided below:

- Wetlands:
  - PA: There is 137.3 ha of wetland area within the Beaver Dam Mine Site at Year 0. Following Project development (Year 5), 27.6 ha or 22% of the Beaver Dam Mine Site wetland area will be altered.
  - LAA: There is 759.9 ha of wetland area within the LAA at Year 0. Following Project development (Year 5), 4% of the LAA wetland area will be altered.
  - RAA: There is 2,772.09 ha of wetland area within the RAA at Year 0. Following Project development (Year 5), 0.01% of the RAA wetland area will be altered.
- Mainland Moose:
  - PA: Of the 137.3 ha of wetland area within the Beaver Dam Mine Site, 56.8 ha or 41% of this area supports Mainland moose habitat at Year 0. Following Project development (Year 5), 10.1 ha or 18% of the Beaver Dam Mine Site habitat will be altered.
  - LAA: Of the 759.9 ha of wetland area within the LAA, 436.5 ha or 57% of this area supports Mainland moose habitat at Year 0. Following Project development (Year 5), 2% of the LAA habitat will be altered.

  - RAA: Not assessed.
- Snapping Turtle:
  - PA: Of the 137.3 ha of wetland area within the Beaver Dam Mine Site, 83.3 ha 60% of this area supports snapping turtle habitat. Following Project development, 10.6 ha or 13% of the Beaver Dam Mine Site habitat will be altered.
  - LAA: Of the 759.9 ha of wetland area within the LAA, 492.0 ha or 65% of this area supports snapping turtle habitat at Year 0. Following Project development (Year 5), 2% of the LAA habitat will be altered.
  - RAA: Not assessed.
- Canada Warbler:
  - PA: Of the 137.3 ha of wetland area within the Beaver Dam Mine Site, 93.5 ha or 68% of this area supports Canada warbler habitat. Following Project development, 15.1 ha or 16% of the Beaver Dam Mine Site habitat will be altered.
  - LAA: Not assessed.
  - RAA: Not assessed.
- Olive-sided flycatcher:
  - PA: Of the 137.3 ha of wetland area within the Beaver Dam Mine Site, 108.6 ha or 79% of this area supports olive-side flycatcher habitat. Following Project development, 15.4 ha or 14% of the Beaver Dam Mine Site habitat will be altered.
  - LAA: Of the 759.9 ha of wetland area within the LAA, 584.8 ha or 77% of this area supports olive-side flycatcher habitat at Year 0. Following Project development (Year 5), 3% of the LAA habitat will be altered.
  - RAA: Not assessed.
- Rusty blackbird:
  - PA: Of the 137.3 ha of wetland area within the Beaver Dam Mine Site, 26.4 ha or 19% of this area supports rusty blackbird habitat. Following Project development, 4.3 ha or 16% of the Beaver Dam Mine Site habitat will be altered.
  - LAA: Of the 759.9 ha of wetland area within the LAA, 251.0 ha or 33% of this area supports rusty blackbird habitat at Year 0. Following Project development (Year 5), 2% of the LAA habitat will be altered.
  - RAA: Not assessed.

6.8.7.2.2 Discussion

Using a combination of field data and desktop resources, the wetland cumulative effects modelling exercise has provided an ability for four wetland function metrics to be predicted within the PA, LAA and RAA. The potential loss of the wetland function metrics post Beaver Dam Mine development has also been evaluated. Development of a predictive future model was beyond the scope and resources available at the time of writing. However, a qualitative approach to assessing the future cumulative effects of the Project on wetland function (by way of evaluating the wetland function metrics) was possible and is discussed below.

The direct and indirect impacts on wetlands within the Beaver Dam Mine Site will affect the functional abilities of these wetlands (i.e., water quality, water storage capacity, regulation of water temperature, nutrient retention, and provision of wildlife habitat among others) during the Project, and into the future. The mitigation and monitoring actions described in Section 6.8.8 will lessen these impacts and help ensure the integrity of wetlands beyond the Beaver Dam Mine Site remain viable.

As discussed in Section 6.8.6.1, direct wetland area loss is expected as a result of the Beaver Dam Mine Project. The loss of wetland area will result in changes to all wetland functions (including the metrics discussed above). For example, loss of wetland area would reduce water storage capacity, and could lead to increased risk of flooding in downstream environments. However, despite the loss of wetland area and thus its function within the Beaver Dam Mine Site, modeling results suggest that when compared to the LAA and RAA wetland area being lost as a result of the Project is 3.5% of the modelled LAA wetland area, and 0.01% of the modelled RAA area.

Four wildlife species metrics were also evaluated as part of the modelling exercise, the results of which can be used to highlight other potential wetland functional losses, as a result of the Beaver Dam Mine Project. The wildlife species metrics evaluated were; mainland moose habitat, snapping turtle habitat, olive-sided flycatcher habitat, rusty blackbird habitat and Canada warbler habitat.

Mainland Moose are a generalist species: instead of occupying a narrow niche they use a variety of habitats. Evidence of moose was observed within the Beaver Dam Mine Site (tracks). As previously discussed, Moose use wetlands with access to aquatic vegetation, a component which was used to model potential wetland habitat within the modeling exercise. However, they have also been found to use large clear-cuts for forage, although this habitat forage availability for moose in a cleared forest doesn't peak until 7 to 15 years after cutting (Snaith and Beazley, 2004). Impact on moose wetland habitat is expected within the Beaver Dam Mine Site and Haul Road as a result of wetland loss, however clearing of vegetation as a result of the Project may eventually provide new habitat for moose, post re-generation in the future. The provision of thermoregulation from mature stands is also required for Moose (Snaith and Beazley, 2004). Within the Beaver Dam Mine Site and Haul Road, there is the potential for direct and indirect impact to wetlands comprising moose habitat, and which could provide the thermoregulation characteristics which moose require. However, moose in Nova Scotia generally prefer areas with few or no roads, which already exist within the PA. While moose have been observed in and near wetlands within the Beaver Dam Mine Site (both during field surveys and according to the ACCDC report), the existing roads extending through the PA reduces the extent of suitable moose habitat The modeling exercise determined that the loss of potential moose wetland habitat within the Beaver Dam Mine Site is 18% which; represents 2% of the predicted suitable moose wetland habitat in the LAA.

Snapping turtle wetland habitat is expected to be impacted by the Project. As it relates to wetlands, snapping turtles prefer muddy sites–in deep anoxic mud in marshy areas for overwintering, and rocky slow-moving streams for mating (COSEWIC 2008). It should be noted, that snapping turtles are one of the more aquatic turtle species and rarely move more than 200 m from water. Snapping turtle was observed within the PA during field surveys and recorded as being present within 16 km of the Project in the ACCDC report. The species has high site fidelity – they will return to the same nesting and overwintering locations year after year (COSEWIC, 2007; Environment and Climate Change Canada, 2016; Pulsifer, pers. comm. 2018). The modelling exercise suggests that loss of suitable turtle habitat within the Beaver Dam Mine Site between Year 0 and Year 5 equates to a 13% loss, which represents approximately 2% of the total available suitable habitat in the LAA.

The potential for impact to migratory bird wetland habitat is expected as a result of the Beaver Dam Mine Project. Three bird species were modelled as part of the cumulative effects assessment: Canada warbler, olive-sided flycatcher, and rusty blackbird. These species were all observed within the Beaver Dam Mine Site and Haul Road during field surveys and recorded as being present within 5 km of the Project in the ACCDC report. The lack of publicly available habitat data for Canada warbler (i.e., dense, deciduous shrub), modeling was not available within the LAA. Canada warbler habitat was however determined for the Beaver Dam Mine Site based on data collected during field programs in combination with desktop resources. The other two birds did have available wetland habitat data layers and were modelled at the LAA spatial extent. Research has shown that some species respond positively to forestry practices and may return to a logged area once the activity is over, especially if it has created open patches that allow for foraging. A study in Alberta showed that the abundance of alder flycatchers, a species with similar foraging requirements to olive-sided flycatcher, increased in a previously cut area (Tittler et al., 2001). Additionally, rusty blackbirds can

also tolerate forestry activities as long has their habitat of coniferous dominant trees of varied heights near waterbodies is maintained (pers. comm. C. Staicer 2018). While forestry is different from the development of a Mine Site, similar activities will be occurring (i.e., forest clearing, transport of large trucks, and disturbance of aquatic features). It is therefore feasible to consider that new habitats suitable to support these birds will be created in the future. The modelling exercise determined that potential habitat loss for the Canada warbler, olive-sided flycatcher and rusty blackbird within the Beaver Dam Mine Site between Year 0 (pre-mine development) and Year 5 (post mine development) was 16%, 14% and 16% respectively. The modelling also determined that the predicted suitable wetland habitat loss within the Beaver Dam Mine Site post mine development, in comparison to the predicted habitat within the LAA (pre-mine development) for the olive-sided flycatcher and the rusty blackbird is 3% and 2% respectively.

Development of the Beaver Dam Mine Site will have cumulative effects on wetland loss and wetland functions. For the purpose of the modelling exercise, wetland function loss is represented by four wetland function metrics: wetland area and habitat provision for moose, turtles, and birds which will be impacted during the construction activities and mine operations.

The modelling exercise has shown that wetland alteration within the Beaver Dam Mine Site is expected to result in a loss of wetland function metrics ranging between 13 to 20% (when comparing pre and post mine development). However, when compared to the LAA, these changes represent smaller percentages of predicted wetland area ranging between 1 to 4%, when comparing Beaver Dam Mine Site wetland loss (post mine development) to the LAA (pre-mine development).

In conjunction with the mitigation and monitoring steps (as described in Section 6.8.7), this assessment results in the determination that the Project will result in adverse effects to wetlands, however these effects are not anticipate to be significant with respect to loss of wetland function and magnitude in comparison to the LAA.

6.8.8 Avoidance and Mitigation

6.8.8.1 Wetland Avoidance

Due to the location in which the proposed activity can be performed (the location of the pit is fixed by geology), the extent to which the proposed Project can be manipulated to avoid impacts to wetland habitat is limited. Through the iterative Project design, infrastructure has been relocated (e.g., stockpiles have been split) to reduce wetland impact and continued detailed design may still be possible to further reduce wetland alteration. The NAG waste rock stockpile location has been relocated west to avoid the large headwater Wetlands 1 and 2. Infrastructure has been relocated from the contributing area to Crusher Lake, and its contributing watercourses. Wetland 2 is no longer impacted by predicted groundwater drawdown. The Project design evaluation and process is described in Section 2 (Project Description).

The preliminary Haul Road design has been based on following the existing footprint of the Beaver Dam Mines Road and the Moose River Cross Road to reduce overall wetland impact and habitat fragmentation. Depending on local topography and landcover, road upgrades will be required to improve sight lines, turning radii, road width, etc. One 4 km section of new road is planned between Highway 224 and Moose River Cross Road (Section 2, Figure 2.3-1). Two sections of new multiuse bypass road, parallel to the Haul Road, are also planned to maintain safe road conditions for local vehicle and ATV traffic (Section 3, Figure 3.3-2. However, wetland avoidance is a key consideration during planning and engineering upgrades and new sections of road, where practicable. Wetland avoidance, landscape conditions, locations of watercourses, sight lines, and safety, will be key planning factors during the detailed engineering for the Haul Road and bypass roads.

Of the five wetlands (WL 4, 14, 17, 29 and 205) assessed as WSS (Section 6.8.4.1.3), three WSS are proposed for partial or complete alteration as the result of the Project (WL14, 17, 205). Direct impacts to Wetlands 4 and 29 were avoided. Previous

impacts to Wetland 4 were eliminated due to the micro-siting and division of the waste rock stockpile. While nearly the entirety of Wetland 4 is situated beyond the groundwater drawdown area, changes to its hydrological connectivity with Wetland 5, may be observed (Section 6.8.7.1.1). However, a consequential alteration to hydrology, and thus indirect effects are not anticipated within Wetland 4. No direct or indirect effects (i.e., groundwater drawdown and flow alteration) are anticipated to impact Wetland 29. Additionally, the boreal felt lichen occurrences observed during field surveys are located in an extent of Wetland 29 that exists beyond the southern Beaver Dam Mine Site boundary, and as such is not expected to be impacted as a result of Project activities. The micro-siting and division of the waste rock stockpile has further increased the distance of Project infrastructure to Wetland 29. No Project infrastructure is situated within the defined Boreal Felt Lichen Critical Habitat Area (NSLF, 2020).

Impacts to Wetland 14 and 17 have been minimized where practicable. However, direct and indirect impacts to Wetland 17 are unavoidable due to ore location and resultant pit placement. Moving the north settling pond outlet channel to the south of the topsoil pile specifically to avoid lichen and wetland habitat was considered, however, it had to be maintained it in its current location to mitigate groundwater drawdown in Cameron Flowage. Further impacts were limited through detailed Project design, such as strategic settling pond, topsoil stockpile and mine road placement. As a result, the directly impacted areas of Wetlands 14 and 17 do not contain occurrences of blue felt lichen. However, where Project infrastructure is located within the 100 m setback of blue felt lichen occurrences in Wetland 17, translocation of these occurrences is proposed, as per the Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.4). Furthermore, the blue felt lichen occurrences in Wetland 17 are located with the groundwater drawdown area and therefore indirect hydrological impacts are possible. There is no planned development or indirect effects anticipated within 100 m of the blue felt lichen occurrences within Wetland 14.

Wetland 205 will be partial impacted by the NAG waste rock stockpile, including the area that contains one occurrence of blue felt lichen, and a decrease in LCA. A detailed alternatives assessment has led to the current placement of the NAG waste rock stockpile and this infrastructure has been placed in consideration of all valued components and minimization of overall impact. Therefore, avoidance of this wetland is not practicable. Translocation of the blue felt lichen occurrence (Appendix P.4) is proposed, which will mitigate the impact to this species.

The predictive NSE WSS database indicates that Wetland 61, 64, 178, 205 and 220 may exists as a possible WSS due to historical presence of mobile species and potential habitat for mobile and non-mobile species, as discussed in Section 6.8.4.1.3. Wetlands 61, 205 and 220 will be partially or completely altered through direct and indirect impacts. Wetlands 64 and 178 have been previously impacted by pre-existing road infrastructure, and it is not anticipated that these wetlands will be further direct impacted as a result of Haul Road upgrades during the construction phase. Wetlands 64 and 178 will be impacted by increased traffic during Project operations. Detailed Haul Road design will consider species use of Wetland 64 and 178 (e.g., greater yellowlegs). New bypass roads have been micro-sited to avoid both wetlands and, as a result of PA and infrastructure modifications, a waterline has been rerouted and will no longer discharge into Wetland 64, avoiding resultant changes in hydrology.

While avoidance and minimization of Project impacts was attempted wherever practicable, as discussed in Section 6.8.4.1.3, it is not anticipated that these wetlands will be classified as WSS because the SAR species observed are mobile and similar suitable habitat is present within the PA, LAA and RAA. Other wetlands within the Beaver Dam Mine Site and Haul Road do not contain other critical wetland functions that necessitate avoidance (e.g., significant fish habitat, presence of critical wildlife habitat, groundwater recharge ability, etc.). Where identified or potential WSS could not be avoided, these wetlands will be prioritized during wetland monitoring (Section 6.8.10).

Efforts will be made during the detailed design process to avoid as much wetland habitat as possible. Infrastructure that may offer more flexibility in this regard includes the detailed design of the Haul Road upgrade alignment, mine roads, water diversion channels, settling ponds, and stockpile areas. Further regulatory consultation will occur with NSE and details associated with micro-sighting and final wetland alteration requirements will be confirmed at the wetland alteration permitting stage of this Project.

6.8.8.2 Wetland Mitigation

To mitigate and reduce overall loss of function of wetland habitat, the actions provided in Table 6.8-25 will be implemented by the Proponent within wetlands where direct impacts and potential indirect impacts to wetland habitat are expected. Mitigation measures will be confirmed through monitoring requirements, as described the Preliminary Wetland Compensation Plan (Appendix H.3), which will be refined at the permitting stage through the Industrial Approval. The Proponent will apply for approval to alter wetlands from NSE and will abide by all site-specific conditions of that approval, which will specify the timing windows in which alterations are permitted.

Table 6.8-25: Mitigation for Wetlands

Project Phase	Mitigation Measure
Construction, Operation, Closure	Complete pre-construction site meetings for all relevant staff/contractors related to working around wetlands and watercourses to minimize unauthorized disturbance, such as the introduction of invasive species
	Implement Erosion and Sediment Control Plan and measures to ensure site runoff is not directed towards wetlands to ensure habitat integrity and existing drainage patterns are maintained (Appendix C of Appendix P.4 [Mine Water Management Plan])
	Maintain pre-construction hydrological flows through wetland habitats and partially altered wetlands, wherever practicable
	Topsoil will be salvaged and stored for use in site restoration where practicable.
	Re-vegetate slopes adjacent to wetlands, using native seed mixes, to limit erosion and sediment release
	Implement the Preliminary Wetland Compensation Plan (Appendix H.3), as refined through the permitting process.
Construction	Ensure all wetlands are visually delineated (e.g., flagged)
	Complete detailed design of Haul Road and micro-siting of Beaver Dam Mine Site infrastructure to avoid or minimize impacts to wetlands
	Implement construction methods that reduce the potential to drain or flood surrounding wetlands
	Acquire and adhere to wetland alteration permits
	Detailed culvert design of upgraded/replaced culverts to maintain current hydrology and necessary fish passage.
	Translocation of blue felt lichen and monitoring of lichen SAR where direct and indirect impacts are expected to occur as per the Preliminary Lichen Mitigation and Monitoring Plan (Appendix P.6)
	Complete work within Wetland 64 outside of the breeding season in consideration of greater yellowlegs observations and probable breeding habitat.
Construction, Operation	Direct runoff through natural vegetation, wherever practicable
	Minimize erosion of wetland soils by limiting flow velocities by means of hydraulic dissipation techniques
	Minimize the rutting of wetland habitat by limiting the use of machinery within wetland habitat and use of swamp mats/corduroy bridges as required
	Conduct vegetation management (cutting and clearing) in or near wetlands and watercourses in accordance with applicable guidelines
	Employ measures to reduce the spread of invasive species (particularly by vehicles) into wetlands and retain habitat integrity Inspect vehicles regularly, particularly vehicles arriving from outside the PA. If necessary, cleaning will be undertaken at a designated cleaning station, away from wetlands and watercourses.
Closure	Compensate for permanent loss of wetland function through implementation of the Preliminary Wetland Compensation Plan, subject to NSE approval (Appendix H.3)
	Review and consider alternatives to traditional hydroseeding methods to advance vegetation re-establishment and reclamation methods
Post-Closure	Follow monitoring requirements in wetland alteration permits and final Wetland Monitoring Plan (to be completed at permitting stage).

In addition, the Proponent is committed to engaging in wetland compensation activities for the wetland loss associated with the Project as required by the provincial wetland alteration process. A Preliminary Wetland Compensation Plan has been developed and can be found in Appendix H.3. This Plan includes the following options for compensation, prepared in consultation with ECCC, NSL&F and NSE:

- On-the-ground restoration opportunities to meet a minimum 2:1 ratio and to be completed in a watershed near the Project area to the extent practicable;
- Wetland restoration opportunities within the Beaver Dam Mine Site will be considered where practicable;
- Translocation of blue felt lichen from WSS WL17, where direct and indirect effects are expected (as described in Appendix H.3);
- Other secondary forms of compensation that ECCC and NSE consider valuable to support the wetland conservation program in Nova Scotia;
- Collaboration with local community groups and the Mi'kmaq of Nova Scotia to the extent possible; and
- Inclusion of a conservation allowance in the Preliminary Wetland Compensation Plan to address restoration of equivalent habitat for wildlife SAR (Appendix H.3).

6.8.9 Residual Effects and Significance

The predicted residual environmental effects of Project development and production on wetlands are assessed to be adverse, but not significant. Direct impacts to wetlands as a result of Project construction were assessed to be moderate (Section 6.8.6.3) based on a 3.5% loss of wetland habitat within the LAA, as calculated by the CEA (Section 6.8.7.2). Indirect wetland impacts anticipated during Project operations, as presented in Section 6.8.7.1.2, represent 0.6% of wetland area within the LAA, and thus are evaluated as low. As presented in the CEA results (Section 6.8.7.2), SAR habitat loss is expected to be ≤ 3% within the LAA, for all evaluated species. No unmitigated or uncompensated wetland loss is anticipated as a result of planned restoration and wetland compensation (Appendix H.3). As a result, the overall residual effect of the Project on wetlands is assessed as not significant after mitigation and compensation measures have been implemented and considering the operational time frame of the Project (5 years). Residual effects to wetlands are summarized in Table 6.8-26.

Table 6.8-26: Residual Effects for Wetlands

Project - VC Interactions	Mitigation and Compensation Measures	Residual Environmental Effects Characteristics						Residual Effect	Significance of Residual Effect
		Magnitude	Geographic Extent	Timing	Duration	Frequency	Reversibility		
Construction – Beaver Dam Mine Site and Haul Road (clearing and grubbing, direct wetland alteration, and upgrading and new Haul Road construction))	Sediment and erosion control, best management practices, spill preparedness, and engagement in the wetland permitting process.	M VC interaction causes direct loss of 4% of NSE mapped wetlands in the LAA. Direct impact to WSS.	PA Potential adverse effect to wetlands inside the PA	A Seasonal aspects may affect VC	P VC unlikely to recover to baseline conditions	O Effects occur once during the construction phase	IR VC will not recover to baseline conditions	Habitat Loss and Disturbance	Not Significant
Operational – Beaver Dam Mine Site (groundwater interactions, water quality, changes to flow regimes, accidents/malfunctions)	Sediment and erosion control, best management practices, spill preparedness, wetland monitoring and water management.	L VC interaction predicted to result in indirect loss of <1% of NSE mapped wetlands in the LAA	LAA Potential adverse effect to wetlands outside of the PA	A Seasonal aspects may affect VC	LT Effects may extend beyond 5 years	R Effects occur at regular intervals throughout the project	PR Mitigation cannot guarantee a return to baseline conditions	Disturbance	Not Significant
Operational – Haul Road (water quality, changes to flow regimes, accidents/malfunctions)	Sediment and erosion control, best management practices, spill preparedness, and wetland monitoring.	L Small change from baseline conditions	LAA Potential adverse effect to wetlands outside of the PA	A Seasonal aspects may affect VC	LT Effects may extend beyond 5 years	S Effects occur at irregular intervals throughout the Project	R VC will recover to baseline condition	Disturbance	Not Significant
Post Closure – Touquoy Mine Site (potential changes to hydrology in Moose River and associated riparian wetlands)	Sediment and erosion control, best management practices, and spill preparedness, wetland monitoring and water management. Discharge to mimic seasonal flows wherever practicable	N Negligible increase in water quantity, no expected impact to downstream wetlands	LAA VC interaction may extend beyond PA	A Seasonal aspects may affect VC	LT Effects may extend beyond 5 years	R Effects are expected to occur over a regular interval	PR VC will partially recover to baseline conditions	Disturbance	Not Significant
Closure (Active) – Beaver Dam Mine Site (wetland restoration and compensation)	Sediment and erosion control, best management practices, spill preparedness, wetland compensation	L VC interaction restores and compensates lost wetland habitat	PA Potential adverse effect confined to the PA	A Seasonal aspects may affect VC	LT Effects may extend beyond 5 years	O Effects occur once during the reclamation phase	PR Mitigation cannot guarantee a return to baseline conditions	Habitat Reclamation	Not Significant

Notes: See Section 5.11, Table 5.11-1 for definitions of the below characteristics.

Magnitude		Geographic Extent		Timing		Duration		Frequency		Reversibility	
N	Negligible	PA	Project Area	N/A	Not Applicable	ST	Short-Term	O	Once	R	Reversible
L	Low	LAA	Local Assessment Area	A	Applicable	MT	Medium-Term	S	Sporadic	IR	Irreversible
M	Moderate	RAA	Regional Assessment Area			LT	Long-Term	R	Regular	PR	Partially Reversible
H	High					P	Permanent	C	Continuous		

A significant adverse environmental effect for wetlands has not been predicted for the Project for the following reasons, with consideration of the ecological and social context of the LAA surrounding the Project:

- During construction:
  - Direct impacts to wetlands will occur. However, these losses are 4% of the total available wetland habitat within the LAA. The majority of wetlands proposed for alteration are common and relatively isolated systems (swamp habitat). A wetland complex will be completely altered to support development of the open pit (WL56 and 59). These wetlands were anthropogenically created/altered as a result of historic mining activities. The combined magnitude of effects (proposed direct and estimated indirect impacts) results in a moderate magnitude of effect.
  - Impacts are anticipated within four identified or potential WSS (WL14, 17, 59 and 205) to support Project design, which are designated as WSS due to the presence of a sessile SAR (blue felt lichen). Translocation of the blue felt lichen is proposed, where necessary (Appendix P.6). No direct or indirect alteration is proposed within two additional WSS (WL4 and WL29).
  - Within the LAA there is a predicted cumulative loss of wetland habitat for SAR:
    - Mainland moose – 2%
    - Snapping turtle – 2%
    - Rusty blackbird – 3%
    - Olive-sided flycatcher – 2%
- During operations:
  - Limited impact to wetlands is predicted based on control of surface water flows to mimic baseline hydrologic conditions and implementation of sediment and erosion control measures.
- During closure:
  - Limited impact to wetlands is predicted based on control of surface water flows to mimic baseline hydrologic conditions and implementation of sediment and erosion control measures. In addition, there is an opportunity to potentially restore wetland habitat within the PA.
  - Wetland compensation will be completed to off-set Project wetland losses (Appendix H.3), including lost SAR habitat (landbirds and turtles). Off-site restoration opportunities will be prioritized within the tertiary watershed or adjacent watersheds wherever practicable.

6.8.10 Proposed Compliance and Effects Monitoring Program

Wetlands are protected under the provincial *Environment Act* and an approval is required for alteration. Wetland alteration applications will be submitted and permitting will be obtained prior to any construction in a wetland. Wetlands altered by the Project will be compensated at the ratio determined in the Preliminary Wetland Compensation Plan (Appendix H.3) in consultation with NSE. The Proponent will continue to work with NSE to develop the required mitigation measures including wetland compensation to mitigate any loss of habitat based on function and relative value. Assuming that the proposed compensation and mine site reclamation mitigation measures are applied, and that existing site drainage conditions are maintained, the Project is not likely to have significant adverse effects on wetland functional attributes in the area.

Wetland management aims to describe actions taken to verify the predictions of negligible significant adverse effects on wetland functional attributes, quantify wetland response to Project activities and alteration events, examine the effectiveness of mitigation measures taken, and signal a need to implement environmental control measures if monitoring indicates adverse environmental effects are or may be occurring due to activities of the Project. Wetland management is intended to verify that the Project is not likely to have significant adverse effects on wetland functional attributes in the area. The methods for monitoring will be those submitted within the Preliminary Wetland Compensation Plan (Appendix H.3).

Wetland monitoring will be completed to verify the accuracy of the predicted environmental effects and the effectiveness of the mitigation measures outlined in Table 6.8-25. A Preliminary Wetland Compensation Plan has been included in Appendix H.3 and will be refined through the life cycle of the permitting process. The plan commits to monitoring during baseline/pre-construction to establish baseline conditions, and through the operational, closure and post-closure phases (as determined to be required). A Final WLMP will be developed prior to construction in consideration of the on-going Project design, wetland alteration permitting and regulatory consultation. The plan will be refined in order to meet the specific activities and timing of activities within the PA.

A Preliminary Wetland Compensation Plan has been developed in order to satisfy the Nova Scotia Wetland Conservation Policy's (2011) objective of preventing no net loss of wetland habitat and function. This plan includes proposed conservation allowances for fauna SAR, as specified in IR2s CEAA-2-24 and CEAA-2-26. Wetland compensation will be initiated within three years of wetland alteration. Refer to the Preliminary Wetland Compensation Plan (Appendix H.3) for further details.

Implementation of the strategies discussed above will support the mitigation process associated with wetland protection. A wetland awareness program will be implemented to clearly identify boundaries of approved alteration areas and communicate these and all approval requirements to relevant site personnel. The Preliminary Wetland Compensation Plan (Appendix H.3) outlines adaptive management strategies should post construction wetland monitoring and/or ongoing construction monitoring indicate a potential issue above normal variation (i.e., atypical wetland responses to adjacent land activities).

Proposed follow up and monitoring programs have been reviewed with the Mi'kmaq of Nova Scotia during engagement efforts including meetings, sharing of technical documents (Draft EIS, poster boards, Summary of Mi'kmaq Effects and Proposed Mitigation Measures, Plain Language Summary). On-going engagement with the Mi'kmaq will continue through the EA process and associated permitting relating to follow up programs and monitoring.

6.9 Fish and Fish Habitat

6.9.1 Introduction

6.9.1.1 Summary of Fish and Fish Habitat Before Updates

The Beaver Dam Mine (the Project) will operate as a satellite surface mine to the existing and fully permitted Touquoy Gold Mine, located nearby in Moose River Gold Mines, Nova Scotia. The ore that is mined from the Beaver Dam Mine Site will be processed at the existing Touquoy Mine.

Prior to updates, Section 6.9 described the methods and results of baseline characterization as well as predictive studies that were undertaken to support characterization of potential Project effects on the Fish and Fish Habitat Value Components (VCs). Fish are considered an important aquatic resource from an economic, recreational, and cultural perspective within Canada. Fish, and the physical components of their natural environment, are protected under both provincial and federal legislation (Canada Water action 1985a, *Fisheries Act* (1985b), *Fisheries Protect Act* (1997), *Nova Scotia Environment Act* (1995)). Fish and Fish Habitat VCs are linked to other VCs identified for the Project, including surface and ground water quality and quantity, human health, and traditional land use.

The effects assessment for fish and fish habitat described direct impacts to fish in the context of the previous version of the *Fisheries Act* and the serious harm to fish threshold. The subsequent assessment of residual effects incorporated mitigation and monitoring programs for Project effects and, although residual effects were identified, they were characterized as not significant provided that mitigation measures were undertaken.

6.9.1.2 Summary of Updates to Fish and Fish Habitat

The Fish and Fish Habitat Effects Assessment (EA) for the Project has been updated to reflect updates of the Project Description (Section 2) and to address Round 2, Information Requests (IR2) issued by the Impact Assessment Agency of Canada (IAAC, formerly the Canadian Environmental Assessment Agency [CEAA 2019]) and Nova Scotia Environment (NSE 2019). This includes:

- updated description of the existing environment based on ongoing baseline fish and fish habitat surveys,(Appendix J.2, Appendix J.4), as well as surface water monitoring studies (Section 6.7.4 and Appendix G.1);
- identification and evaluation of potential water treatment for the Project, including nitrite removal technologies (included in Appendix P.4 Mine Water Management Plan as Appendix F.2 [Operations Phase Water Treatment Assessment] and Appendix F.3 [Post-closure Phase Water treatment Assessment]);
- update of the Mine Water Management Plan (MWMP) (Appendix P.4);
- a revised significance determination and expanded analysis of direct and indirect effects (Section 6.9.9);
- additional groundwater and surface water modelling was also completed at the Touquoy Mine Site to support the proposed plan for in pit disposal of tailings in the exhausted pit; and
- inclusion of Fish Habitat Offset Plan and Habitat Bank: Preliminary Design (Appendix J.3), to compensate for any losses to fish habitat as a result of the Project.

Standalone responses to IR2s are provided in AMNS (2021). An outline of updates to the Fish and Fish Habitat Environmental Effects Assessment are summarized in Table 6.9-1.

Table 6.9-1: Updated Subsections from the 2019 Revised Environmental Impact Statement – Fish and Fish Habitat

Table 6.9-1: Updated Subsections from the 2019 Revised Environmental Impact Statement – Fish and Fish Habitat (continued)

2019 Revised EIS Submission (February 28, 2019)	Updated in 2021	Corresponding 2021 EIS Update Section Number	Reason for Update
			• CEAA-2-18 • CEAA-2-21 • CEAA-2-22 • NSE 2-43 • NSE 2-44 • NSE 2-48
6.9.7 Preferred Alternative Haul Road	Yes	-	• Removed from Project Description.
6.9.8 Mitigation and Monitoring	Yes	6.9.8 Avoidance and Mitigation	• Expanded this section to detail the entire mitigation sequence, of Avoidance, Mitigation and Offsetting. • Addition of a detailed offsetting plan to account for Project-related direct and indirect effects to fish and fish habitat. • CEAA-2-06 • CEAA-2-07 • CEAA-2-08 • CEAA-2-11 • CEAA-2-13 • NSE 2-120 • NSE 2-121
6.9.9 Residual Effects and Significance	Yes	6.9.9 Residual Effects and Significance	• Updated based on field survey results, revisions to Project Description, and revisions to significance threshold and magnitude definition.
6.9.10 Proposed Compliance and Effects Monitoring Program	Yes	6.9.10 Proposed Compliance and Effects Monitoring Program	• Expansion of previous monitoring commitments, and addition of an Preliminary Aquatic Effects Monitoring Plan (to be submitted prior to construction).

Notes: PA = Project Area; LAA = Local Assessment Area; RAA = Regional Assessment Area; - = no update; IR2 = Round 2, Information Requests; CEAA = Canadian Environmental Assessment Agency; EIS = environmental impact statement; N/A = not applicable.

6.9.2 Rationale for Valued Component Selection

Fish and Fish Habitat was selected as a VC for its significance to ecological and socio-economic systems. The Project area encompasses several fish-bearing streams, rivers, and lakes which are protected under provisions of the *Fisheries Act* (1985).

The Fish and Fish Habitat VC could be affected by Project activities during the Construction, Operations, Active Closure, and Post-closure phases. This effects assessment identifies Fish and Fish Habitat as a single VC, whereby changes are, in turn, evaluated using indicators that are relevant, practical, measurable, responsive, accurate and predictable. The assessment of Fish and Fish Habitat as a single VC, rather than assessing individual physical or chemical constituents, was selected through a review of relevant regulations and guidelines, scientific literature, as well as professional experience and judgement.

6.9.3 Baseline Methodology

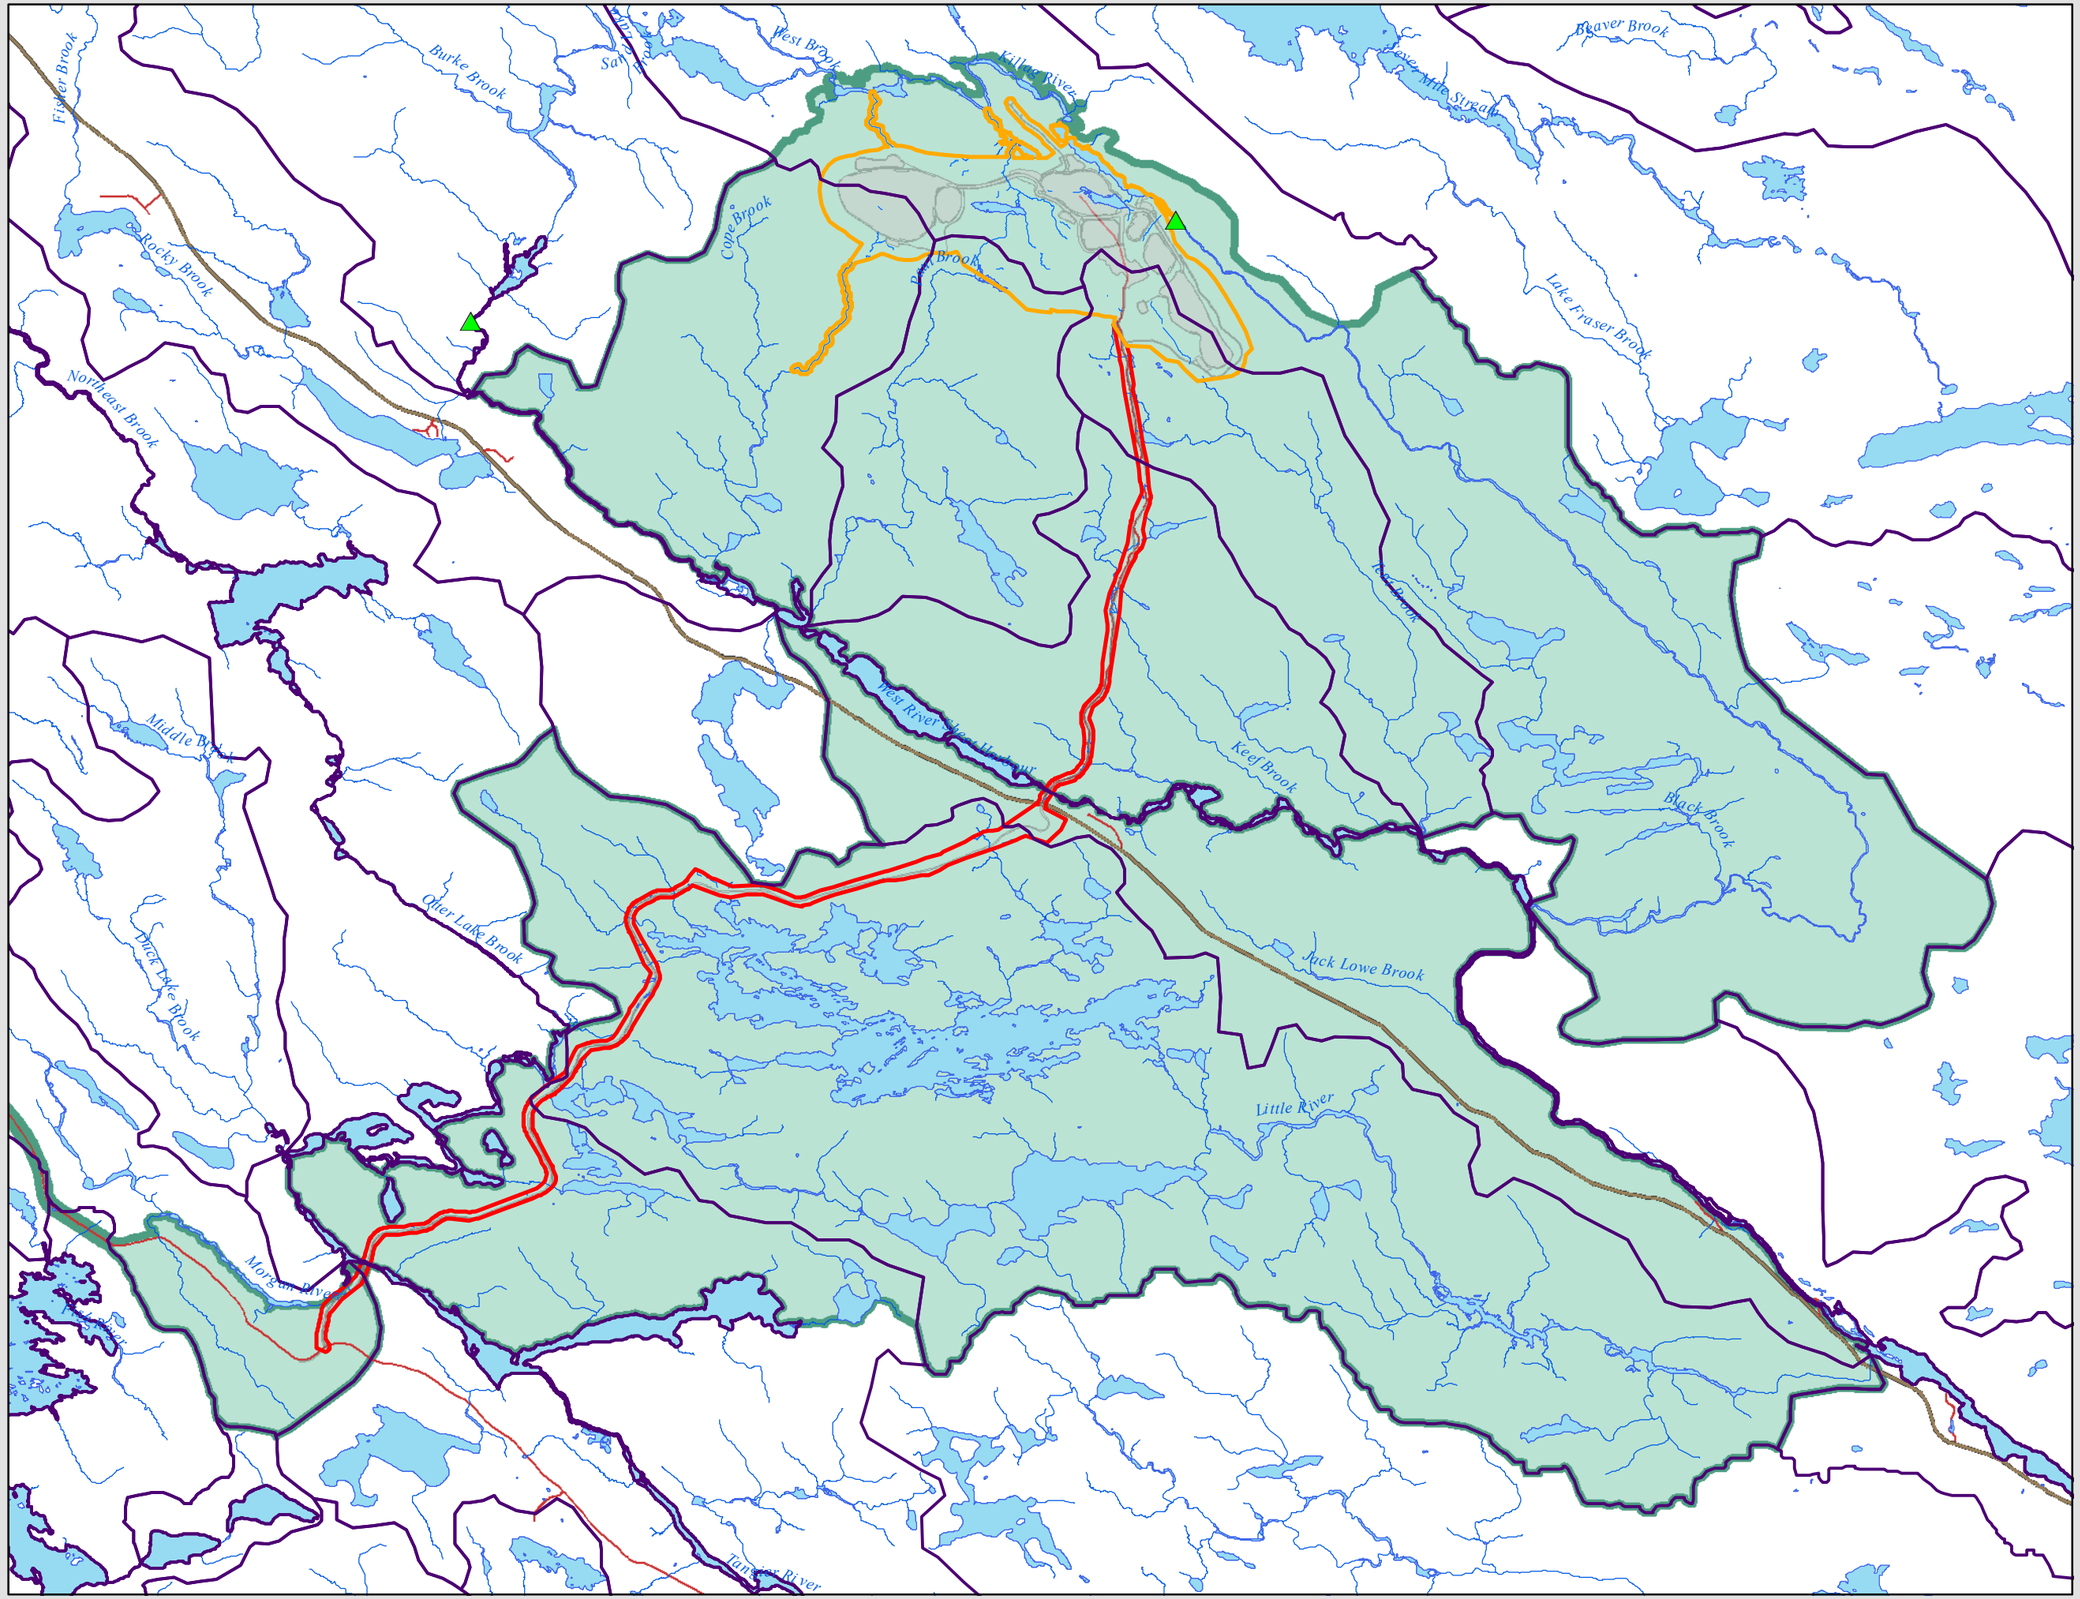
Baseline characterization studies for the proposed Project have occurred since 2014; the scope of monitoring programs has varied slightly from year to year to reflect updates to the Project Description (Section 2) as well as to respond to IR2 requests issued by IAAC (CEAA 2019) and Nova Scotia Environment (NSE 2019). The characterization studies have continued to be focused in three geographically distinct areas:

1. Beaver Dam Mine Site;

2. The Haul Road; and

3. The existing Touquoy Mine.

A Fish Habitat Assessment Area (FHAA) was developed to evaluate the effects of the Project on fish and fish habitat. The FHAA incorporates the Beaver Dam Mine Site and Haul Road portions of the Project Area (PA), and watercourses downstream from the Beaver Dam Mine Site (i.e., WC23, WC26 and WC27, and incorporating all of Cameron Flowage, downstream along the Killag River to the bridge and Nova Scotia Salmon Association (NSSA) Lime Dosing Station).



The downstream watercourses were incorporated into the FHAA to assess the maximum extent of effects of the Project from direct and indirect impacts to fish and fish habitat beyond the Beaver Dam Mine Site. The entire FHAA lies within the Local Assessment Area (LAA), which is defined by a selection of tertiary watersheds (Section 6.9.3.3). Additional details regarding the aquatic spatial boundaries (i.e., PA, LAA, and Regional Assessment Area [RAA]) are provided in the Effects Assessment Methodology (Section 6.9.6).

The baseline program methodology is summarized in the subsections below and results of baseline characterization studies are presented in Section 6.9.4. Figures 6.9-2, 6.9-3 and 6.9-4, included in the corresponding baseline methodology subsections below, present and overview of baseline sampling locations within the FHAA, including: fish, benthic macroinvertebrate, culvert condition, daily flow assessment points, and habitat assessment transects.

Detailed maps of individual sampling type and the locations and habitats/stream reaches (i.e., characterization studies) are presented in Appendix J.4.

Complete baseline characterization studies for the proposed Project are provided in the Baseline Fish and Fish Habitat 2019-2020 Technical Report and the Baseline Fish and Fish Habitat 2015-2017 (herein referred to as the 2019-2020 Baseline Report Appendix J.2 and/or the 2015-2017 Baseline Report Appendix H of Appendix J.2, respectively).

The baseline characterization studies and results from the Touquoy Gold Project (i.e., existing Touquoy Mine) used in this effects assessment have been summarized from the Touquoy Gold Project 2007 Focus Report (CRA 2007b) and Environmental Assessment Registration Document (EARD) (CRA 2007a).

6.9.3.1 Surface Water

Baseline characterization of Surface Water Quantity VC (hydrology) and Surface Water Quality VC conditions at the Project was undertaken to define the existing hydro-climatic regime for the watersheds that could potentially be affected by Project development; baseline methodology for surface water is described in Section 6.7.4 (Surface Water Quantity Baseline) and Section 6.7.5 (Surface Water Quality Baseline). Surface water monitoring (quantity and quality) for the proposed Project has occurred since 2014.

In addition, targeted characterization of surface water conditions at electrofishing locations was completed as follows to support the Fish and Fish Habitat assessment:

- Physicochemical water quality measurements were recorded at each representative section of watercourses and waterbodies selected for electrofishing within the Beaver Dam Mine Site and Haul Road. All water quality measurements were collected using a Horiba multi-probe (W-22XD) or YSI 650 MDS & 600 QS Multi-Probe water quality instrument. Parameters recorded include dissolved oxygen (mg/L), water temperature (°C), pH, and specific water conductivity (µS/cm).
- In 2019 and 2020, in-situ water quality measurements were recorded at all electrofishing and trapping sites prior to each sampling event (Appendix J.2).
- Water quality measurements were recorded for each watercourse reach delineated through detailed habitat assessments. These water quality measurements were collected using a calibrated YSI Multi-Probe water quality instrument or a combination of a Myron Ultrapen Dissolved Oxygen Pen Probe and Hannah Combo pH/Conductivity/TDS Probe at the time of the sampling event/survey.

The Baseline Fish and Fish Habitat 2019-2020 Technical Report (herein referred to as the 2019-2020 Baseline Report (Appendix J.2) presents the survey methods conducted in 2019-2020, supplemental information to 2015-2017 baseline information is described in the Baseline Reports (Appendix H of Appendix J.2).

6.9.3.2 Benthic Macroinvertebrate Sampling

The objective of benthic macroinvertebrate (invertebrate) surveys was to determine abundance and community composition of secondary (benthic invertebrate) producers in the streams, rivers, and wetlands across the FHAA defined for the Project (Figure 6.9-1). Invertebrate sampling was completed using the national standardized CABIN protocol (EC, 2012). Sampling was completed in June 2016 at three locations within the Beaver Dam Mine Site (Figure 6.9-2) and seven locations along the Haul Road (Appendix J.4). Benthic sampling was completed to support fish habitat evaluation as a baseline measurement, as changes in the benthic invertebrate abundance and community structure may indicate perturbations to the natural aquatic environment.

To support baseline characterization, benthic communities in lotic (fast-flowing) and lentic (standing or slow-flowing) environments were sampled. The total number of animals of each type (taxonomic group), as well as total abundance, was determined for each sample collected from the watercourses across the Beaver Dam Mine Site and the Haul Road. These numbers were used to calculate several indices of baseline benthic community health, which can be compared between sites and, with time, at each site. Indices calculated are all commonly used in studies of this kind and include: EPT Ratio (ratio of abundance of mayflies (Ephemeroptera), caddisflies (Trichoptera), and stoneflies (Plecoptera), to total numbers of organisms); Total Abundance (number of animals in the sample and per unit area); and Taxon Richness (number of taxa per sample). Abundance in kicknet samples was expressed on a per sample basis. All organisms present were included in estimates.

Detailed methodology for sample collection and laboratory analyses are provided in Appendix H of the 2019-2020 Baseline Report; (Appendix J.2). Figure 6.9-2 shows benthic macroinvertebrate sample locations.

6.9.3.3 Fish Habitat Assessment

Fish habitat assessments were completed in two phases. During initial site assessments completed in 2015-2017 a qualitative evaluation of fish habitat was completed. This included delineation, characterization, and basic descriptions of all aquatic features, including reach-level measurements of fish habitat parameters. The details associated with the qualitative evaluation of fish habitat are provided in Appendix G.4 as well as in the 2015-2017 Baseline Report (Appendix H of the 2019-2020 Baseline Report, Appendix J.2); a summary is presented in this section.

Further to the initial delineation and description of watercourses, and in response to IR2 CEAA-2-19, a more detailed quantitative evaluation of fish habitat was completed in 2019-2020. The methods to describe habitats are outlined in detail in each of these baseline reports and summarized in this section.

Each habitat type has been characterized via surveys using standard methodologies to gather key measurements such as reach length (m), reach wetted and bankfull width (m), reach slope (%), stream substrate composition (% composition), water depths (m), water velocities (m/s), cover (%), and riparian habitat. The data was used to determine the overall habitat area within each reach as well as the habitat suitability based on measured stream substrate, water depths, and water velocities (habitat parameters) for each fish species identified within the Beaver Dam Mine Site (IR2 CEAA-2-06). Fully tabulated fish habitat data is presented in Appendix G of the 2019-2020 Baseline Report (Appendix J.2). Delineated watercourse reaches are presented in Appendix J.4, Figure J.4-2, and representative photos are presented in Appendix C of the 2019-2020 Baseline Report (Appendix J.2).

6.9.3.3.1 Qualitative Evaluation

Watercourses and waterbodies were identified and described across the Beaver Dam Mine Site in Summer 2015, and the Haul Road in Spring 2016. Wetland delineation and evaluation were completed in 2015 (Beaver Dam Mine Site) and 2016 (Haul Road). As a result of the micro-siting of infrastructure, additional supplementary baseline surveys were conducted in July and August 2019, and December 2020 to delineate and characterize additional surface water features within the broader FHAA to support indirect impacts analysis to fish and fish habitat, which incorporated several down-gradient watercourses surrounding the Beaver Dam Mine Site.

The original qualitative descriptions of fish habitat presented in the Revised 2019 EIS (AMNS, 2019) were based on the *Standard Methods Guide for Freshwater Fish and Fish Habitat Surveys in Newfoundland and Labrador: Rivers and Streams* (Sooley et al., 1998), with the descriptions provided for fish of the Salmonidae family, using the Atlantic salmon as the indicator species. Characterization of fish habitat within watercourses, waterbodies and wetlands within the Beaver Dam Mine Site and Haul Road have since been updated to consider all fish species confirmed or potentially present within each aquatic features and support for their various life stages, in consideration of the updated *Fisheries Act* (2019).

6.9.3.3.2 Quantitative Evaluation

Within the Beaver Dam Mine Site component of the FHAA, quantitative evaluations were completed in any watercourse which was expected to be directly or indirectly affected by the Project (CEAA 2-07), following the MEL Standard Operating Procedure (SOP) for detailed fish habitat assessment in streams (Appendix B of 2019-2020 Baseline [Appendix J.2]). This description of habitat by homogeneous section is provided in the baseline results section (Section 6.9.4, Table 6.9-2) and is described in further detail in the 2019-2020 Baseline Report (Appendix J.2).

The methods outlined in the SOP were derived from the following sources:

- The Nova Scotia Fish Habitat Assessment Protocol: A Field Methods Manual for the Assessment of Freshwater Fish Habitat (NSLC, 2018);
- DNR / DFO – New Brunswick Stream Habitat Inventory Datasheets;
- Standard Methods Guide for the Classification and Quantification of Fish Habitat in Rivers of Newfoundland and Labrador for the Determination of Harmful Alteration, Disruption and Destruction of Fish Habitat (DFO, 2012);
- Reconnaissance (1:20,000) Fish and Fish Habitat Inventory (RIC, 2001);
- The US EPA Rapid Bioassessment Protocols For Use in Streams and Wadeable Rivers: Periphyton, Benthic Macroinvertebrates, and Fish (Barbour et al., 1999); and
- The Canadian Aquatic Biomonitoring Network Field Manual, Wadeable Streams (EC, 2012).

In summary, a total of eight watercourses (WC5, WC12, WC13, WC14, WC23, WC25, WC26, and WC27) and three open water features in wetlands (WL56, WL59, and WL61) were described using quantitative evaluation methods. In addition, modified quantitative fish habitat surveys were performed within a 1.7 km stretch of Cameron Flowage/Killag River from December 8 to 16, 2020, the details of which are provided in the baseline results section (Section 6.9.4, Table 6.9-3), and described in further detail in the 2020 Baseline Report (Appendix J.2). Watercourse reaches identified during the quantitative evaluation of fish habitat are summarized in the baseline results section (Section 6.9.4, Table 6.9-2) and identified in Appendix J.4, Figure J.4-2.

To support fish habitat assessments, each surveyed watercourse was delineated into individual reaches defined by discrete homogeneous units (e.g., riffle, run, pool, flat, etc.) as determined in the field in an upstream to downstream direction. Each habitat type contains discrete gradient, substrate types, water depth, and velocity ranges which have been determined using the described biological 'preferences' outlined in Grant and Lee (2004), whenever possible. In smaller, first-order streams, habitat types were often found to be extremely short and variable. For efficiency in the field, when individual habitat types were less than 5 m in overall length, they were be grouped together into one reach containing multiple smaller habitat units. The upstream and downstream ends of each reach were recorded with a handheld GPS device. Fish habitat reaches are presented in Appendix J.4, Figure J.4-2.

For each reach (homogenous section of watercourse), a detailed fish habitat survey was completed which included water quality measurements, designation of substrate and cover types, riparian habitat descriptions, and barrier assessments. Cross-sectional measurements (transects) were established to describe morphological (channel and wetted widths, bank heights) and flow characteristics (velocities and depths) within the reach. Transect measurements were recorded at every 50 m length of reach – for example, if a reach was 150 m in total length, three transects were established within the reach. If multiple habitat types (<5 m in length) were grouped together to form a reach, transects were established within each habitat type represented within the reach. The amount of transects and transect locations were selected and modified as needed in the field based on specific habitat features observed, or limitations related to access, wadeability, and safety concerns.

Percent cover of various substrate types was described within each individual transect using the following parameters:

- Bedrock: Continuous solid rock exposed by the scouring forces of the river/stream;
- Boulder: Rocks ranging from 25 cm to >1 m in diameter;
- Rubble: Rocks ranging from 14 to 25 cm in diameter;
- Cobble: Rocks ranging from 3 to 13 cm in diameter;
- Gravel: Small stones ranging from 2 mm to 3 cm in diameter;

- Sand: Grains ranging from 0.06 to 2 mm in diameter, frequently found along stream margins or between rocks and stones;
- Silt: Very fine sediment particles, usually <0.06 mm in diameter;
- Muck/detritus: Organic material from dead organisms (plant and/or animal); and
- Clay/Mud: fine mineral soil. <0.06 mm in diameter, with the ability to form a ribbon of soil (unlike silt).

For shallow (<2 m) open water features that (i.e., the ponded area of WL59), depth and substrate checks were performed at various locations throughout the feature, and any cover types (vegetation, woody debris, large substrate) were documented and total cover (%) was estimated.

Aquatic features along the Haul Road were not re-evaluated through quantitative fish habitat evaluations as the original, qualitative fish habitat characterizations were considered to provide appropriate fish habitat data for each specific crossing location. Qualitative fish habitat descriptions were completed on short reaches of watercourses typically representing a single homogeneous unit, in a narrow, discrete study area, which directly overlaps the proposed Haul Road and associated impacts from road crossings. Therefore, fish habitat at each Haul Road crossing location is considered a discrete habitat unit based on the short length of each watercourse described, and further detailed quantification was not deemed necessary at this stage.

6.9.3.3.3 Fish Passage Assessment

Throughout baseline watercourse mapping and fish habitat surveys, an assessment of potential fish passage obstacles was completed. When a potential obstacle was encountered, biologists recorded the type of obstacle, height and length of the obstacle, depth of water, along with an estimate of slope where relevant. For subterranean reaches presenting obstacles to fish passage, the contiguity and spatial relationships of discontinuous pools are described, with the intent of understanding a fish's ability to move and/or jump from one step-pool or isolated pool to another.

If a potential barrier is an anthropogenic in nature (i.e., improperly installed culverts), the type of culvert is noted, along with any issues associated with installation that could be remediated to improve passage. Anthropogenic structures such as improperly installed culverts are not typically identified as permanent barriers to fish passage, because through remediation, fish passage can be restored. The temporal nature of an obstacle is noted as well, recognizing that natural and anthropogenic barriers can change with time (i.e., logjams or beaver dams) or remediation (i.e., culvert installation), while others limit passage seasonally (i.e., ephemeral or intermittent streams), and others may be permanent barriers (i.e., some waterfalls). Where an obstacle was identified but the temporal nature of it was uncertain or if it was dependent on flow regime, multiple site assessments and additional fish sampling were conducted to confirm it's passability. Except in extreme circumstances, logjams and beaver dams are not considered barriers to fish passage.

Further to the typical physical characteristics, the ecological context was used to identify evidence of flow and hydrologic connectivity that would provide passage for fish. The NSE Guide to Altering Watercourses (NSE, 2015) is used to support the discussion of whether a regulated watercourse (i.e., defined, natural channel) is present. This guidance includes identifying whether:

- a mineral soil channel is present;
- there is sand, gravel and/or cobbles evident in a continuous pattern over a continuous length with little to no vegetation;
- there is an indication that water has flowed in a path for a length of time and rate sufficient to erode a channel or pathway;
- there are aquatic plants, animals, or fish; or
- there is aquatic vegetation.

Hydrology indicators are used to identify evidence of flow if an initial assessment occurs during a period of low flow. Some examples of hydrology indicators used include water marks on trees, sediment deposits, drift deposits, algal mats, sparsely vegetated concave surface, water-stained leaves, surface soil cracks, drainage patterns, or moss trim lines. Vegetation communities can provide indication of flow (or absence thereof) as well.

Understanding the swimming capabilities of fishes is key to the determination of barriers to fish passage. Swimming capabilities of fishes is dependent upon abiotic factors such as water depth, flow rate, water temperature, height and length of obstacles, and biotic factors such as fish species, length, darting speed, behavioral adaptations, and life history stage. In the assessment of fish passage obstacles, the swimming capabilities of the following species were considered: American eel, Atlantic salmon, brook trout, white sucker, and white and yellow perch. Detailed fish passage assessment methodology and a literature review of the swimming capabilities of each species is presented in the 2019-2020 Baseline Report (Appendix J.2).

6.9.3.4 Fish Collection

6.9.3.4.1 2015 to 2017 Field Collection

Quantitative electrofishing sites were established in areas of confirmed or potential fish habitat within the Beaver Dam Mine Site and Haul Road area with the goal of providing quantitative data on fish populations in selected watercourse reaches. Detailed methods and results for fish surveys completed within the Beaver Dam Mine Site and Haul Road from 2015-2017 are presented in the 2015-2017 Baseline Report (Appendix H of the 2019-2020 Baseline Report; Appendix J.2). The methodology outlined in the Revised 2019 EIS (AMNS 2019) was followed during these surveys. In summary:

- Each watercourse was evaluated for the presence of fish habitat and potential ability to support fish species during initial assessment and identification. Once this was completed, fishing locations and methods were established within reaches of linear watercourses and waterbodies.
- Electrofishing sampling sites (Figure 6.9-2) were established in representative aquatic habitats with high potential to support fish along the Haul Road and within the Beaver Dam Mine Site. The purpose of the electrofishing surveys was to determine fish species presence and abundance within watercourses and associated wetlands within the Beaver Dam Mine Site and Haul Road.
- Electrofishing sites within the Beaver Dam Mine Site employed an “open” site and a single pass - no barrier nets were used to increase the chance of capturing fish migrating into the sampling reach.
- Electrofishing along the Haul Road was performed in select watercourses with the goal of representing each tertiary watershed. Prior to each sampling event, sampling sites located within linear watercourses along the Haul Road were blocked off with barrier nets that were secured to the streambed at either end of the sampling reach. This created a “closed” system from which quantitative population estimates could be calculated. Two passes of electrofishing were performed within each sampling site along the Haul Road.
- Trapping was completed in Cameron Flowage and Crusher Lake in June 2016 to support and supplement electrofishing efforts completed for the Project (Figure 6.9-2).

6.9.3.4.2 2019 to 2020 Field Collection

Detailed methods and results for fish surveys completed within the Beaver Dam Mine Site and Haul Road from 2019 to 2020 are presented in the 2019-2020 Baseline Report (Appendix J.2) and are summarized in this section.

Continued trapping efforts were conducted in September, November, and December 2019 in the western extension of the Beaver Dam Mine Site, specifically those watercourses within the Cope Brook Tertiary Watershed. The overarching goal of this particular

fish collection program was to saturate selected watercourses with a variety of gear types for extended periods of time in order to clearly establish the presence of fish during a range of seasonal flow conditions and ecological periods.

From April through September 2020, a concentrated fishing program was completed within watercourses and waterbodies within and in proximity to the Beaver Dam Mine Site due to proposed impacts to fish and fish habitat within the Local Assessment Area (LAA). This program consisted of the following tasks:

- Continued trapping during high spring flow regimes within the Cope Brook tertiary watershed within selected watercourses identified within and downstream of the proposed Waste Rock Storage Area (WRSA) (Figure 6.9-3); and
- Three rounds of summer fish sampling (electrofishing and trapping) within watercourses and waterbodies predicted to be directly affected, indirectly affected, and unimpacted by Project development.

Three rounds of quantitative and qualitative electrofishing surveys were conducted between June 1 and September 30, 2020 to identify seasonal fish usage throughout the Beaver Dam Mine Site. Sampling reaches of approximately 100 m in length were established within watercourses predicted to be directly impacted, indirectly impacted, and reference sites likely to be unimpacted by Project development (Appendix J.2). Quantitative and qualitative electrofishing reaches and trapping locations are shown on Figure 6.9-2. A complete description of methods for fish surveys conducted during the 2019-2020 field program is presented in the 2019-2020 Baseline Report (Appendix J.2).

6.9.3.5 Environmental DNA

Environmental DNA (eDNA) is a well-established technique which identifies environmental or exogenous DNA molecules from aquatic or semi-aquatic organisms. The premise of eDNA is that all organisms shed genetic material into the environment. Water samples are collected, filtered and analyzed using a qPCR (quantitative polymerase chain reaction) technique to extract eDNA and identify organisms present within the aquatic environment. When genetic material found in the collected water sample matches with a known genetic primer for the target species or taxa, a positive result is provided by the production of fluorescence in the qPCR process. Genetic primers can be species-specific (i.e., based on matching 20 base pairs of a genetic sequence), or generic (i.e., identifying presence of particular taxa such as fish, amphibians, etc., based on a shorter genetic sequence of ten base pairs). One example of a generic test is the eFish primer, developed by the University of Victoria, and used extensively by Bureau Veritas (BV) Laboratory (Bureau Veritas, n.d.).

To support the Project, eDNA analyses was used to identify presence of fish in aquatic habitats underlain by the proposed WRSA using the eFish primer. While this primer has been calibrated primarily using fish species from western Canada, it has been confirmed to detect both American eel and brook trout. Environmental DNA analyses was performed at two sites with confirmed or suspected fish presence, and four sites where fish presence was not expected based on habitat assessments and fish collection completed from September 2019 through July 2020 (refer to Figures 6.9-2 and 6.9-4 for eDNA locations and trapping locations and Figure 6.9-3 for detailed trapping locations specific only to the WRSA). To date, fish collection effort within the WRSA footprint and downstream receiving environment has only resulted in identification of brook trout in WC23 (Sites 5 and 6). Fish collection has not been completed at Site 6; however, habitat assessments and a desktop review have identified contiguous surface flow between Sites 5 and 6, so it is expected that Site 6 is accessible to fish as well. Sample locations 1 through 4 were selected within watercourses WC20 and WC21, and within standing water within their respective wetland habitats. These sites are expected to be inaccessible to fish, based on the presence of the 250 m long subterranean barrier between WC21 and WC23. Sample locations are shown on Figure 6.9-3.

Additional details of eDNA analyses, sample site selection, and results are presented in Appendix J.2.

6.9.4 Baseline Results

This section presents the most salient results of the baseline characterization studies for the Fish and Fish Habitat VC as well as related VCs, Surface Water Quantity and Surface Water Quality. Detailed results for Fish and Fish Habitat Baseline are presented in Appendix J.2; baseline results for surface water are presented in Section 6.7 (Surface Water Effects Assessment). As described in Section 6.9.3, this section has been updated to include results of the additional surveys required primarily related to habitat quantification and increased fish collection effort, driven by the modernized *Fisheries Act* and revisions to Project infrastructure/ micro-siting of Project infrastructure. Throughout Section 6.9.4, the results of the desktop evaluation for fish species distribution will be presented along with a summary of results from all baseline surveys described in Section 6.9.3.

The potential for each watercourse, waterbody, and wetland to support fish habitat and fish was evaluated throughout the FHAA at the Beaver Dam Mine Site including Cameron Flowage/Killag River, and along the Haul Road, as described in Section 6.9.3. Thirty-five (35) watercourses were identified within the Haul Road (Appendix J.4, Figure J.4-4) and 29 watercourses were identified within the Beaver Dam Mine Site (Appendix J.4, Figure J.4-3). Two waterbodies were identified within the Beaver Dam Mine Site (Crusher Lake and Mud Lake), both of which are confirmed fish frequented. A total of 236 wetlands were also evaluated for fish habitat potential, comprising 117 wetlands within the Beaver Dam Mine Site and 121 wetlands along the Haul Road, with two wetlands (wetlands 64 and 66) located partially within each component.

The underlying subsections present a summary overview of baseline characterization results.

6.9.4.1 Overview

6.9.4.1.1 Hydrological Setting

The Beaver Dam Mine Site lies within the West River Sheet Harbour secondary watershed (1EM-2), which is directly east of the Musquodoboit River Valley system. The watershed occupies an area of roughly 576 square kilometers (km^2). The West River Sheet Harbour watershed (WRSH) discharges to the West River and its tributaries, from north to south. Elevations within the catchment vary from approximately 135 to 165 meters above sea level (masl) in the headwater areas and gradually decrease to sea level at the final outlet located at Sheet Harbour. The headwaters of the drainage basin are located along the topographic divide separating the Musquodoboit River Valley to the northwest. Within the WRSA secondary watershed, the Project intersects eight tertiary watersheds (Killag River, Tent Brook, Paul Brook, Cope Brook, Tent Brook, Keef Brook, Jack Lowe Brook and Little River).

The WRSH watershed is one of 72 watersheds within the Southern Uplands (SU) region. The main river channel, the West River, is approximately 30 km long and has two main tributaries – the Killag and Little Rivers. Fish surveys within the watershed have been ongoing since 1965 and have documented a variety of species present. Of particular research interest has been the presence of Atlantic salmon and provision of salmon habitat within these rivers. According to Ducharme (1972), the Killag River is the most important of the three rivers for Atlantic salmon production due to the presence of excellent spawning grounds. Ducharme (1972) also identified that most of the salmon spawning within the watershed takes place in the Killag River.

The Killag River and Cameron Flowage are the main mapped linear watercourses adjacent to the Beaver Dam Mine Site, and Crusher Lake and Mud Lake are the major mapped lakes. The complex system of streams, lakes, bogs, and wetlands is a direct result of the underlying bedrock geology of greywacke and slate found in the region. The basin ultimately drains to the south via the West River Sheet Harbour, and discharge peaks are likely attenuated to a large extent by the numerous lakes and wetlands through which runoff is routed. Tertiary watersheds for the Project Area (PA) are presented in Section 6.7.4, Figure 6.7-4.

A portion of the Haul Road lies within the Tangier River secondary watershed (1EL-2, including tertiary watersheds associated with Sandy Pond and the Morgan River), and the Touquoy Mine Site exists within the Fish River-Lake Charlotte secondary watershed (1EL-5, including tertiary watersheds associated with Moose River, Square Lake and Scraggy Lake), detailed in Section 6.7.

6.9.4.1.2 Water Quality

Water quality baseline studies have been conducted in the Project area since 2014. Results indicate that overall, the aquatic ecosystem within the Beaver Dam Mine Site and Haul Road is characterized by acidic conditions, with aquatic features within the Cope Brook tertiary watershed exhibiting lower pH levels than aquatic features within the Killag River tertiary watershed. Low pH levels, elevated temperatures, low dissolved oxygen concentrations, and elevated concentrations of some metal parameters may limit fish habitat quality within select systems in the FHAA, particularly within small, sluggish first order streams and shallow open water features that experience with low water depths during the summer months. Additional discussion of water quality results for the FHAA is presented underlying.

The Project is in a highly mineralized region and the geology contributes to naturally acidic pH levels as well as elevated concentrations of many water quality parameters in the area, including iron, arsenic and aluminum (Section 6.7). The occurrence of naturally elevated concentrations in surface waters is commonly observed in regions of planned/proposed mining activities, all over the world (e.g., "Golden Triangle" of northwestern British Columbia, Canada). In such regions, naturally elevated concentrations of certain water quality parameters generally occur where exposure of rock or other geologic materials to oxygen and water results in natural weathering processes, including chemical oxidation and leaching of solid-phase constituents (e.g., metals), which are then transported to surface waters.

Natural acidity and/or exceedances of water quality guidelines in baseline conditions are not a Project effect and, for these parameters, generic water quality guidelines (WQG) such as Canadian Council of Ministers of the Environment Water Quality Guidelines for the Protection of Freshwater Aquatic life (CCME FAL), do not necessarily apply. That is, WQG generally represent generic criteria that are developed by governments or international organizations to identify the concentrations of parameters in the receiving environment that are not expected to cause an adverse effect on various receptors or uses (e.g., aquatic life, wildlife, livestock/agriculture, drinking water. As WQG are intended to apply universally, they do not necessarily account for site-specific factors including the presence/absence of specific species in the receiving environment, or naturally occurring elevated existing water quality due to mineralization of the watershed.

Monitoring results for the Killag River (identified receiving water for the Project) are presented in Section 6.7.5.2, Table 6.7-14; a summary of baseline exceedances for all sampling locations is presented in Section 6.7.5.2, Table 6.7-15. Detailed surface water baseline analytical results and guideline exceedance comparison are presented in Appendix G.1. In general, results indicated that the concentrations of most metals are typically low across the FHAA, often below detectable levels. However, three of the baseline water quality locations (i.e., SW-5, SW-10 and SW14A) located either within, or directly downstream of historic tailings, show metal concentrations exceeding guideline concentrations. During Construction, water impacted by historic activities will be treated as described in Section 6.7.9 and Appendix F.1 (Construction Water Treatment) of Appendix P.4 (Mine Water Management Plan).

The pH of waters in the PA range from circumneutral to acidic; for some monitoring locations proximate to the proposed Beaver Dam Mine Site, pH levels were below acceptable CCME FAL range suitable for fish within freshwater habitat (6.5 to 9.0). In 2016, pH levels in WC4 and Cameron Flowage were recorded within the acceptable CCME FAL range at 6.55 and 6.71, respectively. All watercourses within the Haul Road surveyed in 2016 had recorded pH levels below the range suitable for fish within freshwater habitat. The pH range for aquatic features sampled in 2020 was 4.44 to 7.03, with an average pH of 5.47. Only three sampling sites (Watercourses 13, Cameron Flowage, and WL59) exhibited pH levels within CCME recommended range for freshwater

aquatic life (6.5 to 9.0). Twenty-eight percent (28%) of measurements recorded in-situ during fishing efforts and habitat assessment exhibited pH levels so low (<5.0) as to expect to cause harm to salmonid species. Most of these low pH measurements were recorded in first order streams within the Cope Brook tertiary watershed (WC20, WC21, and WC23). Streams within the Cope Brook tertiary watershed were generally more acidic than those in the Killag River tertiary watershed.

Water temperatures recorded during electrofishing and fish collection in September 2015 and June 2016 ranged from 13.5°C to 23.43˚C. Generally, this range of water temperatures fell within the required ranges for the species expected to inhabit aquatic features within the Beaver Dam Mine Site and Haul Road. Temperatures recorded in WC13 and Wetland 59 in the Beaver Dam Mine Site, and WC-B and WC-AA within the Haul Road were above the optimal range for salmonids (>20°C). The majority of watercourses sampled within the Beaver Dam Mine Site (78%) and Haul Road (71%) had recorded temperatures within the optimal range for cold-water fish species.

In 2020, most watercourses assessed within the Killag River tertiary watershed displayed a general warming trend from early to late summer, with the majority of surveyed watercourses within the Beaver Dam Mine Site measuring at or above 20˚C by the end of August. Of the waterbodies and open water features surveyed in 2020, suitable temperatures for cold-water species were consistently recorded in Crusher Lake. The Mud Lake Outlet (WC27) was also regularly measured as below 20°C, except for one temperature recorded in July. The flooded portion of WL59 ranged above and below 20°C throughout the summer months. WL59 had the highest recorded temperature of all sites at 27°C, and no areas of thermal refuge under 20°C were identified through measurements taken throughout the flooded area during habitat assessments completed on July 21, 2020.

Dissolved oxygen (DO) levels recorded in 2015 across watercourses and waterbodies within the Beaver Dam Mine Site were above the recommended concentrations for both life stages of cold-water biota (>9.5 mg/L). DO levels recorded in the Beaver Dam Mine Site in 2016 (Cameron Flowage and benthic sampling sites) are considered suitable for other life stages of cold-water fishes (>6.5 mg/L). Along the Haul Road, most watercourses had DO levels suitable for other stages of cold-water fishes, with the exception of WC-B (3.9 mg/L) and WC-O (5.3 mg/L). These dissolved oxygen levels are considered limiting to both warm-water and cold-water fish species.

In 2020, ninety-seven percent (97%) of DO levels recorded across aquatic features within the Beaver Dam Mine Site were below the minimum CCME FAL recommended concentration of DO for early life stages of cold-water fishes. Forty-eight percent (48%) of DO levels recorded for watercourses were below levels suitable for any life stage of cold-water fishes, and 44% were below levels suitable for any life stage of cold or warm-water fishes (<5.5 mg/L). Low dissolved oxygen levels were typically associated with small, slow-moving streams and lentic habitats whose riparian habitat is dominated by organic wetlands, including WC20, WC21, WC25, WC26, and WL59. Warmer water temperatures recorded in 2020 is also a likely driver of lower DO levels recorded the Beaver Dam Mine. Most aquatic features within the Beaver Dam Mine Site were at some point measured as having DO concentrations suitable for aquatic life. However, it is likely that DO concentrations within some of these features limit the quality of fish habitat, at least seasonally, and particularly for cold-water species like salmon and trout.

6.9.4.1.3 Benthic Macroinvertebrates

Detailed results including species identifications, summary statistics, and sediment descriptions are provided in Appendix H of the 2019-2020 Baseline Report (Appendix J.2).

Samples were dominated in numbers by Diptera (fly) larvae, principally midges (Chironomidae) at all sites and by juvenile clams (Bivalves), predominantly Sphaeriidae at Watercourse 13. Caddisfly larvae (Trichoptera) occurred frequently at all sites with the exception of one (WC-B.b), and may fly larvae (Ephemeroptera) occurred at twelve of the fourteen sites. Aquatic beetle larvae (Coleoptera), dragonfly/damselfly larvae (Odonata), stonefly larvae (Plecoptera) and dobsonfly/fishfly larvae (Megaloptera)

occurred frequently at most sites. Aquatic Hemiptera (i.e., Gerridae, Corixidae, etc.) also occurred in many of the sites, as well as crustaceans, including the amphipod *Hyalella azteca* (found only at Watercourse 13), and copepods and cladocera (found at a total of eight sites).

Overall abundance and taxon richness within FHAA were low to moderate (110 to 947 individuals/sample and 10 to 31 taxon, respectively). EPT ratios were low at eight of the sites (0.5 to 8.4%), including all watercourses sampled within the Beaver Dam Mine Site, and moderate (16.1 to 50.2%) at the remaining sites (Watercourse N, V, AH, O), all along the Haul Road. The occurrence of EPT groups (Trichoptera, Ephemeroptera and Plecoptera) at most sites suggests that dissolved oxygen and water quality is acceptable, as these groups generally are associated with aquatic habitat having good water quality. However, there are many factors that regulate the distribution and abundance of benthic macroinvertebrates within aquatic environments (as well as biological condition within a waterbody), thus the results of this study only allow for the establishment of baseline conditions that can later be used in a monitoring program to identify potential changes to water quality within these specific environments.

6.9.4.1.4 Atlantic Salmon

The evaluation of expected and potential direct and indirect impacts to fish and fish habitat is being made for all fish species confirmed present within the Beaver Dam Mine Site and Haul Road as required under the *Fisheries Act* (2019). However, a special focus has been paid to Atlantic salmon due to their current population status and the significant habitat restoration efforts undertaken within the WRSH watershed, which is one of the 72 watersheds within the Southern Uplands (SU) Designatable Unit population for Atlantic Salmon.

North American Atlantic salmon breed and spend the early part of their life cycle in freshwater systems throughout Atlantic Canada, eastern Québec, and the northeastern seaboard of the United States. This species requires rivers or streams that are generally clear, cool, and well-oxygenated for reproduction and the first few years of rearing but undertakes lengthy feeding migrations in the North Atlantic Ocean as older juveniles and adults (COSEWIC 2010). The genetic structure and life history traits of Atlantic salmon tend to vary among river populations and this variation among salmon rivers tends to increase with geographic distance. That is, salmon populations are more closely related the nearer their home rivers are located to each other. As a result, DFO manages groups of salmon rivers as metapopulations, called Designatable Units (DUs), based on geography and unique genetic and life history traits (COSEWIC 2010). Based on these features, Atlantic salmon populations are managed under 16 distinct DUs. Among these DUs, COSEWIC has identified five as Endangered (Outer Bay of Fundy, Inner Bay of Fundy, Southern Uplands, Eastern Cape Breton, and Anticosti Island metapopulations). The West River is located within the Southern Uplands DU (Appendix J.3 draft Fish Habitat Offset Plan).

The SU population of Atlantic Salmon has experienced significant reductions over the last few decades, with adult abundance declining from 88 to 99% from observed abundances in the 1980s (DFO, 2013). Salmon assessment activities in the SU region are currently focused on two index populations: the St. Mary's River, and the LaHave River. As of 2019, index populations remain critically low (DFO, 2020). According to DFO (2013), all 22 rivers where juvenile Atlantic salmon were found during 2008/2009 surveys are considered important habitat for SU Atlantic salmon.

Threats to persistence and recovery of SU Atlantic salmon in freshwater environments have been identified by through the Recovery Potential Assessment (DFO, 2013). Threats in freshwater environments that have been recognized with a "high level of overall concern" (DFO, 2013) include: acidification, altered hydrology, invasive fish species, habitat fragmentation due to dams and culverts, and illegal fishing and poaching.

Acidification of freshwater habitats brought about by acidic precipitation is a major, ongoing threat (COSEWIC 2010). Anthropomorphic deposition exacerbates a naturally acidic region where natural sources such as wetlands dominated by

Sphagnum mosses and forests, as well as underlying geology, produce low pH surface waters (NIVA 2001). Even with reduced deposition in recent years, the natural alkalinity is low in the SU region due to natural underlying geology of the system, which results reduced cation-generating capacity, very slow natural neutralization and low natural buffering capacity (DFO 1998; Ritter and Rutherford 2000; MAPS 2013). While sulphate levels have shown significant declines between 1981-1995 (DFO 1997), it did not lead to immediate improvements in river pH due to the low natural buffering capacity (MAPS 2013). Of 60 salmon rivers previously assessed for mean annual pH:

- 14 were identified as extirpated (mean annual river pH less than 4.7);
- 20 were identified as severely impacted (mean annual river pH between 4.7 to 5.0);
- 16 were identified as lightly impacted (mean annual river pH between 5.1 to 5.4); and
- 13 were identified as not impacted (mean annual river pH greater than 5.5) (DFO 1997).

Only rivers with pH greater than 5.4 have non-impacted salmon populations within the SU region of Nova Scotia (NIVA 2001). Mean annual river pH values less than 5.4 are thought to adversely affect salmon spawning success and survival rates (MAPS 2013) and a mean annual river pH less than 5.1 can destabilize salmon productivity (Bowlby et al. 2013).

The Nova Scotia Salmon Association (NSSA) is currently conducting an Acid Mitigation Project in tertiary watersheds that are located within the FHAA for SU Atlantic Salmon populations. In order to offset the acidity of watercourses and improve water quality for Atlantic salmon, the project uses in-stream liming using lime dosing stations installed on the West River Sheet Harbour main branch in 2005 and on the Killag River in 2017, downstream of Cameron Flowage (Appendix J.4, Figure J.4-1). The lime dosing stations are automated systems which contribute specific dosages of powdered limestone directly to the watercourse. Terrestrial/catchment liming via helicopter has ongoing since 2016 with a focus on the headwater riparian areas the Keef Brook (1EM-2G), Paul Brook (1EM-2H) and Tent Brook (1EM-2F) tertiary watersheds (Section 6.7.4, Figure 6.7-4). As a result of the Acid Mitigation Project, treated river pH has increased to 5.5 to 7.5 in the main branch of the WRSH (Halfyard, 2013). The Acid Mitigation Project has also included physical habitat restoration within the West River, fine sediment removal from spawning habitat within the West and Killag Rivers, and terrestrial liming within the catchment area of Keef Brook (NSSA, 2020).

Further details related to Atlantic Salmon in the SU DU and the Acid Mitigation Projects are provided in the Cumulative Effects Assessment (Section 8) (NSE-2-123).

6.9.4.2 Site Specific Study Results

6.9.4.2.1 Fish Habitat: Beaver Dam Mine Site

Fish habitat potential was determined during field identification/delineation through the collection of key fish habitat characteristics of each watercourse and wetland including channel morphology, biophysical descriptions. Quantitative fish habitat assessments revealed suitable habitat for spawning, young of the year, juvenile, and adult life stages for both cold and warm-water species throughout the FHAA. The following subsections provide fish community descriptions by watercourse; detailed fish collection discussion are provided in Appendix J.2 and Section 6.9.4.2.3.

Identified Watercourses and Waterbodies

A summary evaluation of each identified watercourse and open water feature, and the fish species/life stages they support, is provided in Tables 6.9-2 and 6.9-3 and described in further detail in Appendix J.2; watercourses are shown in Appendix J.4, Figure J.4-3.

Within Table 6.9-2, average depth and average velocity are presented as a summary of a minimum of three measured depth and velocity points per transect, as described in the MEL SOP for detailed fish habitat assessments in streams (Appendix B of Appendix J.2). Wherever a range of wetted widths and channel widths are provided, it indicates the range of multiple transects completed within that reach. If, for instance, one reach contained multiple small (<5 m in length) individual units, they were grouped together into one reach, and one transect per habitat type was completed. Complete measurements for each transect within each reach (including each depth and velocity measurement) are provided in Appendix G of the 2019-2020 Baseline Report (Appendix J.2). Qualitative descriptions of each watercourse and waterbody throughout the Beaver Dam Mine Site and Haul Road components of the FHAA are described in Appendix G.4, and fully outlined throughout the 2015-2017 Baseline Report (Appendix J.2).

All waterbodies identified within the Beaver Dam Mine Site (Crusher Lake, Mud Lake) have been confirmed to provide fish habitat. Open water features in wetlands confirmed or presumed to provide fish habitat are described below and displayed on Figure J.4-2 of Appendix J.4. It should be noted that Cameron Flowage while exhibiting both lotic and lentic-like habitat qualities as a contiguous feature with the Killag River, had been considered a waterbody within the context of the Revised 2019 EIS (AMNS 2019), to distinguish it from the more riverine portion of the Killag River. The NSE definition of watercourse includes rivers, lakes, streams, creeks, ponds, etc., so the classification of Cameron Flowage as a waterbody was based on physical parameters, not the regulatory definition. For clarity and consistency with the surface water quality and quantity modelling methods and results, Cameron Flowage is now classified as a watercourse (IR2 NSE-2-121 [AMNS 2021]).

A detailed description of all watercourses that have been evaluated for direct and indirect impacts inside the FHAA is provided in the following sections.

Cameron Flowage – Killag River

Cameron Flowage, located at the northeastern edge of the FHAA, is the primary receiver for most surface water originating from within the Beaver Dam Mine Site prior to it draining offsite through the Killag River to the southeast. No dams or other barriers to fish passage have been observed on Cameron Flowage. The Killag River commences north of Cameron Flowage (Tait Lake) that is located directly northeast of the Beaver Dam Mine Site. The Killag River is one of two major tributaries to the WRSH. The Killag has a rather long and narrow drainage basin, with a main channel length of approximately 27 km. The Killag River system has several associated waterbodies, such as Tait Lake. West Lake, Mud Lake and Crusher Lake are associated with sub-tertiary basins that are tributaries to the Killag River (Section 6.7.4, Figure 6.7-4).

Both Cameron Flowage and the Killag River were selected for focused fishing surveys during the 2019-2020 field program to provide additional baseline data for anticipated future monitoring programs. In December 2020, modified fish habitat surveys were performed within a 1.7 km stretch of this system, from the top of Cameron Flowage (Killag River entrance) to approximately 100 m downstream of the Beaver Dam Road bridge (downstream of the lime doser). Nine cross-sectional measurements (i.e., transects) were taken at representative habitats throughout the system by boat or by wading (Appendix J.4, Figure J.4-2). However, it is important to note that these surveys were performed during high flow with various instances of bankfull flooding; as such, depths and velocities presented below are reflective of high flow conditions.

The Killag River enters Cameron Flowage from the northeast as a series of rapids through a channel width of 10 m. Water depths and velocities measured here at the time of the assessment ranged from 28 to 60 cm, and 0.91 to 1.11 m/s respectively. Substrate was observed to be an even mix of boulder, rubble, and cobble.

As a wide, low velocity flat, habitat within Cameron Flowage is homogenous throughout the first 1 km length. Organic peatlands surround approximately 25% of Cameron Flowage, which is concentrated along its south eastern and northern shorelines. Emergent and floating wetland vegetation is present in the littoral zone adjacent to wetland habitat. Shoreline substrate is comprised of boulders, rubble, and cobble in a muck matrix, which transitions muck-dominance away from the shore. Widths measured along transects ranged from 59.4 to 76.8 m, and maximum water depths and velocities of 3.7 m and 0.16 m/s were recorded. The remaining 200 m length of Cameron Flowage transitions back into a wide, homogenous flat.

A pinch-point (relatively narrow riffle), located approximately 1 km downstream of the inlet of the Killag, separates the two wider flats of Cameron Flowage. Here, the channel confines to a width of 13.7 m, with water depths and velocities at the time of assessment ranging from 38 to 52 cm and 0.61 to 0.80 m/s, respectively. Substrate within the riffle is a boulder, cobble, and rubble mix with traces amounts of muck.

From the outlet of Cameron Flowage to approximately 100 m downstream of the Beaver Dam Road Bridge, the Killag River forms a series of runs, riffles, and slower flats and pools. Channel widths range 7.5 m in confined runs to 14.6 m in wider flats. Water depths and velocities are variable, with depths ranging from 33 cm to just over 1 m in deeper flats and pools, and velocities ranging from slack to 0.45 m/s in faster runs. Immediately downstream of the lime doser, channel width is constricted by constructed banks of riprap. At the time of assessment (December 2020), maximum velocity in this area was measured as 1.2 m/s, and depths ranged from 14 to 71 cm. Boulder, rubble, and cobble-sized rock dominate substrate throughout the surveyed area of the Killag River.

During the 2019-2020 field program, three rounds of trapping efforts (early, mid, and late summer) resulted in the capture of seven species of fish. Species captured included American eel, creek chub, and brook trout, which were not reflected in trap surveys performed during 2015 baseline studies, and banded killifish, golden shiner, white sucker, and yellow perch. Banded killifish made up the vast majority of individuals captured. Within Cameron Flowage, suitable spawning habitat is available for generalist species that show preference for vegetation and soft substrates within lentic environments, including banded killifish, golden shiner, and yellow perch. Spawning habitat for brook trout, white sucker, and creek chub is limited, given the overall lack of clean gravel substrates observed within the along the shoreline. Cameron Flowage also supports both juvenile and adult life stages of American eel with soft substrate and a diversity of cover types.

The Killag River recorded the highest abundance of fish of all sites surveyed during the 2019-2020 field program. The Killag River was also the only site with confirmed presence of Atlantic salmon, with four individual parr captured in July 2020. Additional schools of small (<20 mm) white sucker were also observed during electrofishing surveys but were unable to be captured and are not reflected in population estimates. The Killag River is considered the location of most salmon spawning within the WRSH watershed (Ducharme, 1972), and the most important of the three major rivers (Killag, West, and Little) for overall salmon production. Brook trout, white sucker, and lake chub are also presumed to spawn in this system, which also provides habitat for juvenile and adult American eel.

WC5

WC5 is a permanent watercourse begins as a first order stream draining northward from its headwater wetland source (WL2) towards Crusher Lake. From Crusher Lake, the watercourse continues northward to Mud Lake, collecting flow from smaller mapped watercourses (WC3, WC6, and WC9) along its path.

During the 2019-2020 field program, quantitative electrofishing surveys were conducted within two reaches of WC5 – one south of Crusher Lake and one north of Crusher Lake (Figure 6.9-2). In addition, a detailed fish habitat assessment was conducted along the entirety of the lower reach from the outlet of Crusher Lake to its confluence with Mud Lake (approximately 830 m of linear watercourse). During the detailed habitat assessment, the watercourse was delineated into eight homogenous fish habitat reaches.

Reach 1 begins at the outlet dam of Crusher Lake. This historic, unmaintained dam is owned by the current landowner (Northern Timber) and has been naturalized over time, being infilled by a beaver dam. Reach 1 is a 15 m long high-gradient (20% slope), highly entrenched cascade. Substrate in this area is dominated by boulders, with rubble, cobble, and bedrock present in lesser amounts. Abundant cover is provided by large woody debris and boulder substrate. Channel and wetted widths are 2.0 and 1.2 m, respectively, and average water depth is 11 cm. This reach has been assessed as a permanent barrier to upstream migration for most fish. In addition to the high gradient, there is a 1.3 m vertical drop within the cascade series which ends in a plunge pool with a maximum depth of 20 cm.

After the cascade series, the watercourse transitions into a flatter, 55 m long series of riffle-runs with occasional chutes (Reach 2). Run habitat is the dominant habitat type within this reach. Channel and wetted widths range from 1.7 to 4.0 m and 0.9 to 1.2 m, respectively, and gravel substrates dominate the streambed, which is characterized as a mixture of larger to smaller rocky substrates. A small amount of cover is provided by overhanging vegetation, boulder, and large woody debris. Average water depth within this reach is 7 cm.

Within WL14, the watercourse transitions into a low gradient, low velocity flat connected by short riffle sections for a length of 195 m (Reach 3). Average water depth deepens to 39 cm, and channel and wetted widths range from 1.6 to 2.5 m and 1.3 to 1.7 m, respectively. Deep muck is the dominant substrate type within the flats, rocky substrates dominate the short riffle sections. Moderate cover is provided in various forms (i.e., deep water, overhanging vegetation, undercut banks, boulders, and large woody debris). There are currently two beaver dams located approximately 20 m from the downstream end of the reach which lie approximately 25 m apart.

Reach 4 is characterized as a 66 m long series of beaver dams and debris impoundments (pools) connected by short run sections. Two beaver dams were documented within the reach – one located approximately 35 m from the start of the reach, and another at the end of the reach. Muck substrate dominates the pool sections whereas rocky substrates (bedrock, boulder, and rubble) dominate the short run sections. Channel and wetted widths through the reach are 2.3 m and 1.7 to 1.8 m, respectively, and average water depth is 28 cm. Abundant in-stream woody debris provides the dominant cover types, while boulders, deep pools, and overhanging vegetation provide other forms of cover.

The channel then transitions into a 53 m long riffle-run series, with run as the dominant habitat type. A short debris impoundment (pool habitat) also exists at the downstream extent of the reach. Channel and wetted widths within this section range from 2.1 to 3.2 m and 1.4 to 2.9 m respectively, and average water depth is 0.09. Rubble dominates the substrate present in the riffle-run series, which also contains boulder, cobble, and small amounts of gravel of sand, while muck and rubble co-dominate the substrate within the impoundment pool. Moderate cover is provided by a mix of large woody debris, boulders, undercut banks, and overhanging and emergent vegetation.

From Reach 5, the watercourse de-channelizes through mixed-wood forests, following multiple flow paths for 43 m (Reach 6). Debris jams are present throughout the reach, and boulders dominate the substrate. Within this reach, the average depth of surface water (often occurring between boulders when present) is 24 cm. This reach is thought to pose a navigational challenge to fish species, however, is likely passable and therefore to be conservative, fish passage has been considered based on periodic navigation.

WC5 re-channelizes at Reach 7, which is characterized by a series of a variety of minor habitat types (rapid, run, flat, pool, and cascade). Channel and wetted sections within this reach range from 1.7 to 2.3 m and 0.9 to 2.3 m, respectively, and average water depth is 9 cm. Boulders dominate the substrate, which are intermixed with rubble, cobble, and bedrock. Trace amounts of gravel and muck were also documented. Cover is provided through overhanging vegetation, boulders, and large woody debris.

The final reach (Reach 8) begins as WC5 transitions into low-gradient habitat within WL17. The remaining 340 m of linear watercourse is described as a low velocity flat characterized by deep muck substrate and highly embedded boulders. Channel and wetted widths range from 1.4 to 3.6 m, and average water depth is 48 cm. Overhanging and flooded wetland vegetation, undercut banks, and deeper water provide abundant cover. The reach ends as the watercourse discharges into Mud Lake.

No fish were captured in WC5 south of Crusher Lake during either the 2015 baseline electrofishing surveys or during three rounds of electrofishing conducted during the 2019-2020 field program. North of Crusher Lake, one individual brook trout and three northern redbelly dace were captured during 2015 surveys (Appendix J.2). Over the three electrofishing rounds conducted in Summer 2020, one additional species, lake chub (1 individual) was captured along with brook trout. Population estimates calculated for WC5 peaked in July, with 32 ± 8 individuals. Of all fish survey sites sampled during the 2019-2020 field program, WC5 was the second most productive in terms of brook trout abundance, with 48 individuals captured, accounting for 98% of the total number of fish captured over the three electrofishing surveys (48 of 49 individual fish).

Additional species have been presumed present, specifically within the lowest reach (Reach 8) of WC5, based on direct connectivity, species confirmed, and similar habitat characteristics with Mud Lake. Species that are likely to be present include American eel, banded killifish, brown bullhead, golden shiner, ninespine stickleback, white sucker, and yellow perch.

WC5 provides habitat for a variety of life stages of species confirmed and presumed to be present through the delineated fish habitat reaches. In general, Reaches 1 through 7 are considered to provide a variety of suitable habitats for brook trout, lake chub, northern redbelly dace, and American eel. Of the probable species likely to occur in WC5 due to contiguity with Mud Lake (but not confirmed), American eel was the only species presumed to be present in these reaches (confirmed in Mud Lake) based on their capacity to navigate over and through barriers. Shallow, higher velocity riffle areas dominated by smaller rocky substrate are considered to provide suitable substrate for brook trout and lake chub, while low velocity pools and flats provide suitable spawning areas for northern redbelly dace. Reaches that present a variety of cover types provide suitable habitat for juvenile brook trout and juvenile and adult American eel. Reaches 1 through 7 largely contain multiple, shorter habitat types, and therefore provide a variety of suitable habitats, though the extents of these habitat are naturally small-scale. Reach 6 is considered to provide seasonal passage only. Reach 8 provides suitable habitat for all life stages of banded killifish, brown bullhead, ninespine stickleback, northern redbelly dace, and yellow perch. Suitable habitat was also identified for juvenile and adult American eel, as well as adult life stages of brook trout and white sucker.

WC12

WC12 is a first order stream originating in upland habitat east of WL56. The watercourse disperses through WL56, eventually re-channelizing within the wetland's eastern lobe. The watercourse exits the wetland via culvert under a forestry road and continues east to WL59. It has been described as an ephemeral groundwater seep. Evidence of groundwater seepage into WC12 was suggested by the presence of ferrihydrite; an orange, bacterial slime which often occurs where groundwater reaches the surface. Substrate is dominated by cobble, with lesser amounts or rubble, gravel, and muck. Average channel width is 1 m, and the channel is almost completely shaded by riparian vegetation, mainly in the form of tall shrubs.

No fish surveys were conducted during the 2019-2020 field program. During 2015 baseline surveys, however, three juvenile brook trout were captured in WC12 via electrofishing. It is presumed, therefore, that WC12 may provide suitable juvenile and adult brook trout habitat at some point of the year. Also, Grant and Lee (2004) suggest that groundwater upwelling, as opposed to water velocity, is probably the most critical factor in brook trout spawning site selection. In addition, brook trout have been documented to spawn over silt and detritus providing there is groundwater seepage (Witzel and MacCrimmon, 1983).

Based on the likely presence of groundwater seepage within WC12, the watercourse has been assessed as suitable for brook trout spawning. However, the use of habitat by fish in WC12 is extremely restricted, and is likely only accessible during a small, very wet window of any year.

WC13

WC13 is a second order stream which serves as the outlet channel of WL59. Open water habitat has been created in WL59 through construction of a berm to support historic mining activities in the 1980's. The berm which forms this system has not been maintained, and the culvert and berm are in disrepair. In close proximity to the berm, WC13 (which is the main outlet flowing through the berm/culverts) has been affected by failure of the berm, and fish passage into W5 may be limited for some species. From WL59, the watercourse flows northeast for approximately 280 m through WL61 before emptying into Cameron Flowage. Watercourse WC13 generally contains shallow, higher velocity riffle areas dominated by smaller rocky substrate that are considered to provide suitable substrate for brook trout, creek chub, lake chub, and white sucker based on spawning and rearing habitat preferences of these species (reaches 1, 3 and 5).

Vegetated, low velocity flats and pools also provide suitable spawning habitats for banded killifish, brown bullhead, nine spine stickleback, and northern redbelly dace, and provide rearing habitat for young of the year lake chub (reaches 4 and 5). Suitable juvenile and adult American eel habitat is concentrated in areas of soft substrate and the presence of a variety of cover types (reaches 2, 4 and 5).

WC14

WC14 is an intermittent, first order stream located south of Cameron Flowage, and serves as one of two tributaries to WL59. The watercourse received a detailed fish habitat assessment on July 13, 2020, during which the watercourse was delineated into three homogenous reaches. The upper reach (Reach 1A) is one of two upper branches within the watercourse. It is a 30 m long run, with habitat assumed based on conditions during high flow. At the time of the assessment, the watercourse was mostly dry and only residual, shallow pockets of water remained with an average depth of 9 cm, channel width of 50 cm, and rubble as the dominant substrate, which is intermixed with lesser amounts of muck. Overhanging riparian vegetation (predominantly tree branches) is the major source of cover within the reach.

Reach 1B is the second upper branch within the watercourse and 115 m in length, transitioning between steep, step-pool habitat and areas of no defined channel. Like Reach 1A, this channel was predominantly dry during the assessment, with water restricted to residual, isolated pockets with an average depth of 3 cm, while areas of no defined channel (non-channelized areas of forest drainage) were completely dry. Channelized areas have an average width of 1 m. Large woody debris provides a moderate amount of instream cover, while muck and detritus dominate substrate, with lesser amounts of rubble.

As Reach 1B and 1A converge, the channel becomes contiguous, high-gradient (18% slope), 32 m long series of step-pools. Substrate is dominated by rubble, but also contains boulder, cobble, gravel, and muck. At the time of the assessment, average water depth within residual pools was 3 cm. Average channel width within this reach is 1.3 m.

Electrofishing in WC14 resulted in no fish capture, likely due to dry channel conditions throughout most of the summer. Probable fish presence, based on confirmed species within downstream, fish bearing systems, as well as habitat suitability within the watercourse, include brook trout and American eel.

Suitable, seasonal juvenile and adult brook trout habitat is present throughout the watercourse, provided that fish can access the upstream reaches through the high-gradient of Reach 2 and non-channelized areas of reach 1B. Potential brook trout spawning habitat is restricted to reach 2, which provides a small amount of suitable spawning substrate and probable groundwater seepage. Habitat for adult American eel was documented throughout the watercourse, with more suitable juvenile habitat (deeper muck) provided in reaches 1B and 2. It should be highlighted that these habitat provisions are temporally restricted and are not viable or accessible during periods of low flow.

WC23

Located in the lower western lobe of the PA, WC23 is a first order stream within the Cope Brook tertiary watershed that commences in a boulder field at the southwestern extent of the 250 m expanse of upland forest. This section of upland forest presents a barrier to fish passage which is explained fully in Section 4.1.6 of the 2019-2020 Baseline Report (Appendix J.2). In a letter dated February 23, 2021, ECCC confirmed that watercourses upstream of WC23 (WC 20, 21, 22 and associated wetland habitat) are not considered waters frequented by fish. WC23 forms at the bottom of this upland forest section, and it is considered fish frequented waters, confirmed by fish collection efforts.

Approximately 1 km of the uppermost extent of the watercourse has been surveyed for fish habitat. The surveyed portion of WC23 has been delineated into three homogenous fish habitat reaches and have been described below. After accumulating surface water through the boulder field, WC23 flows southwest, transitioning into a flat characterized by low gradient, low velocity, and muck substrate within a slightly entrenched channel through forested swamp. Boulders comprise approximately 25% of the total substrate. In this reach, channel widths and wetted widths range from 4 to 4.1 m and 2.3 to 3.5 m, respectively. Average water depth throughout this reach is 18 cm, and a moderate amount of cover is present which is largely provided by overhanging trees and a smaller amount of woody debris. In-stream vegetation is scarce. This reach is approximately 150 m in length.

Within the second reach, WC23 remains as a low gradient flat but transitions into a dense alder swamp, with alder shrubs overhanging the entire channel width, and submerged trunks and branches heavily criss-crossing the watercourse channel. Heavy cover is provided by these overhanging and intruding alders, submerged woody debris, and in-stream vegetation. Flow is visibly stagnant, and average water depth is 12 cm. Muck remains the dominant substrate, with lesser amounts of boulder present than in Reach 1. The watercourse flows south for another 150 m, before crossing a forestry road through a corrugated steel culvert.

Reach 3 begins below the culvert. This reach is 754 m in length and is characterized by low gradient flats separated by sections of subterranean flow and a short section of high gradient step-pool habitat. Within the wetted portions of the watercourse, channel

and wetted withs range from 1.1 to 5.3 and 0.9 to 3.0 m, respectively. Substrate is dominated by muck, with lesser amounts of boulder, bedrock, and rubble. Low velocity dominates throughout the reach with the exception of the short step-pool habitat, and average water depth is 20 cm. Cover is mainly provided by overhanging vegetation and large woody debris.

At the time of assessment, there were four documented sections of subterranean flow within the third reach. The lengths of these subterranean areas range from 6 m to approximately 230 m. These areas are characterized by expanses of vegetated boulder fields with no visible surface flow, though unlike the barrier the area lacks soil and flow is mostly audible beneath the boulders, and as such has been defined as a boulder-bed channel. These areas have been assessed as seasonal barriers to fish passage, as water levels are expected to rise between and above the level of the boulders during periods of high flow. Though not complete barriers, it is likely that these subterranean sections restrict passage by acting as navigational obstacles to upstream and downstream migration.

Throughout the extensive electrofishing and trapping efforts performed during the 2019-2020 field program, only seven brook trout were captured in WC23, with a maximum of two individuals caught during any single survey. No suitable spawning or young of the year habitat within WC23 was identified, but all three reaches have been assessed as supporting juvenile and adult brook trout. The low abundance of trout within the watercourse is likely be attributed to a several factors: the absence of suitable trout spawning and young-of-the-year rearing habitat, the presence of multiple seasonal barriers to downstream and upstream migration, and water quality. Although recorded temperatures remained optimal for brook trout throughout the year, pH levels in WC23 demonstrate that on average, the pH is low enough to potentially cause harm to salmonid species (<5.0).

WC25

WC25 exists as the outflow from Wetland WL61. It is a short, first order stream that travels 33 m before emptying into Cameron Flowage. It consists of a short riffle section followed by a low gradient flat. The short riffle exists immediately downstream of the pond where the channel is barely visible, only slightly entrenched from the surrounding wetland habitat. Water depths do not exceed 1 cm and is likely a seasonal barrier to most fish, with the exception of American eel which have been documented to traverse over land in wet, low lying grass habitats (MacGregor et al., 2011). The channel then widens up to 1.0 m and continues as a low gradient, low velocity flat to Cameron Flowage. A relatively small amount of instream cover (10%) is provided by wetland vegetation adjacent to the watercourse. Muck substrate is present throughout the watercourse.

WC25 provides suitable spawning and young-of-the-year habitat to banded killifish, golden shiner, and yellow perch through flooded wetland vegetation and soft substrate in a low velocity stream, though instream vegetation is not abundant. The watercourse may also support juvenile and adult American eel, as well as adult white sucker. Dissolved oxygen levels in WC25 may limit fish production at least seasonally, which was measured in September 2020 as well below the CCME recommended guidelines for any life stage of cold or warm-water fishes (3.6 mg/L).

WC26

WC26 is a first order stream that originates as flow accumulation within WL207, located along the northwestern edge of the PA. The watercourse flows north for approximately 800 m through wetland habitat before discharging into a wide, flat area of the Killag River. The entire watercourse was described through a detailed fish habitat assessment and was delineated into two homogenous reaches.

The uppermost reach (205 m) is described as flat with sections of no defined channel – surface water exists largely as intermittent, isolated pockets of surface water within wetland habitat with an average depth of 34 cm. Substrate is mostly contiguous wetland surface, with some exposed areas of muck in more inundated areas. Abundant cover is present in the form of inundated wetland

vegetation and filamentous algae. During low flow conditions, areas comprising surface water are isolated from each other, impeding fish passage through the reach. It is assumed that during high flow conditions, these inundated areas become hydrologically connected through surface flow. In addition, DO levels recorded throughout the summer within this reach were mostly well below the CCME recommended guidelines for any life stage of cold or warm-water fishes.

The remaining 600 m of habitat is characterized as a permanent, low gradient flat, with channel and wetted widths ranging from 0.7 to 4.7 m, widening as it approaches the Killag River. Abundant cover is available in the forms of overhanging and flooded emergent wetland vegetation, and submergent vegetation within the watercourse channel. Substrate is mostly comprised of muck, with sparse, embedded boulders present at the lower end of the watercourse.

Fishing efforts conducted during the 2019-2020 field program were concentrated within the uppermost reach of the watercourse (Figure 6.9-2). Only one individual ninespine stickleback was captured during the first survey in June, and no other fish were captured during successive surveys, supporting the designation of overall low-quality habitat. However, based on its direct connectivity with the Killag River and habitat characteristics, the lower reach of WC26 has been conservatively presumed to provide habitat for the following species: American eel, banded killifish, brook trout, brown bullhead, golden shiner, white sucker, and yellow perch. The abundant vegetation, low velocity, and soft substrates provide suitable spawning habitat for generalist spawners, including ninespine stickleback, banded killifish, brown bullhead, golden shiner, and yellow perch. No suitable spawning habitat was identified for brook trout or white sucker, but the lower 600 m of the watercourse likely provides refuge and foraging opportunities for adult stages of these species.

WC27 and Mud Lake

Mud Lake and the lacustrine WL17 are located in the northern portion of the Beaver Dam Mine Site. They receive water from WC5, which directs water from Crusher Lake north to WL17 and Mud Lake, flowing into a narrow strip of wetland which separates the eastern and western lobes of the lake. WC27 forms the outlet of Mud Lake, flowing north into the Killag River.

Mud Lake exists as an open waterbody within WL17. The entire shoreline of the lake is composed of this peat wetland, predominantly in the form of a low shrub fen. Adjacent to open water, the wetland consists of low ericaceous shrubs and graminoids. The littoral zone is gently sloped and unshaded by any forest canopy cover, but some shade is provided along the wetland edges by emergent and floating wetland vegetation when water levels are high. Substrate through the lake is composed of deep muck and decaying organic material. Within Mud Lake, the substrate is dominated by mud, with emergent vegetation along the edges when the water level is high. While bathymetry data was not collected for Mud Lake, the depth is not believed to exceed 2 m based on direct observation during wetland and fishing surveys.

The outlet of Mud Lake, WC27, directs water northwest to the Killag River. Like Mud Lake, the riparian area of WC27 is composed of wetland habitat in the form of a low shrub fen. In the spring, the riparian wetland floods which significantly extends the wetted perimeter of the outlet. In the summer, channelized flow narrows into multiple braids which meander through wetland vegetation. The characteristics of WC27 are quite similar to Mud Lake – it is more accurately described as a narrowed extension of the lentic habitat observed in Mud Lake than a true lotic watercourse. Still, a detailed habitat assessment was performed on the outlet via boat based on the methodology described in Section 6.9.3.2.2.

WC27 has been delineated into a single homogeneous reach of a low-gradient flat which extends for 228 m before emptying into the Killag River. The main channel ranges from 3.4 to 9 m wide, velocity is sluggish to visibly stagnant, and the average water depth is 58 cm. Substrate is 100% deep, organic muck - consistent with the substrate in Mud Lake. In-stream cover is abundant, primarily in the form of emergent and submergent vegetation (pickerelweed and various graminoids).

Trapping efforts in Mud Lake and WC27 resulted in the highest species diversity of all lentic sites. The majority of fish captured within this system are considered habitat generalists: golden shiner, banded killifish, white sucker, ninespine stickleback, yellow perch, and brown bullhead. Mud Lake and WC27 support these species' spawning stage by providing abundant in-stream vegetation and soft substrate in a low velocity environment. In addition, the deep muck and vegetation provide usable habitat for juvenile American eel. Although no spawning habitat for lake chub was identified, the system may support young of the year through adult life stages which have been documented over a wider variety of substrates. The system may also provide refuge and feeding opportunities for adult brook trout, but lacks the substrate, flows, and cover diversity to support spawning through juvenile life stages. Water quality within the system is described as generally acidic with areas of low DO but is not considered limiting to overall fish production.

Crusher Lake

The fish and fish habitat characterization of the lake has been updated based on the results of the 2019-2020 field program which included three rounds of trapping within its littoral zone. The lake is located in the central northern zone of the Beaver Dam Mine Site and receives flow from two tributaries. Water exits the lake over a historic, man-made dam which has since been impounded by beavers. Bathymetry data has not been collected for Crusher Lake, but it is estimated that the lake does not exceed 10 m in depth.

Organic peatland surrounds approximately 50% of the lake, which is primarily concentrated along the southern and western shorelines. Floating peatland extends into the waterbody in the eastern and western edges. These lacustrine wetlands support a community of submergent and emergent wetland vegetation (e.g., leatherleaf, Marsh St. John's Wort, and a variety of sedges). In spring, these wetlands flood providing additional seasonal fish habitat. In the summer, mud flats and residual, shallow pools can be observed within these peatlands, but are cut off from the central waterbody. Moderately sloped boulder-lined shores surround the remaining margins of the lake, which is dominated by mature upland forest. Deep, organic muck is the dominant substrate within the lake.

During the 2019-2020 field program, Crusher Lake had the lowest abundance of fish observed of all waterbodies and open water features. A total of five individuals were captured representing three species: brook trout, ninespine stickleback, and golden shiner. Crusher Lake is also known to support banded killifish and brown bullhead, though in low abundance, based on the results of baseline fish collection completed in 2016.

The lentic environment, in-stream vegetation, and soft substrate provide suitable spawning habitat for ninespine stickleback, golden shiner, and brown bullhead. However, no suitable spawning habitat (i.e., gravel shoreline) was identified for brook trout spawning. The lake is unlikely to support any life stage of brook trout other than adults, with provisioning restricted to refuge and foraging opportunities.

Non-Fish Frequented Provincially Regulated Watercourses

Nine additional watercourses within the Beaver Dam Mine Site were identified as provincially regulated, but are not considered fisheries resources. These watercourses are hydrologically isolated, meaning there is no contiguous surface water connecting these watercourses with any upgradient or downgradient fish-bearing systems. Provincially regulated watercourses which have been identified as inaccessible to fish have been described as provincially regulated watercourses, rather than fisheries resources. Fisheries resources and non-fish resource provincially regulated watercourses within the Beaver Dam Mine Site are displayed on Figure J.4-3 of Appendix J.4.

WC10 is a first order stream that forms from pockets of surface water from the western edge of WL27. The channel exists for approximately 75 m then disperses into WL29. No hydrological connection, channelized or otherwise, was observed between the downstream end of WC10 and any downgradient aquatic features (i.e., WC11). High flow evaluations were not completed on WC10 as changes in infrastructure layout resulted in complete avoidance of direct and indirect impacts.

WC15 and WC16 are short channels that form in WL215 and WL207, respectively, located near the northern border of the Beaver Dam Mine Site. These watercourses were originally delineated in 2016, with both observed to go underground at their downstream extents. These watercourses were reassessed during high flow in December 2020 for any signs of hydrological connections to downstream aquatic features. During the high flow assessment, both channels were confirmed to be hydrologically isolated.

WC18 is an ephemeral channel that was originally delineated and characterized in October 2018. The channel was originally observed to turn subterranean, and then disperse into WL217 (softwood swamp). The watercourse was revisited throughout the 2019-2020 field program to confirm connectivity to downstream, fish-bearing resources, characterize fish habitat, and perform fish surveys (trapping, electrofishing). These assessments occurred during both low and high flow regimes in December 2019, May 2020, and again in September 2020. WC18 is rarely channelized – the watercourse is characterized by very diffuse flow that is only identifiable during high flow throughout much of its delineated length. During high flow, the wetted portion of the watercourse is infrequent and extremely shallow. When water is at the surface, depths are not sufficient to put any type of trap or to submerge the anode ring of an electrofisher; as such, no fish sampling was conducted. As it flows northeast towards Cameron Flowage, it completely disperses, preventing any surface connectivity to downstream, fish bearing features.

WC19 is a regulated watercourse located in the southeastern extension of the Beaver Dam Mine Site. The watercourse is intermittently channelized with many subterranean sections. Beginning at the northern extent of WL219, WC10 conducts flow south, eventually completely dispersing into WL66. At the time of the original assessment (July 2019), no channelized or surficial flow was observed through WL66 that would connect WC19 to any downgradient fish-bearing features. This watercourse was reassessed during high flow in December 2020, during which hydrological isolation was confirmed.

WC20, WC21, WC22, and WC24 are located upgradient of a 250 m stretch of upland habitat which prevents fish access into these watercourses. This area was assessed through all flow regimes to identify any indicators of hydrological flow and is consistent across all seasons. This barrier to fish passage is described in detail in the 2019-2020 Baseline Report (Appendix J.2). Supported by extensive fish collection efforts and eDNA results, all wetlands and watercourses upstream of this barrier (WL220, WL205, WC20, WC21, WC22, and WC24) are determined to be not frequented by fish and are not considered fisheries resources. In a letter issued by ECCC on 23 February 2021 (Appendix J.2), it was confirmed that these watercourses and associated wetland habitats are not waters frequented by fish.

Wetlands

To address IR2 CEAA 2-06, fish habitat descriptions for each wetland in in the Beaver Dam Mine Site and Haul Road have been revised, with details presented in Appendix H of the 2019-2020 Baseline Report (Appendix J.2). Wetlands that were assessed as isolated with no surface water connectivity to fish-bearing systems and/or open water features are considered non-fish bearing and do not provide fish habitat. In addition, wetlands with throughflow watercourses are not discussed further if fish habitat was determined to the be confined to the watercourse channel (entrenched), and not provided within the wetland itself.

Fourteen wetlands have been confirmed to provide or potentially provide fish habitat within the Beaver Dam Mine Site and are associated with the following surface water features (Appendix J.4, Figure J.4-3):

- Cameron Flowage: Wetlands 61 and 62;
- Crusher Lake: Wetlands 8 and 10;
- Mud Lake: Wetland 17;
- Watercourse 2: Wetland 4;
- Watercourse 3: Wetlands 4 and 20;
- Watercourse 4: Wetlands 8, 11 and 13;
- Watercourse 5: Wetlands 8, 17 and 44;
- Watercourse 8: Wetland 15;
- Watercourse 10: Wetland 29;
- Watercourse 11: Wetland 29;
- Watercourse 12: Wetlands 56 and 59;
- Watercourse 13: Wetlands 59 and 61;
- Watercourse 14: Wetland 61; and
- Watercourse 25: Wetland 61.

Fish habitat conditions in wetlands is described in Table 3-14 of the 2015-2017 Baseline Report, appended to the 2019-2020 Baseline Report (Appendix J.2). Wetlands with associated fish habitat in shallow open water features anticipated to be directly impacted by Project development within the Beaver Dam Mine Site (Wetlands 56, 59 and 61) were re-evaluated during Summer 2020 through quantitative, detailed habitat assessments and additional fish surveys. The results of these most recent surveys are summarized in Tables 6.9-2 and 6.9-3, and discussed in 2019-2020 Baseline Report (Appendix J.2).

Wetland 56

WL56 is a wetland complex located just west of WL59 within the northern area of the Project Area. The wetland consists of coniferous treed swamp, tall shrub swamp, and low shrub bog habitats, and has been heavily altered through historic mining activities including ditching, road building, and some infilling. Scattered patches of open water exist within this wetland as a result of these historic alterations.

The wetland is described as having a throughflow water regime, receiving drainage from WC12 which commences just 53 m to the west. Water drains into the wetland's western edge, and collects in historic ditching, eventually flooding the central portion of the wetland. This area of open water (approximately 1,274 m^2) is permanently flooded. During wetter times of the year (fall and spring runoff), the wetland passively drains east, which seasonally floods an additional wetland area covering approximately 177 m^2.

This drainage is eventually channelized through a forestry road culvert and disperses into WL59. Fish habitat within the permanently flooded area of WL56 was characterized during the 2019-2020 field program, and a single pass, open site electrofishing survey was completed in September 2020. The maximum depth observed within the flooded area was 0.60 m, with an average depth of 0.47 m. Substrate is largely dominated by organic muck, with lesser amounts of embedded rocky substrate.

The ponded water area is approximately 20% covered with emergent cattails, grasses, and floating algal mats. Ninespine stickleback has been confirmed within WL56; and based on habitat types, it is possible that this habitat supports all life history stages of forage fish such as banded killifish, ninespine stickleback and northern redbelly dace.

Wetland 59

Wetland 59 is a complex consisting of 2.8 ha of treed swamp habitat, completely lacking surface water, and 3.7 ha of open water wetland habitat. Of this 3.7 ha of open water; 3.6 ha is present in one contiguous feature, and three separate small polygons of open water equate to 0.1 ha. These are discontiguous, shallow and often dry during low flow; however, they were included in the fish habitat quantification to be conservatively inclusive. The open water habitat was created by construction of a berm between 1982 and 1992. As a result, what appears to have been a treed swamp at the base of a drumlin, has been flooded to create what is now an open water wetland habitat within a treed swamp wetland complex. The open water habitat is less than 2 m deep and greater than 50% vegetated; as such it is still characterized as wetland habitat. At some point in 2019, a beaver dam was built within this habitat; and it is likely continuing to transition habitat types present within this wetland.

IR2 CEAA-2-07, and follow-up guidance provided by DFO requested clarity in the methods used to calculate impact areas; particularly in habitats underlain by the proposed pit. Within the 2019 EIS, open water habitat accessible to fish was not specifically delineated within the wetland. The 2019 EIS was submitted prior to revisions to the *Fisheries Act*, which now requires more detailed habitat quantification for HADD of fish habitat. Wetland impact areas associated with WL59 presented in the 2019 EIS referred to the entire wetland habitat; rather than fish habitat present within the wetland. WL59 is a disturbed wetland complex, with 2.8 ha which completely lack standing water at all times of the year. To meet the current regulatory requirements, this level of detail has been refined to clearly outline fish habitat within the wetland complex (IR2 CEAA-2-07). A desktop GIS exercise was completed to provide a preliminary delineation of open water within this wetland, which was confirmed by field observations during fish collection and fish habitat assessments. As described above, 2.8 ha of this wetland consists of treed and shrub swamp habitat completely lacking standing water or access to fish at any time of the year.

The permanently flooded area of the wetland comprises approximately 3.6 ha of open water habitat which covers the central, southeastern lobe and a small portion of the northwestern lobe of the wetland. Wetland habitat on the western side of the road was observed to be isolated from the open water portion of WL59 based on assessments conducted in 2015. However, recent (2019) beaver activity has caused the road to flood, creating additional, potential seasonal fish habitat (based on assumed hydrological connectivity during high flow regimes). This potential fish habitat (0.1 ha) completely dries during low flow conditions. The wetland receives input from both WC12 and WC14. WC13 acts as the sole outflow, which drains northeast eventually emptying into Cameron Flowage.

A detailed assessment of fish habitat was completed within the southeastern lobe of WL59 by boat on July 21, 2020. Thirty-three discrete points were established throughout the flooded portion of the wetland where substrate, water depth, and vegetation composition were recorded (Appendix J.4, Figure J.4-1). In-situ water quality measurements were taken at eight randomly selected points out of the 33 discrete points. The flooded portion of WL59 is surrounded by a thin wetland margin along the eastern, northern, and southern shorelines. The northern shoreline is heavily altered and comprises an old access trail and frequent gravel outcrops that extend from the trail south into the wetland. The western wetland lobe is divided by access road which is currently flooded – the wetland habitat west of this road is gently sloped and characterized by abundant broad-leaved cattail. The southern shoreline is characterized by intact, flooded alder swamp, which transitions to moderately sloped mixed-wood forest towards the east. WL59 was likely historically a treed swamp, as evident by abundant standing and fallen woody debris, and landscape position at the base of a drumlin.

The flooded portion of WL59 is approximately 50% vegetated with heavy water lily and bladderwort cover, and less frequent emergent cattail and rushes. Snags and submerged woody debris are abundant throughout. A large beaver dam extends from the southern to northern shorelines approximately 115 m from the western edge. An active beaver lodge is located approximately 110 m west of the eastern shoreline, and an additional beaver dam is located at the outflow dam. The outflow dam, located along the northern eastern shoreline, channelizes water from WL59 into WC13. The dam consists of old concrete barricades which were historically used to flood the wetland. The dam has since eroded away, and old culverts are collapsed, washed out and ineffective. The barricade walls have been infilled by a beaver dam, creating a significant water level drop of approximately 1 m from the south to the north side of the barricade. This beaver dam is considered a seasonal barrier to upstream fish passage from WC13, but likely presents a permanent barrier to fish characterized as weak swimmers.

Substrate throughout the wetland is a thick muck/organic layer. Along the northern shoreline, there is sparse cobble, rubble and gravel sourced from erosion from access trail outcrops. The average water depth within the wetland is 0.75 m, with the maximum water depth recorded of 1.88 m.

Banded killifish, brook trout, brown bullhead, golden shiner and ninespine stickleback have been confirmed within this wetland. It is expected to support all life history stages of banded killifish, brown bullhead, golden shiner and ninespine stickleback, along with juvenile and adult American eel, and adult brook trout.

Wetland 61

In the northwestern lobe of WL61, there is a 173 m^2 headwater pond with water depths up to 1 m. Wetland habitat surrounds approximately 85% of the pond, while moderately sloped mixed-wood upland is present on the southeastern shoreline. Minimal shade is present as a thin band along the shoreline. No submergent or emergent vegetation were documented within the ponded water, nor were any other forms of cover except for water depth near the center of the pond. The visible edges of the pond are gravel dominated, and although not confirmed, substrate towards the center, deeper portion of the pond is assumed to be muck. WC25 exists as the pond's sole outflow – a short, first order stream that travels 33 m before emptying into Cameron Flowage. No fish were confirmed within WL61 or WC25, though it is expected that this habitat supports juvenile and adult American eel, banded killifish, golden shiner, yellow perch and adult white sucker.

Table 6.9-2: Summary of Key Diagnostic Features of Fish Habitat within Watercourses with Potential Direct or Indirect Impact in the Beaver Dam Mine Site Component of the FHAA

Note: Habitat assessments also conducted on WC20-22 but excluded from table due to non-fisheries resource designation.

1-Perennial (P) – A stream that flows continuously throughout the year, Intermittent (I) – Streams that go dry during protracted rainless periods when percolation depletes all flow, Ephemeral (E) - A watercourse that flows during snowmelt and rainfall runoff periods only (AT, 2009).

2-Ranges are provided for reaches measured through multiple transects.

3-Whenever possible, slope measurements were taken in-field using a clinometer and meter stick (“F”). If clinometer readings were not possible due to length of reach or visibility obstructions, slopes were estimated based on overall habitat type (“E”,DFO, 2012a).

4-Cover is calculated as a sum of all available cover types present (large woody debris, boulders, undercut banks, deep pools, overhanging vegetation, emergent vegetation, and submergent vegetation).

5-Probable species presence determined for watercourses based on direct aquatic connectivity with another fisheries resource with confirmed species presence and habitat suitability, and/or previous baseline studies as presented in Revised EIS (AMNS 2019) and in Appendix J.2 (2019-2020 Baseline).

6-Species codes: American Eel (EEL), Atlantic Salmon (ATS), Banded Killifish (BKF), Brook Trout (BKT), Brown Bullhead (BBH), Creek Chub (CKC), Golden Shiner (GSH), Lake Chub (LKC), Ninespine Stickleback (9SP), Northern Redbelly Dace (NRD), White Sucker (WHS), Yellow Perch (YLP).

7-Some reach-level measurements within Cameron Flowage – Killag River were not recorded, as this was a modified transect method to account for safety considerations during high seasonal flow in December 2020.

* For reaches highlighted with an asterisk; one reach consists of multiple, small (<5 m in length) individual habitat types. These were combined into a single reach; and a minimum of one transect per habitat type was completed. As such, the measurements provided are a range (widths) or average (depths and velocity) of measurements recorded on each individual transect. Transect level data is provided in the 2019-2020 Baseline Report (Appendix J.2).

Table 6.9-3: Summary of Key Diagnostic Features of Fish Habitat within Open Water Features Proposed for Direct Impact in the Beaver Dam Mine Site Component of the FHAA

Waterbody / Wetland	Area (m^2)	Open Water Characteristics			Fish Support[2]					
		Depth Range (m)	Dominant Substrate	Cover (%)	Species Confirmed (2019-2020)	Probable Species[1]	Spawning	YOY	Juvenile	Adult

6.9.4.2.2 Fish Habitat: Haul Road

Fish habitat potential was determined at each location during field identification/delineation through the collection of key fish habitat characteristics of each watercourse and wetland including channel morphology and biophysical descriptions. The following subsections provide fish community descriptions by watercourse/wetland with more detailed fish collection discussion provided Appendix J.2 and Section 6.9.4.2.3.

Watercourses

A total of 35 linear watercourses were identified within the Haul Road. A summary of key fish habitat characteristics within each linear watercourse observed along the Haul Road, including current crossing conditions, are presented in Table 6.9-4. Qualitative evaluations of watercourses along the Haul Road were completed on discrete sections of watercourses. As a result, the measurements recorded in 2015-2017 along the Haul Road are appropriate for calculating impact areas for Haul Road upgrades; and more detailed quantitative evaluations of these watercourses was not deemed necessary. All Haul Road watercourses have been confirmed or assumed to be potentially fish bearing. Haul road watercourses and wetlands are shown on Figure J.4-4 of Appendix J.4.

The capacity of each linear watercourse along the Haul Road to support fish species and their life stages (i.e., spawning, young of the year (YOY), juvenile, and adult) has been assessed based on key fish habitat characteristics described through qualitative habitat evaluations and fish species confirmed through electrofishing and trapping surveys in each tertiary watershed intersected by the Haul Road. All species captured within each tertiary watershed along the Haul Road have been considered potentially present within all Haul Road watercourses, to be conservatively inclusive. Atlantic salmon has also been considered for watercourses within the West River Sheet Harbour secondary watershed – Atlantic salmon are considered extirpated from the Morgan River and are therefore not included in the assessment of those watercourses. It is important to note that fish habitat characterization was only performed on short sections of watercourse which overlapped the PA and is not considered representative of the fish habitat along the entire length of each watercourse. Instead, fish habitat characterization is representative of each discrete, homogenous section of watercourse described. In addition, due to the linear nature of the Haul Road Footprint, connectivity to downgradient fish-bearing systems have been assumed for all watercourses in absence of confirmation of barriers to downstream fisheries resources. Descriptions of fish habitat by species and life stage for each linear watercourse with potential impacts due to Haul Road construction are presented in Table 6.9-4.

As noted, the majority of streams delineated along the Haul Road are small, 1st order tributaries located high in their respective watersheds. Many are characterized as low gradient, homogenous streams with low velocity, abundant in-stream vegetation, and soft substrates. These streams may provide suitable spawning, young of year, juvenile and adult life stages of most forage fish/habitat generalists, but lack the habitat provisions necessary to support earlier life stages of white sucker and salmonids. Higher gradient first order streams were observed to contain more complex habitat types (i.e., riffles, runs, pools), moderate velocities, and a variety of rocky substrates with limited fines. These streams likely support various life stages of brook trout, white sucker, and early life stages of lake chub which prefer abundant in-stream cover in the form of rocky substrate, undercut banks and woody debris. Some of these streams were also observed to gravel substrate over shallow riffles and are considered to support brook trout and white sucker spawning.

Higher order streams (2nd to 4th order) commonly contain more complex habitat, including both low velocity habitat types (i.e., flats, pools, glides), and moderate-high velocity types (i.e., runs, riffles, cascades). These streams likely support a more diverse range of species, including habitat generalist and specialists. Two, higher order watercourses are likely to support habitat for Atlantic salmon: the West River Sheet Harbour (WC-N) and Keef Brook (WC-H). The West River Sheet Harbour is considered to provide

suitable habitat for all life stages of salmon, with clean gravel-cobble sized substrate in well aerated areas, to deeper holding pools for adults. Keef Brook is considered to provide suitable habitat for older juveniles, but high velocities, limited water depths, and a lack of gravel substrate limit habitat suitability for spawning, young of year, and adults.

While several waterbodies are identified within close proximity to the proposed Haul Road, the road layout was optimized to avoid impacts to any waterbodies. As a result, detailed descriptions of fish habitat in waterbodies near the Haul Road (i.e., Tent Lake, Kidney Lake, Johns Pond) are not included.

Wetlands

Along the Haul Road, twelve wetlands have been assumed to be fish habitat. Details associated with fish habitat condition in each wetland is provided in Table 3-14 of the 2015-2017 Baseline Report, appended to the 2019-2020 Baseline Report (Appendix J.2). The Haul Road is linear by nature, so a limited evaluation of each watercourse and associated wetland was completed within the confines of the Study Area. Where wetlands provided open water and connectivity to fish bearing watercourses, it was presumed that open water portions of the wetlands were accessible to fish as well, to be conservatively inclusive. Wetlands providing potential fish habitat along the Haul Road are associated with the following surface water features (Appendix J.4, Figure J.4-4):

- Watercourse A: Wetland 64;
- Watercourse B: Wetlands 66 and 68;
- Watercourse C: Wetland 68;
- Watercourse D: Wetland 69;
- Watercourse F: Wetland 74;
- Watercourse G: Wetland 76;
- Watercourse Z: Wetland 146;
- Watercourse AA: Wetlands 159 and 160;
- Cope Pond (outside of PA): Wetland 73;
- Upper Kidney Lake/Big Pond (outside of PA): Wetland 157; and
- Johns Pond (outside of PA): Wetland 168.

Wetland habitat accessible to fish within the Beaver Dam Mine Site and Haul Road may provide suitable habitat for species that prefer slack water, highly vegetated areas and soft, organic substrates for all or some life stages. Wetland habitat is generally considered to provide juvenile rearing, refuge, and food sources for these species.

1Linear extent of watercourse described.

2Gradient: H:>5% slope M: 2-5% slope L: <2% slope (estimated only).

3Velocity: H: flows at a speed at which the water is visually rough and irregular, creates eddies, heavier riffles to light rapids (>0.3 m/s) M: flows at a speed which creates smooth to moderate riffles (0.15-0.3 m/s) L: flows so slowly that the water is smooth and fine sediments are not held in suspension (<0.15 m/s).

4Coarse Woody Debris: H:10+ woody debris per 20 m reach, M: 10-5 woody debris per 20 m reach, L: less than 5 woody debris per 20 m section.

5Species codes: American Eel (EEL), Banded Killifish (BKF), Brook Trout (BKT), Brown Bullhead (BBH), Creek Chub (CKC), Golden Shiner (GSH), Lake Chub (LKC), Ninespine Stickleback (9SP), Northern Redbelly Dace (NRD), White Sucker (WHS), Yellow Perch (YLP).

As noted, the majority of streams delineated along the Haul Road are small, 1st order tributaries located high in their respective watersheds. Many are characterized as low gradient, homogenous streams with low velocity, abundant in-stream vegetation, and soft substrates. These streams may provide suitable spawning, young of year, juvenile and adult life stages of most forage fish/habitat generalists, but lack the habitat provisions necessary to support earlier life stages of white sucker and salmonids. Higher gradient first order streams were observed to contain more complex habitat types (i.e., riffles, runs, pools), moderate velocities, and a variety of rocky substrates with limited fines. These streams likely support various life stages of brook trout, white sucker, and early life stages of lake chub which prefer abundant in-stream cover in the form of rocky substrate, undercut banks and woody debris. Some of these streams were also observed to gravel substrate over shallow riffles and are considered to support brook trout and white sucker spawning.

Higher order streams (2nd to 4th order) commonly contain more complex habitat, including both low velocity habitat types (i.e., flats, pools, glides), and moderate-high velocity types (i.e., runs, riffles, cascades), These streams likely support a more diverse range of species, including habitat generalist and specialists. Two, higher order watercourses are likely to support habitat for Atlantic salmon: the West River Sheet Harbour (WC-N) and Keef Brook (WC-H). The West River Sheet Harbour is considered to provide suitable habitat for all life stages of salmon, with clean gravel-cobble sized substrate in well aerated areas, to deeper holding pools for adults. Keef Brook is considered to provide suitable habitat for older juveniles, but high velocities, limited water depths, and a lack of gravel substrate limit habitat suitability for spawning, young of year, and adults.

While several waterbodies are identified within close proximity to the proposed Haul Road, the road layout was optimized to avoid impacts to any waterbodies. As a result, detailed descriptions of fish habitat in waterbodies near the Haul Road (i.e., Tent Lake, Kidney Lake, Johns Pond) are not included.

6.9.4.2.3 Fish Collection

Results of Desktop Study

A desktop evaluation for priority fish species revealed that four priority species have been identified within 5 km of the PA by the ACCDC. These include Atlantic salmon (*Salmo salar*), American eel (*Anguilla rostrata*), alewife *(Alosa pseudoharengus*) and brook trout (S*alvelinus fontinalis*) (ACCDC 2021). Priority fish species identified as having an elevated potential to be located within the PA, based on habitat preferences, and broad geographic range, include American eel, Atlantic salmon, brook trout, brook stickleback (*Culaea inconstans*), and landlocked rainbow smelt *(Osmerus mordax*).

A desktop review was conducted for fish species within major watercourses and waterbodies within the FHAA. The West River Sheet Harbour, contiguous with the Killag River, is known to support Atlantic salmon, brook trout, American eel, brown bullhead, yellow perch, lake chub, creek chub, banded killifish, ninespine stickleback, golden shiner, and white sucker (Halfyard, 2007; NSFA, 2016).

A portion of the Haul Road lies within the Tangier River secondary watershed. Fish species known to occur within this watershed include white sucker, brook trout, white perch, yellow perch, banded killifish, rainbow trout, golden shiner, stickleback sp., alewife, northern redbelly dace, and brown bullhead (Alexander et al. 1986). Nova Scotia Fisheries and Aquaculture (2019) have also recorded common shiner and smallmouth bass in this watershed. Atlantic salmon are considered extirpated from the Tangier River (DFO, 2009).

Atlantic salmon (Nova Scotia Southern Uplands population) are expected to potentially inhabit watercourses within and adjacent to the FHAA (Section 6.9.4.1.4).

2015 to 2017 Collection

As a result of fishing efforts completed in 2015 and 2016 within the Beaver Dam Mine Site and Haul Road, a total 10 species and 145 individual fish were captured across eleven of the eighteen survey locations (16 electrofishing reaches, Cameron Flowage and Crusher Lake), including:

- WC4;
- WC5 (lower – near WC14);
- WC12;
- WC13;
- Wetland 56;
- Cameron Flowage;
- Crusher Lake;
- WC-N;
- WC-V;
- WC-AA; and
- WC-AH.

A summary of fish species identified during electrofishing and trapping surveys throughout fish collection surveys completed in 2015-2017 and 2019-2020 is provided in Table 6.9-5. Further details associated with fish collection methods and results are provided in Appendix J.2.

2019 to 2020 Collection

As a result of fishing efforts completed between September 2019 and September 2020 within the FHAA, a of total eleven species and 1,732 individual fish were captured across ten of the fifteen survey locations, including:

- WC5 (Lower Reach);
- WC13;
- WC23;
- WC26;
- WL56;
- WL59;
- Killag River;
- Cameron Flowage;
- Crusher Lake; and

- Mud Lake/WC27.

A summary of fish species identified during electrofishing and trapping surveys throughout fish collection surveys completed in 2015-2017 and 2019-2020 is provided in Table 6.9-5.

Table 6.9-5: Summary of Fish Species Captured during Electrofishing and Trapping Surveys within the Beaver Dam Mine Site and Haul Road Study Areas

Fish Species Descriptions

Within the Beaver Dam Mine Site and Haul Road, 12 different species of fish were identified through all electrofishing and trapping surveys. Fish species descriptions for all species captured within the Beaver Dam Mine Site and Haul Road from 2015-2020 are provided in the following sections. Fish presence (confirmed and probable) is provided in Tables 6.9-2, 6.9-3, and 6.9-4 (i.e., Beaver Dam Mine Site, watercourses, open water features, and Haul Road watercourses, respectively), and presented in Appendix J.4, Figure J.4-5. Full details associated with fish abundance and distribution are provided in the 2019-2020 Baseline (Appendix J.2).

Atlantic Salmon

Within the freshwater environment, Atlantic salmon are found in cool, clear, well-oxygenated waters that support a reliable food source of aquatic invertebrates. Gravel and cobble are the preferred substrates for spawning (Bowlby et al., 2013), with redd sites typically located in well aerated areas - a riffle above a pool, or at the tail of pools on the upstream edge of riffles with depths of 10 to 70 cm (Grant and Lee, 2004). Young of year (YOY) will remain near the redd for a few months, after which they disperse downstream, occupying areas of faster velocities as they increase in size (Grant and Lee, 2004). Juveniles can be found occupying a variety of habitats. In summer and fall, they are typically found in moderate velocity runs with clean, rocky substrate free of sand, silt, and detritus (Rimmer et al., 1983). Older parr are usually found in riffles, whereas deeper pools are the preferred habitat during low water levels, high temperatures, and winter freeze (Grant and Lee, 2004).

The SU Population of Atlantic salmon has been assessed as endangered by COSEWIC (2010) and is considered provincially critically imperiled by the ACCDC (S1), but is not currently protected under SARA or NSESA. The SU Population of Atlantic Salmon has experienced significant reductions over the last few decades, with adult abundance declining from 88% to 99% from observed abundances in the 1980s (DFO, 2013). Current adult and juvenile abundance has been assessed as critically low in most rivers, and there is strong evidence for river-specific extirpations – only 54% of rivers in the SU region were found to contain salmon in 2000 (Amiro et al., 2000) and only 38% were found to contain salmon in 2008 (Gibson et al., 2010). The main contributing factors to these declines are considered to be degradation of freshwater habitat, acidification, and poor marine survival (Bowlby et al., 2014). During the 2019-2020 field program, Atlantic salmon parr were captured within the Killag River. No salmon were captured within any other watercourse or waterbody within the Beaver Dam Mine Site or Haul Road.

American Eel

American eel are frequently found in watercourses that offer structural complexity and shade in the form of coarse woody debris, rocks, in-stream vegetation for daytime cover, and an available food source of forage fish, invertebrates, molluscs and vegetation. Migrating elvers are bottom dwellers and spend most of their time burrowed or hidden, including directly into soft bottom sediments (Tomie, 2011). In freshwater, yellow eel continue their migration upstream into rivers, streams, and muddy or silt bottomed lakes (Scott and Crossman, 1998). Like elvers, yellow eel are primarily nocturnal, spending most of the day under cover or buried in soft substrates. These soft substrates are particularly important for overwintering, where the eel hibernate by burying themselves into the bottoms of lakes and rivers (Smith and Saunders, 1995; Scott and Scott, 1998). Trautman (1981) also reported that eel partially or completely bury themselves in mud, sand and gravel during the day, emerging at dusk to begin feeding.

American eel have been assessed as threatened by COSEWIC (2012) and are considered provincially imperiled by the ACCDC (S2). American eel are not currently protected under SARA or NSESA. From 2015-2017, adult American eel were confirmed in watercourses along the Haul Road including WC-N, WC-V, and WC-AH. Juvenile eel were also observed in WC-N and WC-AH. During the 2019-2020 field program, adult American eel were confirmed in Mud Lake/WC27, Cameron Flowage, WC13, and the Killag River. Juvenile eel were also observed in WC13.

Banded Killifish

Banded killifish are freshwater habitat generalists found within the quiet waters of lakes, ponds, and sluggish streams, tolerating a broad temperature, salinity, and DO range (COSEWIC, 2014). Adults tend to school in shallow water characterized by sand, gravel, or muddy substrate, with submerged aquatic plants (Scott and Crossman, 1973). Banded killifish are generally not considered a strong swimmer, and high velocities are thought to limit the species' movement within a watershed (DFO, 2011). Seasonal movement by the species has not been documented, and it is not considered migratory (COSEWIC, 2014).

Banded killifish spawning has been seldom documented; however, it is thought that aquatic vegetation within quiet shallows is a key component in spawning habitat as an attachment point for externally fertilized eggs (Richardson, 1939).

Banded killifish are considered provincially secure by the ACCDC (S5). Banded killifish were captured within both the Beaver Dam Mine and along the Haul Road during the 2015-2017 fish surveys, including WC13, Crusher Lake, the flooded portion of Wetland 56, WC-N, and WC-AA. During the 2019-2020 field program, adult and juvenile banded killifish were confirmed in Mud Lake/WC27, Cameron Flowage, WC13, and the flooded portion of WL59.

Brook Trout

Brook trout are known to inhabit a wide range of cool, freshwater environments, from small headwater streams to large lakes. Water temperature is a critical factor influencing brook trout distribution and production. Though typically not anadromous, brook trout require free passage along streams to move between areas of use, including spawning grounds, overwintering areas, and summer rearing areas.

In Nova Scotia, mature brook trout migrate to spawn in lakes or streams in the fall of the year. Brook trout spawning sites are usually near groundwater upwelling or spring seeps and within a lake or stream with gravel substrate (NSDAF, 2005). Optimal spawning conditions for brook trout include clear substrate 3 to 8 mm in size in shallow water with limited fines (<5%), and velocities of 25 to 75 cm/s (Raleigh, 1982).

Young of the year brook trout require cold water, stable, low velocities and an abundance of in-stream cover. Optimal temperature for juvenile growth is 10 to 16°C, while cover in the form rubble, vegetation, undercut banks, and woody debris should account for a minimum of 15% of total stream area (Raleigh, 1982). In winter, brook trout aggregate in pools beneath silt-free rocky substrate and close to point sources of groundwater discharge (Raleigh, 1982; Cunjak and Power, 1986). Adults use both pools and riffles, with more than 25% in-stream cover being optimal (Raleigh, 1982). Brook trout respond negatively to flashy or hydrologically dynamic systems, and require stable flow for all life stages (Raleigh, 1982).

Brook trout are considered provincially vulnerable by the ACCDC (S3), but have not been assessed by COSEWIC nor are they currently listed under SARA or NSESA. From 2015-2017, juvenile brook trout were captured in WC5 (north of Crusher Lake), WC12, and WC13 within the Beaver Dam Mine Site. Along the Haul Road, juvenile brook trout were confirmed in WC-N and WC-V. One individual adult brook trout was captured in WC-AH. During the 2019-2020 field program, adult brook trout were captured within Crusher Lake, WC5 Reach B, Mud Lake/WC27, Cameron Flowage, WC13, and WC23. Juvenile brook trout (young of the year and parr) were also documented in WC13, WL59, Crusher Lake, WC5, and the Killag River.

Brown Bullhead

Brown bullhead are bottom dwellers that prefer sluggish and warm water in slow-moving streams, ponds, and lakes with abundant aquatic vegetation. The species is resistant to increased levels of pollution and is tolerant of low oxygen concentrations and temperatures up to 31.6°C (Scott and Crossman, 1973).

Brown bullhead spawning occurs in late spring and summer when water temperatures reach 21°C (Scott and Crossman, 1973). Adhesive eggs are deposited into shallow nests that are excavated in mud or sand substrate, covered by at least 15 cm of water (Scott and Crossman, 1973).

Adults can be found in lakes and rivers with a variety of substrates but are typically associated with muddy bottoms. These fish are omnivorous night-feeders and will forage on all types of plant and animal materials that they locate with their barbels.

Brown bullhead are considered provincially secure by the ACCDC (S5). Brown bullhead were confirmed within Crusher Lake and Cameron Flowage, and one juvenile was captured WC-13 during the 2015-2017 fish surveys. No brown bullhead were captured within watercourses along the Haul Road. During the 2019-2020 field program, adult brown bullhead were captured in Mud Lake/WC27 and WL59.

Creek Chub

Creek chub are widely distributed and are considered one of the most common stream minnows in Eastern North America (Scott and Crossman, 1973). Adults prefer small, clear, and cool streams, although the species has been known inhabit the shore waters of small lakes. Optimum habitat is characterized by moderate to high gradients, gravel substrates, and riffle-run and pool habitat with abundant cover (McMahon, 1982).

Spawning occurs in spring in small streams with clean gravel substrate. Males create a pit by swimming vigorously against the stream bottom into which eggs are deposited and then covered with stones (Scott and Crossman, 1973). These pits are most often located just above or below a riffle (McMahon, 1982). Young of the year are often found in shallow areas along the edges of low velocity pools (McMahon, 1982).

Creek chub are considered provincially secure by the ACCDC (S5). During the 2019-2020 field program, 6 individual adult creek chub captured across Cameron Flowage and WC13. No creek chub were identified during the 2015-2017 program.

Golden Shiner

Golden shiner are habitat generalists, primarily found schooling in well vegetated lakes with extensive shallows (Scott and Crossman, 1973). The species can tolerate a wide range of oxygen concentrations and temperatures (Murdy et al., 1997).

Spawning takes place from June to August, when temperatures reach 20°C, during which adhesive eggs are scattered over the substrate, attaching to filamentous algae or other aquatic vegetation (Scott and Crossman, 1973).

Golden shiner are considered provincially apparently secure by the ACCDC (S4). From 2015-2017, adult golden shiner were captured in Crusher Lake and Cameron Flowage, and WC-AA along the Haul Road. During the 2019-2020 field program, adult and juvenile golden shiner were captured in Mud Lake/WC27, Crusher Lake, WL59 and Cameron Flowage.

Lake Chub

Lake chub are a common fish of lakes and rivers, preferring cool, clear water and gravel bottomed streams and lake edges (Page and Burr, 2011). The species is mostly found in shallow water but may move into deeper areas to escape high temperatures (Scott and Crossman, 1973).

When inhabiting lakes and larger rivers, schools of lake chub will undergo spawning migrations to shallow areas of slow tributary streams in the spring, with seasonal movements occasionally being extensive (Scott and Crossman 1973; Stasiak, 2006a). During spawning, non-adhesive eggs are scattered over gravel or rocky substrate (Scott and Crossman, 1973; Stasiak, 2006a). Young of the year and juveniles prefer slow, shallow water. Young of the year are often found in submerged vegetation (Brown et al. 1970), while older juveniles have been found over a variety of substrates (Mecum, 1984).

Lake chub are considered provincially secure by the ACCDC (S5). From 2015-2017, one juvenile lake chub was captured in WC-13 within the Beaver Dam Mine Site. Along the Haul Road, adult lake chub were confirmed present in WC-N and WC-AA. During the 2019-2020 field program, adult lake chub were captured in Mud Lake/WC27, WC5 Reach B, WC13, and the Killag River. Juveniles were also documented in the Killag River, WC5 Reach B and WC13.

Ninespine Stickleback

Ninespine stickleback are found in both brackish waters and the shallow areas of freshwater lakes and ponds. In rivers and streams, the species is generally found in sluggish, cool pools where there is plenty of aquatic vegetation.

Spawning takes place over the summer in fresh water, during which the male constructs a nest off the substrate by binding plant fragments together (Scott and Crossman, 1973). Spawning habitat is primarily characterized by shallow depths, low velocity, dense aquatic vegetation, and mud and silt substrates (McPhail and Lindsey, 1970; Scott and Scott, 1988).

Ninespine stickleback are considered provincially secure by the ACCDC (S5). Ninespine stickleback were only captured in WC-4 during the 2015-2017 fish surveys. During the 2019-2020 field program, stickleback were captured in Mud Lake/WC27, Crusher Lake, WL56, WL59, and WC13, and WC26.

Northern Redbelly Dace

Northern redbelly dace have a strong habitat preference for quiet waters, including beaver ponds, bog ponds, small lakes, and sluggish areas of streams underlain by brown detritus or silt (Scott and Crossman, 1973). Preferred habitats are also characterized by a constant supply of cool groundwater, ensuring sufficient DO levels into the hotter summer months (Stasiak, 2006b).

Characteristics of small streams where this species generally occurs include water supplied by clear, cool springs or seeps, lack of a strong current, cover in the form of undercut banks, heavy vegetation, or brushy debris, and no large piscivorous fish populations (Stasiak, 2006b).

Spawning occurs in the spring to early summer (Scott and Crossman, 1973). Hubbs and Cooper (1936) documented non-adhesive eggs being deposited into dense mats of filamentous algae.
