Executive Summary

Canadian Nuclear Laboratories (CNL) is proposing the construction and operation of a Near Surface Disposal Facility (NSDF) for the disposal of solid, low-level radioactive waste at the Chalk River Laboratories (CRL) site. The NSDF Project is based on the mandate of Atomic Energy of Canada Limited (AECL), a federal Crown corporation, to manage the Government of Canada's radioactive waste and decommissioning liabilities. The NSDF Project will substantially reduce the risks associated with the low-level waste and to create conditions for the revitalization of the CRL site. Canadian Nuclear Laboratories is a private-sector company that is contractually responsible for the management and operation of nuclear sites, facilities and assets owned by AECL.

For more than 70 years, AECL, and now CNL, have been making advances in nuclear science and technology in the interest of Canadians. This includes the production of medical isotopes for the diagnosis and treatment of over one billion patients worldwide, as well as developments in clean energy which help reduce greenhouse gas emissions. Through investments in the revitalization of the CRL site, that mission and innovative science will continue into the future. However, this proud history has created nuclear liabilities in the form of waste. Furthermore, past waste management practices, which met the standards of the day, are no longer acceptable. Specifically, the historic waste management areas lack robust containment, which in some instances has led to contamination of the surrounding environment.

In accordance with *Canada's Radioactive Waste Policy Framework* the waste producers and owners of radioactive waste are responsible for the funding, organization, management and operation of disposal and other facilities required for these materials. Responsible nuclear waste management includes management of the full life cycle of the material, from generation to disposal. Canadian Nuclear Laboratories and AECL are working actively at both the strategic and operational levels to identify strategies and solutions for waste management of the entire life cycle of all radioactive waste classifications including low-level waste, intermediate level waste and high-level waste. Canadian Nuclear Laboratories' high level waste is in safe, secure and suitable storage facilities until a national deep geological repository designed for used fuel becomes available. The current strategy for intermediate level waste from all CNL managed sites is safe, secure, and in suitable temporary storage facilities at the CRL site until a suitable permanent disposal facility is available. The exceptions to this are the Nuclear Power Demonstration Reactor and Whiteshell Reactor 1 facilities which are proposed to be decommissioned in situ.

The purpose of the NSDF Project is to provide the permanent disposal of current and future low-level waste at the CRL site, as well as a small percentage of waste volume from off-site locations, in a manner that is protective of both the public and the environment. The practice of continuing to build additional temporary storage systems at the CRL site for low-level waste is not consistent with modern waste management principles. Further, the NSDF Project would enable the remediation of historically contaminated lands and legacy waste management areas, as well as the decommissioning of outdated infrastructure to facilitate the CRL site revitalization.

The proposed NSDF Project is considered a "designated project" in accordance with paragraph 37(b) of the *Regulations Designating Project Activities.* Under section 15 of the *Canadian Environmental Assessment Act,* 2012, the Canadian Nuclear Safety Commission is the Responsible Authority for this proposed project.

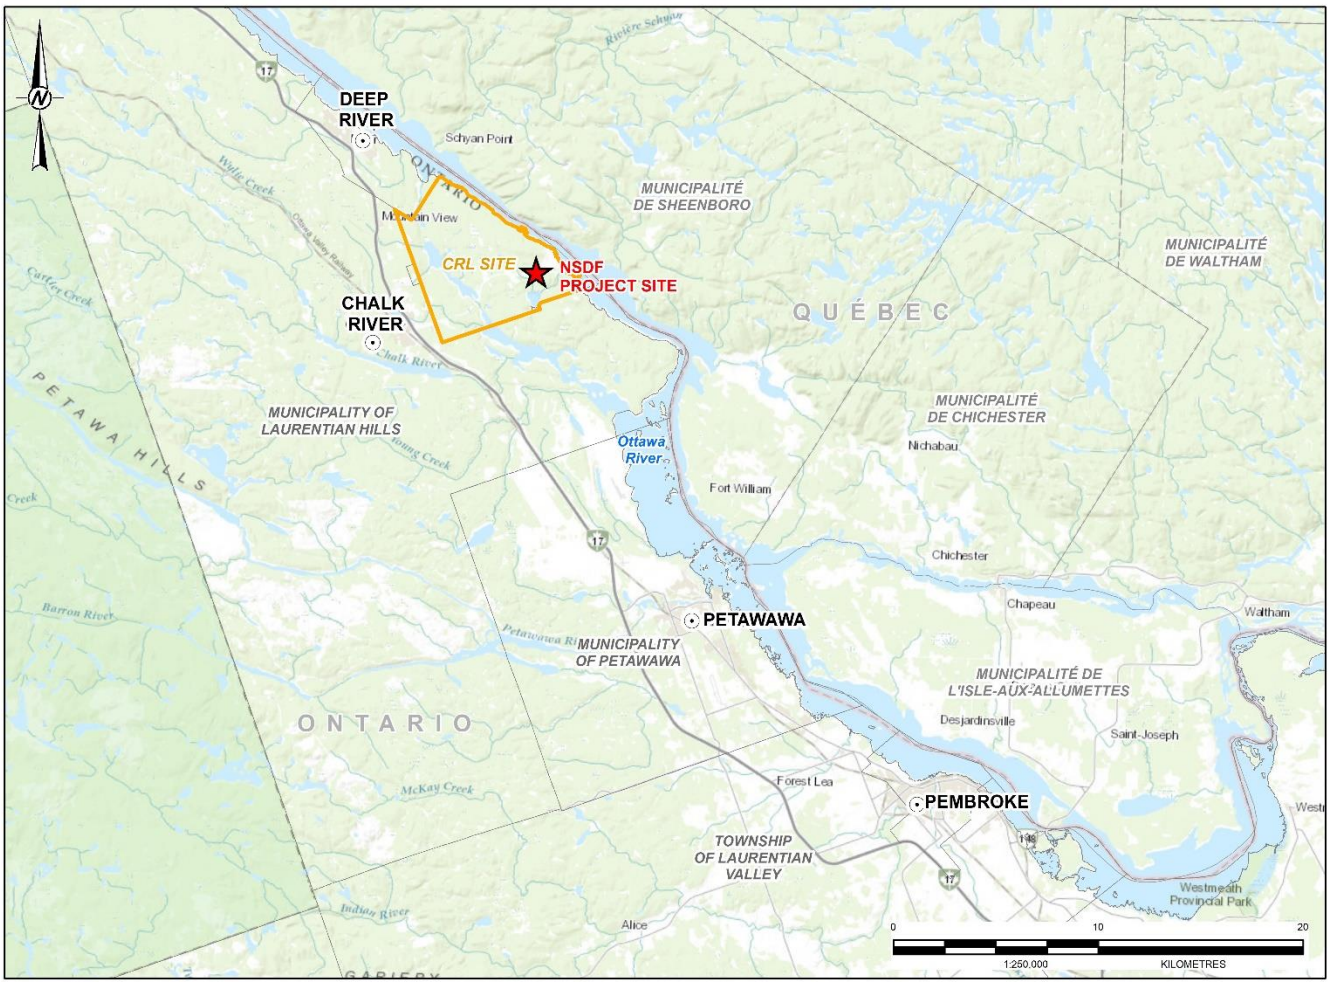
A key element of the regulatory approvals process is the completion of an environmental assessment under the *Canadian Environmental Assessment Act, 2012*, the results of which are documented in this Environmental Impact Statement (EIS). The EIS describes the analysis of alternatives, a process of public and Indigenous engagement, studies of baseline conditions, and assessment of project activities during the construction, operation, closure and post-closure phases of the NSDF Project. All these aspects of the EIS are summarized below in this executive summary.

Analysis of Alternatives

Canadian Nuclear Laboratories undertook a comprehensive analysis of alternatives for the location of the facility, the type of facility, the design of facility, and the approach for treatment of wastewater to meet the needs of the NSDF Project. Consideration was given to technical, economic and environmental factors. Of the alternatives considered, the construction of a near surface disposal facility for the disposal of low-level waste at the CRL site was the preferred alternative. International nuclear industry guidance notes that this model has been found suitable for the disposal of low-level waste. The engineered containment mound design is the best available technology when taking into consideration the proposed waste which consists mostly of contaminated soils and demolition debris.

The Chalk River Laboratories site is the most suitable as more than 90% of the waste to be managed by the NSDF Project is already located there. This site eliminates the additional time and cost of transporting the waste to another location (an effort which would require approximately 45,000 transport truck trips) and reduces the generation of greenhouse gas emissions.

Fifteen potential sites within the CRL site were initially screened to see how they met mandatory criteria such as the minimum space required. Sites that passed this initial screening were then evaluated to see if they met other criteria such as location in relation to the floodplain, geological characteristics and the presence of plants and animals. Based on this review two sites were identified for further evaluation. Both sites were technically feasible, however they differed in how each would be affected environmentally.



The preferred site for the NSDF is closest to the CRL site main campus and thereby eliminating the need to build new support services infrastructure for electricity, water, and heat. The preferred site is located within the Perch Creek and Perch Lake Watershed, which, in the past, have been affected by historic waste management practices. Groundwater flow and contaminant migration at the CRL site has been studied for over six decades and the Perch Creek and Perch Lake Watershed are well understood, allowing CNL to accurately predict environmental effects based on history and to prepare mitigation measures. Protection of the Ottawa River was a key factor in considering the NSDF Project location. The preferred site is located along a bedrock ridge that naturally forces water directly away from the Ottawa River, and it creates a foundation for the engineered containment mound which has been used in the overall design.

Project Description

The NSDF Project is a proposed waste disposal facility using an engineered containment mound design built at ground surface that will hold up to 1,000,000 cubic metres (m^3) of low-level waste. The facility will feature 10 waste disposal cells, built in two phases. The engineered containment mound includes a multilayer base liner and cover system, where waste will be placed in between. The waste in each cell is covered after the cell is full. It is similar to a hazardous waste landfill but with much more robust engineering features. The proposed facility would be licensed under the *Nuclear and Safety Control Act* thus subject to the associated regulations and independent regulatory oversight from the Canadian Nuclear Safety Commission.

Location

The CRL site is in Renfrew County, Ontario on the shore of the Ottawa River, approximately 200 km northwest of Ottawa. The CRL site contains several nuclear and non-nuclear facilities such as research laboratories and waste management facilities. The CRL site has a total area of approximately 4,000 hectares (ha) and is within the boundaries of the Corporation of the Town of Deep River. The Federal Department of National Defence Garrison Petawawa borders the CRL site to the southeast, and the Village of Chalk River in the Municipality of Laurentian Hills is to the southwest. The Ottawa River forms the northeastern boundary of the CRL site. The NSDF Project is located entirely within the CRL site and the footprint of the NSDF Project site is approximately 37 hectares, which is less than 1% of the total area of the CRL site. The NSDF Project has also been graded to minimize visibility from the Ottawa River and the nearest Village of Chalk River.

Waste Inventory

The NSDF will hold only low-level waste which contains primarily short-lived radionuclides with a restriction on waste containing long-lived radionuclides. This material will require isolation and containment for up to a few hundred years. The engineered containment mound design life of 550 years has been established to meet the required time period to allow for radiologic decay of the waste inventory. The radioactivity of the inventory will decrease about 2,000 times in the first 100 years, and then begin to approach natural levels of radioactivity shortly thereafter.

The types of waste destined for the NSDF Project include contaminated soils from remediation activities, demolition debris from decommissioning work and general waste such as used personal protection clothing or equipment. These items are considered low-level waste as they can be safely handled with limited precautions.

The NSDF will primarily contain waste currently in storage at the CRL site, waste generated during environmental remediation and decommissioning activities now underway, as well as future waste that is expected to be produced as a result of on-going nuclear science and technology activities. A small percent of the waste volume will come from other AECL-owned sites (e.g., Whiteshell Laboratories), or from sources such as hospitals and universities.

Facility Design

The NSDF Project has been designed in accordance with regulatory and international design principles for radioactive waste disposal. This includes the incorporation of multiple safety functions, containment and isolation of the radioactive waste as well as incorporation of surveillance and control of the passive safety features. The long-term safety performance of the NSDF Project depends on many safety features which include the following engineered barriers:

- Base liner system, which has a primary and secondary liner to contain the waste and to limit the potential release of contamination to the subsurface and groundwater.
- Final cover system, which will isolate the waste, provides radiation shielding and an intrusion barrier, and prevents precipitation from infiltrating the waste.
- Perimeter berm, which provides structural stability and is designed to withstand natural physical events therefore ensuring containment of the waste.

The base liner and final cover systems are composed of a combination of natural materials (e.g., compact clay liner) and synthetic materials (e.g., high density polyethylene geomembranes) designed to work together to prevent the release of contaminants into the environment. Long-term performance tests demonstrate that the synthetic high density polyethylene geomembrane component of the liner systems will meet the 550-year design life thus complementing the compact clay layer which will provide a hydraulic barrier for thousands of years. Since the perimeter berm is constructed exclusively from natural materials, it is expected to remain intact and performing its function for thousands of years. Further, the waste material placement and compaction are part of the design basis to ensure structural stability in order to avoid settling and subsidence. Similar structures, such as human-made mounds built with earthen materials and limited engineering or construction knowledge, have existed for more than 550 years (e.g., Monks Mound in Illinois, United States of America).

In addition to the engineered barriers, the NSDF Project site is well above the Ottawa River flood levels on a bedrock ridge that naturally forces water to flow in the opposite direction, away from the river. The location and design of the NSDF Project have taken into consideration the physical characteristics of the CRL site to protect the environment and the public with features that will contain and isolate the waste.

Included in the proposed design of the NSDF Project are wastewater collection and treatment systems. The NSDF Project will contain systems within the engineered containment mound to collect and pump leachate as well as other wastewaters to the Wastewater Treatment Plant (WWTP). The wastewater will be treated through conventional processes to remove radiological and chemical contaminants so that the treated effluent meets discharge targets established to be protective of the environment. After treatment, the effluent will be discharged to ground via an exfiltration gallery. In the event that the exfiltration gallery does not have sufficient capacity to

manage the treated effluent (e.g., under spring conditions), a portion of the treated effluent will be piped directly to Perch Lake. Only effluent that meets the discharge targets will be released. Consistent with CNL practices and regulatory requirements, all discharges will be monitored and reported.

Other supporting infrastructure for the NSDF Project includes a vehicle decontamination facility, an administration building, as well as surface water management ponds.

Timeline

The NSDF Project is divided into several phases: construction, operations, closure and post-closure.

The construction phase, which includes site preparation, is anticipated to start in 2022 or as soon as the relevant regulatory permits and approvals are in place. This phase will include activities such as site clearing and construction of the engineered containment mound and WWTP.

The operations phase is expected to begin in 2025 and last approximately 50 years. Activities associated with the operations phase include those necessary for placement of wastes, treatment of wastewater, maintenance of facilities and establishment of long-term monitoring.

The closure phase follows cessation of operations and is scheduled to last 30 years. Activities includes closure of the engineered mound which involves the installation of the final cover and the decommissioning of infrastructure.

The post-closure phase is defined by two distinct periods: institutional control and post-institutional control. For planning purposes, the institutional control period was assumed to last 300 years; however, the institutional control period will continue as long as necessary as determined by regulatory agencies. During institutional control, inspection and surveillance activities will verify the integrity of the disposal facility system, while environmental monitoring activities will verify that the performance continues to demonstrate compliance with the environmental assessment predictions. Controls on land usage would include recognition of a waste disposal facility on the property title or deed to ensure the appropriate zoning restrictions, including buffer or attenuation zones, are enforced by the applicable regulatory agency.

Public Engagement Activities

Engagement is a key component of the environmental assessment process. Canadian Nuclear Laboratories operates an on-going Public Information Program to inform groups about activities at CNL managed sites and the potential effects of these activities on the public, Indigenous Peoples and on the environment. This Public Information Program forms the basis of communication efforts with the public and Indigenous Peoples and helps to direct the establishment of long-term, mutually beneficial working relationships with their communities in proximity to CNL sites.

The NSDF Project has provided current project information in both English and French to communities in Ontario and Quebec which are most likely to be affected or interested in the NSDF Project. Public engagement activities related to the NSDF Project include:

- presentations, information sessions and site visits;
- distribution of public information (e.g., webpage content, infographics and factsheets, community newsletters, etc.);
- participation in public events and as well as media relations;

- use of social media to advertise events as well as share project information (e.g., Facebook, webinars and YouTube videos).

In March 2020, the COVID-19 pandemic impacted in-person engagement activities. Canadian Nuclear Laboratories has adapted to the restrictions providing online platforms for virtual meetings, workshops, webinars, project updates and open houses. Canadian Nuclear Laboratories remains committed to ensure engagement activities are ongoing and in alignment with current pandemic restrictions.

During regularly scheduled meetings of the Environmental Stewardship Council for the CRL site, members are presented with information about CNL and CNL environmental practices, and these meetings provide opportunities for open dialogue between various stakeholder groups, local communities and CNL. Environmental Stewardship Council members share meeting information with their respective constituents. This open dialog and sharing of information is essential to CNL, ensuring that perspectives from our closest neighbours and non-governmental organizations are heard.

These engagement activities have helped inform stakeholders and have enabled the public to provide valuable feedback to the NSDF Project, which helps CNL understand areas of public concern and improve the NSDF Project design and EIS. Key themes of the feedback received to date for the NSDF Project includes:

- justification for the NSDF Project;
- protection of the Ottawa River;
- waste inventory;
- design/engineering;
- long-term accountability;
- alternative means assessment (including site selection); and
- environmental events (e.g., flooding, earthquakes).

This feedback has been incorporated into the EIS where applicable, for example through inclusion of additional analysis or modification of assessment boundaries. A significant change incorporated into the EIS based on feedback was the change in waste inventory to include only low-level waste. In an effort to improve access and transparency CNL continues to post key EIS technical support documents on the NSDF Project's website as they are available.

Canadian Nuclear Laboratories has also engaged with applicable Federal and Provincial regulatory agencies who reviewed and provided comments on each of the drafts of the EIS. Canadian Nuclear Laboratories has worked with these agencies to understand their concerns and where required, has updated the EIS to provide additional information to address their concerns.

Canadian Nuclear Laboratories appreciates all feedback received to date on the NSDF Project and remains committed to continuing discussions with the public, Indigenous Peoples and non-governmental organizations on the NSDF Project. Canadian Nuclear Laboratories will continue engagements throughout the environmental assessment process but encourages interested members of the public to contact the NSDF Project directly with their questions about the NSDF Project (communications@cnl.ca).

Indigenous Engagement Activities

In consultation with the Canadian Nuclear Safety Commission, and using tools provided through the Aboriginal and Treaty Rights Information System, CNL identified a proposed list of Indigenous Peoples with potential interest in the NSDF Project. Engagement with Indigenous Peoples started in October 2015 and is on-going with CNL carrying out information sessions for the NSDF Project within Indigenous communities and organizations. Engagement methods have been largely similar to those for public engagement, and have also included more direct communication including webinars and working group meetings with each identified Indigenous community or organization. CNL has considered and provided capacity funding to specific Indigenous communities and organizations to further their ability to participate in the environmental assessment process.

Canadian Nuclear Laboratories has proactively addressed key concerns raised by interested Indigenous Peoples, using open and transparent communication to share information in regard to protection of the environment, specifically Kichi-Sìbì (Ottawa River), traditional land use and impact on valued components of Indigenous interest, as well as opportunities for involvement in future environmental monitoring. During engagements with Indigenous Peoples, concerns raised include the historical occupancy of the lands, long-term operations and future operations and scenarios which are not necessarily specific to the NSDF Project. Canadian Nuclear Laboratories respects and understands these concerns and has approached Indigenous engagement in such a way as to answer and address some of these broader questions as well as engaging specifically on the NSDF Project.

Canadian Nuclear Laboratories is working towards developing long-term relationships with Indigenous Peoples who occupy and have traditional territories and modern day interests near its operations. Canadian Nuclear Laboratories recognizes that such relationships may take a long time to form but believes this is consistent with the Government of Canada’s approach to reconciliation with Indigenous Peoples.

Environmental Assessment Approach

The environmental assessment approach for the NSDF Project was developed to meet the requirements of *Canadian Environmental Assessment Act, 2012* and the Generic EIS Guidelines developed by the Canadian Nuclear Safety Commission, which provide an outline of the information to be included, along with a high-level description of the methods to be implemented for the environmental assessment.

The assessment started with defining the overall **scope of the assessment** including identifying the **valued components** for each environmental discipline, such as atmospheric environment, hydrogeology, terrestrial biodiversity, human health and the socio-economic environment. Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public. Examples of valued components identified include air quality, groundwater quality, migratory birds and public health.

The next step for the assessment was to define the physical boundaries, the time-related phases of the project and then to identify scenarios which would describe predicted effects of the projects.

Study areas (spatial boundaries) – Three spatial boundaries were considered: the site study area, the local study area, and the regional study area. The site study area includes the area where NSDF Project activities would be undertaken which include the NSDF Project’s proposed facilities, building and infrastructure. A local study area was selected for each environmental component to represent where the NSDF Project would have a direct affect. This most often includes the land and water immediately surrounding the site study area and portions of the downstream environment (e.g., Perch Lake). The largest section is the regional study area is

where the NSDF Project may interact with other existing infrastructure. For many environmental components, the regional study area extends to the full CRL site boundary.

Temporal boundaries (**project phases) –** These establish the timeframe during which NSDF Project effects were assessed. The assessment phases align with those of the NSDF Project: construction phase (2022 to 2024), operations phase (approximately 50 years, i.e., 2025 to 2070), closure phase (approximately 2070 through to 2100), and post-closure phase (from 2100 and into the future).

The next step was to describe the existing conditions. A **description of the environment** subsection was developed for each environmental component and includes a description of the baseline conditions. **Potential effects** of the NSDF Project on the environment were then identified and mitigation was developed to reduce adverse effects on the environment. **Residual effects** (i.e., effects that remain after the application of mitigation) were classified (e.g., low to high magnitude, short-term duration, etc.) so that it could be determined if each residual effect was significant or not. Cumulative effects (i.e., the combined impact of the NSDF Project with other reasonably foreseeable developments) were also evaluated to determine significance of these effects. Any uncertainty in the assessment and the general confidence in the predictions from the assessment were also evaluated. Finally, **monitoring programs** were proposed to verify the predictions and assumptions from the environmental assessment and to confirm that the proposed mitigation is effective.

Atmospheric Assessment Results

The climate in the region surrounding the NSDF Project site is classified as humid continental, with warm summers, cold winters, and no distinct dry season. The average daily temperature is 5.6°C while the daily average temperature in the winter season is -9.3°C and the daily average temperature in the summer season is 19.1°C. Annual precipitation of 859 millimetres equivalent (mm[eq]) is calculated for the region, with the highest precipitation typically occurring in the summer. The wind conditions at the NSDF site are considered to travel predominantly along the Ottawa River. When air quality is measured, contaminants are well below provincial and federal criteria, suggesting that the region has generally good air quality.

NSDF Project activities have the potential to release air emissions that could contribute to changes in air quality and incrementally to climate change. During the construction and operations phases, NSDF Project activities will result in emissions, including dust associated with construction activities such as the operation of vehicles and equipment. Examples of mitigation practices implemented to limit potential effects on air quality and climate change include:

- implementation of the *Dust Management Plan* developed for the NSDF Project, which includes appropriate management techniques to control dust generated by the NSDF Project;
- maintenance of on-site vehicles and equipment; and
- limiting idling of vehicles and equipment on site.

With the implementation of these measures, the predicted changes to air quality as a result of the NSDF Project during both construction and operations phases do not exceed air quality guidelines and/or standards with one exception (1-hour nitrogen dioxide Canadian Ambient Air Quality Standard). However, the exceedance of the 1-hour nitrogen dioxide standard is not likely to occur given the conservative nature of the air quality assessment modelling. For example, in the model, heavy equipment is assumed to run simultaneously and continuously during working hours, which is unlikely to be the case. With the implementation of CNL's robust environmental

protection program, including the *Dust Management Plan* for the NSDF Project, **residual effects from the NSDF Project on air quality are not significant.**

A **slight residual effect to** greenhouse gas **emissions was identified because of the NSDF Project.** The change is estimated to be less than a 0.02% increase in total provincial greenhouse gas emissions and a 0.005% increase in total national greenhouse gas emissions. **Consequently, the residual effect from the NSDF Project on greenhouse gases is not significant.**

Monitoring of air quality at the CRL site is conducted under CNL's Effluent Verification Monitoring Program, which is compliant with the CSA Group standard *N288.5-11 Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills*. Air quality monitoring for the NSDF Project is intended to verify that mitigation is being implemented effectively and to verify the predictions of the assessment.

Geology and Hydrogeology Assessment Results

The CRL site is located within the Canadian Shield. Bedrock outcrops in several locations in the region, and a widespread but thin deposit of glacial sediment covers the bedrock in most areas where soil is present. Soil layers generally consist of well-drained sandy soils in the area. Groundwater table depth varies significantly throughout the NSDF Project site and changes with the seasons. The average groundwater depths range from approximately 0.06 m in the vicinity of the wetlands to 15.95 m in the northern section of the study area, which corresponds to the thickest overburden. Groundwater flow from the NSDF Project site is to the adjacent wetlands, and ultimately discharges to the Ottawa River via Perch Lake and Perch Creek. However, as mentioned previously the NSDF Project has been designed to prevent the release of contaminants into the environment, including groundwater, to protect local waterbodies.

Without mitigation, NSDF Project activities have the potential to alter soil quantity, quality, and distribution, as well as geomorphology as a result of construction and closure activities. Blasting activities, site grading, excavating and emissions of air contaminants could change soil quality during construction. The construction of the NSDF Project will physically alter groundwater levels and flows, and surface drainage. During operations, discharge of treated effluent could cause changes to groundwater quality, levels and flows. During the post-closure phase, without mitigation, leakage of leachate could cause changes to groundwater quality. Examples of design features and mitigation implemented to limit these potential effects to geology and hydrogeology include:

- physical changes to the bedrock from blasting will be limited to the local area within the engineered containment mound footprint;
- the base liner design includes both primary and secondary liner systems that are designed to have redundancy in case of premature failure and are designed to be suitable for the disposal of low-level waste; and
- implementation of the *Surface Water Management Plan* developed for the NSDF Project, which includes appropriate management techniques for erosion and sediment control.

The residual effects of the NSDF Project on geology are related to changes in soil quantity and quality and geomorphology as a result of construction of the NSDF Project, and changes to soil quality from blasting activities and air emissions. Mitigation and environmental design features implemented for the NSDF Project include existing practices at the CRL site and those used at similar facilities. Consequently, **changes in geology are not expected to result in significant adverse effects to other valued components (e.g., terrestrial environment)**.

The residual effects of the NSDF Project on hydrogeology are related to the alteration of groundwater levels and flows due to the construction of the NSDF Project. For groundwater quality, releases from the engineered containment mound are not anticipated during operations. Potential releases during post-closure (after the design life of the facility safety features) are not anticipated to result in significant residual effects because the inventory is sufficiently decayed and environmental concentrations are negligible. Therefore, **changes in groundwater quality and quantity are not expected to result in significant adverse effects to other valued components (e.g., aquatic environment and human health).**

Operational monitoring will be implemented to verify predictions from the environmental assessment for geology. For example, visual inspections of surface water management systems will be completed to confirm erosion control measures are effective. Groundwater monitoring will be integrated into the overall CNL Groundwater Monitoring Program, and will be compliant with CSA Group standard *N288.7-15 Groundwater Protection Programs at Class I Nuclear Facilities and Uranium Mines and Mills*. Groundwater monitoring is intended to verify that the environmental assessment predictions on groundwater during the operations phase are accurate, and to verify the effectiveness of mitigation. Groundwater monitoring will continue through operations, closure and post-closure phase.

Surface Water Environment Assessment Results

The CRL site is located in the Allumette Lake and Lac Coulonge reach of the Ottawa River. The distance from the centre of the NSDF Project site to the closest point on the Ottawa River shoreline is approximately 1.1 km. The NSDF Project is located entirely within the Perch Creek and Perch Lake Watershed, which drain into the Ottawa River. Surface drainage from approximately 18% of the CRL site flows through Perch Creek and subsequently into the Ottawa River. The drainage basin slopes from a highpoint ridge along the eastern limit of the CRL site, westerly towards Perch Lake and the wetlands located on the western boundary. Surface water monitoring at on-site lakes and streams, off-site streams, and locations in the Ottawa River upstream and downstream of the CRL site is routinely conducted to describe the surface water quality, in accordance with CNL's *Environmental Monitoring Program*.

Without mitigation, NSDF Project activities have the potential to change water levels, flows and channel and bank stability due to discharge of treated effluent and non-contact water into adjacent wetlands or downstream locations during operations. Also, the construction and installation of the engineered containment mound will physically alter drainage patterns, and intaking water from the Ottawa River could change its hydrology. Without mitigation, changes to local hydrology, discharge of treated effluent, air and dust emissions, surface water runoff, leakage of leachate or other releases of substances may affect surface water quality at downstream locations.

Examples of mitigation practices that will be implemented to limit predicted effects to surface water include:

- implementation of the *Surface Water Management Plan* developed for the NSDF Project, which includes appropriate management techniques to collect and direct surface drainage, including stormwater management ponds, and erosion and sediment control practices (e.g., silt fences, runoff management) will be used during construction around disturbed areas, where appropriate;
- treated effluent will be sampled to confirm it meets the effluent discharge targets before release; and
- the final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound and minimize leachate generation.

Residual effects to hydrology were identified because the installation of the engineered containment mound will physically alter drainage patterns and may change downstream discharge, water levels in adjacent wetlands, and channel and bank stability. Residual effects to surface water quality were predicted because the discharge of treated effluent from the WWTP to ground via the exfiltration gallery and via a transfer line to Perch Lake could cause changes to downstream surface water quality, and leakage of leachate from the engineered containment mound during the post-closure phase could cause changes to downstream surface water quality. Changes in hydrology and surface water quality were provided to other environmental components for inclusion in their assessment (e.g., aquatic biodiversity). Overall, **changes in hydrology and surface water quality are not expected to result in significant adverse effects to other valued components (e.g., aquatic biodiversity and human health)**.

Monitoring and follow-up programs for surface water hydrology will focus operational performance and environmental monitoring (e.g., monitoring of water levels in the stormwater management ponds to verify they are performing as designed). Stormwater management pond monitoring will be integrated into the NSDF Project *Environmental Protection Plan*, while water-level monitoring of the wetland system will be integrated into the current CNL Environmental Monitoring Program.

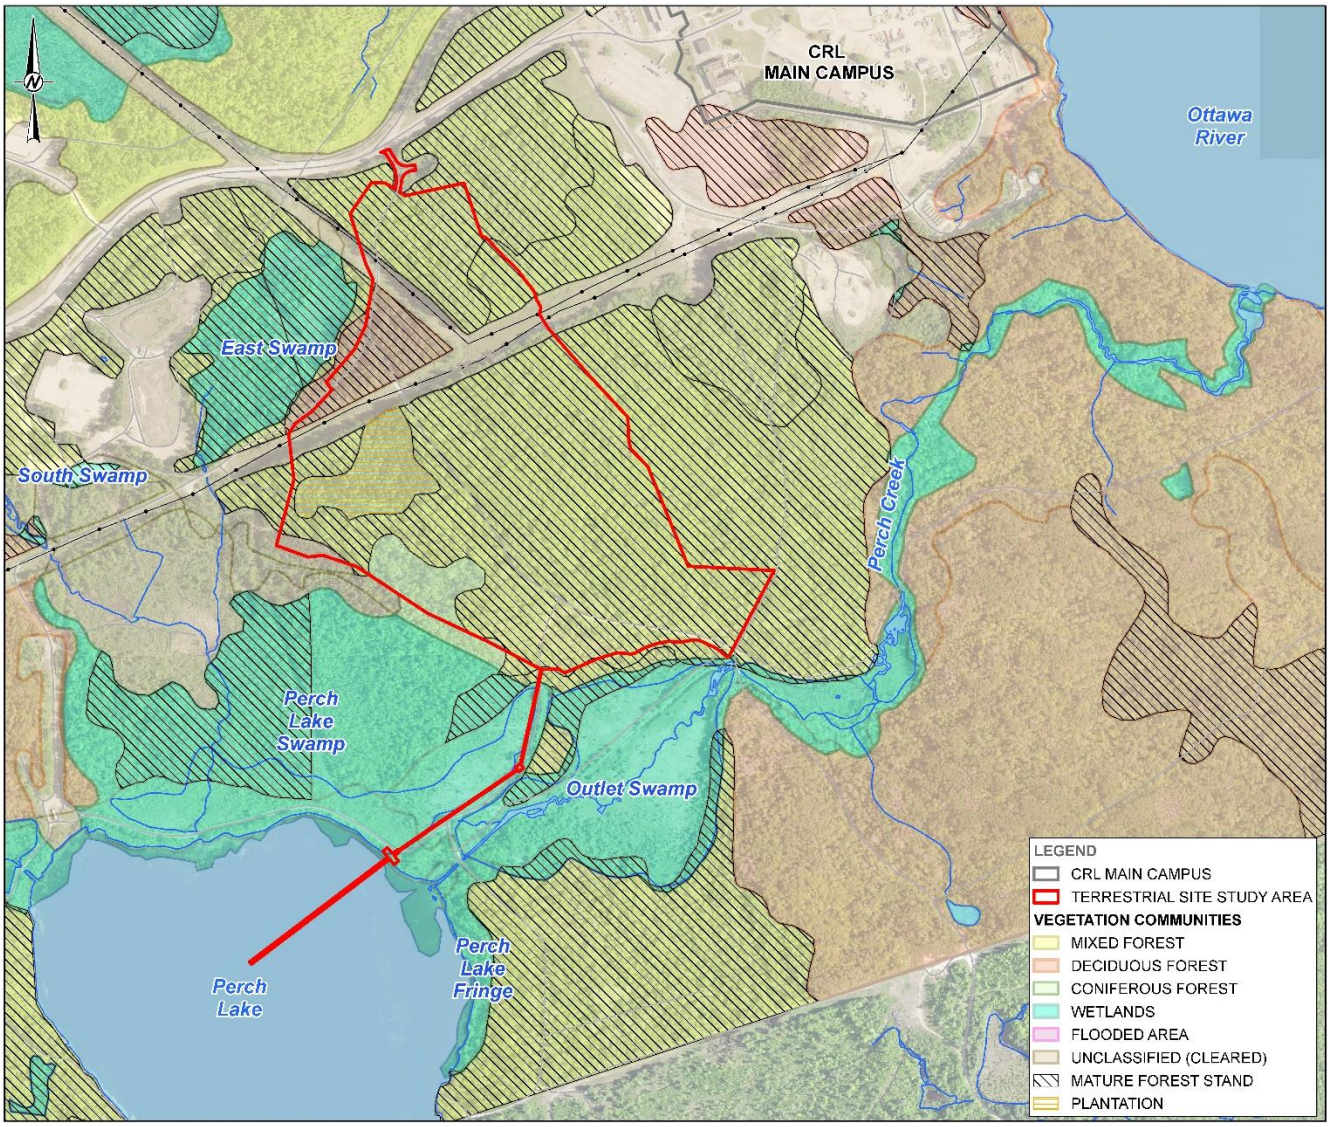
Routine surface water quality monitoring for the NSDF Project will be included in CNL's current Environmental Monitoring Program, which is compliant with CSA Group standard *N288.4-10 Environmental Monitoring at Class I Nuclear Facilities and Uranium Mines and Mills*. Effluent water quality from the surface water management ponds and wastewater treatment facility will be monitored in accordance with CNL's Effluent Verification Monitoring Program, which is compliant with the CSA Group standard *N288.5-11 Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills*. Together, these programs will be used to verify environmental assessment predictions related to surface water quality, verify the surface water management ponds are performing as designed, and demonstrate compliance with effluent discharge targets developed for the NSDF Project. The water quality monitoring will continue through operations, closure and post-closure (institutional control).

Aquatic Environment Assessment Results

Aquatic habitat in the local study area is found largely in Perch Lake and Perch Creek. Several fish species have been identified in the Perch Creek and Perch Lake Watershed during field programs since the 1980s through 2018. Major changes to fish productivity and community structure over time have not been observed, since the introduction of northern pike to Perch Lake in the mid-to-late 1980s, suggesting that the historical effects of past operations on water quality pose minimal risk to the fish community and populations in Perch Lake. Specifically, Perch Lake continues to support a large-bodied fish community that includes northern pike, yellow perch, brown bullhead and pumpkinseed. Based on historical reports of fish sampling in the Ottawa River, four fish species of conservation concern occur or have the potential to occur in the river reach adjacent to the CRL site (e.g., Allumette Lake). These species include lake sturgeon, American eel, river redhorse and northern brook lamprey. To the north of Perch Lake are extensive wetlands, notably Perch Lake Swamp, South Swamp and East Swamp. The fish habitat potential of wetlands such as Perch Lake Swamp and East Swamp is predicted to be low.

Without mitigation, the potential for effects to aquatic biodiversity are primarily related to changes in groundwater, surface water, and air quality. NSDF Project activities have the potential to affect water levels, flows, water quality and therefore fish habitat quality, and fish survival and reproduction. Activities that could affect fish habitat quality include changes to local hydrology, installation of treated effluent transfer line, discharge of treated effluent, leakage of leachate, release or deposition of harmful substances into downstream waterbodies, and physical changes to fish habitat such as along the riverbank. As well, blasting near fish-bearing waterbodies may result in

pressure changes, vibrations and affect fish survival and reproduction. Examples of mitigation practices that will be implemented to limit predicted effects to aquatic biodiversity include:



- work will be completed within the in-water work timing window to avoid spawning and egg/larval development periods for spring spawning fish species;
- runoff will be managed to avoid adverse environmental effects in downstream waterbodies; and
- clearing of any vegetation and organic materials along the riverbank will be minimized. Disturbed shorelines and wetlands will be re-vegetated and restored to the original stable gradient and contour.

Canadian Nuclear Laboratories is prepared to implement mitigation and environmental design features for the NSDF Project that are well understood and include existing practices at the CRL site. Therefore, **it is not expected that residual effects from the NSDF Project on aquatic biodiversity will be significant.**

As mentioned above for surface water, planned monitoring will include routine monitoring of surface water quality which is protective of aquatic biodiversity. If the environmental monitoring program for surface water quality identifies that adverse environmental effects are greater than predicted, then CNL will evaluate the need for revised mitigation actions and management practices to manage effects related to aquatic biodiversity.

Terrestrial Environment Assessment Results

The CRL site is characterized by deciduous and coniferous forest and the Ottawa River. The NSDF Project is in a primarily undisturbed area adjacent to heavily disturbed areas, including the CRL site main campus and various waste management areas. The area is a mix of forested vegetation communities and wetlands (South Swamp, East Swamp, and the marsh wetlands) surrounding Perch Lake and Perch Creek. The area provides suitable habitat for numerous migratory birds, including species at risk such as the Canada warbler, eastern whip-poor-will, eastern wood-pewee, golden-winged warbler and wood thrush. Likewise, the area provides suitable habitat for several wildlife species of mammals, reptiles, amphibians and invertebrates including species at risk such as bats (little brown myotis, northern myotis and tri-colored bat), Blanding’s turtle, eastern milksnake, and monarch butterfly.

During all phases of the NSDF Project, there are some activities such as the clearing of vegetation, use of heavy equipment, and discharge of treated effluent, that – without mitigation – have the potential to affect vegetation and wetland communities and could have an effect on wildlife habitat, influencing abundance and distribution, or survival and reproduction. Activities that cause changes to other valued components, such as surface water quality, soils and vegetation communities (including wetlands), could in turn affect wildlife habitat availability and distribution, and survival and reproduction. Construction activities could also result in injury or mortality to wildlife. These effects may apply to terrestrial species at risk and their habitats as well.

Examples of mitigation practices to be implemented to limit residual effects to terrestrial biodiversity include:

- avoiding activities with highest levels of noise and habitat disturbance during the most sensitive life history phase (i.e., breeding and nesting for birds) to limit effects on nesting birds;
- a comprehensive Sustainable Forest Management Plan will be implemented at the CRL site to ensure the long-term retention of trees serving as maternity roosts for bat species; and

- Canadian Nuclear Laboratories is currently implementing a detailed Blanding's Turtle Road Mortality Mitigation Plan to eliminate road mortality at the CRL site and increase connectivity between habitats. This existing plan will continue to be implemented during the NSDF Project.

The assessment predicted residual effects to vegetation communities (including wetlands), Canada warbler, eastern whip-poor-will, eastern wood-pewee, golden-winged warbler, wood thrush, bats, Blanding's turtle, eastern milksnake and monarch butterfly. The residual effects to vegetation are due to loss of forest, change to forest distribution and edge effects. The residual effects to wildlife species primarily result from loss of suitable habitat (e.g., due to clearing), avoidance due to sensory disturbance (e.g., noise), change in movement of wildlife species, risk of injury or mortality (e.g., on roads due to traffic). With the implementation of appropriate mitigation, **residual effects of the NSDF Project on the terrestrial environment (vegetation communities and wildlife species) are not significant.**

Monitoring and follow-up programs are recommended for Canada warbler, eastern whip-poor-will, eastern wood-pewee, golden-winged warbler, wood thrush, bats, Blanding's turtle and eastern milksnake. These will be integrated into CNL's existing *Species at Risk Program* and will be used to confirm the predictions made in the terrestrial biodiversity assessment, including the effectiveness of mitigation. Monitoring will be on-going during the construction and operations phases, and closure where appropriate.

Ambient Radioactivity and Ecological Health Assessment Results

Background radiation and radioactivity is present in the environment due to natural and anthropogenic (human-made) sources which include, legacy operations at the CRL site. The main natural sources of radiation are cosmic rays; naturally occurring radionuclides in air, water and food; and naturally occurring radionuclides in the soil, rocks and building materials used in homes. Some radionuclides released from the CRL site are already present in the environment due to natural and human activities. The CRL site *Environmental Monitoring Programs* includes sampling and analysis of surface water, groundwater, sediment, soil, vegetation, ambient air, milk, garden produce, game animals, farm animals and fish at the CRL site boundary and at relevant off-site locations. Environmental concentrations are compared to expected background levels or measurements of samples to distinguish the effect of the CRL site operations from radiological contamination that is present due to other sources.

Without mitigation measures, NSDF Project activities have the potential to affect ecological health during the operations and closure phases through the release of dust when handling bulk materials, emissions of gases during storage and disposal of radioactive materials, and changes to groundwater quality and downstream surface water quality. As well, effects could result from the release of volatiles or leakage of leachate during the post-closure phase. The robust NSDF design provides containment for hundreds of years allowing for radiologic decay of the waste inventory. Once the NSDF engineered barriers degrade, after 550 years, the levels of radioactivity released to the environment is quite small.

Controls will be in place to minimize the generation of wastewater in the engineered containment mound. For example, waste will be covered as each disposal cell is filled. A WWTP has been designed to remove both radiological and chemical contaminants. Through pilot testing CNL has demonstrated that the effluent discharge targets which are protective of the public and the environment can be achieved. Furthermore, the plant is designed for batch releases, which means all treated effluent must be sampled and proven to meet targets before being discharged to the environment.

During the operations and closure phases, airborne emissions are negligible, and waterborne emissions result in environmental concentrations that are below levels that would result in potential adverse effects on aquatic life. During the post-closure phase, airborne and waterborne releases are below the dose benchmark values. Therefore, **residual effects of the NSDF Project on ambient radioactivity and ecological health are not significant.**

Monitoring air quality (i.e., dust), treated effluent, ambient radioactivity and groundwater for the NSDF Project will be integrated into CNL's existing Environmental Monitoring Program, Groundwater Monitoring Program, and Effluent Verification Monitoring Program, as well as NSDF-specific environmental monitoring activities. For example, the Effluent Verification Monitoring Program includes continuous monitoring of airborne radiological particulates from applicable operational facilities on the CRL site. These programs will verify effects predictions for ecological health and effectiveness of mitigation. Monitoring will be on-going during operations, closure and during the institutional control period as needed based on annual reviews of monitoring data.

Human Health Assessment Results

Radiation occurs naturally from cosmic and terrestrial sources as well as from man-made materials, independent of the CRL site operations. Natural background radiation can vary depending on location and within Canada the average dose from natural background radiation is 1.8 mSv in a year (mSv/yr). The Canadian regulations for radiation protection also set limits on the amount of radiation the public or nuclear energy workers may receive from licensed activities to manage nuclear substances. In Canada that public dose limit is 1 mSv/yr and the dose limit for a nuclear energy worker is 50 mSv/yr.

Access to the CRL site is restricted, however, without mitigation, there may be instances where the public may receive a dose as a result of potential waterborne or airborne emissions from the NSDF Project. Dose to the public from waterborne emissions is calculated during the operations phase, as well as during the post-closure phase for the NSDF Project. Canadian Nuclear Laboratories limits public dose through the establishment of effluent discharge targets, which are protective of the public's drinking water and based on Health Canada Drinking Water guidelines. Airborne releases of dust are controlled during operations thus mitigating airborne releases. The dose to the public during the operations phase is expected to be negligible and is almost 50 times lower than the regulatory public dose limit of 1 mSv/yr. The dose to the public during the post-closure phase was conservatively calculated using the hypothetical case of a farmer with a family living directly on the engineered containment mound who would be exposed to any potential contamination released from the facility. Under that scenario, the robust NSDF design provides containment for hundreds of years, so it will continue to isolate the waste inventory during radiologic decay. As well, the levels of radioactivity released to the environment will continue to decrease after 550 years even if the NSDF engineered barriers degrade. Even with a most disruptive event, such as unintentional intrusion, the radiological dose to a member of the public will still be at least 60 times lower than the regulatory public dose limit of 1 mSv/yr, meaning that residual effects from the NSDF Project on public health are not significant. **Therefore, residual effects from the NSDF Project on the public health are not significant.**

Radiological dose to an on-site worker will mainly occur during the operational phase as the result of carrying out tasks related to the placement of waste and activities within the WWTP, and will be kept as low as reasonably achievable. For the on-site worker, the maximum estimated dose is 5 times lower than the regulatory nuclear energy worker limit of 50 mSv/yr, thus **residual effects from the NSDF Project on worker health are not significant.**

Monitoring of airborne and waterborne emissions at the CRL site is conducted under CNL's Effluent Verification Monitoring Program, which is compliant with the CSA Group standard *N288.5-11 Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills*. Air and water quality monitoring for the NSDF Project is intended to verify that mitigation is being implemented effectively and to verify predictions for public dose. Radiation dose monitoring for nuclear energy workers will verify predictions for worker dose.

Land and Resource Use Assessment Results

The NSDF Project is located entirely within the CRL site, on federal lands. Aside from the operations and activities undertaken by CNL, other land uses of the CRL site are prohibited and public access is restricted. The NSDF Project area is bordered by the remaining CRL site to the north, east and west, the Garrison Petawawa (which is another federal land with restricted public access) to the south, and the Ottawa River to the northeast. Therefore, there are limited land and resource uses that have the potential to be disturbed by the NSDF Project. The adjacent Ottawa River is valuable for recreational and tourism-based fishing industries, and it is not expected that the NSDF Project will have any interaction with these activities as it is in a restricted area. Potential trapping has been identified in the southern and western portions of the study area outside the boundary of the CRL site.

An archaeological assessment for the NSDF Project was conducted. The areas of archaeological potential have been fully excavated and documented to the extent required under the *Standards and Guidelines for Consultant Archaeologists*. No cultural heritage value or interest remains and the locations have been fully documented; therefore, no further archaeological work is required.

Without mitigation efforts, NSDF Project activities have the potential to affect land and resource tenures and other registered interests (i.e., land use designations, mining and aggregates, forestry and agriculture), outdoor tourism and recreation (i.e., parks and protected areas, fishing, hunting, trapping and non-consumptive tourism and recreation), during the construction and operations, closure, post-closure phases as a result of change in access or opportunities for these activities. In addition, there is potential for unanticipated archaeological sites to be affected during construction. Examples of mitigation practices implemented to limit potential effects to land and resource use include:

- Canadian Nuclear Laboratories will consult with trappers about their use of the surrounding areas for trapping activities and to understand any concerns; and
- implementation of CNL's Cultural Resource Management Program to protect unexpected archaeological resources encountered during construction activities and implement adaptive management.

The NSDF Project is not predicted to have any terrestrial effects beyond the CRL site, and results of the aquatic environment assessment identified only negligible residual effects on aquatic biodiversity valued components as a result of the NSDF Project. Access along the Ottawa River will continue to occur and not be restricted because of the NSDF Project. No effect to archaeological resources is expected as most mitigation for archaeological resources are applied and completed in advance of ground disturbance activities. **The assessment concluded that no residual effects on land and resource use are anticipated as a result of the NSDF Project.**

Monitoring and follow-up programs are not specifically identified for land and resource use; however, monitoring for environmental pathways (i.e., for air quality, surface water quality and groundwater quality) will be integrated into CNL's existing Environmental Monitoring Program. The programs will be used to verify effects predictions for land and resource use, and to promote land user comfort with regard to the safety of the surrounding areas for traditional land use, outdoor tourism and recreation, and commercial (i.e., tenured) land use activities.

Monitoring will be on-going during operations, closure and post-closure (institutional control) as needed based on annual reviews of monitoring data.

Socio-economic Environment Assessment Results

The NSDF Project is located on the CRL site in Renfrew County, approximately 12 km southeast of the Town of Deep River, 9 km northwest of the Garrison Petawawa, and 7 km east of the Village of Chalk River. The two largest employers within the vicinity of the NSDF Project are Garrison Petawawa and CNL. As of May 2019, the CRL site employed approximately 2,850 people. Future economic growth and development opportunities are a key concern for communities in the area. The major arterial highway that connects the NSDF Project to the local communities and other regions of Ontario is Highway 17, which is the longest highway in Ontario. In 2010, annual average daily traffic counts found that traffic levels between the Village of Chalk River and Deep River ranged from 6,700 and 8,150 vehicles per day. A study of the existing traffic to and from the site indicated that the traffic volumes were between 700 and 800 vehicles during peak hours in the morning and afternoon. The nearest hotel or motel accommodations are available in the Town of Deep River, Petawawa and Pembroke.

Near Surface Disposal Facility Project activities have the potential to positively affect employment and income, economic development and government finances through the employment of personnel, procurement of goods and services, and expenditures. These positive residual effects to the socio-economic environment were identified, primarily from activities that occur during the construction phase, because the NSDF Project could provide employment of personnel in the region, provide contracting and supplier opportunities to local and regional businesses, and make some use of services such as commercial accommodations. Overall, the NSDF Project may result in small positive effects to local Indigenous Peoples through potential contracting or employment opportunities. Indigenous Peoples have expressed an interest in potential opportunities and CNL will continue to engage with Indigenous Peoples on potential employment and contracting opportunities for the NSDF Project. Therefore, **residual effects of the NSDF Project on the labour market, economic development, and housing and accommodation are positive**.

On the other hand, there is the potential for the NSDF Project to have certain negative socio-economic effects. It could put pressure on commercial accommodations, increase public transportation and road degradation (both on an off the campus of Chalk River Laboratories) and increase demand for community services such as health, education, protective and emergency services. For these adverse effects, with the implementation of appropriate mitigation, **residual effects of the NSDF Project on housing and accommodation, and services and infrastructure are not significant.**

Examples of mitigation practices implemented to limit predicted residual effects to socio-economic valued components include:

- Canadian Nuclear Laboratories will competitively procure material and services for the NSDF Project;
- continued implementation and maintenance of compliance with all applicable health and safety standards and CNL's existing environmental, safety and security programs; and
- coordinate transportation of construction materials during construction phase to minimize overlap with peak employee traffic times.

Monitoring for environmental pathways (i.e., for air quality, surface water quality and groundwater quality) will be integrated into CNL's existing Environmental Monitoring Program to verify effects predictions, including as they relate to predicted socio-economic effects. In addition, recognizing people's interest in understanding and participating in decisions that affect them, CNL will proactively seek, engage, and support meaningful discussion on issues and opportunities related to the NSDF Project as part of the Public Information Program. Canadian Nuclear Laboratories will continually evaluate both the process and the outcome of the on-going engagement and communication activities to address and manage issues as they arise. This will be on-going during construction, operations, closure phases, as needed based on annual reviews of monitoring data. The level and nature of engagement with the communities will depend on the feedback received.

Indigenous Interests

Indigenous interests expressed to CNL during engagement with the identified Indigenous communities or organizations with potential or established Indigenous or treaty rights in the vicinity of the NSDF Project have been considered in the environmental assessment. This includes the Algonquins of Ontario, Algonquins of Pikwaknagan First Nation, Métis Nation of Ontario, Algonquin Anishinabeg Tribal Council (AANTC) which includes Kitigan Zibi Anishinabeg and Keboawek First Nations; Williams Treaties First Nations which includes Chippewas of Beausoleil, Georgina Island and Rama First Nations and the Mississaugas of Alderville, Curve Lake, Hiawatha, Scugog Island First Nations; Anishinabek Nation; and, Mohawks of the Bay of Quinte First Nation. It should be noted that the Mohawks of the Bay of Quinte are not identified on CNL's engagement list but have provided correspondence on the NSDF Project.

The closest Indigenous community is the Algonquins of Pikwakanagan First Nation, located at Golden Lake, approximately 50 km southeast of the CRL site. The Algonquins of Pikwakanagan First Nation are part of the larger Algonquins of Ontario organization, which has reached an Agreement-In-Principle with the Governments of Ontario and Canada regarding a land claim in the Ottawa Valley, which they consider their traditional homelands. The area that is subject of the Algonquin claim in Ontario includes the National Capital Region, all of Renfrew County and most of Algonquin Park, which is a provincial park. In addition, the CRL site falls within the Métis Nation of Ontario's Ottawa River traditional harvesting territory.

Information on traditional land use activities by Indigenous Peoples has been drawn from: existing studies and reports; Indigenous community and organization websites; the Métis Nation of Ontario Traditional Knowledge and Land Use Study; the Algonquins of Ontario Algonquin Knowledge and Land Use Study; the Algonquins of Pikwakanagan First Nation Algonquin Knowledge and Land Use Study; formal and informal consultation activities; and general knowledge of the region. In the absence of specific feedback from other Indigenous communities and organizations, traditional land and resource use is assumed wherever there are accessible lands, which is a conservative approach to the assessment and also to reflect the dynamic practice of traditional land and resource use by Indigenous Peoples in time and space.

The NSDF Project is located entirely within the CRL site boundary, on federal lands. Therefore, aside from the operations and activities undertaken by CNL, other land uses of the CRL site are prohibited due to restricted public access. The NSDF Project is not predicted to have any terrestrial effects beyond the CRL site, and results of the aquatic environment assessment identify that measurable residual effects on aquatic biodiversity are not predicted as a result of the NSDF Project. Traditional access to the Pointe au Baptême and Oiseau Rock sites along the Ottawa River will continue to occur and will not be restricted because of the NSDF Project. There are no effects anticipated to archaeological resources as most mitigation for archaeological resources is applied and completed in advance of ground disturbance activities. Consequently, the **residual effects from the NSDF Project on traditional land and resources use are not significant**.

Indigenous Peoples have expressed a general concern about the potential effect of the NSDF Project on their health and a perception of risk of harvesting near the CRL site. This has partially arisen from the understanding that they have a greater degree of reliance on foods obtained from traditional land and resource use than the general public. Although these concerns are not specific to the NSDF Project, CNL acknowledges its role as providing education opportunities and undertaking communications with Indigenous Peoples to alleviate such concerns and fears. The potential dose to an Indigenous person was conservatively calculated using the hypothetical case of a self sufficient Indigenous person completely reliant on local traditional food sourced from the NSDF Project site and surrounding areas. The results indicated that the estimated radiological dose to this individual would be more than 13 times lower than the current regulatory dose limit of 1 mSv/yr., meaning that **residual effects from the NSDF Project on Indigenous health are not significant**.

Furthermore, CNL is willing to involve all Indigenous communities and organizations who have interest in the NSDF Project environmental monitoring and have shared the draft Environmental Assessment Follow-Up Monitoring Program with Indigenous communities and organizations for input. The Environmental Assessment Follow-Up Monitoring Program will not be finalized until after a regulatory decision is rendered by the Canadian Nuclear Safety Commission, thus there remains opportunity for direct involvement in its development and implementation. As well, CNL's robust environmental protection program will be used to identify protect unexpected archaeological resources encountered during construction activities and implement adaptive management.

Recognizing Indigenous Peoples interest in understanding and participating in decisions that affect them, CNL will continue to proactively seek, engage and support meaningful discussion on issues and opportunities related to the NSDF Project through Indigenous engagement activities. Where there are differences of opinion or concerns that need to be addressed, CNL is willing to explore mitigation measures and formulate commitments with Indigenous communities and organizations with the intention of trying to remove or lessen the concern. The Indigenous Engagement Report, as a living document, will include any updates related to the progress of these commitments in support of a regulatory decision for the NSDF Project.

Accidents and Malfunctions

To identify potential accident and malfunction events during the construction and operation phases, as well as their potential health and environmental effects, the NSDF Project used a systematic and comprehensive approach. Credible events were identified through a review of project activities to identify hazards, which were assigned frequency, severity and risk rankings. The bounding or key potential accidents and malfunctions during the operations of NSDF include:

- dropped load during waste placement which could result in the potential spread of contamination;
- dropped load during wastewater treatment operations (i.e., dewatering of filter press) which could result in the potential spread of contamination;
- fire within the engineered containment mound resulting in the ignition of combustible waste which could result in an airborne release;
- fire within the WWTP, such as from flammable gas, which could result in an airborne release; and
- spill of contaminated resin during the wastewater treatment operations which could result in the potential spread of contamination.

Each of these events underwent an analysis to determine the dose estimate for the on-site workers as well as the public. The assessment considered both radiological and non-radiological contaminants. The dose consequences to the on-site workers and the public for all potential accidents and malfunctions meet the respective regulatory limits thus **residual effects from accidents and malfunctions of the NSDF Project are not significant**.

Conventional occupational hazards are anticipated to be typical of a major construction project and evaluated to be controlled by human performance, thus CNL has put in place provisions including training, procedures and oversight of contractors to achieve as-low-as-reasonably possible accident and malfunction rates.

If an accident or malfunction situation occurs, CNL has procedures in place that address requirements for immediate response and post-event clean-up or remediation.

Effect of the Environment on the Project Assessment Results

In addition to assessing the potential effects of the NSDF Project on the environment, the EIS also considers how the environment could adversely affect the NSDF Project. This included an evaluation of how climate change, severe weather and other environmental events may interact with and potentially alter the condition and function of the NSDF Project, resulting in effects on the environment or public safety. Due to the recognized long timeframe of the NSDF Project as a permanent disposal facility for low-level waste, the potential magnitude and severity of future environmental events were taken into account. For example, natural hazards such as extreme weather caused by climate change, flooding, tornados, forest fires, seismic events and glaciation were all assessed.

To ensure the effects of the NSDF Project are minimized, the design basis of the NSDF accounts for expected and extreme environmental conditions of the site. Some of the events considered and the design features which mitigate against their consequences include:

- Extreme rainfall events are considered in the design of the wastewater collection and treatment systems. The storage capacity and maximum flow rate of the WWTP was based on two back-to-back, 100 year, 24-hour storm events. Within the engineered containment mound, stormwater features such as drainage, ditches, culverts and surface water management ponds have been designed appropriately for peak flows that accounted for climate change.
- Flooding of the Ottawa River as well as nearby creeks and wetlands has been taken into consideration in the siting of the NSDF Project. The base of the proposed NSDF is located approximately 163 meters above sea level which is approximately 50 meters above the current water levels of the Ottawa River. Other design features provide additional mitigation to flooding including the topographical slopes of the engineered containment mound.
- Significant seismic events and the potential for damage to the safety features are considered in the design of the engineered containment mound. The design of the engineered containment mound is robust enough to withstand significant seismic events beyond what have been recorded for the Ottawa Valley (i.e., once in 10,000 years). The use of earthen materials and specifications for waste material placement and compaction are part of the design basis of the engineered containment mound that provide the necessary structural stability. The WWTP and other infrastructure required only for the operations phase have followed current national building codes and will withstand typical seismic events for the Ottawa Valley (i.e., once in 2,475 years).

- Tornadoes are recognized as a hazard to the facilities on the CRL site, including the NSDF Project. It is acknowledged that the NSDF Project is in a geographical area that could reasonably expect a tornado strike, because of this, the design of the WWTP and other infrastructure will be robust – built to withstand potential tornadoes and high winds. The effects of a tornado or extreme winds on the engineered containment mound are expected to have negligible consequences.

Since the next predicted glaciation event may not occur until 100,000 years into the future, far beyond the hazardous lifetime of the NSDF inventory, an assessment of the consequences as the result of glaciation was not warranted. The NSDF Project incorporates design features to minimize its effect on the environment during facility operation as well as into the post-closure phase thus residual effects from the effects of the environment on the NSDF Project are not significant.

If an extreme environmental event occurs, CNL already has procedures in place for an immediate response and post-event clean-up or remediation.

Monitoring and Follow-up Programs

A conceptual follow-up and monitoring program was developed to verify that mitigations are being implemented effectively and to confirm environmental assessment predictions. This plan provides a preliminary description of the activities and framework for monitoring proposed for the NSDF Project. The details of this program will be further developed into detailed monitoring and follow-up programs as the environmental assessment process continues, with input from the public, Indigenous Peoples and regulatory agencies.

If an environmental monitoring and follow-up program identifies that adverse environmental effects are greater than predicted, then CNL will evaluate whether they result in changes to the conclusions in this EIS. If changes are confirmed, then CNL will evaluate the need for revised mitigation actions and management practices to manage effects. Canadian Nuclear Laboratories' evaluation process for monitoring data include environmental performance criteria that are based on statistical measures and ecological health benchmarks.

Conclusion

This EIS describes the NSDF Project and the existing environmental conditions on the CRL site and assesses the likely effects of the NSDF Project on the environment. The EIS also includes an assessment of likely cumulative effects of the NSDF Project in combination with other previous, existing or reasonably foreseeable developments, as required. It describes the effects for normal conditions and as a result of accidents and malfunctions. The EIS also describes and assesses the likely effects of the environment on the NSDF Project. Throughout the environmental assessment process, CNL has solicited input from the public and Indigenous Peoples and incorporated this feedback into the EIS where appropriate. Examples of this include changes to the waste inventory (i.e., only low-level waste) and expansion of the EIS study areas to include a larger downstream portion of the Ottawa River. Further, CNL is working to develop long-term relationship agreements with Indigenous Peoples to work collaboratively to meet the needs of the individual communities in the context of the NSDF Project as well as the broader operations of the CRL site into the future.

The development of a near surface disposal facility for low-level waste at the CRL site will reduce potential risks associated with AECL's legacy wastes liabilities. The NSDF Project will enable the remediation of historically contaminated lands and legacy waste management areas, as well as decommissioning of outdated infrastructure to facilitate the CRL site revitalization. The current CRL site waste management practice is to safely store radioactive waste on-site in individual facilities in accordance with current licence conditions. However, appropriate nuclear waste management includes full life cycle management from generation to disposal.

The NSDF Project will accommodate the permanent disposal of current and future low-level waste at the site. The EIS demonstrates that the NSDF Project can be constructed, operated and closed in a manner that is protective of human health and the environment.

Residual adverse effects were identified for air quality, greenhouse gases, hydrogeology, hydrology, surface water quality, terrestrial biodiversity ecological health, human health and socio-economics (housing and accommodations, and services and infrastructure). Beneficial effects were identified for socio-economics (labour market, economic development, Indigenous interests). Canadian Nuclear Laboratories has addressed key issues raised by interested Indigenous Peoples, after open and transparent communication to share information in regard to traditional land use, biodiversity and archaeology. Overall, it is CNL's conclusion that with the identified mitigation, the implementation of **the NSDF Project is not likely to result in significant residual adverse effects**.

All predicted effects for human health are well below regulatory criteria during the life of the NSDF Project, including post-closure. The maximum estimated dose during the operations period for an on-site worker is 5 times lower than the regulatory limit of 50 mSv/yr and for the public is almost 50 times lower than the regulatory dose limit of 1 mSv/yr. During post-closure, the maximum estimated dose associated with the most likely future state of the facility is more than 60 times lower than the regulatory dose limit of 1 mSv/yr. Residual effects on Ottawa River water quality are determined to be negligible during operations and post-closure phases and may result in a net benefit due to remediation of legacy waste storage areas.

Chalk River Laboratories employees live in the Ottawa Valley and use the Ottawa River as a source of drinking water and for recreation. As such, its protection is as important to us as it is to you and considerable effort has been spent on the design of the NSDF Project to ensure it is suitable to contain the proposed inventory and protect the environment. The engineered containment mound is designed to contain and isolate the wastes from the environment for 550 years. Since the NSDF only accepts low-level waste and most of the radioactivity, thus, the hazard, decays in the first 100 years after closure, the design of the NSDF is commensurate with the hazard. The safety of the NSDF during post-closure is provided by means of passive features (e.g., berm, base liner and cover systems) that will end the need for active management, in alignment with regulatory requirements and international nuclear industry guidance.

Canadian Nuclear Laboratories has a comprehensive environmental and effluent monitoring program in place which includes monitoring of the Ottawa River water quality and fish. This environmental and effluent monitoring program will be expanded to include waste water treatment plant effluent from the NSDF Project, surface water in the Perch Lake Basin, and groundwater to confirm performance of the engineered containment mound and ongoing monitoring of the Ottawa River. The details of this program will evolve into detailed monitoring and follow-up programs as the environmental assessment process continues, with input from the public, Indigenous Peoples and regulatory agencies. The facility will be a licenced nuclear facility under the *Nuclear Safety and Control Act* with regulatory oversight as long as required.

2.5.5.4 Summary 2-53

2.5.6 Leachate Management 2-55

2.5.6.1 Existing Waste Treatment Centre 2-56

2.5.6.2 Wastewater Treatment Plant (New) 2-56

2.5.6.3 No Discharge Option - Leachate Evaporation Pond 2-56
2.5.6.4 Summary 2-57
2.5.7 Effluent Discharge Options 2-57
2.5.7.1 Discharge to Ground 2-57
2.5.7.2 Discharge to Surface Water (Perch Creek, Perch Lake or the Ottawa River) 2-59
2.5.7.3 Co-discharge with the NSDF Project Stormwater System and Discharge to Ground 2-60
2.5.7.4 Discharge to Ground and Discharge to Surface Water 2-61
2.5.7.5 No Liquid Discharge (Thermal Evaporator) 2-61
2.5.7.6 Environmental Effects 2-61
2.5.7.7 Summary 2-65
2.5.8 Discharge Type 2-69
2.5.8.1 Discharge by Surface Spray onto Perch Lake 2-70
2.5.8.2 Piped Outfall to Perch Lake (Submerged Outlet in Perch Lake) 2-70
2.5.8.3 Piped Outfall to Perch Lake (Above Water Discharge) 2-71
2.5.8.4 Submerged Diffuser in Perch Lake (Alignment along Lakebed) 2-71
2.5.8.5 Submerged Diffuser in Perch Lake (Diffuser Suspended in Water Column) 2-72
2.5.8.6 Environmental 2-72
2.5.8.7 Summary 2-72
2.5.9 Final Grade of the Facility 2-74
2.5.9.1 ECM Below Existing Grade 2-75
2.5.9.2 ECM Above Existing Grade Alternative 2-75
2.5.9.3 Mid-range Grade Alternative 2-75
2.5.9.4 Summary 2-75
2.6 Conclusion 2-76
3.0 PROJECT DESCRIPTION 3-1
3.1 Introduction 3-1
3.1.1 Project Overview 3-1
3.1.1.1 Alignment of NSDF to Regulatory and International Guidelines 3-5
3.1.2 Project Schedule 3-7
3.1.3 Project Site Overview 3-8

3.1.4 Project Design Changes 3-8

3.2 Project Phases 3-9

3.2.1 Construction Phase (including Site Preparation) 3-9

3.2.1.1 Site Preparation 3-9

3.2.1.2 Construction Phase 3-13

3.2.2 Operations Phase 3-14

3.2.3 Closure Phase 3-15

3.2.4 Post-closure Phase 3-17

3.2.4.1 Maintenance 3-18

3.2.4.2 Institutional Controls 3-19

3.3 Waste Strategy 3-19

3.3.1 Waste Types, Volumes, and Inventory 3-20

3.3.1.1 NSDF Waste Types 3-23

3.3.1.2 Waste Volumes 3-23

3.3.1.3 Waste Inventory 3-24

3.3.2 Waste Approval, Verification and Acceptance 3-28

3.3.3 Waste Acceptance Criteria 3-28

3.3.3.1 Physical Characteristics 3-28

3.3.3.2 Radiological Characteristics 3-29

3.3.3.3 Chemical Characteristics 3-30

3.4 Project Components and Activities 3-30

3.4.1 Engineered Containment Mound 3-30

3.4.1.1 Containment Mound Fill Capacity 3-33

3.4.1.2 Disposal Cells 3-33

3.4.1.3 Base Contours 3-33

3.4.1.4 Base Liner System 3-36

3.4.1.5 Perimeter Berm 3-39

3.4.1.6 Transfer of Waste to ECM 3-39

3.4.1.7 Waste Placement 3-41

3.4.1.8 Temporary Storage and Stockpiling Areas 3-43

3.4.1.9 Disposal Cell Cover 3-44
3.4.1.10 Final Grading and Drainage Plan 3-51
3.4.1.11 Construction Materials 3-53
3.4.1.12 Leachate Collection and Removal 3-54
3.4.2 Wastewater Treatment 3-55
3.4.2.1 Wastewater Quantity 3-55
3.4.2.2 Wastewater Quality 3-57
3.4.2.3 Leachate and Contact Water Transfer System 3-61
3.4.2.4 Wastewater Treatment Plant and Process 3-62
3.4.2.5 Treated Effluent Discharge Concentrations 3-63
3.4.2.6 WWTP Treated Effluent Discharge Systems 3-64
3.4.3 Support Facilities 3-65
3.4.3.1 North and South Kiosks 3-66
3.4.3.2 Administration Building 3-66
3.4.3.3 Operations Support Centre 3-66
3.4.3.4 Vehicle Decontamination Facility 3-66
3.4.3.5 Site Vehicle Refueling Station 3-66
3.4.3.6 Potable Water Pump Station 3-66
3.4.4 Site Infrastructure 3-67
3.4.4.1 Access Roads 3-67
3.4.4.2 Site and Worker Parking 3-67
3.4.4.3 Site Security 3-68
3.4.4.4 Sanitary Sewage Disposal System 3-68
3.4.4.5 Surface Water Management Collection, Conveyance, Treatment and Discharge 3-68
3.4.4.6 Utilities 3-75
3.4.5 Management of Waste Generated by the Project 3-76
3.4.6 Human Resource Requirements 3-76
3.5 Application of Existing Policies, Objectives, and Programs 3-77
3.5.1 Existing Policies and Procedures 3-77
3.5.1.1 Environmental Policy 3-77
3.5.1.2 Safety Policies and Objectives 3-78

3.5.1.3 Procedure for Management and Monitoring of Emissions....3-79
3.5.2 Existing Health, Safety, Security and Environmental Programs....3-80
3.5.2.1 Radiation Protection Program....3-81
3.5.2.2 Environmental Protection Program....3-81
3.5.2.3 Waste Management Program....3-83
3.5.2.4 Occupational Safety and Health Program....3-83
3.5.2.5 Emergency Preparedness Program....3-83
3.5.2.6 Nuclear Criticality Safety Program....3-83
3.5.2.7 Physical Security Program....3-83
3.5.2.8 Nuclear Materials and Safeguards Management Compliance Program....3-84
3.5.2.9 Fire Protection Program....3-84
3.5.2.10 Quality Assurance Program....3-84
3.5.2.11 Human Performance....3-85
3.5.2.12 Transportation of Dangerous Goods....3-85
4.0 PUBLIC AND STAKEHOLDER ENGAGEMENT....4-1
4.1 Engagement Objectives....4-1
4.1.1 Evaluation....4-2
4.2 Engagement Methods and Activities....4-6
4.2.1 Presentations / Site Tours....4-7
4.2.1.1 Environmental Stewardship Council Meeting – October 2015....4-7
4.2.1.2 Environmental Stewardship Council Meeting – June 2016....4-8
4.2.1.3 World Nuclear University Site Visit – July 2016....4-8
4.2.1.4 Non-governmental Organizations Site Visit – July 2016....4-8
4.2.1.5 Organization of Canadian Nuclear Industries Suppliers' Day – September 2016....4-8
4.2.1.6 Nuclear Waste Management, Decommissioning and Environmental Restoration Conference Presentation – September 2016....4-9
4.2.1.7 Canadian Nuclear Society Site Visit – September 2016....4-9
4.2.1.8 Environmental Stewardship Council Meeting – October 2016....4-9
4.2.1.9 Near Surface Disposal Facility Industry Day – November 2016....4-9
4.2.1.10 Renfrew County Council Meeting, Presentation and Site Visit – December 2016....4-9
4.2.1.11 Local Elected Officials Meeting and Presentation – December 2016....4-10

4.2.1.12 Ottawa Valley Economic Development Meeting – December 2016 4-10
4.2.1.13 Meeting and Project Briefing with Pontiac Member of Parliament – December 2016 4-10
4.2.1.14 Technical Discussion Meeting – January 2017 4-10
4.2.1.15 Presentation and Meeting with Renfrew County Council – January 2017 4-10
4.2.1.16 Presentation to the Town of Deep River – January 2017 4-11
4.2.1.17 Presentation to the Upper Ottawa Valley Chamber of Commerce – January 2017 4-11
4.2.1.18 Presentation to the Eastern Ontario Wardens' Caucus – January 2017 4-11
4.2.1.19 Presentation to the United Counties of Prescott Russell – February 2017 4-11
4.2.1.20 Presentation to Pontiac Regional County Municipality – February 2017 4-11
4.2.1.21 Environmental Stewardship Council Meeting – March 2017 4-12
4.2.1.22 Sheenboro Municipal Council Meeting and Presentation – April 2017 4-12
4.2.1.23 Pembroke City Council Meeting and Presentation – April 2017 4-12
4.2.1.24 Laurentian Hills Town Council Meeting and Presentation – April 2017 4-12
4.2.1.25 Arnprior Town Council Meeting and Presentation – April 2017 4-12
4.2.1.26 Petawawa Town Council Meeting and Presentation – May 2017 4-12
4.2.1.27 L'Isle-Aux-Allumettes Town Council Meeting and Presentation – May 2017 4-13
4.2.1.28 Environmental Stewardship Council Meeting – June 2017 4-13
4.2.1.29 Pontiac Regional County Municipality Council Site Visit – July 2017 4-13
4.2.1.30 Old Fort Williams Cottagers' Association Meeting and Presentation – July 2017 4-13
4.2.1.31 Bloc Québécois Leader Mme Ouellette Presentation and Site Visit – August 2017 4-13
4.2.1.32 Nuclear Energy Agency Presentation and Site Visit – October 2017 4-14
4.2.1.33 Environmental Stewardship Council Meeting – October 2017 4-14
4.2.1.34 Take Our Kids to Work Day – November 2017 4-14
4.2.1.35 Ottawa Riverkeeper Presentation and Site Tour – November 2017 4-14
4.2.1.36 Near Surface Disposal Facility Technical Discussion Meeting Day 1 – December 2017 4-14
4.2.1.37 Near Surface Disposal Facility Technical Discussion Meeting Day 2 – December 2017 4-15
4.2.1.38 Meeting with Hull-Aylmer Member of Parliament Greg Fergus – February 2018 4-15
4.2.1.39 Town Hall with Hull-Aylmer Member of Parliament Greg Fergus – March 2018 4-15
4.2.1.40 Nuclear Footprints Program Presentation and Site Tour – March 2018 4-15
4.2.1.41 Member of Ontario Provincial Parliament John Yakabuski Site Visit – April 2018 4-15
4.2.1.42 Member of Parliament Will Amos Site Visit – April 2018 4-16

4.2.1.43 Environmental Stewardship Council Meeting – April 2018 4-16
4.2.1.44 Canadian Nuclear Workers Council (CNWC) Presentation – June 2018 4-16
4.2.1.45 Environmental Stewardship Council Meeting – June 2018 4-16
4.2.1.46 Eastern Ontario Water Works Association Conference – October 2018 4-16
4.2.1.47 Environmental Stewardship Council Meeting – October 2018 4-17
4.2.1.48 Carleton University Journalism Master's Students Presentation and Site Visit – November 2018 4-17
4.2.1.49 Warden Jane Toller and Pontiac Regional County Municipality Staff Presentation and Site Visit – December 2018 4-17
4.2.1.50 Renfrew and Pontiac Counties Elected Officials Information Day – February 2019 4-17
4.2.1.51 Meeting with Representatives of the Government of Quebec – February 2019 4-17
4.2.1.52 Carleton University Civil and Environmental Engineering Students Presentation and Site Tour – March 2019 4-18
4.2.1.53 Environmental Stewardship Council Meeting – March 2019 4-18
4.2.1.54 Breakfast Briefing – April 2019 4-18
4.2.1.55 Presentation to Laurentian Valley Township Council – May 2019 4-18
4.2.1.56 NSDF Effluent Discharge Alternatives Focus Group – May 2019 4-18
4.2.1.57 Hill Times Journalist Presentation and Site Visit – May 2019 4-19
4.2.1.58 Moderated Forum with City of Gatineau Councillor Duggan – May 2019 4-19
4.2.1.59 Environmental Stewardship Council Meeting – June 2019 4-19
4.2.1.60 Breakfast Briefing – June 2019 4-19
4.2.2 Webinars 4-19
4.2.2.1 Public Information Sessions 4-20
4.2.2.2 Poster Boards 4-21
4.2.2.3 Communications Materials at Public Information Sessions 4-22
4.2.3 Employee Engagement 4-23
4.2.3.1 Employee Information Sessions – June 2016 4-23
4.2.3.2 Employee Information Sessions – November 2016 4-23
4.2.3.3 Canadian Nuclear Laboratories All-Staff Meeting – March 2017 4-23
4.2.3.4 myCNL TV – Near Surface Disposal Facility – May 2018 4-23
4.2.3.5 Near Surface Disposal Facility 3-D Model – February 2019 4-23
4.2.3.6 New Employee Orientation – On-going 4-24

4.2.4 Community Events and Conferences 4-24
4.2.4.1 Rotary Club of North Renfrew – Annual Dinner – July 2016 4-24
4.2.4.2 Petawawa Showcase – September 2016 4-24
4.2.4.3 Canadian Nuclear Association Annual Conference – February 2017 4-24
4.2.4.4 Petawawa Showcase – April 2017 4-24
4.2.4.5 Canadian Nuclear Society Annual Conference – June 2017 4-24
4.2.4.6 Canadian Nuclear Laboratories Open House – August 2017 4-25
4.2.4.7 Renfrew County Plowing Match – September 2017 4-25
4.2.4.8 Canadian Nuclear Association Annual Conference – February 2018 4-25
4.2.4.9 Waste Management Symposium – March 2018 4-25
4.2.4.10 Petawawa Showcase – April 2018 4-25
4.2.4.11 CNL Downtown Connect Pembroke – May 2018 4-25
4.2.4.12 Canadian Nuclear Society Annual Conference – June 2018 4-25
4.2.4.13 Canadian Nuclear Association Annual Conference – February/March 2019 4-25
4.2.4.14 Near Surface Disposal Facility 3-D Model – February/March 2019 4-26
4.2.4.15 Near Surface Disposal Facility 3-D Model – March/April 2019 4-26
4.2.4.16 NSDF 3D Model – May 2019 4-26
4.2.4.17 Downtown Connect Pembroke – May 2019 4-26
4.2.4.18 Canadian Nuclear Society (CNS) Conference – June 2019 4-26
4.2.5 Webpage Content 4-26
4.2.6 Infographics/Fact Sheets 4-27
4.2.7 Newsletters 4-27
4.2.8 Email 4-28
4.2.9 Advertising 4-28
4.2.9.1 Advertising Methods 4-28
4.2.9.2 Public Service Announcements 4-29
4.2.9.3 Intranet – myCNL 4-29
4.2.10 Social Media 4-29
4.2.11 Media 4-30
4.2.12 Document Repository 4-30

4.2.13 Release of Documents....4-30
4.2.14 Participant Funding....4-30
4.3 Feedback....4-31
4.3.1 Informal Public Engagement Feedback....4-31
4.3.2 Formal Public Comments Feedback....4-34
4.4 Planned Future Engagements....4-37
4.5 Conclusions....4-38
5.0 ENVIRONMENTAL EFFECTS....5-1
5.1 Environmental Assessment Approach....5-1
5.1.1 Scope of the Assessment....5-2
5.1.2 Valued Components....5-3
5.1.3 Assessment Boundaries....5-15
5.1.3.1 Spatial Boundaries....5-15
5.1.3.2 Temporal Boundaries....5-16
5.1.3.3 Assessment Cases....5-17
5.1.4 Description of the Environment....5-17
5.1.5 Project Interactions and Mitigation....5-18
5.1.6 Residual Effects Analysis....5-19
5.1.6.1 Application Case....5-19
5.1.7 Prediction Confidence and Uncertainty....5-20
5.1.7.1 Reasonably Foreseeable Development Case....5-21
5.1.8 Residual Effects Classification and Determination of Significance....5-22
5.1.8.1 Residual Effects Classification....5-22
5.1.8.2 Determination of Significance....5-23
5.1.9 Monitoring and Follow-up....5-25
5.2 Atmospheric Environment....5-27
5.2.1 Air Quality....5-27
5.2.1.1 Scope of the Assessment....5-27
5.2.1.2 Valued Components....5-29

5.2.1.3 Assessment Boundaries 5-31
5.2.1.4 Description of the Environment 5-36
5.2.1.5 Project Interactions and Mitigation 5-49
5.2.1.6 Residual Effects Analysis 5-53
5.2.1.7 Prediction Confidence and Uncertainty 5-66
5.2.1.8 Residual Effects Classification and Determination of Significance 5-68
5.2.1.9 Monitoring and Follow-up 5-74
5.2.1.10 Conclusions 5-76
5.2.2 Greenhouse Gases 5-79
5.2.2.1 Scope of the Assessment 5-79
5.2.2.2 Valued Components 5-80
5.2.2.3 Assessment Boundaries 5-81
5.2.2.4 Description of the Environment 5-83
5.2.2.5 Project Interactions and Mitigation 5-84
5.2.2.6 Residual Effects Analysis 5-87
5.2.2.7 Prediction Confidence and Uncertainty 5-92
5.2.2.8 Residual Effects Classification and Determination of Significance 5-93
5.2.2.9 Monitoring and Follow-up 5-95
5.2.2.10 Conclusions 5-97
5.3 Geological and Hydrogeological Environment 5-99
5.3.1 Geology 5-99
5.3.1.1 Scope of the Assessment 5-99
5.3.1.2 Valued Components 5-100
5.3.1.3 Assessment Boundaries 5-101
5.3.1.4 Description of the Environment 5-106
5.3.1.5 Project Interactions and Mitigation 5-139
5.3.1.6 Monitoring and Follow-up 5-151
5.3.1.7 Conclusions 5-151
5.3.2 Hydrogeology 5-153
5.3.2.1 Scope of the Assessment 5-153
5.3.2.2 Valued Components 5-154

5.3.2.3 Assessment Boundaries 5-155
5.3.2.4 Description of the Environment 5-156
5.3.2.5 Project Interactions and Mitigation 5-189
5.3.2.6 Residual Effects Analysis 5-199
5.3.2.7 Prediction Confidence and Uncertainty 5-211
5.3.2.8 Monitoring and Follow-up 5-211
5.3.2.9 Conclusions 5-213
5.4 Surface Water Environment 5-219
5.4.1 Hydrology 5-219
5.4.1.1 Scope of the Assessment 5-219
5.4.1.2 Valued Components 5-220
5.4.1.3 Assessment Boundaries 5-221
5.4.1.4 Description of the Environment 5-226
5.4.1.5 Project Interactions and Mitigation 5-247
5.4.1.6 Residual Effects Analysis 5-253
5.4.1.7 Prediction Confidence and Uncertainty 5-257
5.4.1.8 Monitoring and Follow-up 5-258
5.4.1.9 Conclusions 5-259
5.4.2 Surface Water Quality 5-263
5.4.2.1 Scope of the Assessment 5-263
5.4.2.2 Valued Components 5-264
5.4.2.3 Assessment Boundaries 5-265
5.4.2.4 Description of the Environment 5-268
5.4.2.5 Project Interactions and Mitigation 5-274
5.4.2.6 Residual Effects Analysis 5-295
5.4.2.7 Prediction Confidence and Uncertainty 5-309
5.4.2.8 Monitoring and Follow-up 5-309
5.4.2.9 Conclusions 5-311
5.5 Aquatic Environment 5-315
5.5.1 Scope of the Assessment 5-315
5.5.2 Valued Components 5-316

5.5.3 Assessment Boundaries 5-319
5.5.3.1 Spatial Boundaries 5-319
5.5.3.2 Temporal Boundaries 5-323
5.5.3.3 Assessment Cases 5-323
5.5.4 Description of the Environment 5-324
5.5.4.1 Methods 5-324
5.5.4.2 Results 5-325
5.5.5 Project Interactions and Mitigation 5-339
5.5.5.1 Methods 5-339
5.5.5.2 Results 5-340
5.5.6 Monitoring and Follow-up 5-359
5.5.7 Conclusions 5-359
5.6 Terrestrial Environment 5-361
5.6.1 Scope of the Assessment 5-361
5.6.2 Valued Components 5-363
5.6.3 Assessment Boundaries 5-372
5.6.3.1 Spatial Boundaries 5-372
5.6.3.2 Temporal Boundaries 5-377
5.6.3.3 Assessment Cases 5-377
5.6.4 Description of the Environment 5-378
5.6.4.1 Vegetation Communities 5-380
5.6.4.2 Migratory Birds 5-394
5.6.4.3 Canada Warbler 5-401
5.6.4.4 Eastern Whip-poor-will 5-408
5.6.4.5 Eastern Wood-pewee 5-415
5.6.4.6 Golden-winged Warbler 5-421
5.6.4.7 Wood Thrush 5-429
5.6.4.8 Bats 5-435
5.6.4.9 Blanding’s Turtle 5-445
5.6.4.10 Eastern Milksnake 5-460

5.6.4.11 Monarch Butterfly 5-465
5.6.5 Project Interactions and Mitigation 5-473
5.6.5.1 Methods 5-473
5.6.5.2 Results 5-475
5.6.6 Residual Effects Assessment Methods 5-503
5.6.6.1 Residual Effects Analysis 5-503
5.6.6.2 Prediction Confidence 5-503
5.6.6.3 Residual Effects Classification 5-504
5.6.6.4 Determination of Significance 5-505
5.6.7 Residual Effects Assessment Results 5-507
5.6.7.1 Vegetation Communities 5-507
5.6.7.2 Canada Warbler 5-518
5.6.7.3 Eastern Whip-poor-will 5-526
5.6.7.4 Eastern Wood-pewee 5-535
5.6.7.5 Golden-winged Warbler 5-544
5.6.7.6 Wood Thrush 5-552
5.6.7.7 Bats 5-560
5.6.7.8 Blanding's Turtle 5-573
5.6.7.9 Eastern Milksnake 5-587
5.6.7.10 Monarch Butterfly 5-592
5.6.7.11 Reasonably Foreseeable Developments Case 5-601
5.6.8 Monitoring and Follow-up 5-604
5.6.9 Conclusions 5-607
5.7 Ambient Radioactivity and Ecological Health 5-613
5.7.1 Scope of the Assessment 5-613
5.7.2 Valued Components 5-615
5.7.3 Assessment Boundaries 5-621
5.7.3.1 Spatial Boundaries 5-621
5.7.3.2 Temporal Boundaries 5-625
5.7.3.3 Assessment Cases 5-625

5.7.4 Description of the Environment 5-627
5.7.4.1 Background Sources of Radiation and Radioactivity 5-627
5.7.4.2 Radioactive Releases from Chalk River Laboratories 5-630
5.7.4.3 Environmental Monitoring Program 5-636
5.7.4.4 Radioactivity in the Atmospheric Environment 5-644
5.7.4.5 Radioactivity in Surface Water 5-650
5.7.4.6 Radioactivity in Groundwater 5-655
5.7.4.7 Radioactivity in Soil and Vegetation 5-663
5.7.4.8 Radioactivity in Aquatic Sediment 5-666
5.7.4.9 Radioactivity in Fish 5-669
5.7.4.10 Radioactivity in Terrestrial Foodstuffs 5-677
5.7.5 Project Interactions and Mitigation 5-687
5.7.5.1 Methods 5-687
5.7.5.2 Results 5-688
5.7.6 Residual Effects Analysis 5-693
5.7.6.1 Radiological Dose Assessment 5-693
5.7.6.2 Non-Radiological Exposure Assessment 5-709
5.7.6.3 Application Case Results 5-713
5.7.7 Prediction Confidence and Uncertainty 5-717
5.7.8 Residual Effects Classification and Determination of Significance 5-723
5.7.9 Monitoring and Follow-up 5-724
5.7.10 Conclusions 5-725
5.8 Human Health 5-727
5.8.1 Scope of the Assessment 5-727
5.8.2 Valued Components 5-729
5.8.3 Assessment Boundaries 5-730
5.8.3.1 Spatial Boundaries 5-730
5.8.3.2 Temporal Boundaries 5-733
5.8.3.3 Assessment Cases 5-733
5.8.4 Description of the Existing Environment 5-735

5.8.4.1 Background Sources of Radiation and Radioactivity 5-735
5.8.4.2 Radiation Dose from CRL Operations 5-737
5.8.5 Project Interactions and Mitigation 5-737
5.8.5.1 Methods 5-737
5.8.5.2 Results 5-738
5.8.6 Residual Effects Analysis 5-742
5.8.6.1 Radiological Dose Assessment 5-742
5.8.6.2 Non-radiological Exposure Assessment 5-759
5.8.7 Prediction Confidence and Uncertainty 5-766
5.8.8 Residual Effects Classification and Determination of Significance 5-769
5.8.9 Monitoring and Follow-up 5-770
5.8.10 Conclusions 5-771
5.9 Land and Resource Use 5-773
5.9.1 Scope of the Assessment 5-773
5.9.2 Valued Components 5-775
5.9.3 Assessment Boundaries 5-777
5.9.3.1 Spatial Boundaries 5-777
5.9.3.2 Temporal Boundaries 5-781
5.9.3.3 Assessment Cases 5-781
5.9.4 Description of the Environment 5-782
5.9.4.1 Land and Resource Tenures and Outdoor Recreation and Tourism 5-782
5.9.4.2 Archaeological Environment 5-793
5.9.5 Project Interactions and Mitigation 5-803
5.9.5.1 Methods 5-803
5.9.5.2 Results 5-804
5.9.6 Monitoring and Follow-up 5-809
5.9.7 Conclusions 5-810
5.10 Socio-economic Environment 5-813
5.10.1 Scope of the Assessment 5-813
5.10.2 Valued Components 5-815

5.10.3 Assessment Boundaries 5-817
5.10.3.1 Spatial Boundaries 5-817
5.10.3.2 Temporal Boundaries 5-821
5.10.3.3 Assessment Cases 5-821
5.10.4 Description of the Existing Environment 5-822
5.10.4.1 Methods 5-822
5.10.4.2 Results of Socio-community Characteristics 5-823
5.10.5 Project Interactions and Mitigation 5-840
5.10.5.1 Methods 5-840
5.10.5.2 Results 5-841
5.10.6 Residual Effects Analysis 5-850
5.10.6.1 Methods 5-850
5.10.6.2 Application Case Results 5-850
5.10.6.3 Reasonably Foreseeable Development Case Results 5-852
5.10.7 Prediction Confidence and Uncertainty 5-855
5.10.8 Residual Effects Classification and Determination of Significance 5-855
5.10.8.1 Residual Effects Classification 5-856
5.10.8.2 Determination of Significance 5-858
5.10.9 Monitoring and Follow-up 5-862
5.10.10 Conclusions 5-863
6.0 INDIGENOUS INTERESTS 6-1
6.1 Introduction 6-1
6.2 Indigenous Engagement 6-3
6.2.1 Objectives 6-3
6.2.2 Identified Indigenous Communities and Organizations 6-5
6.2.3 Engagement Methods 6-7
6.2.4 Engagement 6-9
6.2.4.1 Introduction 6-9
6.2.4.2 Algonquins of Ontario (AOO) 6-19
6.2.4.3 Algonquins of Pikwakanagan First Nation (AOPFN) 6-32

6.2.4.4 Métis Nation of Ontario (MNO) 6-47
6.2.4.5 Algonquin Anishinabeg Nation Tribal Council (AANTC) 6-55
6.2.4.6 Kitigan Zibi Anishinabeg First Nation 6-63
6.2.4.7 Kebaowek First Nation 6-69
6.2.4.8 Williams Treaties First Nations (WTFN) 6-73
6.2.4.9 Anishinabek Nation Engagement 6-107
6.2.4.10 Algonquin Nation Secretariat Engagement 6-111
6.2.4.11 Mohawks of Bay of Quinte (MBQ) 6-114
6.2.5 Continued Engagement Activities 6-118
6.2.6 Conclusion 6-119
6.3 Valued Components 6-120
6.3.1 Methods 6-120
6.3.1.1 Indigenous Engagement 6-120
6.3.1.2 Selection of Valued Components by Canadian Nuclear Laboratories 6-122
6.3.2 Results 6-122
6.4 Traditional Land and Resource Use 6-128
6.4.1 Scope of the Assessment 6-128
6.4.2 Valued Components 6-130
6.4.3 Assessment Boundaries 6-132
6.4.3.1 Spatial Boundaries 6-132
6.4.3.2 Temporal Boundaries 6-135
6.4.3.3 Assessment Cases 6-135
6.4.4 Description of the Environment 6-136
6.4.4.1 Traditional Land and Resource Use by Indigenous Peoples 6-136
6.4.5 Project Interactions and Mitigation 6-150
6.4.5.1 Methods 6-150
6.4.5.2 Results 6-151
6.4.6 Monitoring and Follow-up 6-160
6.4.7 Conclusions 6-161
6.5 Indigenous Health and Indigenous Receptor 6-162

6.6 Canadian Nuclear Laboratories' Long-term Relationship with Indigenous Peoples 6-163

7.0 ACCIDENTS AND MALFUNCTIONS 7-1

7.1 Regulatory Context 7-1

7.2 General Approach 7-2

7.2.1 Hazard Identification and Hazard Analysis 7-2

7.2.2 Screening of Hazards and Events 7-5

7.2.3 Assessment of Key Accidents and Malfunctions 7-8

7.2.3.1 Identification of Valued Components 7-8

7.3 Radiological Accidents and Malfunctions 7-8

7.3.1 Radiological Dose Acceptance Criteria for Accidents 7-8

7.3.2 Construction 7-9

7.3.2.1 Assessment of Construction Radiological Accidents and Malfunctions 7-9

7.3.3 Operations and Closure 7-9

7.3.3.1 Assessment of Key Potential Hazards and Accidents during the Operations 7-9

7.3.4 Risk Matrix of Radiological Accidents and Malfunctions 7-12

7.4 Conventional (Non-radiological) Accidents and Malfunctions 7-13

7.4.1 Construction 7-13

7.4.1.1 Assessment of Potential Conventional Accidents and Malfunctions during Construction 7-15

7.4.2 Operations and Closure 7-19

7.4.3 Assessment of Potential Conventional Accidents and Malfunctions during Operations and Closure 7-19

7.4.4 Risk Matrix of Conventional Accidents and Malfunctions 7-21

7.4.5 Mitigation for Conventional Non-radiological Hazards 7-21

7.5 Emergency Preparedness 7-22

8.0 SUMMARY OF CUMULATIVE EFFECTS 8-1

8.1 Introduction and Approach 8-1

8.2 Reasonably Foreseeable Developments 8-2

8.2.1 Ten-year Integrated Plan for Chalk River Laboratories 8-3

8.2.1.1 Small Modular Reactor 8-3

8.2.2 Nuclear Power Demonstration Closure Project 8-7
8.2.3 Garrison Petawawa....8-7
8.3 Summary of Cumulative Effects....8-7
8.3.1 Atmospheric Environment....8-7
8.3.1.1 Air Quality....8-8
8.3.1.2 Greenhouse Gas....8-9
8.3.2 Geology and Hydrogeology 8-9
8.3.3 Surface Water Environment....8-10
8.3.4 Aquatic Environment....8-12
8.3.5 Terrestrial Environment....8-13
8.3.5.1 Bats....8-14
8.3.5.2 Blanding's Turtle 8-15
8.3.6 Ambient Radioactivity and Ecological Health 8-15
8.3.7 Human Health 8-16
8.3.8 Land and Resource Use 8-17
8.3.9 Socio-economics....8-17
8.3.9.1 Labour Market and Economic Development....8-18
8.3.9.2 Service and Infrastructure....8-18
8.3.9.3 Housing and Accommodations 8-19
8.3.10 Indigenous Interests....8-20
8.3.10.1 Traditional Land and Resource Use 8-20
8.3.10.2 Socio-economics....8-20
8.3.11 Uncertainty in the Assessment 8-21
9.0 SUMMARY OF SIGNIFICANCE OF RESIDUAL EFFECTS....9-1
10.0 EFFECTS OF THE ENVIRONMENT ON THE PROJECT 10-1
10.1 Extreme Weather Events....10-1
10.1.1 Temperature Fluctuations....10-1
10.1.2 Extreme Rainfall Events, Snowmelts and Flooding....10-2
10.1.3 Heavy Snowfall 10-4

10.1.4 High Winds 10-5

10.2 Forest Fires 10-6

10.3 Seismic Events 10-7

10.4 Climate Change 10-8

10.4.1 Global Climate Change Trends 10-8

10.4.2 Current and Future Climate Change Trends 10-9

10.4.2.1 Current Climate Trends 10-9

10.4.2.2 Future Climate Conditions 10-10

10.4.3 Climate Change Effects on the NSDF Project 10-11

10.5 Glaciation 10-12

10.6 Summary of NSDF Project Design Features and Mitigation 10-13

11.0 SUMMARY OF MONITORING AND FOLLOW-UP PROGRAMS 11-1

11.1 Data Management 11-2

11.2 Adaptive Management 11-2

11.3 Engagement and Communication 11-3

1.0 INTRODUCTION

Canadian Nuclear Laboratories (CNL) is proposing the construction and operation of a Near Surface Disposal Facility (NSDF) for the disposal of solid, low-level radioactive waste (LLW) at Chalk River Laboratories (CRL) (referred to as the NSDF Project). The NSDF Project is based on the mandate of Atomic Energy of Canada Limited (AECL), a federal crown corporation, to substantially reduce the risks associated with the waste and to create conditions for the revitalization of the CRL site. CNL is a private-sector company that is contractually responsible for the management and operation of nuclear sites, facilities and assets owned by AECL.

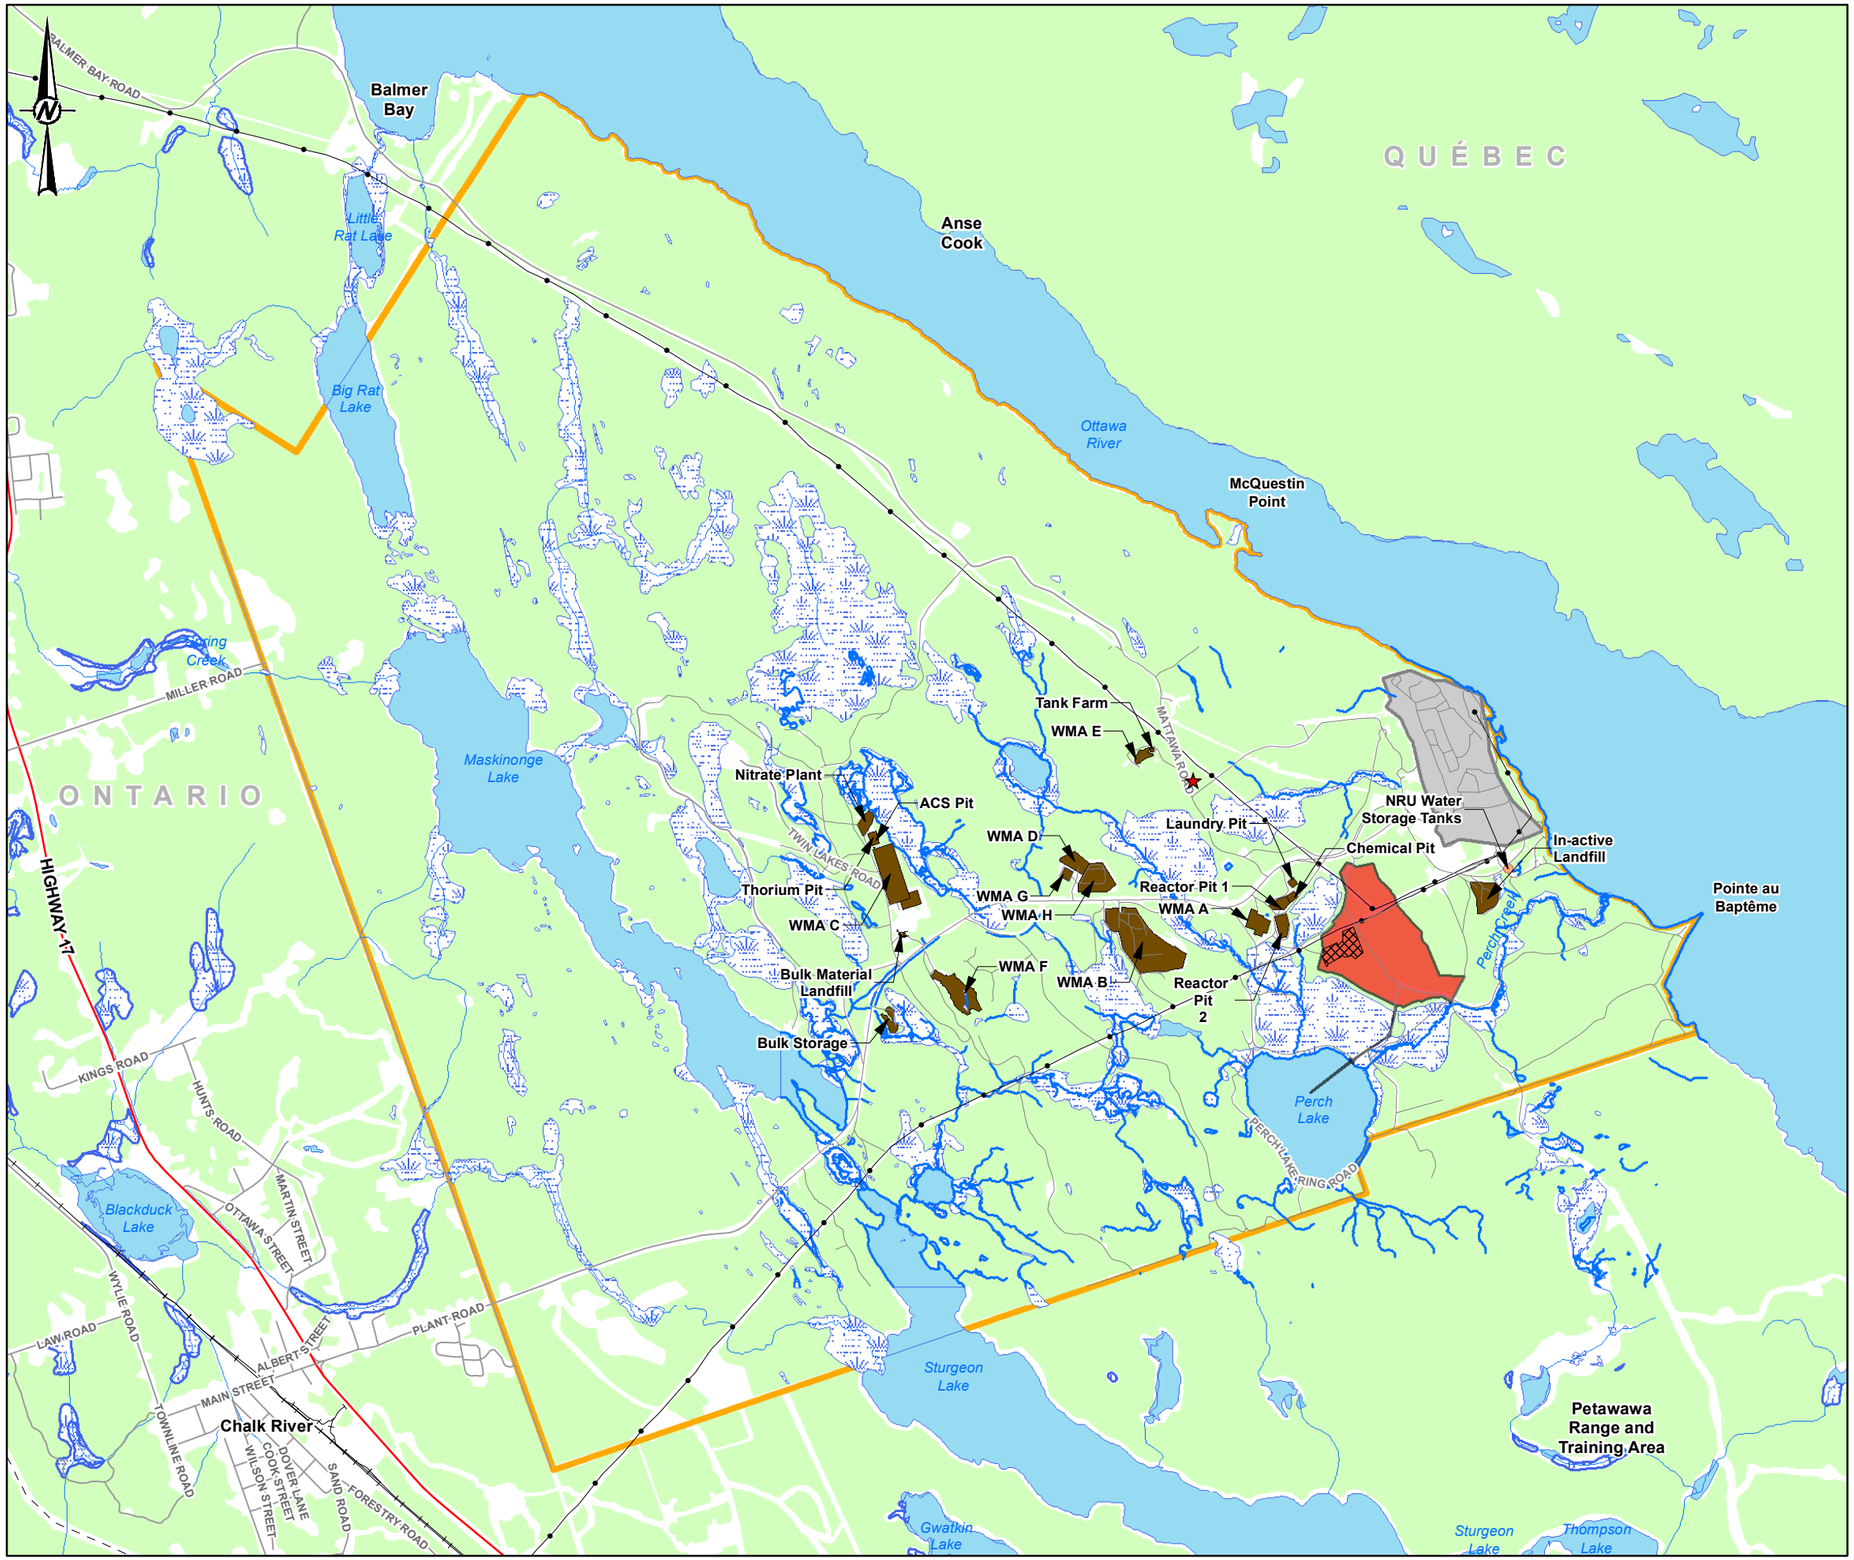
For more than 70 years, AECL (and now CNL) has been making advances in nuclear science and technology in the interest of Canadians. This includes the production of medical isotopes that have treated over one billion patients worldwide, as well as developments in clean energy which help reduce greenhouse gas emissions. Through investments in the revitalization of the CRL site, that mission and innovative science will continue into the future. However, this proud history has created nuclear liabilities in the form of waste. Furthermore, past waste management practices, which met the standards of the day, are no longer acceptable now. Specifically, the historic waste management areas lack robust containment, which has led to impacts in the surrounding environment.

Presently, wastes at the CNL sites are temporarily and safely contained in waste storage systems in accordance with current licence conditions that protect workers, the public and the environment. However, the practice of continuing to build additional temporary storage systems at the CRL site for LLW is not consistent with modern waste management principles. In accordance with *Canada's Radioactive Waste Policy Framework* (Government of Canada 2015), the waste producers and owners of radioactive waste are responsible for the funding, organization, management and operation of disposal and other facilities required for their wastes. Responsible nuclear waste management includes full life cycle management from generation to disposal.

The purpose of the NSDF Project is to provide the permanent disposal of current and future LLW at the CRL site in a manner that is protective of both the public and the environment. Further, the NSDF Project would enable the remediation of historically contaminated lands and legacy waste management areas, as well as the decommissioning of outdated infrastructure to facilitate the CRL site revitalization.

The NSDF is designed to be a permanent solution which will reduce the risk associated with temporary waste storage at the CRL site because the facility has the appropriate design life to contain and isolate the inventory until it is sufficiently decayed. The facility has been designed so that the wastes will be safely managed long-term without a need for retrieval. An overview of the CRL site, including the CRL main campus, existing waste management areas and proposed NSDF Project location is presented on Figure 1.0-1.

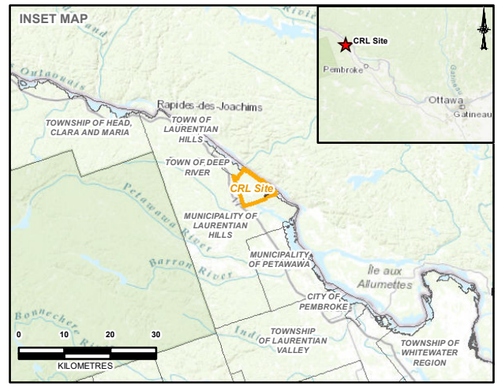
The waste to be placed in the NSDF will be LLW, which is a type of radioactive waste suitable for disposal in engineered near surface facilities that provide isolation and containment for periods of up to a few hundred years in alignment with international standards. All LLW to be disposed at the NSDF Project will be required to meet the waste acceptance criteria established to assure that it is acceptable for disposal at the NSDF to meet operational and post-closure safety requirements. This is described in detail in Section 3.3.3.



The majority of LLW proposed for the NSDF is currently located on the CRL site, with a small percentage of the waste volume coming from off-site locations (i.e., approximately 10% by volume). The sources of waste proposed for the NSDF by percentage are as follows:

- 90 percent (%) waste from CRL – past, present and future (waste owned by AECL);
- 5% from commercial waste Canadian sources such as universities and hospitals; and
- 5% waste from decommissioning at Whiteshell Laboratories in Manitoba and other AECL nuclear liabilities.

CNL, and previously AECL, has been transporting wastes safely and without incident for over 50 years. Transportation of radioactive wastes has been demonstrated to be safe and will be carried out in order to consolidate all radioactive wastes at the CRL site. CNL implements a *Transportation of Dangerous Goods Program* to ensure that all shipments are carried out in accordance with the applicable Canadian regulatory requirements and best industry practices (CNL 2019a). Continuing this program will ensure that transportation activities do not result in negative consequences to Canadians. CNL also engages with the public and Indigenous Peoples on a regular basis to explain the status of work underway to consolidate wastes at the CRL site, and how this work will reduce Canada's nuclear liability and long-term risk.



CNL is proposing to carry out the designated NSDF Project on land that is owned by AECL. As such, CNL is the proponent for the development of the NSDF Project and associated infrastructure.

A key element of the regulatory approvals process is the completion of an environmental assessment under the *Canadian Environmental Assessment Act, 2012* (CEAA 2012), the results of which are documented in this Environmental Impact Statement (EIS). This EIS describes the analysis of alternatives, process of public and Indigenous engagement, studies of baseline conditions, and assessment of project activities during the construction, operations, closure and post-closure phases of the NSDF Project.

1.1 Project Overview

The NSDF will be a waste disposal facility using an engineered containment mound (ECM) that will hold LLW waste at near-surface level on the CRL site, similar to a municipal landfill, yet with more robust measures to contain and isolate the wastes from the surrounding environment. The facility is expected to be operational for approximately 50 years and will receive up to 1,000,000 cubic metres (m3) of LLW over its operational lifetime. The placement of the wastes in the ECM will be completed in phases as follows:

- Phase 1: with a design capacity of 525,000 m^3 to accommodate wastes currently in storage and wastes to be generated over the next 20 to 25 years, to create the conditions for the revitalization of the CRL site.
- Phase 2: during which the design capacity will be expanded to 1,000,000 m^3 to accommodate wastes expected to be generated following Phase 1.

Phase 2 will allow for the inclusion of waste from future operations, decommissioning and remediation at the CRL site and off-site CNL managed facilities. Following its closure, the ECM will resemble a grassy hillside, but will not be visible from the CRL main campus or the Ottawa River.

The main physical works related to the NSDF Project are the ECM that will contain the waste, the Wastewater Treatment Plant (WWTP), operation support facilities and site infrastructure. These are briefly described below.

The ECM includes the following components.

- Base liner system, which includes a primary and secondary liner to contain the waste and to limit the potential release of contamination to the subsurface and groundwater.
- Interim cover as each disposal cell is filled, including a sacrificial temporary geomembrane to limit water requiring treatment.
- Leachate collection and leak detection system.
- Surface water management system, which will control clean surface water on-site, and prevent contact with contaminated waste.
- Final cover system (i.e., cap for the mound); which will isolate the waste, provide radiation shielding, and prevent water from entering. The waste will be covered as each disposal cell is filled.
- Environmental monitoring systems, which will monitor air, surface water and groundwater consistent with existing CRL licence requirements.

The WWTP is designed to treat leachate (i.e., precipitation water that has percolated through the ECM), contact water (i.e., precipitation surface water that has not infiltrated into the ECM, but is treated as suspect of contamination), and wastewaters arising from NSDF operations. The WWTP will use the best available technology that is economically achievable. Treated effluent will meet effluent discharge targets for the protection of the environment and human health and will be discharged to an approved discharge location or locations.

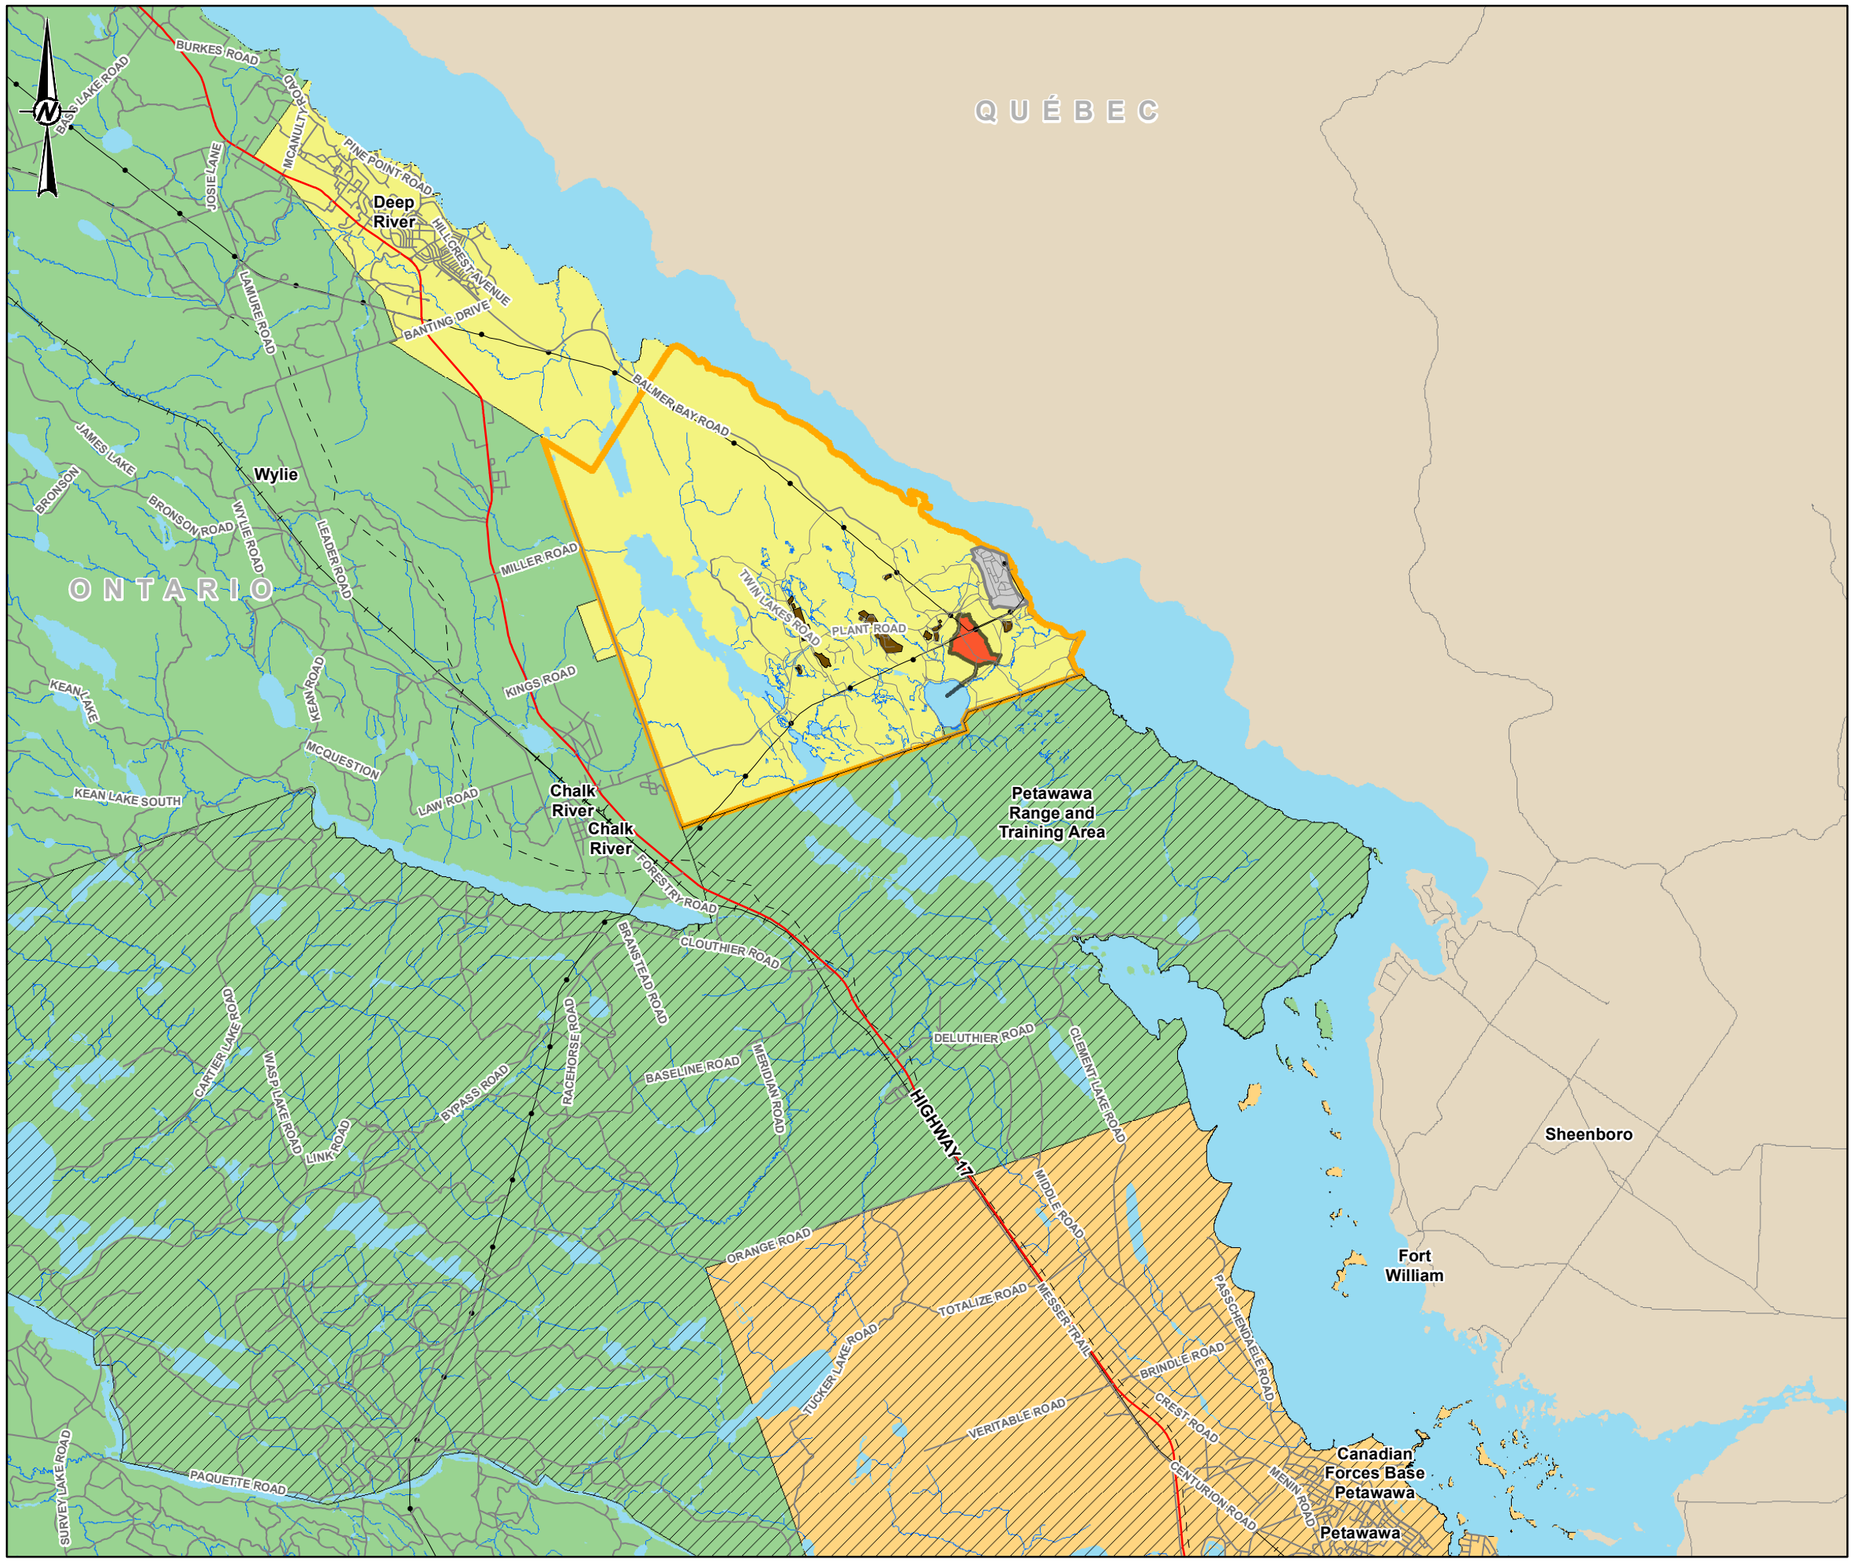
Operation support facilities include an administration building, operation support centre, vehicle decontamination facility, potable water pump station, and weighing station kiosks. Site infrastructure includes access roads, parking, site security, temporary storage areas, and utilities.

Development of the NSDF Project is planned to occur in several phases. The construction phase, which includes site preparation, is anticipated to start in 2022 or as soon as the relevant regulatory permits and approvals are in place. The operations phase is anticipated to begin in 2025 and will end in approximately 2070 (i.e., approximately 50 years). The operations phase will be completed in two phases as described above. The closure phase primarily includes activities needed to complete the installation of the final cover of the ECM, continued treatment of residual leachate and continued environmental monitoring. Closure activities are expected to start in 2070 and continue through to 2100, after which the NSDF Project will transfer into the post-closure phase. The post-closure phase is defined by two discrete periods: institutional control and post-institutional control. The institutional control period includes implementation of institutional controls throughout 2100 to 2400 (i.e., 300 years). During the institutional control period, groundwater monitoring and groundwater quality management will continue to demonstrate compliance with the environmental assessment predictions. Regulatory approval will be required to cease monitoring activities. The post-institutional control period occurs after year 2400 and continues indefinitely.

1.2 Project Location

The NSDF Project is proposed to be located entirely within the CRL site (Figure 1.0-1). The CRL site is located in Renfrew County, Ontario, adjacent to the Ottawa River. The CRL site contains several licenced nuclear facilities, waste management areas and other nuclear and non-nuclear facilities and laboratories. Two hydro lines cross the CRL site and provide electricity for CRL operations. The CRL site has a total area of approximately 4,000 hectares (ha) and is located approximately 185 kilometres (km) northwest of Ottawa, within the boundaries of the Corporation of the Town of Deep River (Figure 1.2-1). The federal Department of National Defence Garrison Petawawa borders the CRL site to the southeast, and the Village of Chalk River, in the Municipality of Laurentian Hills, is to the southwest. The Ottawa River forms the northeastern boundary of the CRL site. The approximate geographic coordinates of the NSDF Project are 46 02’ 33” N, 77 22’ 13” W.

Nearby population centres include the Village of Chalk River (7 km west of the CRL site) and the Town of Deep River (9 km northwest of the CRL site). Surrounding these communities are the Townships of Rolph, Buchanan, Wylie and McKay, which with Chalk River, form the Municipality of Laurentian Hills. The Town of Deep River has approximately 4,100 residents and the Municipality of Laurentian Hills has approximately 2,800. The Town of Petawawa and the Garrison Petawawa, totalling about 17,200 residents, are located 20 km and 17 km southeast of the CRL site. The other main population centre in the region is the City of Pembroke, with about 15,940 residents, is 34 km southeast of the CRL site. The portion of the Pontiac Regional County Municipality in the Province of Quebec that lies on the opposite side of the Ottawa River (i.e., the north side) is normally uninhabited, except during the summer months when a few cottage dwellers may be present (CNL 2015). The closest permanent residents in the Pontiac Regional County Municipality are located 3 km southeast of the CRL site, in the Harrington Bay area. The closest community on the Quebec side of the Ottawa River is the Municipality of Sheenboro, approximately 16 km downstream.



The closest Indigenous community is the Algonquins of Pikwakanagan, located at Golden Lake, approximately 50 km southeast of the CRL site. The Algonquins of Pikwakanagan First Nation are part of the larger Algonquins of Ontario organization, which has reached an Agreement-In-Principle with the Governments of Ontario and Canada regarding a land claim in the Ottawa Valley, which they consider their traditional homelands. The area that is subject of the Algonquin claim in Ontario includes the National Capital Region, all of Renfrew County and most of Algonquin Park, which is a provincial park (CNL 2016a). In addition, the CRL site falls within the Métis Nation of Ontario’s Ottawa River traditional harvesting territory (MNO 2004).

The Ottawa River is the dominant drainage feature in the area. The CRL site contains several small drainage basins that drain directly to the Ottawa River or to smaller on-site lakes and streams, which in turn drain to the Ottawa River. The CRL site is located in the Allumette Lake and Lac Coulonge reach of the Ottawa River, between La Passe and the Des-Joachims Dam. The distance from the NSDF Project site to the closest point on the Ottawa River is approximately 1.1 km. Perch Lake is located southwest of the NSDF Project site (Figure 1.0-1).

The CRL site supports a diverse mix of upland and wetland habitats. Vegetation includes deciduous and coniferous forest and a wide variety of plant species. In the western region of the NSDF Project site, approximately 2.6 ha of land is occupied by a Petawawa Research Forest Plantation. The plantation was established in 1956 to determine frost and White Pine weevil resistance in Norway spruce. The Petawawa Research Forest has confirmed it no longer has interest in this plantation. The south and west boundaries of the NSDF Project site are adjoining the Perch Lake wetland complex (Figure 1.0-1).

Aside from the operations and activities undertaken by CNL, other land uses of the CRL site are prohibited due to restricted public access (CNL 2018). No hunting or fishing is permitted on the CRL site. The CRL site is not used for traditional purposes by Indigenous Peoples (CNL 2018). Land use in the region consists primarily of forestry, recreation and tourism, with limited agriculture, trapping and mining (CNL 2018). The nearest area of considerable agriculture and dairy farming is 15 km southeast on the Quebec side of the Ottawa River and 35 km southeast on the Ontario side (CNL 2018). The Ottawa River is an important recreational resource for swimming, sport fishing and boating; there is little commercial fishing opportunity. There are several sand beaches along both sides of the river that provide popular recreational sites. In addition, two provincial parks, Algonquin and Driftwood, are located to the west of the CRL site and offer opportunities for canoeing, hiking, fishing and hunting. Winter recreational activities in the region include cross-country skiing, snowmobiling and ice-fishing.

1.3 Proponent

CNL is the proponent for the NSDF Project, on land owned by AECL (i.e., located on federal property). AECL is responsible for the long-term management of the lands including the CRL site. AECL is responsible for managing its radioactive waste and decommissioning responsibilities at its sites for which the Government of Canada has accepted responsibility, and AECL has contracted CNL to manage the licenced sites and nuclear activities.

1.3.1 Corporate Purpose

CNL is Canada's leading nuclear science and technology organization and a world leader in developing innovative applications from nuclear technology. Services offered through CNL include research and development, design and engineering of specialized technology, waste management, environmental remediation and decommissioning. CNL is committed to ensuring that Canadians and the world receive energy, health and environmental benefits from nuclear science and technology with confidence that nuclear safety and security are assured. CNL works to deliver safety, execution and innovation in all work activities, and provide the highest performance in meeting the commitments expected of them by regulators, customers, stakeholders and the public.

AECL is a federal Crown corporation, with a mandate to manage the Government of Canada's radioactive waste and decommissioning responsibilities and enable nuclear science and technology. It fulfils this mandate through a long-term contractual arrangement with CNL and its parent companies for the management and operation of AECL's sites, facilities and assets, and the performance of AECL's waste and decommissioning responsibilities under a Government-owned, Contractor-operated ("GoCo") model.

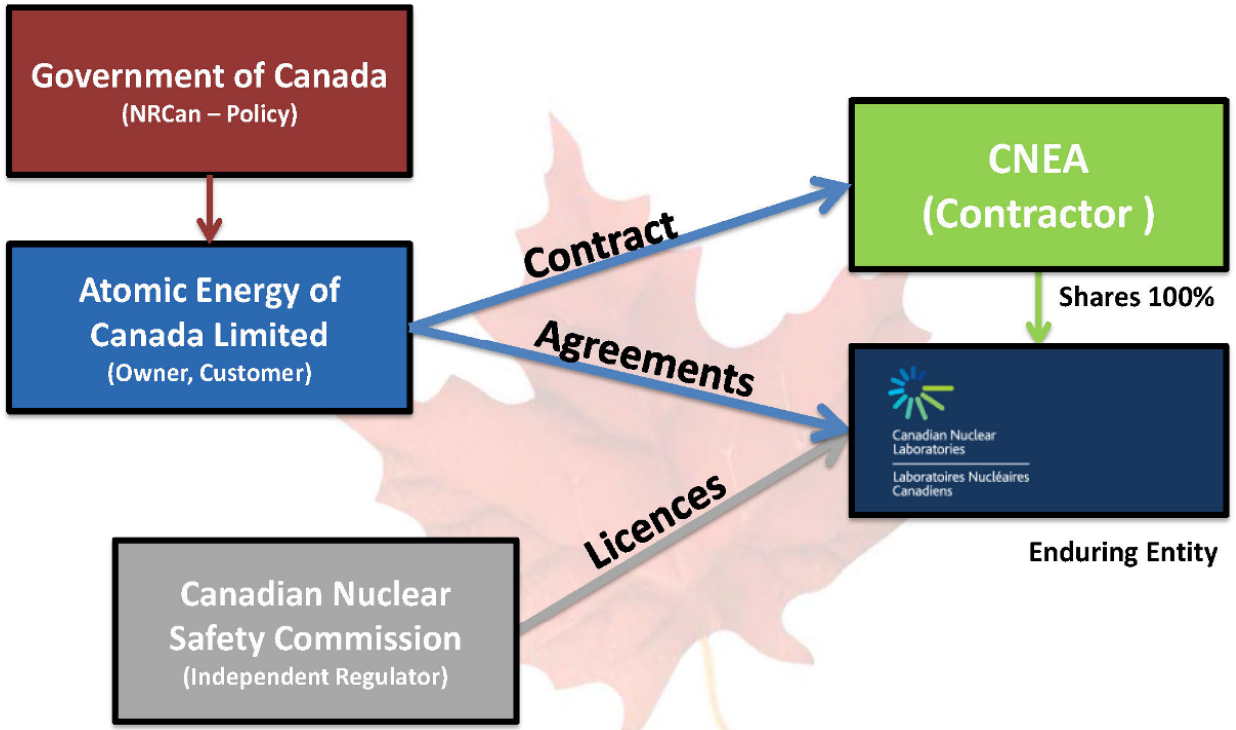
1.3.2 Management Structure

In 2014, as part of an overall government restructuring of AECL, the formation of Canadian Nuclear Laboratories was launched. AECL had maintained and operated the CRL site, as well as other government owned sites (e.g., Whiteshell, Nuclear Power Demonstration, Port Hope Area Initiative) for much of the long history of CRL (60 years). In 2015, Canadian Nuclear Energy Alliance, a consortium of nuclear engineering and management firms, was announced as the preferred bidder to take over management and operation of CNL, including the CRL site. In 2016, the majority of the workforce and management systems that were in place as AECL were transferred to CNL as it took over management and operations of the CRL site, and other government owned sites. As such, CNL is a private-sector entity, while AECL, as a government Crown Corporation, oversees the performance of CNL.

This model is a "Government-Owned Contractor-Operated" (GoCo) model under agreement with AECL, who retains ownership of the CRL site and associated liabilities on behalf of the Government of Canada. The GoCo model is shown on Figure 1.3-1.

As discussed in Section 1.3, CNL is the licensee and the proponent for this Project.

CNL is led by an Executive Team and a Board of Directors. The President and Chief Executive Officer, along with a Chief Operating Officer and five Vice Presidents, are responsible for different aspects of the business. An organizational chart outlining CNL's internal structure relevant to the NSDF Project is provided on Figure 1.3-2. A full listing of CNL's Board of Directors and Executive Team can be found online at www.cnl.ca. Three Vice Presidents are directly associated with the execution of the NSDF Project.



The Vice President, Environmental Remediation Management, has overall responsibility for the development of the NSDF Project. The Vice President has delegated the responsibility for NSDF Project completion to the NSDF Project Director.

The Vice President, Operations and Chief Nuclear Officer, is also the CRL Site Licence Holder and is responsible for the safe and compliant operation of the facility after it is turned over to operations. The Vice President, Operations and Chief Nuclear Officer, will delegate the responsibility for safe operation of the proposed facility to the NSDF Facility Authority. The Vice President, Operations and Chief Nuclear Officer has also delegated the overall responsibility for compliance programs to the Health, Safety, Security and Environment & Quality Director, such as Radiation Protection, Environmental Protection, Occupational Health and Safety, and Emergency Preparedness. The NSDF Project has been designed and will be operated in accordance with compliance program requirements.

The Vice President, Business Management and Chief Financial Officer has delegated to Corporate Affairs and Corporate Communications the overall responsibility for the facilitation of engagement activities with public and Indigenous Peoples to support the NSDF Project development. The Director of Corporate Communications is also responsible for the public relations activities for the CRL site.

1.3.3 Key Contact Information

The primary contact for the purposes of this EIS is:

Mr. Pat Quinn
Director, Corporate Communications
Canadian Nuclear Laboratories
Chalk River Laboratories
286 Plant Road, Building 700
Chalk River, Ontario K0J 1J0
Telephone: 613 584 8811 Extension 43417
Email: pat.quinn@cnl.ca

1.4 Regulatory Framework

1.4.1 Federal Review Process

On August 28, 2019, the *Impact Assessment Act* (IAA) came into force, repealing the CEAA 2012. The IAA contains transitional provisions for environmental assessments of designated projects commenced under CEAA 2012 and for which the CNSC is the Responsible Authority. The CNSC has informed CNL that the Environmental Assessment for the NSDF Project will continue under CEAA 2012 (CNSC 2019a). CNSC notes that as per the transition provision described in subsection 182 of the IAA: “Any environmental assessment of a designated project by the Canadian Nuclear Safety Commission or the National Energy Board commenced under the 2012 Act, in respect of which a decision statement has not been issued under section 54 of the 2012 Act before the day on which this Act comes into force, is continued under the 2012 Act as if that Act had not been repealed.” As outlined in subsection 182, given that the NSDF Project was commenced under CEAA 2012 and a decision statement has not yet been issued, it therefore will continue to be completed under its current process.

The federal environmental assessment requirements are detailed in CEAA 2012. In accordance with section 8 of CEAA 2012, a project description document is required to initiate the screening process, which the CNSC uses to determine if a federal environmental assessment is required for each “designated project”. Designated projects are listed in the *Regulations Designating Physical Activities* (Government of Canada 2012) under CEAA 2012. The *Regulations Designating Physical Activities* identify the CNSC as the Responsible Authority for projects that are regulated under the *Nuclear Safety and Control Act*. As such, the CNSC is responsible for the conduct of the environmental assessment and ensuring that the requirements of CEAA 2012 are met.

Following submission of the Project Description (CNL 2016a) for the NSDF Project in 2016, the CNSC issued a Notice of Commencement and determined that the NSDF Project requires a federal environmental assessment pursuant to CEAA 2012.

Federal permits, licences and authorizations that may be required for the NSDF Project include the following:

- Environment and Climate Change Canada:
  - A permit from Environment and Climate Change Canada will be required under the *Species at Risk Act* (SARA) (section 73 of the Act). It is noted that the terms and conditions related to the SARA permit for the NSDF Project are being finalized in parallel to the completion of this NSDF EIS. While this EIS does include mitigation measures for the protection of Species at Risk, the terms and conditions of the finalized SARA permit will be the overarching requirements.

  - Petroleum storage tank permit(s) may be required, depending on the size of fuel tanks installed on the site.
- Fisheries and Oceans Canada: a project review will be required for the discharge of treated effluent to Perch Lake.
- Natural Resources Canada: a licence under the *Explosives Act* may be required if explosives are to be stored at the CRL site.

The NSDF Project is located on federal lands and is regulated under the CNSC, therefore, it is anticipated that provincial permits, licences or other authorizations are not required.

1.4.2 Relevant Standards, Codes and Guidelines

It is critical that the environmental assessment be conducted in accordance with relevant standards and codes, while also taking into consideration appropriate guidelines. The environmental assessment and this EIS document were completed in a manner consistent with directions outlined in the following documents.

Canadian Environmental Assessment Act, 2012

- *Canadian Environmental Assessment Act, 2012. S.C. 2012, c. 19, s. 52*
- *Generic Guidelines for the Preparation of an Environmental Impact Statement pursuant to the Canadian Environmental Assessment Act, 2012 (CNSC 2016)*
- *Operational Policy Statement: Assessing Cumulative Environmental Effects under the Canadian Environmental Assessment Act, 2012 (The Agency 2015a)*
- *Operational Policy Statement: Addressing the "Purpose of" and "Alternative Means" under the Canadian Environmental Assessment Act, 2012 (The Agency 2015b)*
- *Operational Policy Statement: Determining Whether a Designated Project is Likely to Cause Significant Adverse Environmental Effects under the Canadian Environmental Assessment Act, 2012 (The Agency 2015c)*
- *Reference Guide Considering Aboriginal Traditional Knowledge in Environmental Assessments Conducted Under the Canadian Environmental Assessment Act, 2012 (The Agency 2015d)*
- *Interim Technical Guidance for Assessing Cumulative Environmental Effects under the Canadian Environmental Assessment Act, 2012 (The Agency 2018a)*
- *Interim Technical Guidance for Determining Whether a Designated Project is Likely to Cause Significant Adverse Effects under the Canadian Environmental Assessment Act, 2012 (The Agency 2018b)*

Canadian Nuclear Safety Acts and Regulations

- *Nuclear Safety and Control Act. S.C. 1997, c. 9.*
- *REGDOC-2.9.1 Environmental Protection: Environmental Principles, Assessments and Protection Measures (CNSC 2017)*
- *REGDOC-3.2.2 Public and Indigenous Engagement: Indigenous Engagement (CNSC 2019b)*

- *REGDOC-2.11.1 Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management (CNSC 2018a)*
- *REGDOC-2.4.1 Deterministic Safety Analysis (CNSC 2014)*
- *REGDOC-2.4.3 Nuclear Criticality Safety (CNSC 2018b)*

Canadian Standards Association (CSA)

- *CSA N286-12: Management System Requirements for Nuclear Facilities (CSA Group 2012a); and*
- *CSA N288.6-12: Environmental Risk Assessment at Class 1 nuclear facilities and uranium mines and mills. (CSA Group 2012b).*

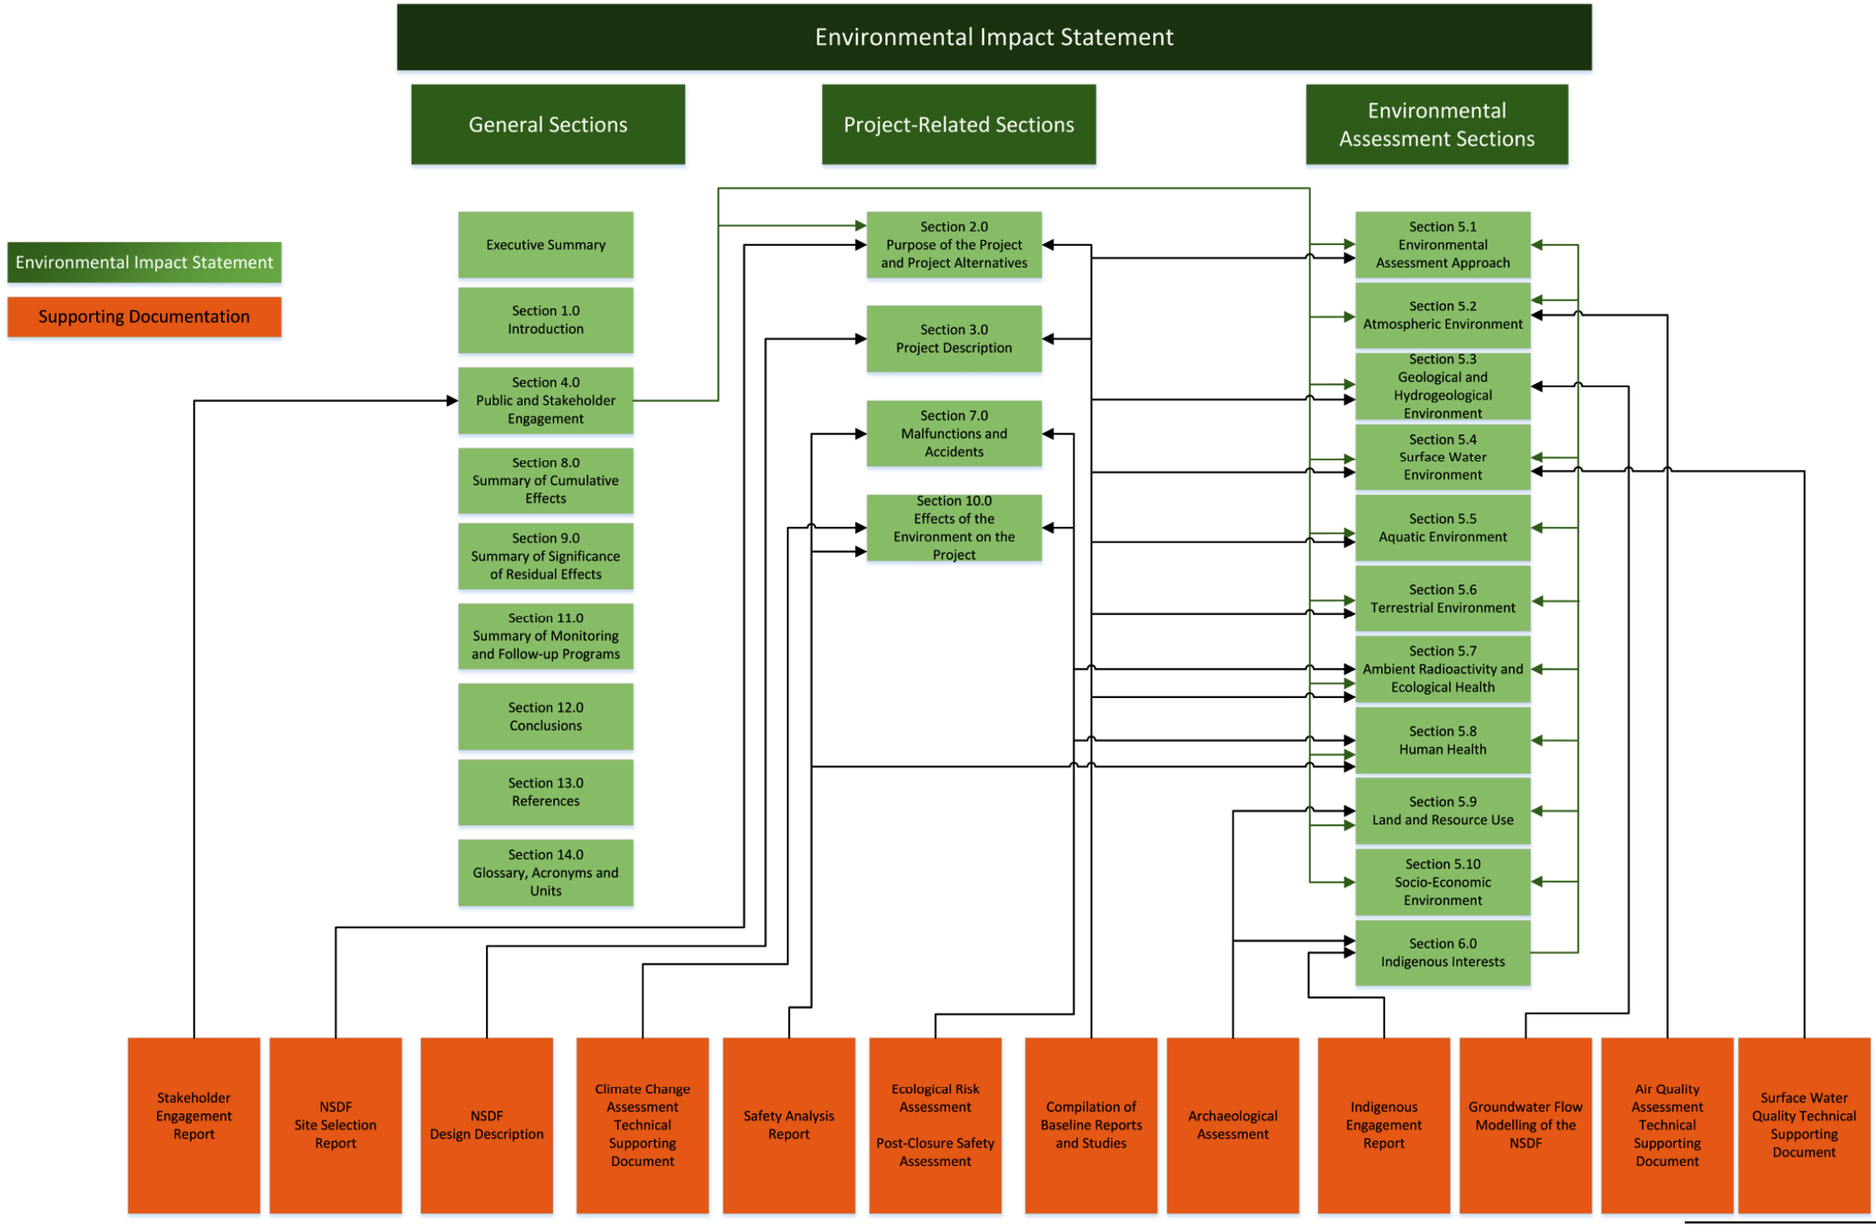
Discipline-specific standards, codes and guidelines used in the assessment of effects are identified within each discipline section (Sections 5.2 to 5.10).

A concordance table is provided in Appendix 1.0-1 to help demonstrate compliance with the *Generic Guidelines for the Preparation of an Environmental Impact Statement pursuant to the Canadian Environmental Assessment Act, 2012* (Generic EIS Guidelines) (CNSC 2016) and with *REGDOC-2.9.1 Environmental Protection: Environmental Principles, Assessments and Protection Measures* (CNSC 2017). The concordance table lists the requirements detailed in the Generic EIS Guidelines and in *REGDOC-2.9.1*, and the location of the corresponding information in the EIS.

1.5 Structure of this Document

This document is CNL's EIS for the NSDF Project. It has been prepared following the Generic EIS Guidelines (CNSC 2016). This EIS is organized into the sections described below and shown on Figure 1.5-1.

- **Executive Summary** – This section contains a description of all key components of the NSDF Project and related activities, a summary of all engagement activities, an overview of the results of the environmental assessment, and a summary of the conclusions on the residual environmental effects of the NSDF Project after considering mitigation and the significance of those residual effects.
- **Section 1.0 Introduction** – This section includes an overview of the NSDF Project and location, an introduction to CNL, an overview of the regulatory framework the NSDF Project will follow and an outline of the organization of this EIS document.
- **Section 2.0 Purpose of the Project and Project Alternatives** – This section identifies the objectives of the NSDF Project, the problems and opportunities the NSDF Project is intended to address, and the rationale for proceeding with the development. This section also considers the effects of alternative means of carrying out the NSDF Project, identifies the economically and technically feasible alternatives, and includes environmental and social considerations that were evaluated as means of implementing the NSDF Project.
- **Section 3.0 Project Description** – This section provides a description of all phases of the NSDF Project in detail to allow CNL to predict potential adverse environmental, economic, social and health effects and to address concerns from interested parties; a timeline for all phases of the NSDF Project, and a discussion of components and activities, including infrastructure that will be developed as part of the NSDF Project.



- **Section 4.0 Public and Stakeholder Engagement** – This section summarizes CNL's engagement activities, including documentation of meetings, discussion topics and outcomes, and relevant agreements that were developed.
- **Section 5.0 Environmental Effects** – This section presents the environmental assessment approach, selection of valued components, discipline-specific definitions of assessment boundaries, the NSDF Project setting and baseline characterization, results of the environmental assessment, and determination of significance of the residual effects of the NSDF Project on the environmental, economic, social, heritage and health valued components. Section 5.0 Environmental Effects comprises the following subsections:
  - Section 5.1 Environmental Assessment Approach;
  - Section 5.2 Atmospheric Environment;
  - Section 5.3 Geological and Hydrogeological Environment;
  - Section 5.4 Surface Water Environment;
  - Section 5.5 Aquatic Environment;
  - Section 5.6 Terrestrial Environment;
  - Section 5.7 Ambient Radioactivity and Ecological Health;
  - Section 5.8 Human Health;
  - Section 5.9 Land and Resource Use; and
  - Section 5.10 Socio-economic Environment.
- **Section 6.0 Indigenous Interests** – This section presents a summary of relevant issues of expressed interest to Indigenous Peoples through engagement completed to date, including traditional land and resource use, socio-economics, and valued components. This section also summarizes CNL's engagement activities with Indigenous Peoples, including documentation of meetings, discussion topics and outcomes, and relevant agreements that were developed.
- **Section 7.0 Malfunctions and Accidents** – This section presents a description of potential credible malfunctions and accidents that could be associated with the NSDF Project, the conditions under which they could occur, proposed mitigations and contingency plans.
- **Section 8.0 Summary of Cumulative Effects** – This section contains a summary of the approach to the assessment of cumulative effects, reasonably foreseeable future projects considered in the assessment, and the environmental, economic, social and health effects predicted to occur as a result of the NSDF Project that cannot be avoided or mitigated through the redesign or relocation of the NSDF Project or through commitments made by CNL.
- **Section 9.0 Summary of Significance of Residual Effects** – This section contains a summary of significance of residual environmental, economic, social and health effects predicted to occur as a result of the NSDF Project that cannot be avoided or mitigated through the redesign or relocation of the NSDF Project or through commitments made by CNL. It also presents the high-level conclusion of the evaluation of significance for residual effects as a result of the NSDF Project effects and cumulative effects.

- **Section 10.0 Effects of the Environment on the Project** – This section contains the assessment of effects of the environment on the NSDF Project including the likelihood and severity of the changes or effects and mitigation planned to avoid or limit the changes or effects. The assessment also includes consideration of effects from climate change.
- **Section 11.0 Summary of Monitoring and Follow-up Programs** – This section presents an overview of the follow-up monitoring plans and commitments made for the NSDF Project.
- **Section 12.0 Conclusions** – This section includes a summary of the findings of the effects assessment, the residual effects predicted to occur because of the NSDF Project including cumulative effects, the significance of the residual effects of the NSDF Project, and an overall conclusion for the EIS.
- **Section 13.0 References** – This section includes the references cited throughout the EIS.
- **Section 14.0 Glossary, Acronyms and Units** – This section includes a compilation of key terms and definitions, acronyms and units used in this EIS document.

Figure 1.5-1 shows the EIS sections in green and key technical support documents in orange. Key technical support documents are:

- *NSDF Site Selection Report* (CNL 2016b) for Section 2.0 of the EIS (Purpose of the Project and Project Alternatives).
- *Design Description* (AECOM 2019) for Section 3.0 of the EIS (Project Description).
- *Stakeholder Engagement Report* (CNL 2017a, 2017b, 2019b) for Section 4.0 of the EIS (Public and Stakeholder Engagement).
- *Indigenous Engagement Report* (CNL 2021) for Section 6.0 of the EIS (Indigenous Interests).
- *Air Quality Assessment Technical Supporting Document* (Golder 2019a) for Section 5.2 Atmospheric Environment
- *Groundwater Flow Modelling of the NSDF* (Golder 2019b) for Section 5.3 (Geological and Hydrogeological Environment).
- *Surface Water Quality Technical Supporting Document* (Golder 2019c) for Section 5.4 (Surface Water Environment).
- *NSDF Safety Analysis Report* (CNL 2020) for Section 5.8 (Human Health), Section 7.0 (Malfunctions and Accidents) and Section 10.0 (Effects of the Environment on the Project).
- *Post-Closure Safety Assessment* (Arcadis and Quintessa 2020b) and *Ecological Risk Assessment for the NSDF Project* (Arcadis 2020a) for Section 5.7 (Ambient Radioactivity and Ecological Health), Section 5.8 (Human Health), Section 7.0 (Malfunctions and Accidents), and Section 10.0 (Effects of the Environment on the Project).
- *Stage 4 Archaeological Assessment EMR* Site (Kinickinick Heritage Consulting and Cameron Heritage Consulting Inc. 2018) for Section 5.9 (Land and Resource Use) and Section 6.0 (Indigenous Interests).

- *Climate Change Assessment Technical Supporting Document* (Golder 2019d) for Section 10.0 (Assessment Effects of the Environment on the NSDF Project).
- *Compilation of Baseline Reports and Studies* for Section 2.0 (Purpose of the Project and Project Alternatives), Section 3.0 (Project Description), Section 5.1 (Environmental Assessment Approach), Section 5.3 (Geological and Hydrogeological Environment), Section 5.4 (Surface Water Environment), Section 5.5 (Aquatic Environment), Section 5.6 (Terrestrial Environment), Section 5.7 (Ambient Radioactivity and Ecological Health), Section 5.8 (Human Health).

2.0 PURPOSE OF THE PROJECT AND PROJECT ALTERNATIVES

2.1 Introduction

Canadian Nuclear Laboratories (CNL) is proposing the construction and operation of a Near Surface Disposal Facility (NSDF) for the disposal of up to 1,000,000 m^3 of solid, low-level radioactive waste (LLW) from legacy waste management areas (WMAs), current operations site, future environmental remediation and decommissioning projects at the Chalk River Laboratories (CRL) site and sites owned by AECL (e.g., Whiteshell Laboratories [WL]) and waste from, commercial sources such as hospitals and universities. The NSDF will provide a safe, permanent solution at the CRL site for the disposal of LLW, and will replace the current CNL practice of placing waste in interim storage. The intent of this section is to provide an overview of the existing, planned and anticipated waste disposition routes of CNL-managed radioactive wastes, describe the purpose of the NSDF Project as it relates to this overall waste disposal strategy, and to present alternative means of carrying out the proposed NSDF Project.

2.2 Canadian Nuclear Laboratories Integrated Waste Strategy

In the interest of effectively managing AECL's nuclear liabilities, CNL and AECL are working actively at strategic and operational levels to identify strategies and solutions for waste management of the entire life cycle of all waste classifications including LLW, intermediate level waste (ILW), high level waste (HLW), hazardous waste and clean (non-radiological) waste. Aligned to this, CNL has developed an Integrated Waste Strategy (CNL 2019a) that concisely details a cradle to grave approach for all CNL-managed waste classifications, from generation to disposal. The Integrated Waste Strategy is based on CNL's waste inventory and forecast data and built on the fundamental principles of waste avoidance, minimization and reuse.

This section provides a brief overview of the existing and anticipated storage and disposal routes of CNL wastes, of which the development of the NSDF Project is a key part. Table 2.2.1-1 and Figure 2.2-1 summarize this information.

Table 2.2.1-1: CNL Waste Classification and Disposal Plan

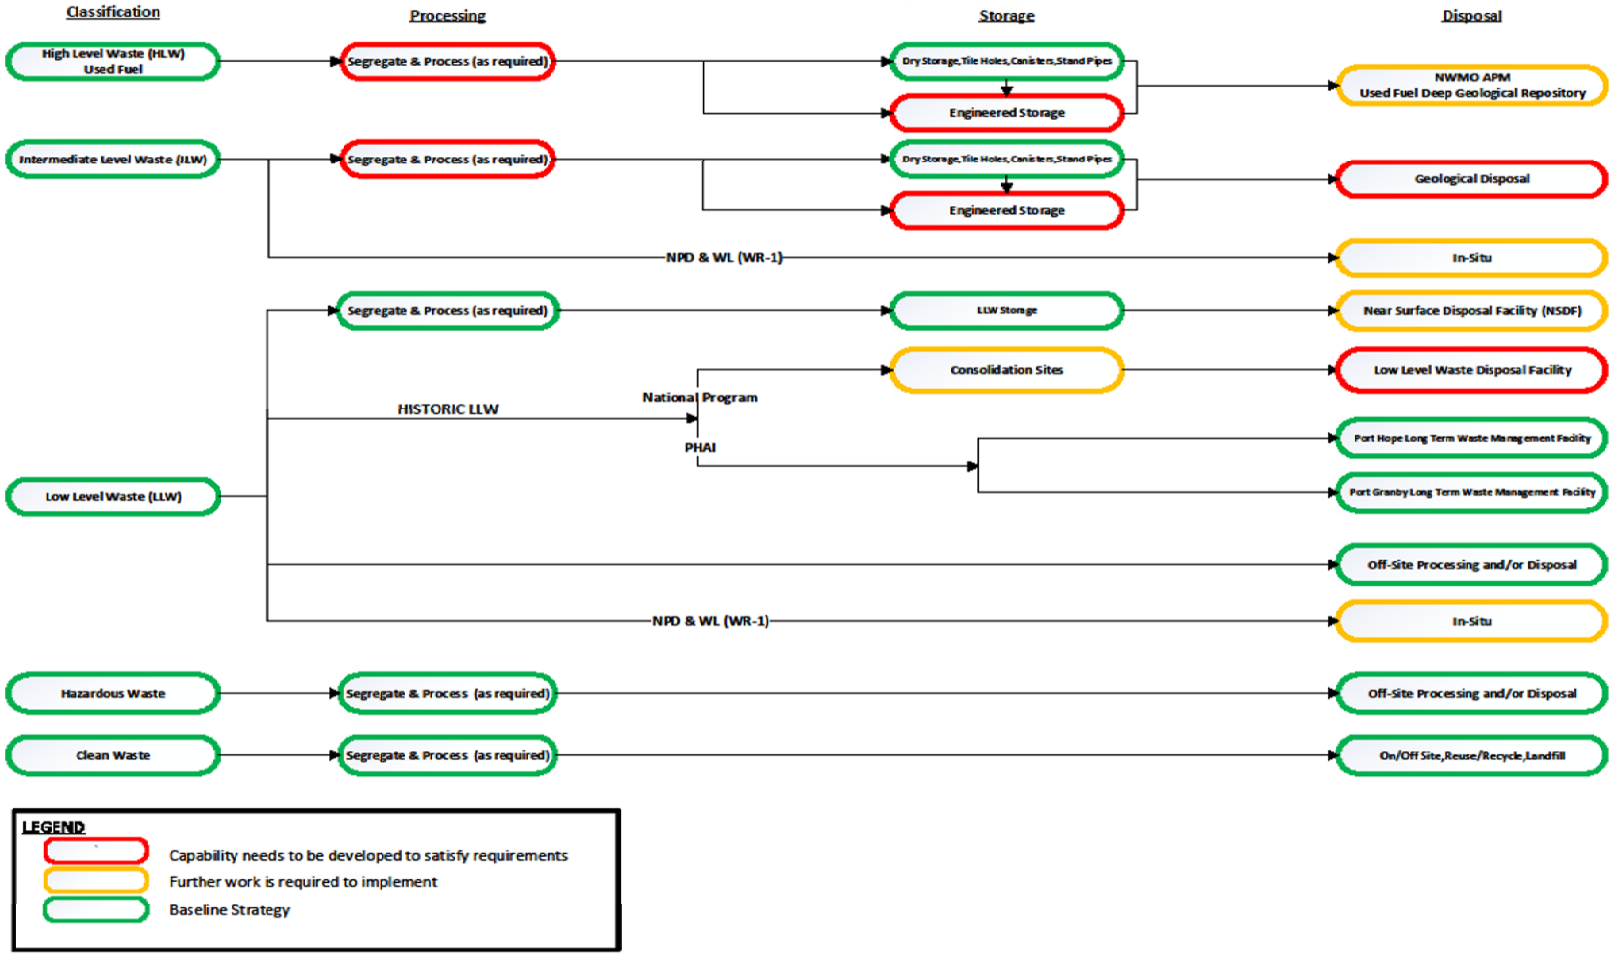
Waste Classification	Description of Waste	Planned Long-Term Waste Strategy
High Level Waste (Used Fuel)	HLW is used nuclear fuel and other wastes (e.g., fuel reprocessing wastes) that have been declared as radioactive waste that generates significant heat via radioactive decay. Used nuclear fuel is associated with penetrating radiation and contains significant quantities of long-lived radionuclides.	▪ National used fuel repository (proponent is Nuclear Waste Management Organization) consistent with the Nuclear Fuel Waste Act.
Intermediate Level Waste	ILW typically exhibits levels of penetrating radiation sufficient to require shielding during handling and interim storage and contains significant quantities of long-lived radionuclides.	▪ Interim storage at CRL until a geological disposal facility is available ▪ WL Whiteshell Reactor (WR-1) and Nuclear Power Demonstration (NPD) – in situ disposal)

Table 2.2.1-1: CNL Waste Classification and Disposal Plan

Waste Classification	Description of Waste	Planned Long-Term Waste Strategy
Low-Level Waste	▪ LLW contains material with radionuclide content above established clearance levels and exemption quantities, but generally has limited amounts of long-lived activity. LLW requires isolation and containment for up to a few hundred years. ▪ LLW does not require significant shielding during handling and transportation.	▪ NSDF ▪ In situ disposal (WL WR-1 and NPD)(a) ▪ Sewage sludge in the CRL Bulk Material Landfill ▪ Port Hope Long-Term Waste Management Facility(b) ▪ Port Granby Long-Term Waste Management Facility(b)
Hazardous Waste	Solid, liquid or gaseous waste material, other than a radioactive material, that may pose a potential hazard to human health or the environment when improperly treated, stored, transported or disposed of, or otherwise managed, and as specified in applicable regulations.	▪ Licensed commercial disposal facility
Clean (Non-radiological) Waste	Non-hazardous material that is declared to be non-radioactive by its history, location and use, or non-hazardous material that has been determined to meet regulatory requirements for unconditional clearance by means of suitable radiological monitoring.	▪ Reuse and recycling ▪ Landfill

(a) The Whiteshell Decommissioning Project is for decommissioning of the WL facility in Pinawa, Manitoba, including the proposed in situ decommissioning of WR-1. The NPD Closure Project is for the proposed in situ decommissioning of the NPD reactor in Rolphton, Ontario.

(b) The Port Hope and Port Granby long-term waste management facilities are facilities for the long-term management of wastes within the Municipality of Port Hope, Ontario, and Municipality of Clarington, Ontario, respectively.



HLW = high level waste; ILW = intermediate level waste; LLW = low-level waste; NPD = Nuclear Power Demonstration; WL = Whiteshell Laboratories.

As shown in Table 2.2.1-1 and on Figure 2.2-1, the NSDF Project provides a disposal solution for LLW that meets the NSDF Waste Acceptance Criteria (see Section 3.3.3). Any waste that does not meet the NSDF Waste Acceptance Criteria will be directed to another appropriate waste management facility. Each of the waste classifications defined in Table 2.2.1-1 are discussed further below.

Overall, LLW comprises the vast majority by volume of the radioactive waste in storage at the CNL-managed sites. In 2015, approximately 95% of the waste in storage at CNL sites by volume was LLW, 4% was ILW and less than 1% was HLW (Figure 2.2-2).

2.2.1 Waste Classification

2.2.1.1 High Level Waste (Used Fuel)

CNL's used fuel that has been declared as radioactive waste will be placed in safe, secure and suitable storage facilities until a national deep geological repository designed for used fuel becomes available. The solution is currently being developed by the Nuclear Waste Management Organization as part of its Adaptive Phased Management Plan (NWMO 2019), as per the *Nuclear Fuel Waste Act*.

2.2.1.2 Intermediate Level Waste

Historically, ILW has been stored on CNL managed sites and segregated based on handling and storage requirements. The current strategy is that ILW from all CNL managed sites will be packaged and stored at CRL until a Geological Disposal Repository is available. The exceptions to this are the Nuclear Power Demonstration (NPD) and Whiteshell Reactor 1 (WR-1) facilities which are proposed to be decommissioned in situ.

2.2.1.3 Low-Level Waste

Historically, LLW has been stored on CNL managed sites. At WL, Douglas Point and Gentilly 1 prototype reactor sites, LLW that is not being disposed in-situ will be packaged and shipped to CRL for placement in storage pending availability of the NSDF Project. The exceptions to this are the LLW arising from the NPD and WR-1 facilities, which are proposed to be decommissioned in situ. Historic LLW from the Port Hope Area Initiative (PHAI) are placed in the Long-Term Waste Management Facilities as part of the Port Hope and Port Granby projects. LLW being managed through the National Programs initiative are stored at the sites of generation pending long-term solutions.

In the event that historic LLW is identified in the PHAI after the closure of the two long-term waste management facilities (engineered containment mounds), it will be packaged to meet the NSDF WAC and sent to CRL for disposal.

2.2.1.4 Hazardous Waste

Small quantities of hazardous waste as defined by provincial and/or federal regulations (e.g., lead, polychlorinated biphenyls [PCBs]) are generated at CNL-managed sites. Hazardous waste will continue to be sent to an off-site licensed waste management service for processing and/or disposal.

2.2.1.5 Clean (Non-radiological) Waste

Clean (non-radiological) waste is disposed as it is generated. Clean waste suitable for reuse or recycling (e.g., paper, cardboard, plastics, metal and compostable waste) is sent to a commercial operator for processing. Concrete at CRL that has been confirmed as clean is processed and reused for on-site roads and backfill. For CRL and WL, the remainder of the waste goes to the on-site non-radiological landfill or off-site municipal landfills. At the prototype reactor sites, suitable clean waste will be sent to a commercial processor for reuse or recycling, with the remaining waste sent to local conventional municipal landfills.

2.2.2 Long-Term Waste Management Facilities for Chalk River Laboratories

The following strategies are in place for the long-term management of ILW and LLW at the CRL site.

2.2.2.1 Intermediate Level Waste

The current strategy for AECL's ILW (managed by CNL) is that it will be disposed in a deep geological repository although the type and location of this is not yet defined. A program of work is planned to assess the options and decide on a path forward. Future work will follow all applicable regulatory processes.

2.2.2.2 Low-Level Waste

The current strategy for AECL's LLW (managed by CNL) is that it will be disposed in the NSDF Project, which will be composed of an engineered containment mound (ECM), Wastewater Treatment Plant (WWTP), supporting facilities for NSDF Project operations, and various site infrastructure. Radioactive waste will be placed in the ECM and, as necessary, treated in advance of shipment to the NSDF Project. The NSDF Project will accept LLW that meets the waste acceptance criteria. The anticipated wastes that will be disposed in the ECM are further described in Section 3.3.

2.3 Purpose of the Project

AECL's nuclear legacy liabilities are the result of nuclear operations supported nuclear science and technology activities, including the production of medical isotopes, which have been underway for over 70 years. The majority of these liabilities are located at the CRL site and consist of shutdown nuclear facilities and radioisotope laboratories, radioactive wastes in interim storage, and contaminated lands.

A nuclear facility for the disposal of LLW is required to manage the volume of LLW arising from:

- past operations of AECL and CNL; waste dating back to the 1940s currently placed in interim storage within the CRL waste management areas which may not meet modern environmental or waste management practices;
- current and future operational activities of CNL's science and technology mission;
- decommissioning and waste management activities, including the near-term campaign to decommission and demolish more than 100 obsolete facilities/buildings and to remediate contaminated lands at the CRL site, as well as the closure of the WL; and
- commercial waste activities (e.g., waste generated by hospitals and universities).

CNL aims to have the NSDF Project operational and ready to accept waste by 2025 and the facility is expected to be operational for approximately 50 years. The ECM will be sized to hold up to up to 1,000,000 m^3 of LLW that is expected to be generated through 2070. Approximately 90% of the LLW will originate at the CRL site, with 5% of the LLW coming from decommissioning at WL in Manitoba and other AECL nuclear liabilities, and 5% from other Canadian sources, such as universities and hospitals.

Presently, wastes at the CNL sites are temporarily and safely contained in waste storage systems in accordance with current licence conditions that protect workers, the public and the environment. However, the practice of continuing to build additional temporary storage systems at the CRL site for LLW is not consistent with modern waste management principles. In accordance with *Canada's Radioactive Waste Policy Framework* (Government of Canada 2015), the waste producers and owners of radioactive waste are responsible for the funding,

organization, management and operation of disposal and other facilities required for their wastes. Responsible nuclear waste management includes full life cycle management from generation to disposal.

Since CRL site operations began, wastes produced have been managed with the evolving practices of the time. Early waste management practices included burying LLW in sand trenches with no engineered barriers. To reduce the liability associated with these historical waste management practices, the stored wastes must be retrieved and disposed of using modern engineering technology. Generally, the more significant environmental risks on the CRL site reside in and around the earliest waste management areas that were in operation as early as 1946, where wastes were buried in unlined trenches or liquids were discharged directly into infiltration pits. One of the earliest waste management areas was also used to safely manage the waste produced as a result of the National Research Experimental accident in 1952. Waste management areas are subject to monitoring and remediation is implemented, as required. Although historical contamination is localized to the CRL site, wastes stored in waste management areas are the source of surrounding soil and groundwater contamination that would be better controlled by moving these wastes to a modern engineered facility.

The remediation of contaminated lands is anticipated to generate large volumes of LLW as impacted soils and legacy waste. Currently, large-scale environmental remediation of CRL contaminated lands is deferred until the proposed NSDF is available to mitigate the need for additional storage capability.

AECL has asked CNL to find solutions for the disposal of its LLW as a means to reduce its legacy liabilities and to enable the remediation and revitalization of the CRL site. The baseline strategy for solid LLW at the CRL site, WL site (excluding WR-1), NPD and off-site prototype reactors is to segregate where practical, process as required and place in storage until the proposed NSDF becomes available (CNL 2019a). The NSDF Project will enable the remediation of historically contaminated lands and legacy waste management areas, as well as the decommissioning of outdated infrastructure to facilitate the CRL site revitalization. Remediation will involve progressively reducing the risk and liability through prudent management and cleanup of contaminated and affected sites at the CRL site.

CNL has a wealth of operating experience for LLW facilities (including the Port Hope and Port Granby Long-term Waste Management Facilities), and there is international operating experience for LLW disposal facilities. The NSDF Project has been specifically designed as a permanent solution to reduce environmental risk and achieve isolation and containment of the sources of contamination for a sufficiently long period, according to the requirements set forth in the International Atomic Energy Agency (IAEA) *Disposal of Radioactive Waste Specific Safety Requirements No. SSR-5* (SSR-5; IAEA 2011). The facility has been designed so that the wastes will be safely managed long-term without a need for retrieval. Although the intent is not to retrieve the waste, and to prevent inadvertent exposure to the public, consistent with international practices, the design of NSDF does not preclude future generations from retrieving NSDF contents.

2.4 Project Design Principles

The NSDF Project safety requirements have been captured by the NSDF Project design (AECOM 2019) and can be summarized as the following:

- The NSDF Project shall be designed and operated to ensure radiation safety is provided by multiple engineered barriers.
- The NSDF Project shall be designed to ensure safety is provided by passive means during the post-closure phase.

- The NSDF Project shall be designed, constructed, and operated so that projections of incremental doses to members of the public do not exceed 0.3 millisieverts (mSv) in a year from natural processes (i.e., all processes other than human intrusion into the waste).
- The NSDF Project shall comply with CRL site licence conditions and be licenced as a radioactive waste disposal facility.
- The NSDF Project shall comply with all CNL Management System Requirements.
- Safety classified NSDF systems must meet specified safety functions throughout their operation in order to protect radiological safety of public or facility personnel by limiting release of radioactive material and/or hazardous material, or limiting radiation exposure during and following normal, anticipated transient and accident conditions.

Any nuclear facility designed, constructed and operated at the CRL site is required to satisfy the CRL licence requirements and CNL Management Systems thus are not carried into the alternative means assessment. With respect to the first three safety requirements CNL has utilized CNSC and IAEA design principles which ensure the safety of radioactive waste long-term waste management or disposal facilities. These principles are essential elements in the design and development of a disposal facility and were used to inform the definition of evaluation criteria in Section 2.5.1. The alternative selected as the preferred or most favourable means of developing a disposal facility must meet the design principles and requirements discussed in Sections 2.4.1 and 2.4.2.

2.4.1 Canadian Nuclear Safety Commission

A primary driver for the NSDF Project is to safely and responsibly dispose of radioactive low-level as required in CNSC's *REGDOC-2.11.1 Waste Management, Volume I: Management of Radioactive Waste* (CNSC 2019, in development). CNL's current practice of interim storage of waste does not provide a cradle to grave management strategy thus pushes the burden of radioactive waste management forward in time to future generations. The NSDF Project is proposed as a responsible and safe solution for disposal of up to 1,000,000 cubic metres of LLW.

Canadian regulatory guidance for approaches to long-term safety of radioactive waste management is provided in CNSC's *REGDOC-2.11.1 Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* (CNSC 2018). The CNSC identifies the need for long-term management of radioactive waste arising from licensed activities and considers the extent to which the owner of the waste has addressed the following principles:

- The management of radioactive waste is commensurate with its radiological, chemical and biological hazard to the health and safety of persons and the environment, and to national security;
- The assessment of future impacts of radioactive waste on the health and safety of persons and the environment encompasses the period of time when the maximum impact is predicted to occur; and
- The predicted impact on the health and safety of persons and the environment from the management of radioactive waste is no greater than the impact that is permissible in Canada at the time of the regulatory decision.

The design concepts for long-term management are based on the containment and isolation of the waste, which can be achieved through a robust design based on multiple barriers providing defense in depth. Isolation is achieved through proper site selection and institutional controls to limit access and land use.

2.4.2 International Atomic Energy Agency

The safety principles to be applied in all activities for radioactive waste management are set out in the IAEA Safety Fundamentals. The IAEA's *Fundamental Safety Principles* (IAEA 2006) outline and describe 10 safety principles in terms of radiation protection in design:

1) responsibility for safety;
2) role of government;
3) leadership and management for safety;
4) justification of facilities and activities;
5) optimization of protection;
6) limitation of risks to individuals;
7) protection of present and future generations;
8) prevention of accidents;
9) emergency preparedness and response; and
10) protective actions to reduce existing or unregulated radiation risks.

The IAEA has published safety requirements relating to the disposal of radioactive waste of all types in SSR-5 (IAEA 2011). The objective of IAEA's SSR-5 is to set out the safety objectives and criteria for the disposal of all types of radioactive waste and to establish, on the basis of the IAEA's *Fundamental Safety Principles* (IAEA 2006), the requirements that must be satisfied in the disposal of radioactive waste. Design principles and concepts to ensure safety in the disposal of radioactive waste shall include:

- multiple safety functions;
- containment of radioactive waste;
- isolation of radioactive waste; and
- surveillance and control of passive safety features.

Furthermore, the disposal facility and its engineered barriers shall be designed to contain the waste with its associated hazard, to be physically and chemically compatible with the host geological formation and/or surface environment, and to provide safety features after closure that complement those features afforded by the host environment. The facility and its engineered barriers shall be designed to provide safety during the operational period.

2.5 Alternative Means for Carrying Out the Project

The *Canadian Environmental Assessment Act, 2012* (CEAA 2012), requires that federal environmental assessments evaluate alternative means of carrying out a project that are technically and economically feasible and the environmental effects of any such alternative means. The Canadian Environmental Assessment Agency identifies in its operational policy statement *Addressing "Purpose of" and "Alternative Means" under the Canadian Environmental Assessment Act, 2012* the overall approach for considering the “alternative means” of carrying out a project (The Agency 2015). “Alternative means” is defined as the “various technical and economically feasible ways under consideration by the proponent that would allow a designated project to be carried out”. In addition, environmental effects of each alternative means are also considered including biophysical, socio-economic, and public and worker health and safety. The CNSC’s *REGDOC-2.9.1 Environmental Protection: Environmental Principles, Assessments and Protection Measures* (CNSC 2017) also requires that an assessment under the CEAA 2012 considers the different alternative means for carrying out a project.

The purpose of this section is to present the alternative means of developing a disposal facility for the long-term management of 1,000,000 m^3 of LLW. The consideration of alternatives is presented for each category in three steps:

- identification of technical and economically feasible alternative means;
- identification of effects on Valued Components (VCs); and
- application of criteria and completion of a comparative evaluation to identify the preferred option.

Each alternative is assessed and the most preferable option is selected after a systematic consideration of technical feasibility, economic feasibility and environmental effects. Public engagement is a key aspect of the decision-making process. A summary of the alternative means assessment was made available to the public and Indigenous Peoples, and input received was taken into consideration for the final NSDF Project design. Topics addressed included:

- The alternative site locations for the potential NSDF Project were presented. The public requested additional information on the site selection process including “why the CRL site.” Additional information has been included in Sections 2.5.4 and 2.5.5 regarding the process used and the sites considered.
- Alternative means for NSDF’s effluent management strategy was explored as a one-day session with a focus group. Participants included stakeholders who expressed concern with respect to the NSDF Project’s effluent management strategy and specifically included members of the public, local municipalities and non-governmental organizations. The purpose of the session was to elicit stakeholder insights and evaluation of the NSDF Project’s proposed effluent management strategy. CNL solicited the participants’ evaluation of the effluent discharge options using focus group developed criteria. The discussions from the focus group session have been considered by CNL for potential improvements to the NSDF Project, and have been incorporated into discussions within Section 2.5.6 (leachate management), Section 2.5.7 (effluent discharge options) and Section 2.5.8 (discharge type).

A social acceptability criterion was also included as part of the alternative means analysis to provide weight to any concerns and preferences expressed by the public and Indigenous Peoples (Section 2.5.1).

The alternative means considered in the Environmental Impact Statement (EIS) are grouped into seven categories, as presented in Table 2.5-1. These alternatives were evaluated in the context of the NSDF Project design principles (described in Section 2.4) for the development of a permanent solution for the disposal of LLW.

Table 2.5-1: Alternative Means Evaluated for the Near Surface Disposal Facility Project

Aspect of the Disposal Facility	Alternatives Considered in the EIS
Facility Type (Near Surface vs. Deep Underground)	▪ NSDF ▪ Geologic waste management facility (GWMF)
Facility Design of Near Surface Options	▪ Engineered containment mound (ECM) ▪ Above-ground concrete vault (AGCV)
Facility Location	▪ On-site (at CRL) ▪ Off-site (WL or NPD site)
Site Selection	▪ 15 potential sites at CRL
Leachate Treatment System	▪ Existing wastewater treatment facility ▪ WWTP (new) ▪ No discharge option – leachate evaporation ponds
Effluent Discharge Options	▪ Discharge to ground ▪ Discharge to surface water (Perch Creek, Perch Lake and Ottawa River) ▪ Co-discharge with the NSDF stormwater system and discharge to ground ▪ Discharge to ground and discharge to surface water ▪ No liquid discharge (i.e., thermal evaporator)
Discharge Type	▪ Discharge by surface spray onto Perch Lake ▪ Piped outfall to Perch Lake (submerged outlet in Perch Lake) ▪ Piped outfall to Perch Lake (above-water discharge) ▪ Submerged diffuser in Perch Lake (alignment along lakebed) ▪ Submerged diffuser in Perch Lake (diffuser suspended in water column)

EIS = Environmental Impact Statement; GWMF = geologic waste management facility; WL = Whiteshell Laboratories; NPD = Nuclear Power Demonstration; WWTP = Wastewater Treatment Plant; EMR = East Mattawa Road

2.5.1 Evaluation Criteria

As defined by the Brundtland Commission in *Our Common Future: Report of the World Commission on Environment and Development* (Brundtland Commission 2013), sustainable development is “development that meets the needs of the present without compromising the ability of future generations to meet their own needs.” Sustainability is a holistic approach that considers ecological, social and economic dimensions, recognizing that all must be considered together to find lasting success. The sustainability of each alternative mean was evaluated through the use of the various criteria (which were categorized as technical feasibility, economic feasibility, or environmental), both independently and holistically. The evaluation criteria selected considered the Environmental and Social Sustainability Performance Standards developed by the International Finance Corporation (IFC 2012), including:

- management of environmental and social risks and effects;
- pollution prevention;

- community health safety, and security;
- biodiversity conservation and sustainable management of living natural resources;
- Indigenous Peoples; and
- cultural heritage.

Although not specifically identified as a separate criterion, sustainability is inherent in each of the criteria for the assessment of alternatives. Sustainability as a value is shared by many individuals and organizations who demonstrate this value in their policies, everyday activities and behaviours. For example, CNL's Environmental Policy has recently been amended to include a clear commitment to sustainability. This change supports CNL's alignment to standards set by the Government of Canada, specifically the 2016 to 2019 Federal Sustainable Development Strategy (Government of Canada 2016).

To determine the preferred or most favourable means of developing a disposal facility, each alternative is evaluated first for its technical feasibility. For those alternatives deemed technically feasible, a comparison of economic feasibility (i.e., cost) and the likely environmental effects is completed. Criteria for evaluating each of the alternatives are summarized in Table 2.5.1-1, with further rationale provided in the following sections.

Table 2.5.1-1: Criteria For Evaluating Alternatives

Category		Criteria
Technical Feasibility		▪ Does the alternative meet the project purpose, as defined in Section 2.3? ▪ Does the alternative meet the required storage capacity? ▪ Is the alternative an example of best available technology? ▪ Does the design incorporate compatible construction materials for the radioactive wastes planned for disposal to provide sufficient design robustness to protect the environment? ▪ What is the complexity of monitoring requirements for the alternative?
Economic Feasibility		▪ How does the life cycle cost of each alternative compare in relation to each other?
Environmental Effects	Biophysical	▪ Environmental setting - does the alternative result in new disturbance (i.e., Greenfield site) or is it located within a previously disturbed area (i.e., brownfield site)? ▪ How do the likely effects on biophysical VCs compare (e.g., atmospheric environment, aquatic biodiversity, and terrestrial biodiversity)? ▪ Can it be constructed, operated, and decommissioned in a manner that provides long-term protection of ecological health?
	Social	▪ How do the effects on socio-economic VCs compare (e.g., land and resource use, heritage resources, socio-economic)? ▪ How are the alternatives perceived by the public and Indigenous Peoples and is one alternative preferred over another?
	Human Health & Safety	▪ Can the alternative be constructed/operated in a manner that provides protection of public health and safety? ▪ How does the long-term protection of public health and safety compare? ▪ Can the alternative be constructed/operated in a manner that provides protection of worker health and safety?

VC = Valued Component.

The alternatives are described using the above criteria (where applicable) and are summarized in a matrix illustrating the relative preference of each alternative, as shown below. If the alternative has a high chance of successfully addressing a particular criterion, it is rated as most favourable. Similarly, if the alternative has a moderate likelihood of addressing a criterion, it is rated as favourable, while if the alternative is assessed as having a low likelihood of success or having unacceptable risk with a particular criterion, a least favourable rating is used. For the technical criteria, a rating of "least favourable" was also generally considered to be the threshold for an alternative to not be technically feasible.

2.5.1.1 Technical Feasibility

The following criteria were developed for the technical feasibility category:

- **Project Purpose:** The purpose of the NSDF Project is to substantially reduce the risks associated with the CNL legacy wastes, liabilities and the cost of CNL operations to taxpayers and to facilitate CNL's cleanup mission, which allows for the revitalization of the CRL site. The most favourable alternative will satisfy the NSDF Project purpose, while the least favourable alternative will not satisfy the project purpose. Alternatives were considered to be favourable if they partially satisfied the purpose of the NSDF Project.
- **Storage Capacity:** The alternative must accommodate 1,000,000 m^3 of LLW, the majority of which is impacted soils and demolition waste. This volume is based on waste forecasting from future facilities and approaches to waste management. Alternatives that accommodated 1,000,000 m^3 were most favourable, Alternatives that did not accommodate 1,000,000 m^3 of waste were assessed as not technically feasible.
- **An Example of Best Available Technology:** This criterion evaluated the technology to be implemented with the alternative being considered relative to the types of wastes to be disposed. A best available technology was most favourable, while an available technology was considered to be favourable. An alternative was considered to be least favourable if the technology was unavailable, outdated or not appropriate for the type of waste to be disposed.
- **Disposal Facility Design Robustness:** This criterion considers the compatibility of the disposal facility construction materials with the LLW to be disposed as well as the design life of the facility. It is known that certain materials deteriorate over time when subjected to exposure to certain chemicals that may be contained in the leachate that is expected to be generated within the facility. The most favourable alternative will use construction materials compatible with the radiological and chemical characteristics of leachate that is expected to be generated such that the facility will perform effectively for a 500-year or greater post-closure period. A favourable alternative includes use of compatible construction materials that would result in the performance of the facility for less than a 500-year post-closure but more than a 300 year post-closure period. An alternative was assessed as not technically feasible if the construction materials were considered to be incompatible with the leachate and would result in deterioration of the construction materials during the operations phase or near-term post-closure period (i.e., less than 100 years).

- **Complexity of Monitoring:** This criterion considered the monitoring requirements that may be needed in support of each alternative. Standard monitoring requirements were considered most favourable, while a slight increase in monitoring requirements and/or complexity of the program was considered to be favourable. Least favourable alternatives were those that require complex or substantially increased monitoring requirements.

2.5.1.2 Economic Feasibility

The economic feasibility was evaluated by comparing the life cycle cost estimate for each alternative. This estimate includes costs for construction of the facility and supporting infrastructure, operations, and ongoing monitoring and maintenance activities. Additionally, costs incurred during decommissioning and closure, and those associated with long-term monitoring and maintenance activities required during the post-closure period were also considered. Cost information used for other projects and types of facilities can be highly variable depending on where the project is in its lifecycle and certainty in cost estimates (e.g., conceptual design versus construction complete).

2.5.1.3 Environmental Effects

The evaluation of environmental effects is based on a qualitative comparison of biophysical and socio-economic effects on VCs and potential effects on public and worker health and safety. VCs refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). The selection of appropriate VCs allows the assessment to be focused on those aspects of the natural and human environment that are of greatest importance to society.

The list of VCs selected for the NSDF are described in Section 5.1, and considered a number of factors, including:

- presence, abundance and distribution within or relevance to the area associated with the NSDF Project;
- potential for interaction with the NSDF Project and sensitivity to effects;
- species conservation status or concern;
- ecological and socio-economic value to communities, government agencies and the public;
- traditional, cultural and heritage importance to Indigenous Peoples; and
- experience with similar projects.

Environmental effects are evaluated for biophysical, social, and human health components. To facilitate comparison of potential environmental effects on VCs between the alternatives, effects are described by discipline; rather than for each individual VC. For example, VCs for the terrestrial biodiversity discipline include species at risk and vegetation communities; however, for the alternatives assessment, environmental effects are evaluated for the terrestrial biodiversity discipline as a whole. The alternatives assessment considers effects on the biophysical (i.e., atmospheric environment, geological and hydrogeological environment, surface water environment, aquatic biodiversity, terrestrial biodiversity, and ecological health), social (socio-economic, land and resource use, and heritage resources), and human health and safety (i.e., public and worker) disciplines.

Environmental setting was included as an additional criterion in the evaluation of effects to the biophysical environment for alternatives (where applicable). The environmental setting criterion considered brownfield versus greenfield site; namely whether construction would occur within existing disturbed or undeveloped area. Development within an existing disturbed area was considered most favourable, while construction within an undeveloped area was favourable. Development within an environmentally sensitive area or that would affect significant cultural resources were considered to be least favourable.

Engagement with the public and Indigenous Peoples is a key aspect of the decision-making process. A social acceptability criteria was included to provide weight to any concerns and preferences expressed by the public and Indigenous Peoples.

2.5.2 Facility Type

Various types of disposal facilities have been constructed and are in operation around the world. These facility types have different degrees of containment and isolation capability appropriate to the radioactive waste that they will receive and its associated risk. However, regardless of the facility type selected, the specific aims of disposal remain the same according to IAEA's SSR-5:

- to contain the waste;
- to isolate the waste from the accessible biosphere and to reduce substantially the likelihood of, and all possible consequences of, inadvertent human intrusion into the waste;
- to inhibit, reduce and delay the migration of radionuclides at any time from the waste to the accessible biosphere; and
- to confirm that the amounts of radionuclides reaching the accessible biosphere due to any migration from the disposal facility are such that possible radiological consequences are acceptably low at all times.

To meet the requirements of IAEA's SSR-5, CNL has defined the near surface disposal within its Integrated Waste Strategy as the primary disposal path for LLW that meet the Waste Acceptance Criteria.

The alternative facility types to the NSDF considered were:

- a geologic waste management facility (GWMF), which is a deep underground facility for disposal of radioactive waste;
- shallow or intermediate-depth caverns; and
- a separate dedicated very low-level waste (VLLW) repository.

2.5.2.1 Ongoing Waste Storage

2.5.2.1.1 Technical Feasibility

When developing the NSDF Project, CNL also considered maintaining the status quo which would involve the continued use of interim storage. This could involve the use of CRL waste management areas, the use of bunkers and storage buildings and rolling stewardship and monitored retrievable storage. However, as noted in Section 2.3 of the revised EIS, continuing to build additional temporary storage systems at the CRL site for LLW is not consistent with modern waste management principles. In accordance with *Canada's Radioactive Waste Policy Framework* (Government of Canada 2015), the waste producers and owners of radioactive waste are responsible

for the funding, organization, management and operation of disposal facilities required for their wastes. As such CNL does not consider the ongoing waste storage as technically feasible as it is not aligned with national policies.

Furthermore, the historic WMAs have minimal to no engineered barriers to contain their inventory. Although the releases and groundwater impact from these WMAs is currently being managed, the risk of future releases and environmental impacts the inventory poses could be substantially reduced through improved containment and isolation of the source term. Leaving the historic WMAs in their current configuration as an alternative to LLW disposal is not technically feasible as it is unlikely to satisfy regulatory and licensing requirements for long-term waste management, specifically those specified within REGDOC-2.11.1 Volume III (CNSC 2018).

2.5.2.2 Near Surface Disposal Facility

2.5.2.2.1 Technical Feasibility

The IAEA definition of a near surface disposal is the placement of solid, or solidified, radioactive waste in a disposal facility located at or near the land surface (IAEA 2014). The preferred option for disposal of LLW is in near surface disposal facilities (IAEA 2001). An NSDF is a suitable and technically feasible means of disposing of LLW and the effectiveness of such facilities for disposal of LLW has been demonstrated as illustrated through the following near surface facilities currently in operation North America. Within Canada, CNL is implementing the Port Hope and Port Granby Projects, on behalf of AECL, in eastern Ontario for the safe, long-term management of historic LLW arising from the operations of the former Crown Corporation Eldorado Nuclear Ltd and its private-sector predecessors. These projects are building facilities for the long-term storage of LLW that are similar in design to the NSDF proposed for CRL.

Selected examples of NSDFs for LLW are provided in Table 2.5.2-1, which provides a summary of the key attributes for these facilities. A number of these are located in wet climates and in close proximity to surface waterbodies similar to the NSDF proposed for CRL.

The NSDF has been designed as a permanent disposal facility, incorporating best available technologies and industry practices, including documented experience from the IAEA and other similar national and international facilities (as described above). In accordance with Requirement 5 of IAEA's SSR-5, the NSDF would also be sited, designed and operated to provide features that are aimed at the isolation of the radioactive waste from people and the environment. Subsurface investigations have concluded that the geology and hydrology on the selected CRL site is acceptable for the construction and operation of the NSDF. Designed and operated in accordance with applicable codes and best practices, the NSDF technology will feature a multilayer, base-liner and cover system to contain the waste, a WWTP with dual process trains to treat the leachate generated, and robust safety monitoring systems such as leak detection, radiation monitoring and environmental monitoring to ensure the safety of workers and the public and the protection of the environment during the operations and post-closure periods.

The safety of the NSDF during post-closure is provided by means of passive features (e.g., berm, final base-liner and cover systems) that will end the need for active management, which is in alignment with Requirement 5 of IAEA's SSR-5. The features of the selected site and the performance of the combined natural and engineered barriers assure safety following the closure of the ECM (IAEA 2014). For example, a primary barrier material, the high-density polyethylene geomembrane, has been specifically tested for compatibility with the leachate quality and concentrations expected during NSDF operations. In addition, institutional controls, including restrictions on land use, and a program for monitoring, will be implemented in the post-closure period to provide long-term safety of the public and the environment.

Adaptive management is a means by which uncertainties in outcomes can be reduced through monitoring. The role of adaptive management is to evaluate the results of monitoring programs in order to develop appropriate responses on an ongoing basis. As such, the potential for applying adaptive management to the NSDF Project has been implicitly incorporated into project design thus facilitating future modifications should monitoring indicate that changes are necessary.

In summary, the NSDF design addresses all of the relevant technical feasibility criteria set out in Table 2.5.1-1.

Table 2.5.2-1: Attributes of Selected Near Surface Facilities in Canada and USA for Long-Term Management of Low-Level Waste

Facility	Location	Built	Status	Capacity (m3)	Waste Type	Climate	Annual Precipitation	Terrain	Distance to Nearest Surface Water Body
Proposed CNL Near Surface Disposal Facility	Ontario, Canada	Proposed	Proposed	1,000,000	LLW from past operations, environmental remediation and decommissioning	Wet	87 cm	On a ridge	~0.35 km to Perch Creek, 1.2 km to Ottawa River
Port Granby Long-Term Waste Management Facility	Ontario, Canada	2017	In Operation	774, 000	LLW, hazardous and mixed waste from uranium processing and environmental remediation	Wet	83 cm	Flat	0.7 km Lake Ontario
Port Hope Long-Term Waste Management Facility	Ontario, Canada	2017	In Operation	1,200,000	LLW, hazardous and mixed waste from uranium processing and environmental remediation	Wet	83 cm	Flat	0.1 km to Brand Creek, 3 km to Lake Ontario
Oakridge National Laboratories, Environmental Management Waste Management Facility	Tennessee, USA	2002	In Operation	1,300,000	LLW, hazardous waste from environmental remediation and decommissioning	Wet	140 cm	On a ridge	0.5 km to Bear Creek & Clinch River
Hanford Environmental Restoration Disposal Facility	Washington, USA	1996	In Operation	16,800,000	LLW, hazardous and mixed waste from environmental remediation and decommissioning	Arid	16 cm	Flat	12 km to Columbia River
Portsmouth On-site Waste Disposal Facility	Ohio, USA	Under Construction	Under Construction	1,000,000	LLW, hazardous and mixed waste from uranium processing	Wet	102 cm	On a ridge	2.4 km to Sciota River
Fernald On-site Disposal Facility	Ohio, USA	1996	Closed	2,250,000	LLW and mixed waste from uranium processing	Wet	105 cm	Flat	~1 km to Great Miami River

2.5.2.2.2 Economic Feasibility

The estimated cost of licensing and constructing the NSDF using an engineered containment mound (i.e., Phase 1 as well as initial development of the Phase 2 footprint) is approximately $365 million (M) (2018 Class 1 estimate). This estimate includes site preparation and construction of the engineered containment mound, WWTP, site development and infrastructure and support facilities. This estimated cost has increased since the NSDF Project draft EIS in 2017 primarily due to an improvement in cost certainty for construction as well as is reflective of project design changes and necessary revisions to environmental studies and modelling to incorporate feedback received on the draft EIS. Installation of capping over Phase 1 as well as completing construction of Phase 2 to operate will cost approximately $110 M.

Operating costs associated with a 50-year operating life that includes both Phases 1 and 2, site closure costs, and surveillance and long-term maintenance costs for a 30-year period following end of operations are estimated at $275 M. This cost is broken down into $240 M for 50 years of operation and maintenance of both Phases 1 and 2 including replacement of operational equipment, $5 M for surveillance and long-term maintenance (30 Years beyond the 50 Years Operation), and $30 M for final closure costs.

This results in a total lifecycle cost of approximately $750 M for the NSDF alternative using an engineered containment mound, which is more than an order of magnitude less than the cost of a GWMF alternative. The total life cycle cost for above ground concrete vaults, another type of near surface disposal facility, is $3,414.8 M which is also less than a GWMF alternative (Section 2.5.3.2.2). The reduced cost of either type of NSDF is more preferable as it further contributes to the reduction of the cost of laboratory operations to the Government of Canada and Canadian taxpayers.

2.5.2.3 Geologic Waste Management Facility

2.5.2.3.1 Technical Feasibility

A GWMF provides an alternative to the NSDF Project as proposed (CNL 2016a). GWMFs are designed for the long-term management of LLW, ILW and HLW. Wastes are processed and packaged for disposal in intermediate to deep underground repositories in stable geological formations.

While there are no GWMFs currently operating in Canada, the US Department of Energy's Waste Isolation Pilot Plant developed a deep geologic repository (more than 700 m deep) for ILW and HLW, which has been in operation since 1999. There are a number of GWMFs that are either under construction or with licence applications to construct under regulatory review, including:

- Finland's deep geologic repository for used fuel from Olkiluoto and Loviisa, approximately 400 to 450 m below ground in the Olkiluoto bedrock, as proposed by Posiva.
- Sweden's Final Repository for Short-Lived Radioactive Waste for operational wastes (up to ILW) is approximately 50 m below the bottom of the Baltic Sea near Forsmark. Sweden is also proposing an underground repository for disposal of spent fuel, approximately 500 m below ground near Forsmark.
- The French National Radioactive Waste Management Agency's proposed 500 m deep geological repository complex in clay at Bure, France for HLW and long-lived ILW.
- Ontario Power Generation's (OPG) proposed Deep Geologic Repository (DGR) for LLW and ILW on the Bruce Site in Tiverton, Ontario, approximately 680 m below ground surface.

In addition, China, Germany, India, Japan, Switzerland, the United Kingdom, United States and Canada are also pursuing geologic repositories for the long-term management and disposal for used fuel and other HLW. The use of GWMF as the preferred disposal solution is primarily for HLW and long-lived ILW, where additional barriers for protection are warranted.

CNL conducted assessments of its site geology and confirmed that the geologic characteristics required for a GWMF are present on the CRL site. Significant surface and subsurface investigations including approximately 12,000 m of borehole drilling, core logging, geological mapping, geophysical surveys, hydrogeological surveys, and various geotechnical tests were performed on the CRL site since the 1970s to examine the suitability of the crystalline bedrock to host a GWMF for the permanent disposal of CNL's ILW at a depth between 500 and 1,000 m. Both shallow boreholes (less than 300 m) and deeper boreholes (approximately 1,200 m) were drilled as part of the investigations.

Information derived from characterization activities was used to define bedrock structures on both macroscopic and mesoscopic scales. A descriptive hydrogeological model of the CRL site was developed, outlining the hydrogeological properties and 3D spatial distribution of all important hydrogeological units and features within the bedrock of the CRL site. The rock mass characterization conducted to date provides a reasonable basis for a positive decision to proceed to siting studies for a GWMF at the CRL site. As for the GWMFs discussed above, CNL would need to undertake comprehensive siting assessments and develop a robust design that protects the environment.

Because GWMFs are built subterranean, provided suitable geology is available, there are no practical limitations on the size of the repository. As such, the GWMF can be designed to provide a total waste volume of 1,000,000 m^3.

In GWMFs, isolation is provided primarily by the host geological formation and the depth of disposal. The passive safety features (barriers) of the GWMF design have to be sufficiently robust so as not to require repair or upgrading, in keeping with requirements that disposal facilities for radioactive waste not rely on active institutional control (IAEA 2011). However, institutional controls may contribute to safety by preventing or reducing the likelihood of human actions that could inadvertently interfere with the waste or degrade the safety features of the GWMF. In addition, a program for monitoring would be needed in the post-closure period to demonstrate long-term safety of the public and the environment.

In summary, the GWMF facility type meets most technical feasibility criteria, as set out in Table 2.5.1-1. The GWMF has been demonstrated to provide an adequate level of environmental protection through international experience (as described above). It would satisfy the purpose of the NSDF Project in that it would provide the needed disposal capacity for CNL's LLW. The technology for GWMFs is an example of best available technology and a robust design with monitoring systems that meet international requirements for disposal facilities could be developed at the CRL site based on available geologic data.

2.5.2.3.2 Economic Feasibility

The costs associated with constructing a GWMF are considerably higher than a NSDF. Similarly, the operating costs for a GWMF would also be greater than that of the NSDF due to the need for additional waste packaging and handling of all waste. For example, the total waste volume to be disposed in OPG's DGR Project is 200,000 m^3 of LLW and ILW (OPG 2011a). The estimated capital costs for the DGR Project are estimated at $1,000 M (OPG 2011a). Annual operating costs are estimated at $25 M (Golder 2004). Using these values, the inferred lifetime expenditure for a GWMF with a total waste volume of 1,000,000 m^3 and 50-year operations phase could be greater than $6,250 M.

2.5.2.4 Very Low-Level Waste Disposal Facility

2.5.2.4.1 Technical Feasibility

Very-low-level waste is a considered a subcategory of LLW as per CSA standard for the nuclear industry *N292.0-19 General Principles for the Management of Radioactive Waste and Irradiated Fuel*. CNL previously considered the development of a VLLW disposal facility at the CRL site and implemented a trial to demonstrate the viability of segregation and storage of VLLW (CNL 2016b). The trial demonstrated that the fraction of the total LLW that could be segregated as VLLW was disproportionate to the time, effort and storage requirements that were expended to realize any net benefit from the work. In addition, the LLW with higher activity that is segregated from the VLLW will still require a separate LLW disposal facility. Therefore, the development of a VLLW disposal facility does not meet the NSDF Project purpose which recognizes the need for an LLW disposal facility and a VLLW disposal facility is not considered technically feasible.

2.5.2.4.2 Economic Feasibility

The planned cost of developing a VLLW disposal facility is expected to be similar to the cost of developing an LLW disposal facility (i.e., the current NSDF Project); however, a VLLW disposal facility would require additional time and effort to segregate and manage the VLLW from the rest of the LLW (CNL 2016b). The development of an LLW disposal facility (inclusive of VLLW) would eliminate duplication of effort, time, dose and facility construction, operation and closure costs and would enable reduction of Canada's liabilities earlier than it would have if a small percentage of the total inventory had been segregated and disposed separately. Therefore, the development of a separate VLLW disposal facility is not considered economically feasibility when compared to the cost savings associated with the development of a LLW facility that is inclusive of VLLW.

2.5.2.5 Environmental Effects

The key pathways by which a NSDF or GWMF may interact with the environment is through surface water and groundwater intrusion, migration of contaminated water (leachate), inadvertent intrusion, release of radioactive particulates to the atmosphere, and disturbance to the terrestrial environment from the project footprint. Regardless of whether the facility is a NSDF or GWMF, engineered barriers and mitigation measures would be implemented to prevent or delay the migration of contaminants, protect human and ecological health, and limit effects to the aquatic and terrestrial environments. These barriers and mitigation measures represent an important component of the safety from the operations phase through the post-closure phase.

The majority of effects to air quality would occur during the construction and operations phases for both alternatives. Blasting activities would be required for the construction of both an ECM and a GWMF and fugitive dust emissions would be generated during earth moving activities. During operations and post-closure of the ECM, radioactive gases (e.g., radon and tritium) and radioactive particulates may be released from the wastes within the facility during the operations and post-closure phases. During operations, there would be differences in atmospheric emissions between the two alternatives; the ECM would have heavy equipment placing wastes and cover material at surface, whereas the majority of the equipment during operations of the GWMF will be below ground, and emissions managed through ventilation shafts. Both alternatives would have different types of effects on air quality; they would each implement mitigation that provides for worker and public health and safety and protection of the environment. Greenhouse gas emissions are expected to be of the same order of magnitude for both alternatives.

Potential effects on hydrogeology are related to the alteration of groundwater levels and flows due to the construction of the facility and potential changes to groundwater quality due to migration of leachate following post-closure activities. Subsurface investigations at the CRL site have concluded that the geology on-site is

acceptable for the construction and operation of an NSDF. The surface geology of the CRL site is composed of four types of glacial and post-glacial sediments including till, water-deposited sands (fluvial), wind-deposited (Aeolian) sands and organic deposit. To limit potential effects to groundwater, engineered barriers to control for infiltration of surface water, groundwater intrusion, and migration of contaminated water (leachate), would be implemented. Engineered barriers can be used as physical and/or chemical obstructions and can provide either partial containment or complete isolation of the waste or both (IAEA 2001).

In GWMF facilities, the waste is normally placed below the ground water table and will thus have a water saturated environment outside the engineered barriers soon after closure of the repository (Argonne National Laboratory 2011). A study has been performed to gather sufficient facts for the resultant geoscientific interpretations and analyses to determine whether or not suitable bedrock conditions likely exist at CRL for a GWMF. Hydraulic testing was completed which suggests that intrablock regions of the CRL rock base is generally low to very low below the 400 to 500 m depth. In accordance with the groundwater flow models, the deeper bedrock at the CRL site appears to be able to provide moderately strong natural barrier against transport of contaminants from a GWMF. In summary, although both alternatives would be designed to be protective of groundwater; a GWMF is considered to be more favourable as it would provide additional barriers against potential groundwater transport.

Both facility types may affect existing availability of the spatial and temporal distribution of water quantity for aquatic and terrestrial ecosystems. For both the NSDF and GWMF facility types, surface water drainage would be managed within the project footprint. Proposed design features would be based on best available surface water management practices controlling erosion, capturing sediment, and for safely conveying flows associated with a back to back 1:100-year or regional storm event. Because the GWMF design would not be prone to infiltration of precipitation through the waste during placement, only the NSDF alternative would require some form of water treatment to mitigate potential effects to surface water quality associated with the seepage of leachate from the facility (i.e., changes to groundwater quality). The NSDF's water treatment facility would be designed to meet site-specific risk-based effluent quality criteria to be protective of the environment and humans. In conclusion, there are no anticipated differences between the NSDF and GWMF alternatives when considering potential effects to the surface water environment from each facility except the infiltration of water to the waste and related need for treatment to mitigate effects.

Potential effects to terrestrial biodiversity are primarily related to the amount of surface disturbance to vegetation and wildlife habitat. The footprint for a NSDF large enough to accommodate 1,000,000 m^3 of LLW is approximately 37 ha. The surface footprint required for a GWMF is dependent on the size of the underground repository and the volume of waste rock to be managed at surface. As a comparison, the surface footprint required for the DGR Project is approximately 30 ha for management of 200,000 m^3 of waste (OPG 2011a). Therefore, the footprint required for waste rock management at the CRL site for 1,000,000 m^3 could be much larger. This larger footprint would result in greater indirect effects on the terrestrial environment. However, in both cases, mitigation will be implemented to eliminate or reduce potential effects on Species at Risk that may be found or critical habitat.

The objective of the design of a disposal facility is to ensure the facility can be built and the waste received, handled, and disposed without undue risk to human health and the environment, both during facility operation and after facility closure. There are numerous examples of both NSDF and GWMF type facilities that have been successfully constructed and operated. Within Canada, CNL is implementing the Port Hope and Port Granby Projects for the safe, long-term management of historic LLW arising from the operations of the former Eldorado Nuclear Ltd. These projects are building near surface management facilities similar to the design proposed for the

NSDF Project. Public dose estimates were calculated in 2018 for Port Hope and Port Granby. The public dose estimate at Port Hope is 0.0275 millisievert per year (mSv/yr) based on 60 hours at the east fence (CNL 2019b) and the public dose at Port Granby is 0.020.0 mSv/y based on 60 hours at south fence line (CNL 2019c). Both public dose estimates are well below the CNSC dose limit of 1 mSv/yr for members of the public. Radiation doses to members of the public for the long-term maintenance and monitoring phase are predicted to be indistinguishable from the background conditions (Golder 2005).

A detailed safety assessment, performed for OPG's Deep Geologic Repository Preliminary Safety Report (OPG 2011b), concluded that the results of the analysis indicate very low doses to the public, far below the CNSC regulatory limit of 1 mSv/yr. A preliminary post-closure performance and safety assessment for OPG's long-term management of LLW and ILW in a GWMF type facility examined the long-term evolution of the performance post-closure. Results from the simulation showed that estimated dose rates were orders of magnitude below 0.3 millisieverts (mSv), and concluded that there were no results found which would preclude the safe disposal of the six LLW and ILW groups which were used in this study. For a similar GWMF facility (i.e., OPG's Deep Geologic Repository) for the Human Intrusion scenario, a borehole is drilled into the repository and gases and material are released (OPG 2011a). The calculated doses were estimated to be about 1 mSv for the future person farming on the site. However, the likelihood of inadvertent human intrusion into the waste will be low as a consequence of the chosen depth for a GWMF (IAEA 2011).

Regardless of the type of facility, the design would aim to ensure that such releases do not exceed applicable regulatory limits during either the operations or post-closure phases and are protective of humans and the environment. However, given the nature of the GWMF located at a nominal depth, this facility type may be considered more robust against surface activities and therefore is more favourable.

Both a NSDF and GWMF facility type would meet all regulations and be constructed in a manner that protects worker health and safety. Operations at the NSDF will be similar to those applied by CRL at the WMAs for over 70 years. It is expected that the majority of environmental remediation and decommissioning waste will be disposed as bulk material, in unpackaged form. Approximately 13% of LLW will have sufficiently high radionuclide content to require use of packaging in the NSDF. Conversely, increased packaging would be a requirement for a GWMF, and the additional handling and packaging of wastes may result in increased exposure to workers. The design process provides for worker health and safety by maintaining occupations exposures ALARA regardless of which facility type is selected; however, because of the reduced handling and packaging requirements, the NSDF type facility is most favourable.

While both an NSDF and a GWMF can be constructed in a manner that protects public and worker safety, a GWMF includes a natural geologic barrier that provides additional isolation of the wastes. This is expected to be viewed more favourably and considered safer by the public and Indigenous Peoples even though this extra layer of protection is not required for the disposal of LLW.

Overall, mitigation through the implementation of the above-described engineered barriers for an NSDF or GWMF facility are anticipated to reduce or limit environmental effects and subsequently risk to human and environmental health. Effects to ecological health are expected to be similar between alternatives (e.g., air and dust emissions and employment and business opportunities generated for both design options are assumed to be similar; both design options would avoid lakes and streams, sensitive and/or critical habitat, and significant cultural resources, and both would require restrictions on future land use).

2.5.2.6 Summary

Both the NSDF and GWMF alternatives meet CNL's overall need and are environmentally feasible options. However, the GWMF does have substantially higher life cycle costs, which are potentially an order of magnitude higher than for an NSDF. Although a GWMF would provide increased barriers for potential releases to the environment in the long-term, the nature of the waste (i.e., LLW), the majority of which is impacted soils and demolition waste, does not warrant the need for these barriers. Low-level waste requires isolation and containment for periods of time up to a few hundred years. A GWMF also requires additional waste handling for waste placement whereas LLW does not require shielding during handing or interim storage. GWMFs are most typically proposed for HLW and ILW, which are not within the scope of the NSDF Project.

Near surface disposal facilities, as proposed for the NSDF project, have been demonstrated globally to be an effective disposal solution for LLW. Therefore, a NSDF is the most feasible and most favourable alternative. Table 2.5.2-2 provides a summary of the evaluation of alternatives.

Table 2.5.2-2: Evaluation of Alternatives - Facility Type

Criteria	Alternative 1 – Near Surface Disposal Facility (NSDF)		Alternative 2 – Geologic Waste Management Facility (GWMF)	
Technical Feasibility				
Project Purpose	The NSDF satisfies the project purpose and allows for the planned decommissioning and site restoration activities and reduces liabilities associated with the CNL legacy wastes.		Construction of a GWMF allows for the planned decommissioning and site restoration activities and reduces liabilities associated with the CNL legacy wastes.	
Storage Capacity	The NSDF can be designed to provide a total waste volume of 1,000,000 m^3.		The GWMF can be designed to provide a total waste volume of 1,000,000 m^3.	
An Example of Best Available Technology	The NSDF facilities have been applied for the disposal of LLW globally (e.g., Oak Ridge Tennessee EMWM Facility) and is recognized by the IAEA as a suitable disposal option for LLW (IAEA 2009), especially for non-consolidated waste (e.g., soil and demolition material).		The GWMF facilities have been applied for the disposal of ILW (e.g., Waste Isolation Pilot Plant). The GWMF offers a level of containment that exceeds the requirement for LLW.	
Design Robustness	The NSDF incorporates best available technology, including documented experience from the IAEA and other similar national and international facilities. It is the performance of the combined natural and engineered barriers that provides safety after closure for the NSDF.		Conceptually, a GWMF has been demonstrated to provide an adequate level of environmental protection through international experience, thus is considered to be robust and technically feasible. The natural geologic barrier of a GWMF provides additional isolation of the wastes, as compared to a NSDF.	
Monitoring Complexity	Environmental monitoring is straightforward and could be incorporated into the monitoring program at an existing site (e.g., CRL site).		Environmental monitoring (i.e., groundwater monitoring) is expected to be more complex given the depth of the facility.	

Table 2.5.2-2: Evaluation of Alternatives - Facility Type

Criteria	Alternative 1 – Near Surface Disposal Facility (NSDF)		Alternative 2 – Geologic Waste Management Facility (GWMF)	
Economic Feasibility				
Life Cycle Cost	Approximately $750 million (ECM) to $3,400 million (AGCV)		Up to approximately $6,250 million	
Environmental Effects				
Biophysical				
Atmospheric Environment	No anticipated difference between alternatives.			
Geological and Hydrogeological Environment	Engineered barriers to control infiltration of surface water and prevent release of contaminated water (leachate) from the NSDF, would be implemented.		The natural geologic barrier of a GWMF provides additional isolation of the wastes, as compared to a NSDF.	
Surface Water Environment	There are no anticipated differences between the alternatives.			
Aquatic Biodiversity	There are no anticipated differences between the alternatives.			
Terrestrial Biodiversity	The footprint required for a NSDF is anticipated to be 37 ha; however, mitigation would be implemented to eliminate or reduce potential effects on Species at Risk that may be found or critical habitat.		The footprint required for waste rock management of a GWMF could be much larger. Mitigation would be implemented to eliminate or reduce potential effects on Species at Risk that may be found or critical habitat.	
Ecological Health	No anticipated difference between alternatives.			
Social				
Socio-economics	No anticipated difference between alternatives.			
Land and Resource Use	No anticipated difference between alternatives.			
Social Acceptability	A GWMF is expected to be perceived more favourably compared to an NSDF due to the perception that a GWMF is safer.		A GWMF is expected to be perceived more favourably compared to an NSDF due to the perception that a GWMF is safer.	

Table 2.5.2-2: Evaluation of Alternatives - Facility Type

Criteria	Alternative 1 – Near Surface Disposal Facility (NSDF)		Alternative 2 – Geologic Waste Management Facility (GWMF)	
Human Health and Safety				
Public Health & Safety (construction and operations)	Both alternatives can be developed in a manner that protects public health and safety during construction and operations.			
Public Health & Safety (long-term)	Institutional controls, including restrictions on land use, and a program for monitoring will be implemented in the post-closure period to confirm long-term safety of the public and the environment.		Institutional controls, including restrictions on land use, and a program for monitoring will be implemented in the post-closure phase to confirm long-term safety of the public and the environment. However, given the nature of the GWMF located at a greater depth, human intrusion is less likely.	
Worker Health & Safety	Because of the reduced handling and packaging requirements, the NSDF type facility is most favourable.		All waste will require packaging which increases potential exposure and risk to workers.	

Note:

GWMF = Geological Waste Management Facility; LLW = low-level waste; ILW = intermediate level waste; IAEA = International Atomic Energy Agency.

2.5.3 Facility Design

This section evaluates the proposal of disposing waste within two types of NSDF's: an above-ground concrete vault (AGCV) design and an ECM design.

2.5.3.1 Engineered Containment Mound

Disposal facilities constructed on the surface, typically in the form of a mound or hill, primarily use engineered barriers to prevent water from infiltrating the disposed waste, thus maintaining diffusion-controlled transport of radionuclides, which is an extremely slow process (Bergman 2006). To meet the above-mentioned design principles and objectives, the ECM design features composite final cover and base liner systems comprising natural and synthetic materials. The base liner contains both engineered leachate collection and leak detection systems as well as natural drainage elements. The performance of the ECM will be monitored to provide early indications of any need for maintenance or repair. The design of the ECM for the NSDF Project is fundamentally consistent with those for the Port Granby and Port Hope Long-term Waste Management Facilities now in operation.

2.5.3.1.1 Technical Feasibility

An advantage of this mound-type repository design is that the waste is placed above the groundwater table and the waste stays dry as long as the protective barriers are intact, which may be on the order of hundreds of years (Argonne National Laboratory 2011). These mound-type disposal facilities also have relatively moderate technical requirements for the site, so it is usually easy to find places to locate them. For the proposed ECM, soil will be used to fill the space between the waste packages. This type of fill material will help to stabilize the waste in the ECM. This added stability is also important in the long-term as the waste degrades and there is potential for the final cover to settle. These fill materials also allow easy removal of the waste, if such action ever became necessary after disposal.

The vast majority of the waste streams are comprised of impacted soils and demolition debris, which can be readily placed into compacted layers within the ECM. This type of less consolidated waste is typically disposed in ECMs (examples of other ECM facilities are provided in Table 2.5.2-1). When compaction rates are adhered to, the facility throughout its life cycle behaves as a single "entity" and will survive significant seismic events without much damage or implication. Although ECM facilities may require extensive monitoring; these monitoring programs are relatively straight-forward and similar programs are currently in place at CRL site.

The main disadvantage for surface disposal is that the protective cover of the waste is exposed to weathering and erosion that can endanger the integrity of the repository. The cover is designed to divert the precipitation away from the ECM. Available literature on geomembrane service life under the conditions expected for the ECM (i.e., temperature, leachate quality, radiation and stresses) indicates that HDPE geomembrane liner (i.e., primary composite liner and final cover liner) is expected to remain functional over the 500-year post-closure design life of the ECM. The cover liner is also the feature of the facility that is the easiest and cheapest to repair or replace if infiltration does occur (R. Kerry Rowe Inc. 2019).

2.5.3.1.2 Economic Feasibility

The estimated cost to build (i.e., capital expenditures,) the NSDF for the 1,000,000 m^3 of CNL waste is $475 M. This estimate includes site preparation and construction of the engineered containment mound, supporting facilities and buildings, and access roads. Operating costs associated with a 50-year operating life, site closure costs and surveillance and long-term maintenance costs for a 30-year period following end of operations are estimated at $275 M. This results in a total lifecycle cost of $750 M for the NSDF Project.

2.5.3.2 Above-Ground Concrete Vaults

Above-ground concrete vaults (AGCV) are another type of disposal facility employing engineered multi-barrier concrete structures set partially into the ground. With this technology, isolation is provided by a reinforced-concrete building constructed on the surface. Waste containers may be loaded into a vault through an open side or top, which is sealed after the vault has been filled. Concrete containment vaults add structural stability to the disposal unit, help to prevent any infiltrating water from coming in contact with the waste and provides an intrusion barrier around the waste. The waste in the building would be isolated from humans and the environment as long as the integrity of the building is maintained.

2.5.3.2.1 Technical Feasibility

Although AGCV facilities may require extensive monitoring; these monitoring programs are relatively straightforward and similar programs are currently in place at the CRL site.

Disposal facilities using AGCV provide concrete barriers to the waste and are therefore not as heavily impacted by weathering and erosion, when compared to the ECM-type; however, there are disadvantages (Argonne National Laboratory 2011). Above-ground facilities are subject to deterioration through exposures to wind, rain, and freeze-thaw cycles and are vulnerable to cracking as a result of uneven settlement and seismic events. While some of these trigger events could be mitigated by earth covers surrounding the AGCV, not all can be reduced. Design features such as reinforcement, expansion joints, sealants and drainage collection would serve to mitigate the impacts of these forces. Further, concrete has been extensively studied and can be made durable enough to last for a few hundred years and perhaps longer (US Congress, Office of Technology Assessment 1989). Some predictive models even indicate that concrete will last longer than 1,000 years; however, beyond about 500 years, the uncertainty of such predictions increases (US Congress, Office of Technology Assessment 1989).

There are several international examples of the use of AGCV, including facilities in France and Spain. The facility located at Centre de l'Aube in France, which began operations in 1992, has been designed to be Europe's largest repository for LLW and ILW. Waste are placed in concrete vaults constructed on the surface under a movable shelter that protects the wastes from weather during placement. Once a vault is full, a concrete cover is poured in place to completely isolate the waste from the environment. This facility is designed for 1,000,000 m^3 of LLW and ILW, with a future forecast of 1,900,000 m^3, so a future facility will be required at some point. The Centre l'Aube facility receives waste from power plants, research activities and fuel manufacturing and reprocessing plants. This type of waste is suitable for an AGCV given the packaged nature of the waste. The majority of the waste proposed for the NSDF Project is impacted soils and demolition waste which is less consolidated and would be easier to manage in a facility like the ECM (i.e., unconsolidated waste can be moved around more easily).

2.5.3.2.2 Economic Feasibility

The construction cost estimate for AGCV option was developed from the 1999 Organization for Economic Co-operation and Development report titled *Low Level Waste Repositories: An Analysis of Cost* (OECD-NEA 1999) using information from El Cabril facility for LLW in Spain. The construction cost, including research and development, site screening, facility design, 28 disposal vaults, supporting buildings and facilities, for a 100,000 m^3 facility was approximately $229 M (Canadian dollars), plus $762 for every additional cubic metre of waste. For the CNL waste volume of 1,000,000 m^3, the cost to construct an AGCV design would be approximately $914.8 M, which is considerably higher than the ECM design. Annual operating costs are estimated at $2,500/$m^3$ of waste placed (present day value) (OECD-NEA 1999). Using these values, the inferred lifetime expenditure for the AGCVs with a waste volume of 1,000,000 m^3 and 50-year operations phase is

estimated. This results in a total life cycle cost of $3,414.8 M ($914.8 M for construction and $2,500 M operations); approximately five times the cost of the ECM alternative.

2.5.3.3 Shallow Cavern

2.5.3.3.1 Technical Feasibility

Another type of NSDF includes the disposal of LLW in shallow caverns. However IAEA guidance (IAEA 2014) recognizes that in the siting process of a near surface disposal facility, the facility design ought to consider the hydrogeological characteristics of the siting location. The groundwater table at the host site should be deep, well below the base of the cavern, to ensure that the cavern does not flood and release radionuclides to the environment. As such shallow caverns were eliminated from consideration for CNL's LLW facility design primary due to the CRL site characteristics.

In the Site Study Area, average groundwater depths range from 0.06 meters below ground surface (mbgs) to 15.95 mbgs, with an average of 4.81 mbgs under normal conditions, and 3.61 mbgs during seasonal high conditions (Section 5.3.2.1.2.1). Near-surface caverns constructed in, or near the water table, are at a very high risk of immediate flooding, and are therefore not appropriate or technically feasible for the disposal of radioactive waste. Furthermore, no single cavern could be excavated to meet the volume of 1,000,000 m^3, resulting in multiple caverns and multiple designs to suit the localized hydrogeology.

Wastes placed into shallow caverns on the CRL site are more likely to come into contact with groundwater very quickly, providing a very short flowpath for the migration of radionuclides into the environment. Thus, the shallow cavern facility design at the CRL site does not align with IAEA guidance (IAEA 2014), and is therefore not suitable or technically feasible.

2.5.3.4 Environmental Effects

The pathways by which contaminants from a NSDF may migrate or be brought into contact with humans and biota is through infiltration of surface water, groundwater intrusion, migration of contaminated water (leachate), inadvertent intrusion and escape of radioactive gas (IAEA 2001). Regardless whether the facility incorporates an ECM or AGCV, engineered barriers will be implemented to prevent or delay the migration of contaminants via these pathways. These barriers represent an important component of the NSDF safety from the operations phase through the post-closure phase. The design of the NSDF will provide that all safety and regulatory requirements are met such that the ECM or AGCV would be constructed and operated in a manner that is safe to the public and workers.

Engineered barriers to control for infiltration of surface water, groundwater intrusion, migration of contaminated water (leachate), inadvertent intrusion and escape of radioactive gas for the ECM include installation of a primary and secondary liner, and a final cover at closure. For the ECM, most of the waste placed in the facility will be unpackaged (i.e., loose/bulk); although some wastes may be packaged (e.g., in high integrity containers) to provide additional short-term containment. Most of the waste to be disposed will arise from the decommissioning of buildings and is lightly contaminated and safe to be disposed in bulk form (i.e., without double-handling and packaging), reducing unnecessary processing and packaging decreases potential exposure and risk to workers.

Greenhouse gas emissions for the AGCV facility are expected to be above that of the ECM because of concrete production. The AGCV facility is constructed of reinforced concrete that offers structural stability and provides an intrusion barrier around the waste. The AGCV also deters infiltration of water to the wastes, and therefore does not generate leachate which requires treatment. The footprint required for the AGCV is 1.5 to 2 times that required for an ECM due to the need to package all waste for an AGCV and constraints on the stacking of waste

packages. Based on constructible areas available at the CRL site, it would be necessary to develop at least two sites/locations to establish disposal capacity for 1,000,000 m^3 of waste in an AGCV type facility. Developing multiple sites would have a greater biophysical effect.

Overall, mitigation through the implementation of the above described engineered barriers for an ECM or AGCV facility are anticipated to reduce or limit environmental effects and subsequently risk to human and environmental health. Effects to all other VCs are expected to be similar between alternatives (e.g., air and dust emissions and employment and business opportunities generated for both design options are assumed to be similar; both design options would avoid lakes and streams, sensitive and/or critical habitat, and significant cultural resources, and both would require restrictions on future land use). Because the pathways through by which contaminants may migrate or be brought into contact with humans and biota are similar for both alternatives, similar monitoring programs would also be required during operations and through the post-closure phase to demonstrate long-term safety of the public and the environment. In terms of worker safety, an ECM reduces unnecessary processing and packaging which would be required for an AGCV, thereby decreasing potential exposure and risk to workers.

2.5.3.5 Summary

As summarized in Table 2.5.3-1, both alternatives are technically and environmentally feasible. Both alternatives can be constructed such that they meet the purpose of the NSDF Project and both alternatives can be constructed to accommodate up to 1,000,000 m^3 of radioactive waste. The AGCV and ECM facility designs are best available technology and there are several international examples of each. Both have relatively moderate technical requirements and can be sited on the CRL site. The AGCV is expected to be more vulnerable to seismic events compared to an ECM which behaves as a single “entity” and is more resilient to seismic events. The monitoring requirements for these surface-located options are similar and employ conventional environmental technologies. The life cycle costs associated with an AGCV design are approximately five times the cost of the ECM alternative. In addition, the additional packaging and containment is not required for most of the LLW intended to be disposed on the CRL site. Therefore, the most favourable alternative facility design for the NSDF is an ECM.

Table 2.5.3-1: Evaluation of Alternatives - Facility Design

Criteria	Alternative 1 – Engineered Containment Mound (ECM)		Alternative 2 – Above-ground Concrete Vaults (AGCV)	
Technical Feasibility				
Project Purpose	Both alternatives meet the technical requirements.			
Storage Capacity	The ECM would require approximately 17 ha to contain 1,000,000 m^3 of radioactive waste within the engineered mound, and approximately 20 additional ha for the WWTP, support facilities and site infrastructure. All NSDF Project elements can fit on a single site on the CRL site.		The AGCV would require 1.5 to 2 times the spatial area of an ECM for the disposal of the same quantity of waste. The concrete vault has limitations on stacking of waste containers resulting in a larger footprint needed to contain CNL's 1,000,000 m^3 volume. Due to the large number of surface waterbodies and wetlands, CRL does not have a single site large enough for an AGCV sized to hold 1,000,000 m^3 of waste and would need to develop (at least) two sites.	
An Example of Best Available Technology	ECM is an example of a best available disposal technology and widely used internationally for disposal of LLW which is mainly composed of impacted soils and demolition waste.		AGCVs are an example of best available disposal technology and have been used for packaged LLW and ILW. The AGCV offers a level of containment that exceeds the requirement for LLW.	
Design Robustness	The ECM offers multiple engineered barriers including a double composite base liner system with redundant leachate systems, and a composite cover system. Natural and manmade materials are employed for system robustness.		The AGCV offers multiple engineered barriers that provide design robustness. These include high strength concrete structural elements and engineered packages for all wastes.	
Monitoring Complexity	Both alternatives may require extensive monitoring; however, these monitoring programs are relatively straight-forward and are currently in place at the CRL site.			
Economic Feasibility				
Life Cycle Cost	Approximately $750 million		Approximately $3,400 million	

Table 2.5.3-1: Evaluation of Alternatives - Facility Design

Criteria	Alternative 1 – Engineered Containment Mound (ECM)		Alternative 2 – Above-ground Concrete Vaults (AGCV)	
Environmental Effects				
Biophysical				
Atmospheric Environment	No anticipated difference between alternatives.			
Geological and Hydrogeological Environment	Leachate will be generated by the ECM during operations which will require treatment and management to ensure effects are mitigated.		Minimal leachate will be generated by an AGCV during operations.	
Surface Water Environment	No anticipated difference between alternatives.			
Aquatic Biodiversity	No anticipated difference between alternatives.			
Terrestrial Biodiversity	The disturbance footprint would be designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible.		The disturbance footprint would be designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible, however AGCVs are likely to have a larger footprint as a result of additional packaging requirements.	
Ecological Health	No anticipated difference between alternatives.			
Social				
Socio-economic	No anticipated difference between alternatives.			
Land and Resource Use	No anticipated difference between alternatives.			
Social Acceptability	An AGCV is expected to be perceived more favourably compared to an ECM due to the perception that it is safer		An AGCV is expected to be perceived more favourably compared to an ECM due to the perception that it is safer. Further, operation of an AGCV generates minimal leachate requiring treatment, and may therefore also be perceived to be preferable.	
Public Health & Safety (construction and operations)	Both alternatives can be developed in a manner that protects public health and safety in during construction and operations.			
Public Health & Safety (long-term)	Both alternatives can be developed in a manner that protects public health and safety in the long-term.			

Table 2.5.3-1: Evaluation of Alternatives - Facility Design

Criteria	Alternative 1 – Engineered Containment Mound (ECM)		Alternative 2 – Above-ground Concrete Vaults (AGCV)	
Human Health and Safety				
Worker Health & Safety	Reduces unnecessary processing and packaging which decreases potential exposure and risk to workers.		All waste will require packaging which increases potential exposure and risk to workers.	

Note:

ECM = engineered containment mound; AGCV = above-ground concrete vaults; LLW = low-level waste; ILW = intermediate level waste; WWTP = Wastewater Treatment Plant.

2.5.4 Facility Location

A few of the factors affecting siting decisions for radioactive disposal include national policies, scale of geography, volumes of waste to be disposed. The Canadian federal government has chosen not to mandate a national repository for disposal of LLW and ILW radioactive wastes, and this policy has implications for disposal choices for various waste owners. Nonetheless the different approaches in siting or design of the disposal facility will always consider of the level of risk the respective waste inventory poses for current and future generations. For example, long-lived radioactive inventories require substantially more collaboration with the public due to the associated hazard and uncertainties of future land use planning. Whereas siting decisions for short-lived radioactive inventories, which decay within approximately 100 years to ranges representative of naturally occurring materials, necessitate less public involvement if reasonable land-use planning by the owner can be demonstrated within the timeframe of decay.

AECL and CNL's preference for an LLW disposal was a technically feasible site on lands currently under AECL ownership and CNL control, ideally close to the location of generation and/or storage of the waste and in an area that is already covered by a nuclear licence.

Previous endeavours by AECL in planning and siting for radioactive waste disposal had already deemed the CRL site technically sufficient. The CRL site is the most suitable host site for AECL/CNL's LLW disposal due to its complex history (e.g., past waste management practices) and the vast majority of waste is already at or will be generated at the CRL site thereby significantly reducing the need for transportation. Low-level waste is by far the largest volume among radioactive waste categories (i.e., in the millions of cubic meters), thus facility siting must underpin the impact of transportation. Similar to national research sites in the US, the CRL site is fairly complex with higher levels of environmental contamination and large volumes of waste thus amalgamation of the associated liabilities at this location is practical. As the owner of the CRL site and associated liabilities, AECL (a federal Crown corporation) will continue to put in place measures to ensure that the site is managed and controlled (e.g., restricting the land use of the NSDF Project footprint) for as long as necessary.

CNL also considered locating the facility at alternative sites owned by AECL for the Government of Canada and operated by CNL, specifically WL in Pinawa, Manitoba, and the NPD prototype reactor site in Rolphton, Ontario. The land at these sites is controlled by CNL and are likely to have suitable technical characteristics to safely

manage the waste. The non-CRL options are more likely to raise public concerns related to transportation safety of larger volumes of LLW radioactive wastes. Also, both WL and NPD are scheduled to be closed within the next decade, and therefore, will not have the services and management infrastructure required to safely and securely operate the NSDF.

This section evaluates the proposal of disposing waste at sites owned by AECL either on-site at CRL or off-site at WL or NPD. When evaluating the technical feasibility of the facility location, many of the criterion can be satisfied by both alternatives.

2.5.4.1 On-site Location at Chalk River Laboratories

The CRL site (approximately 4,000 ha) extends approximately 6.5 km inland from the Ottawa River. The controlled WMAs are located within the CRL site. The CRL main campus contains the majority of buildings, laboratories, and nuclear facilities on-site and is located adjacent to the Ottawa River.

2.5.4.1.1 Technical Feasibility

More than 90% of the CNL waste to be managed in the ECM is already on the CRL site thereby reducing the distance the waste needs to be transported.

Subsurface investigations on the CRL site have concluded that the geology on-site is acceptable for the construction and operation of an ECM. The surface geology of the CRL site is composed of four basic types of glacial and post-glacial sediments including till, water-deposited sands (fluvial), wind-deposited (aeolian) sands and organic deposit.

Access within the CRL site is well established and upgrades required for heavy equipment and truck traffic would be minimal. Mandatory services (i.e., Class IV power, water for sanitary and process requirements, gas or other heating sources) are also readily accessible. A robust environmental monitoring program is already in place at the CRL site and the monitoring requirements specific to the NSDF Project could be incorporated into this program.

2.5.4.1.2 Economic Feasibility

As described in Section 2.5.3.1.2, the total life cycle cost of an NSDF facility on the CRL site is approximately $750 M.

2.5.4.2 Off-site Location (CNL Sites excluding Chalk River Laboratories)

The non-CRL off-site locations selected for the alternative means evaluation are those operated by CNL: WL in Pinawa, Manitoba, and the Prototype Reactor Site NPD in Rolphton, Ontario.

2.5.4.2.1 Technical Feasibility

Both WL and NPD sites have sufficient area available on-site to accommodate the construction and operation of a NSDF facility with a storage capacity of 1,000,000 m^3. In addition, both locations may be geologically suitable sites for a NSDF.

Both NPD and WL sites are scheduled to be decommissioned within the next decade. As a result, these sites would need to continue to provide the physical services (i.e., Class IV power, water for sanitary and process requirements, gas or other heating sources, or other nuclear operating infrastructure) and management infrastructure required to support the operation of the NSDF for the 50-year operating period. Both sites have robust environmental monitoring programs in place, but would need to be expanded to address the additional requirements of a NSDF. Shipping of the waste to NPD or WL by transport truck and/or rail is a feasible option.

2.5.4.2.2 Economic Feasibility

Both alternatives are assumed to have similar capital costs for site characterization needed to confirm the suitability for a NSDF. Operational costs would be higher for an off-site facility as the majority of the wastes are located at CRL and would require packaging and transportation. Approximately 90% of the proposed waste for the NSDF Project originate from the CRL site and would require off-site transport. In addition, management and maintenance of services would be higher for sites that would be otherwise decommissioned. Overall, the costs associated with transporting radioactive waste to an off-site facility makes this alternative less favourable. Eventual closure of the NSDF facility and post-closure monitoring and maintenance costs are assumed to be similar for both alternatives.

2.5.4.3 Environmental Effects

The CRL site is located in the Central Gneiss belt of the Grenville Structural Province of the Canadian Shield. The bedrock consists of highly altered gneissic rock and felsic igneous rock of late Precambrian-early Paleozoic age. The overburden of the CRL site consists of boulder, silty sand till deposited during the most recent glaciation, overlain with fine to medium sands. The till contains a wide range of size fractions, from large blocks of rock to fine silts and clay. The general geology of the region is the Precambrian shield with old folding and faulting of the metamorphic rocks (gneiss).

The surface of the NPD site is covered by a boulder pavement (i.e., large boulders), which in most areas has been left as a result of water scouring the area and removing the finer fraction of the river-lain sediments. The base rock is quartz and granite gneiss with some overburden of alluvial sand and gravel. The small amount of overburden and relatively steep incline of the base rocks makes ground and subsurface water run off very quickly to the river.

At the WL site, the regional surficial geology comprises widespread deposits of till and glacio-fluvial and glaciolacustrine materials. The stratigraphic units in sequence from bedrock upwards are silty sand till, clayey silt till, silty clay and an upper soil complex comprised of laminated clayey silt with minor interbeds of massive silty clay and finally surface organics.

Subsurface investigations on the CRL site have concluded that the geology on-site is acceptable for the construction and operation of an ECM. Both WL and NPD locations may be geologically suitable sites for a NSDF. It is expected that a facility could be constructed safety at either of the locations based on similar geology at the sites.

All three sites support a diverse mix of upland and wetland habitats. Vegetation on the CRL site includes deciduous and coniferous forest and a wide variety of plant species, including eight provincial species at risk plant species. The NPD site is mainly wooded with the exception of open wetland areas. Wooded uplands generally range from 40 to 80 years old and wetlands are mainly found on the western half of the NPD site.

The WL site is primarily under treed cover, consisting of a mixture of wetlands and forests of broadleaf, mixed and coniferous stand types. A large area contains a complex of bog, fen and swamp wetlands spanning the center and east portions of the WL site. The disturbance footprint of the NSDF would be similar for all sites, and similar mitigation would be implemented to reduce or limit effects to the terrestrial biodiversity. For example, the disturbance footprint would be designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible.

Wildlife species found on the CRL and NPD sites are generally typical for a boreal region in Ontario. At the CRL site, a total of 23 federal and/or provincial species at risk have been confirmed including four species

of turtles, three species of bats, several forest songbirds, eastern milksnake (*Lampropeltis triangulum*), western chorus frog (*Pseudacris triseriata*), and monarch butterfly (*Danaus plexippus*) (*Species at Risk Act* Schedule 1: List of Wildlife Species at Risk; *O. Reg. 230/08 Species At Risk In Ontario List*). A full list of species at risk at CRL is presented in Appendix 5.6-1.

Seven federal species at risk (*Species at Risk Act*, Schedule 1: List of Wildlife Species at Risk) have been confirmed on the overall NPD site: little brown myotis (*Myotis lucifugus*), northern myotis (*Myotis septentrionalis)*, eastern milksnake, monarch butterfly, and three bird species, eastern wood-pewee (*Contopus virens*), common nighthawk, (*Chordeiles minor*) and, most notably, chimney swift (*Chaetura pelagica*).

Over 50 species of mammals can be expected to be found around the WL site; many of the mammals are common and widespread. The Winnipeg River is an important migratory corridor for many bird species and there are important bird migration staging areas on, or near the WL site, centering on the Winnipeg River. Five federal species at risk have been confirmed on the overall WL site, including little brown myotis, northern myotis, snapping turtle (*Chelydra serpentine*), Canada warbler (*Wilsonia canadensis)* and barn swallow (*Hirundo rustica*).

Although the footprint for each alternative would be similar, the wildlife habitat potentially affected is different. A portion of the CRL site has identified critical habitat for Blanding's turtle (*Emydoidea blandingii*), whereas there is no critical habitat identified by Environment and Climate Change Canada at the WL or NPD sites with the exception of a stack at the NPD site which is proposed critical habitat for chimney swift. However, as mentioned above, the disturbance footprint would be designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. Other potential effects are similar between the alternatives and include short-term sensory effects of noise on bats and songbirds, and increased injury and mortality to wildlife from traffic, particularly turtles. Mitigation to be implemented is standard at all CNL sites and includes, for example, implementation of a Blasting Plan and enforcement of reduced speed limits on-site, respectively.

The Ottawa River is the dominant drainage feature in the area for both the CRL and NPD sites, and all surface drainage on these sites ultimately drains to the river. The CRL and NPD sites are located in the Allumette Lake and Lac Coulonge reach of the Ottawa River, which extends approximately 90 km between La Passe and the Des-Joachims hydroelectric dam. The Ottawa River supports diverse warm-water and cool-water fish communities consisting of at least 85 documented species. Typical catches from the Ottawa River include Walleye (*Sander vitreus*), Northern Pike (*Esox lucius***)**, Channel Catfish (*Ictalurus punctatus*), Smallmouth Bass (*Micropterus dolomieu*) and Lake Sturgeon (*Acipenser fulvescens*), Channel Catfish being the most abundant. The provincial and federal fish Species At Risk in the Ottawa River are American Eel (*Anguilla rostrata*), Lake Sturgeon, Northern Brook Lamprey (*Ichthyomyzon fossor*), and River Redhorse (*Moxostoma carinatum*). Fish in inland lakes on the CRL site include Pumpkinseed (*Lepomis gibbosus*), Northern Pike, bass species, and Yellow Perch (*Perca flavescens*). Minnow species such as shiner, dace, and chub are abundant in streams and lakes on the CRL site.

The Winnipeg River is the dominant drainage feature in the area of the WL site, where all surface water runoff drains into the Winnipeg River. The Winnipeg River supports a variety of forage fish species such as carp and minnow species. Predator fish in the area include Walleye, Northern Pike, Smallmouth Bass, mooneye species, and Lake Trout (*Salvelinus namaycush*). The Carmine Shiner (*Notropis percobromus*), listed as Threatened under the *Species at Risk Act*, is likely to occur in the vicinity of WL site. No differences are anticipated between the alternatives as mitigation would be implemented to reduce or eliminate effects to aquatic diversity. For example, regardless of whether or not the facility is constructed and operated on-site or off-site, leachate from the ECM would be collected and treated via a WWTP prior to discharge to the receiving environment.

Shipping nearly 1,000,000 m^3 of waste from CRL to WL or the NPD site, at an average of 20 m^3 of waste per truck, would result in 50,000 shipments. The potential environmental effects of transporting such large volumes by truck will be greater than disposal in an on-site facility at CRL. The off-site transport of large amounts of radioactive waste on public roads (i.e., 50,000 shipments travelling roughly 1,900 km from CRL to WL or 35 km from CRL to NPD) may raise perceived safety concerns amongst the public.

2.5.4.4 Summary

The comparative evaluation between facility location alternatives is provided in Table 2.5.4-1. All three sites are anticipated to have the suitable geology and area needed for the safe construction and operation of a NSDF. Building a disposal facility on the CRL site has the advantages of being closest to future decommissioning waste and legacy waste stored at CRL WMAs. The associated cost of transporting waste to a facility at CRL is considerably less than transporting the waste to a WL or NPD location. Moreover, the non-CRL options are more likely to raise public concerns related to transportation safety of large volumes of LLW radioactive wastes. Both WL and NPD are scheduled to be closed within the next decade, and therefore, will not have the services and management infrastructure required to safely and securely operate the NSDF. As such, WL and NPD off-site locations are less favourable.

Table 2.5.4-1: Evaluation of Alternatives – Facility Location

Criteria	Alternative 1 – On-site at CRL		Alternative 2 – Off-site at Non-CRL sites	
Technical Feasibility				
Project Purpose	The CRL site satisfies the NSDF Project purpose and allows for the planned decommissioning and site restoration activities and reduces liabilities and the cost of CNL operations to taxpayers.		As closure is planned at WL and NPD and will be completed within the next decade, these sites are not considered technically feasible without continuation of the support services required.	
Storage Capacity	Both alternatives have sufficient area available to develop a facility with a storage capacity of 1,000,000 m^3.			
An Example of Best Available Technology	Both alternatives would be using the same best available technology for the NSDF design.			
Design Robustness	Design requirements would be the same for a NSDF facility at CRL or off-site.			
Monitoring Complexity	Robust monitoring is currently in place at the CRL site which can be expanded to accommodate any additional monitoring requirements for the NSDF.		Both sites have monitoring programs in place. Additional resources may be required to implement monitoring for a NSDF during the 50-year operating period at these sites.	
Economic Feasibility				
Life Cycle Costs	Total life cycle costs are estimated to be approximately $750 million for a facility on the CRL site.		Operations costs would be much higher at a non-CRL site as a result of the additional packaging and transportation of waste off-site that would be required.	 (WL site)  (NPD site)

Table 2.5.4-1: Evaluation of Alternatives – Facility Location

Criteria	Alternative 1 – On-site at CRL		Alternative 2 – Off-site at Non-CRL sites	
Environmental Effects				
Biophysical				
Atmospheric Environment	Decreased air emissions and greenhouse gases as most of the waste to be disposed in the NSDF is from the CRL site.		Additional transportation of waste would result in increased air emissions and greenhouse gases.	
Geological and Hydrogeological Environment	Subsurface investigations on CRL site have concluded that the geology on-site is acceptable for the construction and operation of an ECM.		Geotechnical investigations to support in-situ disposal have been conducted at both WL and NPD and confirm that these sites are suitable for an NSDF type facility.	
Surface Water Environment	No differences are anticipated between the alternatives; all three sites are located within close proximity to a major water feature (i.e., Winnipeg River or Ottawa River).			
Aquatic Biodiversity	No differences are anticipated between the alternatives.			
Terrestrial Biodiversity	Critical habitat for species at risk have been identified at CRL, whereas it is not at WL or NPD. However, the disturbance footprint would be designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible.		No critical habitat for species at risk is present on the NPD or WL site with the exception of a stack at the NPD site which is proposed critical habitat for chimney swift.	
Ecological Health	No differences are anticipated between the alternatives.			
Social				
Socio-economics	New employment and business opportunities associated with the NSDF Project.		New employment and business opportunities associated with the NSDF Project.	
Land and Resource Use	No off-site transport of waste required therefore minimizing energy use.		Transport of waste is an energy intensive activity.	
Social Acceptability	Most waste to be disposed is already located at the CRL site which limits the transportation of waste off-site and is expected to be more acceptable to the public and Indigenous Peoples compared to Alternative 2.		The off-site transport of large amounts of radioactive waste on public roads may raise perceived safety concerns amongst the public and Indigenous Peoples.	

Table 2.5.4-1: Evaluation of Alternatives – Facility Location

Criteria	Alternative 1 – On-site at CRL		Alternative 2 – Off-site at Non-CRL sites	
Human Health and Safety				
Public Health & Safety (construction and operations)	Most waste to be disposed is already located at the CRL site which limits the transportation of waste off-site.		The off-site transport of large amounts of radioactive waste on public roads may raise perceived safety concerns amongst the public.	
Public Health & Safety (long-term)	Transport of waste on public roads is minimized reducing the risk of traffic accidents		Higher risk of traffic accidents from transport of waste on public roads (50,000 trips)	
Worker Health & Safety	Both alternatives can be developed in a manner that protects worker health and safety.			

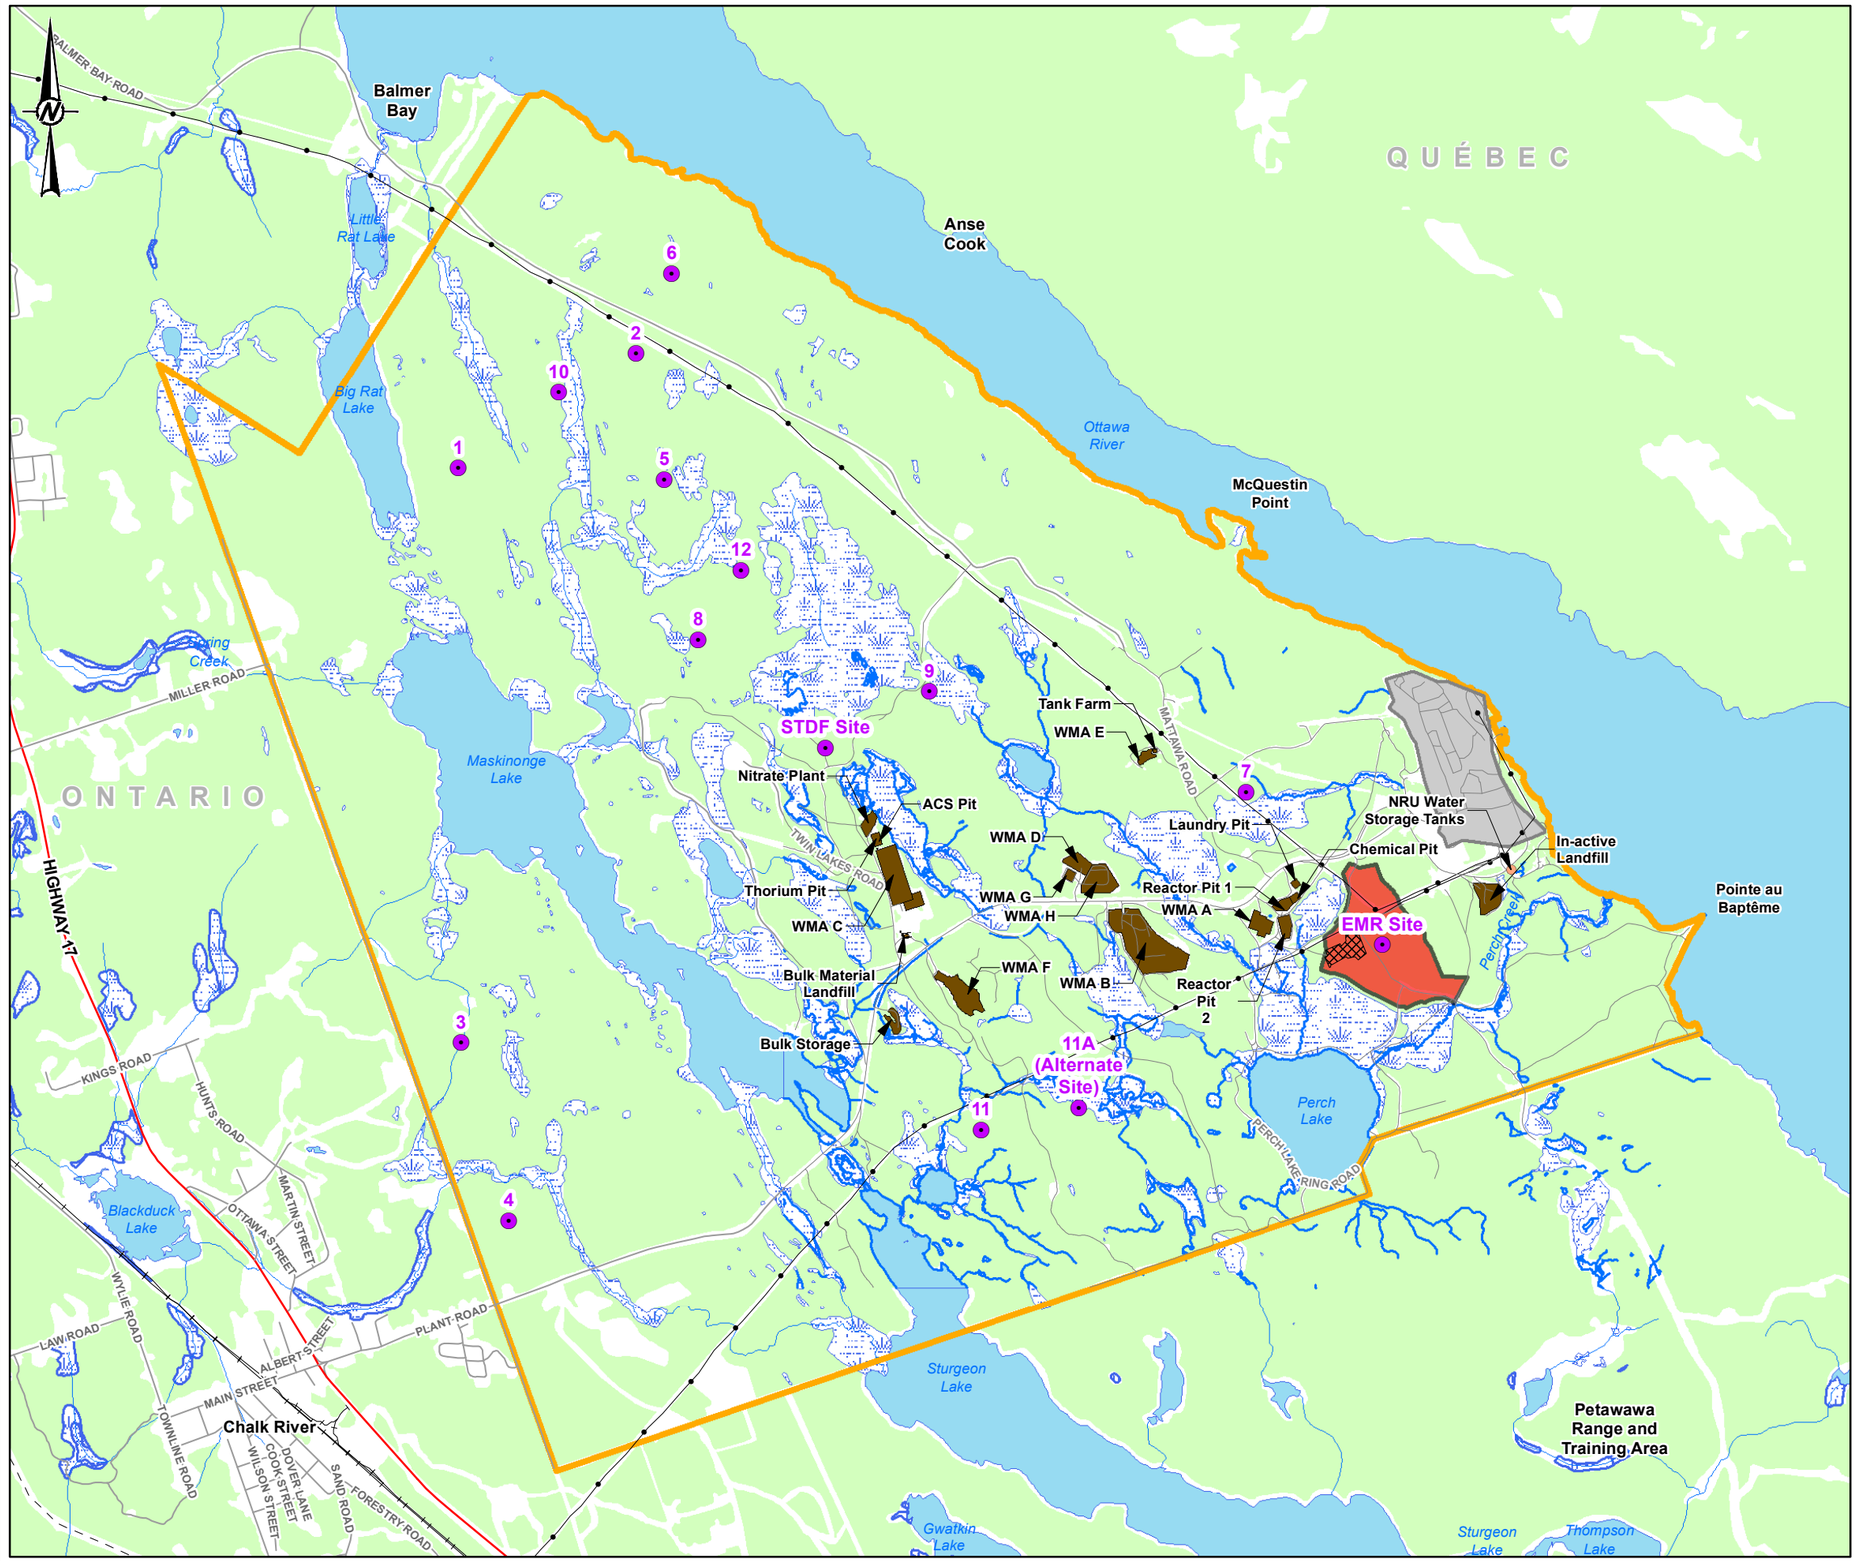
Note:

WL = Whiteshell Laboratories; NPD = Nuclear Power Demonstration; ECM = engineered containment mound.

2.5.5 Site Selection

The selection process for the siting of the NSDF at CRL included the identification of 15 potential sites within the CRL site for initial screening. This screening process included the development of mandatory criteria that must be satisfied by candidate locations; mandatory criteria included:

- minimum area of 14 ha;
- site must be at least 200 m wide;
- access to Class IV electricity for power;
- access to water for sanitary and process requirements; and
- access to gas or other heating source.



Exclusion criteria were then applied to remove any locations that were constrained by NSDF Project requirements or by pre-defined factors; exclusion criteria were physical, cultural, and biological features that would eliminate a location from the list of potential sites because development is either not permitted or poses a risk for the intended use/project (CNL 2016c). Exclusion criteria included:

- Ottawa River Floodplain:
  - Areas which are below the 1 in 100 year Ottawa River flood elevation of 115 metres above sea level (masl).
  - Areas that are below the flood elevation of 130 masl which would result from a hypothetical failure of the Des-Joachims hydroelectric dam and McConnell Lake Control Dam.

- Areas with a slope in excess of 25%; areas with a slope of less than 10% are desirable.
- Areas within 50 m of Plant Road. The three key reasons for this setback are:
  - Protection of CRL workers in transit on Plant Road during waste placement.
  - Limiting visibility of structures from Plant Road.
- Geotechnical Characteristics:
  - Areas with outcrops and organics less than 20% of the proposed siting area.
  - Areas with liquefaction potential and active fault lines.
- Species at Risk:
  - Areas of nationally or provincially significant plant or tree species, in small groups or stands, in accordance with the Federal *Species at Risk Act* and habitat of those threatened or endangered species as per the *Committee on the Status of Endangered Wildlife in Canada* (COSEWIC) listing. Research plantations at CRL may contain these species.
  - Known or likely habitats of national or provincially significant wildlife species in accordance with the Federal *Species at Risk Act* or COSEWIC listing as per guidance by CNL Environmental Protection.
- Wetlands:
  - Areas that are seasonally or permanently inundated with water.
  - Areas within 30 m from watercourses or wetlands.
- Located adjacent to provincially registered archaeological sites.
- Areas within 100 m from existing CRL site boundaries.
- Sites of existing or previously sited facilities.

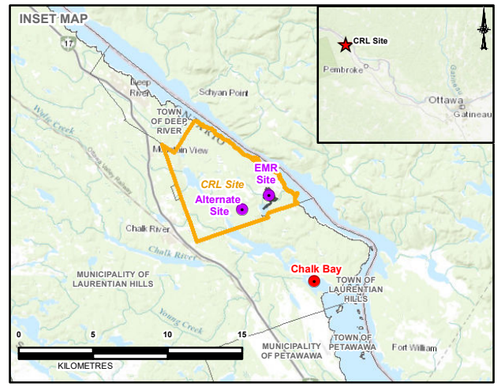


Table 2.5.5-1 summarizes the candidate sites and provides rationale for the exclusion of select sites, and identifies those sites carried forward for further evaluation based on the mandatory and exclusion criteria listed above.

Two candidate locations were identified for further evaluation after the application of the mandatory attribute criteria and the exclusion criteria; 1) the East Mattawa Road (EMR) site; and 2) the Alternate site (11A). The locations of the two sites are shown on Figure 2.5.5-2 and described below. When evaluating the technical feasibility of the facility location, many of the criterion can be satisfied by both alternatives. For example, both alternatives can be constructed such that they meet the purpose of the NSDF Project and both alternatives can be constructed to accommodate 1,000,000 m^3 of LLW. Key differences in the alternatives are primarily related to monitoring complexity, life cycle costs and potential environmental effects; as such, the evaluation focuses on these criterion.

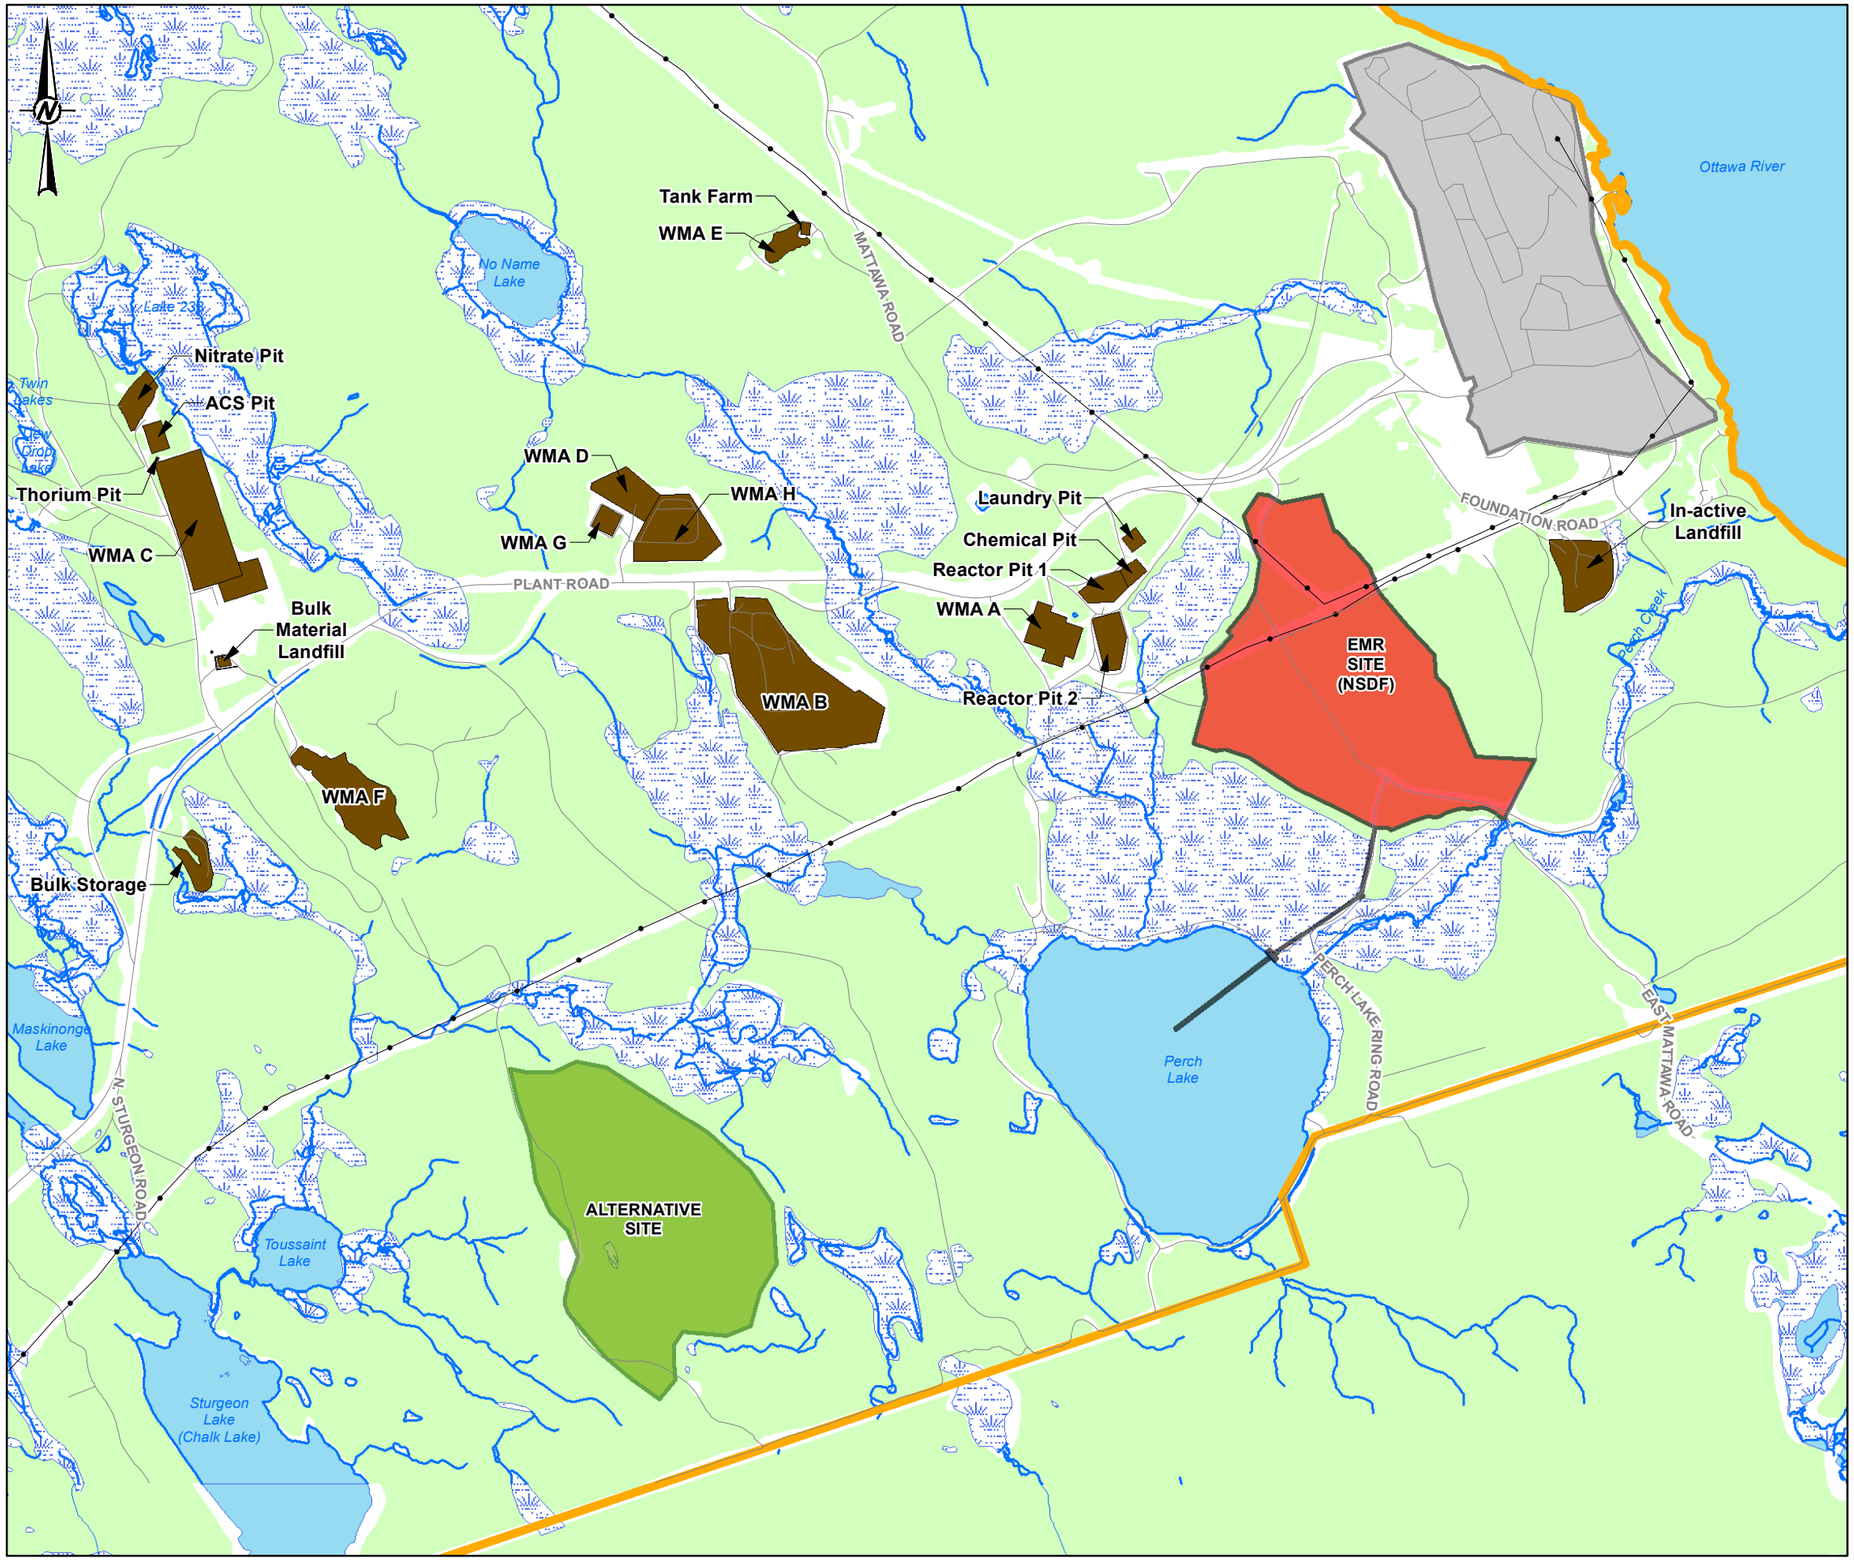
Table 2.5.5-1: Potential Sites for the Project Considered by CNL

Site Number	Description	Rationale for Exclusion or Inclusion
1	▪ 42 ha in size; ▪ Located at the north end of the CRL site; and ▪ Located in the Balmer Bay drainage basin.	Excluded: ▪ Less than 100 m from the CRL site boundary
2	▪ 31 ha in size; ▪ Located at the north end of the CRL site; ▪ Several areas of exclusion (i.e., small ponds and archaeological sites) interspersed through the area; ▪ Hydro is available 0.4 km from the site; ▪ The site is located a long distance from Plant Road (5 km on Mattawa Road); and ▪ Located in the Maskinonge Lake / Balmer Bay drainage basins	Excluded: ▪ Located adjacent to recorded archaeological sites
3	▪ 24 ha in size; ▪ Located at the south west boundary of the CRL site; and ▪ Located in the Chalk Lake West drainage basin.	Excluded: ▪ Less than 100 m from the CRL site boundary.
4	▪ 17 ha in size; ▪ Located at the south west boundary; and ▪ Located in the Chalk Lake West drainage basin.	Excluded: ▪ Less than 100 m from the CRL site boundary.
5	▪ 12 ha in size; ▪ Area is interrupted by a small stream; ▪ No access road from within the 300 m distance; ▪ Approximately 4.3 km from Plant Road; ▪ The area is generally flat or gently sloping; ▪ Number of woodland pools throughout; and ▪ Located in the Maskinonge Lake / Balmer Bay drainage basin.	Excluded: ▪ Area is less than 14 ha and not considered large enough to accommodate the NSDF Project.
6	▪ 12 ha in size; ▪ Located at the north end of the CRL site; and ▪ Located in the Ottawa River watershed.	Excluded: ▪ Area is less than 14 ha and not considered large enough to accommodate the NSDF Project.
7	▪ 11 ha in size; ▪ Located adjacent to the Mattawa Road and close to Plant Road; ▪ Large areas of exclusion (wetland areas) along the north-east edge; ▪ Hydro is available at the site; and ▪ Located in the Perch Creek and Perch Lake Watershed.	Excluded: ▪ Area is less than 14 ha and not considered large enough to accommodate the NSDF Project.

Table 2.5.5-1: Potential Sites for the Project Considered by CNL



Site Number	Description	Rationale for Exclusion or Inclusion
8	▪ 10 ha in size; ▪ Access to the site is poor (an old logging road which is not maintained is the only existing access); ▪ The closest road is approximately 500 m (Bass Lakes Road); ▪ The site is surrounded by wetlands and surface ponds, which interrupt the usable areas; and ▪ Located in the Maskinonge Lake drainage basin.	Excluded: ▪ Area is less than 14 ha and not considered large enough to accommodate the NSDF Project.
9	▪ 10 ha in size; ▪ Site is interrupted by areas of wetlands and much of the site is covered by wetlands; ▪ Adjacent areas are not considerably above the wetland elevation; therefore, the site is prone to flooding; ▪ Hydro is available within 1 km of the site; and ▪ Located in the Perch Lake / Maskinonge Lake drainage basins.	Excluded: ▪ Area is less than 14 ha and not considered large enough to accommodate the NSDF Project.
10	▪ The site is 10 ha in size; ▪ Located at the north end of the CRL site; and ▪ Located in the Balmer Bay drainage basin.	Excluded: ▪ Area is less than 14 ha and not considered large enough to accommodate the NSDF Project.
11	▪ The site is 8 ha in size; ▪ There is hydro available approximately 1.2 km from the site; ▪ The site is 2.2 km from the Plant Road and 3.4 km from WMA B; and ▪ Located in the Chalk Lake East drainage boundary.	Excluded: ▪ Area is less than 14 ha and not considered large enough to accommodate the NSDF Project.
11A (Alternate Site)	▪ The site is 40 ha in size; ▪ Slope is greater than 10% in some areas of the site; ▪ There is a small pond at the north end of the site; ▪ Several woodland pools are present on the site; ▪ There is hydro available approximately 2.2 km from the site at the Plant Road; ▪ The site is 3.4 km from WMA B; ▪ Portion of the site is partially located in Blanding's turtle potential candidate critical habitat zone; and ▪ Located in the Chalk Lake East drainage boundary.	Carried forward for further analysis.

Table 2.5.5-1: Potential Sites for the Project Considered by CNL

Site Number	Description	Rationale for Exclusion or Inclusion
12	▪ The site is 8 ha in size; ▪ Access to the site is poor (an old logging road which is not maintained is the only existing access); ▪ The site is surrounded by areas of bog (organic material) and surface water (ponds, marshes, etc.) which interrupt the usable areas; and ▪ Located in the Maskinonge Lake drainage boundary.	Excluded: ▪ Area is less than 14 ha and not considered large enough to accommodate the NSDF Project.
Sand Trench Disposal Facility (STDF) Site	▪ Centrally located within the CRL site; ▪ The site is bounded by wetland (bog), Twin Lakes, 233 Lake, and the Nitrate Plant and associated plume; ▪ The site overlaps critical Blanding's turtle habitat and is adjacent to a Great Blue Heron colony, a protected species under the Migratory Birds Convention Act; ▪ Located in the Maskinonge Lake drainage boundary.	Excluded: ▪ This area contains habitat of significant wildlife species (Blanding's Turtles); ▪ The site is not large enough to accommodate the NSDF Project.
East Mattawa Road (EMR) Site	▪ The site has a capacity of >30 ha in size; ▪ Close proximity to the CRL main campus; ▪ Water service, natural gas and power sources are available in close proximity; ▪ Located in the Perch Creek and Perch Lake Watershed. ▪ Located in close proximity to the Perch Lake Swamp wetlands;	Carried forward for further analysis

2.5.5.1 East Mattawa Road

In general terms the EMR site is located on a ridge, that slopes away from the Ottawa River and towards the Perch Lake Basin, approximately 1.1 km from the Ottawa River and 500 m from the CRL main campus and is approximately 34 ha[1] in size (Figure 2.5.5-2). The northern boundary abuts Power Line Road and the southern boundary is just short of ER-3 (Emergency Road) and the Perch Lake Ring Road. On the western side, a 30 m setback from the Perch Lake Swamp wetlands forms the site boundary and to the east a local ridge line of the Ottawa Valley forms the boundary. The site boundary to the north is forested land between the hydro corridor and Plant Road. To the west and south is a low-lying marsh area, with the existing WMA A and B further northwest. The South East Mattawa Road leads to ER-3 (Emergency Road) and the Perch Lake Ring Road. To the east is forested land, which drops down to the main CRL site on the opposite side of the ridge.

2.5.5.1.1 Technical Feasibility

East Mattawa Road is one of three existing designated emergency evacuation routes from the CRL main campus. Access to the site is provided by both the ER-3 (Emergency Road) and the Emergency Route #3. Both access routes are regularly travelled and subject to routine maintenance. Emergency Route #3 has been re-routed as part of a previously planned upgrade to this road. Overall, access to the EMR site is well established and upgrades required for heavy equipment and truck traffic to the NSDF would be minimal.

Mandatory services (i.e., Class IV power, water for sanitary and process requirements, gas or other heating sources) can be readily accessed for the EMR site. The EMR site is approximately 500 m from the CRL main campus, which is the source of CRL's decommissioning work that will generate much of the waste. Overall, the services required to support the NSDF Project are all located much more proximate to the EMR site. A potential water source could be taken from 500 m from the EMR site, and a natural gas pipeline is installed along Plant Road at the juncture of EMR site. The EMR site is located within the Perch Creek and Perch Lake Watershed, which has been impacted by plumes emanating from the WMA A and the Liquid Dispersal Areas. As such, extensive environmental studies of contaminant hydrogeology have been completed in the last 60 years and continue to be ongoing as part of CNL's existing Environmental Management Plan thus a robust understanding of the Perch Creek and Perch Lake Watershed exists, and CNL has confidence in predictions of how radiological releases would behave. The Environmental Management Plan for the CRL site can easily be expanded to include monitoring and sampling locations for the NSDF Project.

2.5.5.1.2 Economic Feasibility

Both site areas' overburden is adequate and site clearing costs will be comparable between the sites as tree growth density characteristics are similar. Overall, the services required to support the NSDF Project are all located much more proximate to the EMR site. A potential water source could be taken from 500 m from the EMR site, and a natural gas pipeline is installed along Plant Road at the juncture of EMR.

[1] The EMR site considered during initial siting is approximately 34 ha. This site continued to be refined throughout the engineering and design process for the NSDF Project resulting in a footprint of approximately 37 ha for the NSDF Project site.

2.5.5.2 Alternate Site

The Alternate site is located within the Chalk Lake Basin, southeast of WMA F (Figure 2.5.5-2) and is approximately 37 ha in size. Access to the Alternate site is via the existing Port Hope Road, a narrow gravel road adjacent to the western border of the site. The existing access road to the site from the Plant Road is 2.2 km long and will require considerable upgrades to provide safe passage of heavy equipment and truck traffic.

2.5.5.2.1 Technical Feasibility

Electricity is available from along the Plant Road, as well as natural gas from the pipeline recently installed on the CRL site, but are approximately 2.2 km from the Alternate site. Water service is available at the CRL main campus, but a new feed will be needed. The proposed tie-in to the water supply will be approximately 5 km from the Alternate site and a pipeline and pumping station would be needed to deliver water uphill to the facility. Additional space is available to the area to the north of WMA F for use as a trainer/lay down areas (currently used to store marine containers) or future facility expansion. Space is also available south of the Alternate site, close to the border with Garrison Petawawa.

The Alternate site is located in a largely undeveloped area. As such, extensive modifications to CNL's existing Environmental Management Plan are needed to include monitoring and sampling locations for the NSDF Project as there is a lesser understanding of site characteristics for the alternate site.

2.5.5.2.2 Economic Feasibility

Both site areas' overburden is adequate and site clearing costs will be comparable between the sites as tree growth density characteristics are similar. The Alternate site will require considerable road upgrades for the 2.2 km route from the Plant Road to provide safe passage of heavy equipment and truck traffic. Electricity, natural gas and water supply would need to be brought in from a further away source. Overall, infrastructure costs are higher for the Alternate site as compared to the EMR site.

2.5.5.3 Environmental Effects

The EMR site is located within the Perch Creek and Perch Lake Watershed, which has been impacted by groundwater plumes emanating from the WMA A and the Liquid Dispersal Areas. Extensive environmental studies have been completed in the Perch Lake Swamp wetland complex, located to the west of the EMR site, to characterize the existing radiological contamination in the soil and vegetation. Of particular interest are the adjacent legacy Liquid Dispersal Areas and WMA A, which discharge contaminated groundwater into the Perch Lake Swamp wetlands creating an environmentally impacted site. The EMR site is in close proximity to existing brownfield waste sites, and as such, consolidates land uses. The Chalk Lake Basin, within which the Alternative site is located, contains no operating facilities, WMAs, or any known contamination, and is therefore unaffected by CRL activities. The WMA F is the nearest WMA located approximately 1.5 km the north of the Alternate site, in the Maskinonge Lake basin. The Alternate site is in a largely undeveloped area. There are no pre-existing plumes or contamination from WMAs in the vicinity of the Alternate site, thus introducing a new waste disposal area which is not contiguous with current CRL brownfield areas or impacted areas.

The EMR site is close to the CRL main campus, which is where the vast majority of waste from building decommissioning will be generated. The EMR site is approximately 4 km closer to the CRL main campus as compared to the Alternate site; trucks will travel approximately 6 to 7 km for delivering waste to the Alternate site from the CRL main campus. The increased transportation distance of wastes to the Alternate site would result in increased air emissions, and therefore greenhouse gases. Any dust created from the NSDF construction and operation on either site would be abated as per environmental protocols. Noise transmission to the

CRL main campus will be mitigated by the topography as the EMR site is situated on the lower side of the hill facing inland. The Alternate site would not be visible to traffic on Plant Road or at the CRL main campus; noise is not anticipated to be an issue as the area is isolated.

In 2016, geotechnical surveys were completed at the EMR site (Golder 2016). Ground surface elevations range at the EMR site from a low of approximately 160 masl within the low-lying and relatively flat terrain bordering the north side of Perch Lake, to a high of 196 masl along the crest of the ridge to the east of Emergency Road #3 that separates the Perch Creek and Perch Lake Watershed and the Ottawa River watershed. The overburden thickness at the site typically ranges from approximately 0 to 10 m, depending on bedrock topography. The surficial geology consists primarily of sands, underlain by dense sandy silt till which contains some cobbles and occasional boulders. Organic soils (e.g., peat) have been deposited in the low-lying and wetland areas.

Precipitation in the EMR site area recharges a shallow groundwater system that includes the overburden and the upper few metres of fractured bedrock. Groundwater levels range from about 0.5 m to more than 11.4 m depth, corresponding to elevations of between approximately 173 and 158 masl. Groundwater flow directions reflect the site topography with the overall direction being southwesterly from the ridge bounding the east side of the site and semi-radial from elevated lands within the bedrock bench. Within the low saturated lands to the west of the siting block, groundwater flow parallels the Perch Lake surface drainage. The crest of the ridge along the eastern side of the siting block is interpreted to roughly coincide with a groundwater (and surface water) divide between the Perch Creek and Perch Lake Watershed and the Ottawa River.

In 2014, geotechnical surveys were completed at the Alternate site (Golder 2016 [referred to as Block 11 in the report]). The Alternate site is reflective of the CRL site as a whole. The overburden thickness ranges from approximately 0 to 20 m depending on the bedrock topography. Generally, the overburden contains a thin layer of organic topsoil at the surface with a layer of loose sand, then compacted sand. The site is characterized by an undulating ground surface ranging from approximately 172 masl in the east and northeast to a low of approximately 115 masl in the wetland areas bordering Chalk (Sturgeon) Lake, which is located roughly 600 m to the southwest. Overall, the ground surface slopes to the west.

Precipitation falling on topographically high areas results in the recharge of the shallow-scale groundwater system that includes the overburden and the upper few metres of fractured bedrock. Groundwater levels beneath the Alternate site range from about 0.5 m to more than 9 m depth, corresponding to elevations of between roughly 164 and 150 masl. The southwestern part of the Alternate site is well drained, but much of the central portion of the area is low-lying terrain resulting in with seasonal accumulations of surface water and saturated ground.

The proposed EMR site is 1.1 km from the main channel of the Ottawa River, but groundwater passing below it, discharges to Perch Creek before draining to the Ottawa River, providing a flowpath distance of about 2.6 km. It is the transit time through the groundwater portion of the flowpath; however, that represents almost all of the average 7-year water residence time. By contrast, the Alternate site is about 3.5 km from the main channel of the Ottawa River, but about 850 m from Chalk Lake. Chalk Lake is a long narrow bay in the Ottawa River, and for the site evaluation it has been considered to be a part of the river. The groundwater residence time from the Alternate site to the location where the groundwater discharges to surface is about 2 years. Overland flow from the Alternate site's groundwater discharge area passes through a small lake (Toussaint) before discharging to Chalk Lake, but this only adds a few months of mean residence time.

The predictions above are based on both measured and calculated data. The information for the EMR site is founded on observation of contaminant movement from the Reactor Pit #2 to Perch Lake and Perch Creek, (just west of the EMR site) over several decades, as well as calculations using groundwater gradients and soil characteristics arising from extensive study and site assessment. The predictions from the Alternate site are calculated based on gradient and soil characteristic data collected for the assessment of that site. In summary, the EMR site has a longer groundwater flowpath and slower groundwater flow velocities over most of the flowpath, compared to the Alternate site.

The EMR site is similar to the majority of the undisturbed forested areas of the CRL site in terms of terrestrial biodiversity. In the spring and summer of 2016, a biodiversity study was completed at both the EMR site and Alternate site. No butternut trees were found within the EMR site or in the surrounding area during the biodiversity surveys. Several bird species, including eastern whip-poor-will, eastern wood-pewee, wood thrush, golden-winged warbler and the Canada warbler were observed in the vicinity of the EMR site. Four bat species were also detected including the little brown myotis, northern myotis, the tri-coloured bat and eastern small-footed myotis.

Extensive environmental studies have been completed in the Perch Lake Swamp wetland complex (located to the west of the EMR site) to characterize the existing radiological contamination in the soil and vegetation. These wetlands are home to Blanding's and snapping turtles. Biodiversity studies to date by CNL do not indicate that Blanding's turtles are making extensive overland movement in this area during their migration as no individuals have been sighted on the road in this location. Although the EMR site does not appear to fragment the Blanding's turtle habitat, development at the EMR site may encroach on some portion of the species terrestrial habitat. The EMR site is located immediately adjacent to the Perch Lake Swamp wetland and, therefore, has an increased potential for indirect effects on terrestrial species that use this habitat.

The Alternate site is similar to the majority of the undisturbed portion of CRL site in terms of terrestrial biodiversity. Several songbirds were observed during the 2016 biodiversity surveys including Canada warbler, eastern wood-pewee and eastern whip-poor-will. Bat surveys confirmed the presence of little brown myotis, northern myotis, and the tri-coloured bat and eastern small-footed myotis. Blanding's turtles have been observed using the adjacent wetlands habitat and crossing Port Hope Road during their spring migration. The Alternate site encroaches on the Blanding's turtles travelling corridor within the CRL site, which would potentially cause a slight fragmentation between habitats and may increase the potential for road mortality. No Butternut trees were observed during the biodiversity surveys.

Similar mitigation for both site locations would be required to limit effects to terrestrial biodiversity. Mitigation includes the protection of migration pathways for Blanding's turtles, installation of bat boxes, tree removal before and after the migratory bird nesting period and environmental awareness training for Contractor personnel. In addition, erosion and sediment control practices (e.g., silt fences, runoff management) already in place at the CNL property will be used during construction around disturbed areas, and existing programs such as CNL's Management of Land and Habitat Procedure will be implemented. As well, all work on the site would be subject to a *Species At Risk Act* permit.

There are six archaeological sites previously recorded within 1 km of EMR site, but none are located directly within the proposed footprint. An archaeological assessment was completed at the EMR Site in 2016 to identify cultural resources, determine their significance and identify any mitigation that may be required. Test pits were excavated during Stage 2 and 3 archaeological assessment. During the shovel testing and infilling activities of the Stage 2 survey, lithic material predominantly made up the artifact assemblage. As a result, a total of 68

locations were recommended for Stage 3 site assessment and recorded as Pre-Contact archaeological site CaGi-65, 66 and 67. A small collection of historic material was found on the outer edge of the proposed Project boundary and was identified as belonging to an existing Euro-Canadian Site CaGi-36. Due to this existing site's location on the outer boundary, the decision to maintain a 50m buffer around the existing site and remove it from the NSDF Project footprint was determined. During the Stage 3 assessments of CaGi-65, 66 and 67, the sites yielded material meeting the cultural heritage value or interest criteria and therefore were recommended for Stage 4 mitigation; a full excavation and documentation of all material recovered. An archaeological assessment was completed for the Alternate site in 2013 and 2014 and results indicate that there are no significant cultural resources within the areas surveyed (Swayze 2015).

In 2008, CNL developed an Archaeological Master Plan that resulted in a formal Cultural Resource Management (CRM) program at CNL. If during site preparation or construction activities, cultural material is identified, activities will be stopped and the CNL CRM specialist will be contacted.

Both alternatives would implement mitigation that provides for worker and public health and safety during all phases of the NSDF Project. In addition, mitigation implemented to protect the surface water environment, aquatic biodiversity and ecological health would be similar for both sites. Employment and business opportunities, and community well-being would also be similar for both site locations.

2.5.5.4 Summary

The comparative evaluation between facility location alternatives within the CRL site is provided in Table 2.5.5-2. As shown in the table, the EMR site is preferable for both economic and environmental reasons. In summary, the EMR site is adjacent to a Legacy WMA and in closer proximity to the existing waste operational areas. This represents a tighter consolidation of land uses and less effects on undeveloped areas. Extensive environmental studies have been completed in the Perch Creek and Perch Lake Watershed where the EMR site is located over the past decades, which adds additional confidence in how the facility will react with the natural environment. In addition, the Perch Creek and Perch Lake Watershed has been impacted by plumes emanating from the WMA A and the Liquid Dispersal Areas. There may be perceived increased risks of the EMR site as it is located closer to the Ottawa River; however, the groundwater transit time from the EMR site to nearest surface waterbody is estimated to be 5 to 15 years with an average transit time of approximately 7 years compared to approximately two years for the Alternate site.

Table 2.5.5-2: Evaluation of Alternatives - Site Selection

Criteria	Alternative 1 – EMR Site		Alternative 2 – Alternate Site	
Technical Feasibility				
Project Purpose	Both sites are technically feasible.			
Storage Capacity	The EMR site has sufficient area available to develop a facility with a storage capacity of 1,000,000 m^3.		The Alternate site has sufficient area available to develop a facility with a storage capacity of 1,000,000 m^3	

Table 2.5.5-2: Evaluation of Alternatives - Site Selection

Criteria	Alternative 1 – EMR Site		Alternative 2 – Alternate Site	
Monitoring Complexity	Extensive monitoring programs already exist in the vicinity of the EMR site; therefore, the existing Environmental Monitoring Plan for the CRL site can easily be expanded to include monitoring and sampling locations for the NSDF Project.		Limited monitoring is place at the Alternate Site. Significant expansion of CNL's existing Environmental Monitoring Plan would be required to include monitoring and sampling locations for the NSDF Project.	
Economic Feasibility				
Life Cycle Costs	The site is close to existing services and has the lowest costs to provide project site services and access routes.		There would be increased costs in extending services, including new roads, at the Alternate site.	
Environmental Effects				
Biophysical				
Environmental Setting	The EMR site is located in the Perch Creek and Perch Lake Watershed, which has been impacted by plumes emanating from the WMA A and the Liquid Dispersal Areas (i.e., brownfield site) and as such, consolidates waste land uses.		The Alternate site is located in the Chalk Lake basin, which is an undisturbed area with no previous contamination.	
Atmospheric Environment	The EMR is approximately 4 km closer to the CRL main campus as compared to the Alternate site.		The increased transportation distance of wastes to the Alternate site would result in slightly increased air emissions, and therefore greenhouse gases.	
Geological and Hydrogeological Environment	The groundwater transit time from the EMR site to nearest surface waterbody is calculated to be 5 to 15 years with an average transit time of approximately 7 years.		The groundwater transit time from the Alternate site to nearest surface waterbody is calculated to be 2 years.	
Surface Water Environment	No anticipated difference between alternatives.			
Aquatic Biodiversity	No anticipated difference between alternatives.			
Terrestrial Biodiversity	The EMR site is located immediately adjacent to the Perch Lake Swamp, and therefore has an increased potential for indirect effects on terrestrial species that use this habitat.		The Alternate site encroaches on the Blanding's turtles travelling corridor within the CRL site, which would potentially cause a slight fragmentation between habitats and increases the potential for increased road mortality.	
Ecological Health	No anticipated difference between alternatives.			
Social				
Socio-economics	No anticipated difference between alternatives.			

Table 2.5.5-2: Evaluation of Alternatives - Site Selection

Criteria	Alternative 1 – EMR Site		Alternative 2 – Alternate Site	
Land and Resource Use	An archaeological assessment was completed for the NSDF Project site. The site boundaries were adjusted to mitigate any potential impacts.		An archaeological assessment was previously completed and results indicate that there are no significant cultural resources within the areas surveyed.	
Social Acceptability	There may be perceived increased risks of the EMR site as it is located closer to the Ottawa River		Located further from the Ottawa River and may be perceived more favourably.	
Human Health and Safety				
Public Health & Safety (construction and operations)	Both alternatives can be developed in a manner that protects public health and safety during construction and operations.			
Public Health & Safety (long-term)	Both alternatives can be developed in a manner that protects public health and safety in the long-term.			
Worker Health & Safety	Both alternatives can be developed in a manner that protects worker health and safety.			

Note:

EMR = East Mattawa Road; WMA = Waste Management Area.

2.5.6 Leachate Management

Leachate is generated as water infiltrates through the ECM during operations (and to a much lesser extent during the post-closure phase). The operating period of the NSDF is 2025 to 2070, and wastewater treatment is required for the full duration of operations and plus several years following closure of the ECM and installation of the final cover. The average annual wastewater volume to be produced during operations is predicted to be approximately 11,000 m^3/yr. Another important hydraulic consideration is the maximum wastewater flow rate that must be received and processed by the WWTP. Leachate and decontamination water are produced at relatively low rates compared to contact stormwater, especially during major storm events. The maximum hydraulic flow rate was determined by back-to-back 100-year, 24-hour storm events (4,710 m^3) and was selected as a worst-case design condition for determining the required volume of wastewater to be treated.

A comparison of projected leachate concentrations and discharge targets show that several radionuclides and non-radionuclides may be present at concentrations in the wastewater that exceed discharge targets, and treatment for these designated contaminates of potential concern (COPC) will be required. The WWTP must therefore be designed for removal of radionuclides and selected non-radiological constituents (e.g., metals).

Three alternative means of leachate management were considered for meeting the above-mentioned design requirements for the NSDF Project:

1) Use of an existing wastewater treatment facility;

2) Construction of a new WWTP; and

3) No discharge through the use of a leachate evaporation pond.

2.5.6.1 Existing Waste Treatment Centre

This alternative considers sending the wastewater discharge to the existing WTC.

2.5.6.1.1 Technical Feasibility

The existing WTC at CRL was built more than 40 years ago to treat low-level radioactive liquid waste originating from reactor and site operations. The WTC is expected to reach its end life in the next decade and will not be available for the operating life of the NSDF Project (i.e., 2025 to 2070). In addition, although WTC has the capacity to treat the volume of leachate predicted to be generated, this kind of throughput would pose a reliability risk to NSDF Project operations even if there were reinvestment in WTC. An underground pipeline to bridge the 2 km distance between facilities would be required. The 2 km pipeline distance is longer than the distance to discharge points for the WWTP; and therefore, more costly. It is also not certain that WTC decontamination performance is sufficient to meet treated leachate discharge/infiltration requirements, and therefore WTC may not be fit for purpose. The WTC operations are labour and energy intensive ($7 M annually for the required throughput, exclusive of capital reinvestment). The WTC depends on powerhouse support (steam, steam condensate return in particular), and the powerhouse is slated for shutdown prior to 2025. For these reasons, the existing waste treatment facility is not a technically feasible option and is not further evaluated.

2.5.6.2 Wastewater Treatment Plant (New)

This alternative considers a new WWTP that would treat wastewater sources at the NSDF Project site, including contact stormwater and leachate generated from the ECM, equipment and personnel decontamination water, and laboratory wastewater.

2.5.6.2.1 Technical Feasibility

The proposal to build a new, stand alone treatment plant would meet the NSDF Project purpose and would use the best demonstrated available technology that is economically achievable for removal of the COPC from the NSDF wastewater. Further, this alternative would have the capacity to treat the volume of leachate predicted to be generated over the operating life of the NSDF Project (i.e., 2025 to 2070) and not limit the ECM's storage capacity over the long-term. This alternative would have a design life of 50 years, after which the ECM would be sealed with the final cover and the volume of leachate would significantly decrease. Effluent monitoring will be required at the WWTP to ensure treated water meets effluent discharge targets.

2.5.6.3 No Discharge Option - Leachate Evaporation Pond

Evaporation ponds are artificial ponds with very large surface areas that are designed to efficiently evaporate water by sunlight and exposure to the ambient temperatures.

2.5.6.3.1 Technical Feasibility

Leachate evaporation ponds are used in hot dry climates and are not effective in the mid-continental climate of central Canada with no distinct dry season. Therefore, a leachate evaporation pond is not considered to be a technically feasible alternative and is not further evaluated.

2.5.6.4 Summary

The new WWTP is the only technically feasible option available to treat the leachate to be generated from the NSDF. The WTC is expected to reach its end life by end of the next decade and will not be available for the operating life of the NSDF Project (i.e., 2025 to 2070). Leachate evaporation ponds are used in hot dry climates and are not effective in the mid-continental climate of central Canada with no distinct dry season. As there is only one technical feasible alternative, potential environmental effects on VCs are not presented in this section; rather the potential environmental effects of the new WWTP are evaluated in the EIS.

2.5.7 Effluent Discharge Options

Following treatment in the WWTP, the treated effluent will need to be managed on-site or be discharged to the natural receiving environment. The estimated annual volume of the treated effluent to be discharged is approximately 11,000 m^3. Options for discharge of the treated effluent are:

- discharge to ground;
- discharge to surface water (i.e., Perch Creek, Perch Lake or the Ottawa River);
- co-discharge to the NSDF Stormwater System and to ground;
- discharge to ground and discharge to surface water; and
- No liquid discharge (i.e., thermal evaporator).

2.5.7.1 Discharge to Ground

Discharge of treated effluent to ground would entail the construction of an exfiltration gallery which would promote the exfiltration of treated water into the local groundwater regime. Discharge to ground utilizes the ground for retention capabilities allowing for radionuclide decay. The exfiltration gallery would be located within the NSDF Project site up-gradient of the East Swamp Wetland. The treated effluent, once discharged to ground, would be returned to the adjacent wetlands and eventually discharge to Perch Lake and the Ottawa River. Discharge to ground provides the added benefit of enabling control of recharging water to the wetlands. Further, an exfiltration gallery provides additional retention time for radioactive decay for tritium[2] that will be present in the effluent before discharge to the Perch Lake and Perch Creek receiving systems.

The exfiltration gallery would be designed to operate all year round. Winter conditions would be accounted for by doubling the calculated required design area of the gallery in line with the Ministry of Environment, Conservation and Parks *Stormwater Management Planning and Design Manual* (MOE 2003).

In the event that the gallery overflow pipe is activated, an overflow relief pipe is provided from the exfiltration gallery to route flows that exceed the exfiltration capacity of the gallery to the East Swamp. A rip rap stone dispersion pad is provided at the outlet point of the overflow culvert to dissipate the energy effluent discharged and reduce erosion. Further erosion protection is provided at the culvert outlet to mitigate the ponding of water on the east side of East Mattawa Road, thereby, mitigating erosion potential of both the roadway and disruption

[2] Tritium is of interest to the public and has a relatively short half-life of 12.3 years and therefore benefits from decay over transit time from the exfiltration gallery to Perch Lake.

of surface and subsurface infrastructure located downgradient of the exfiltration gallery and upstream of the East Swamp.

2.5.7.1.1 Technical Feasibility

Exfiltration galleries have been used as a low impact approach to water management and serve to replenish and maintain surface and groundwater levels. They have been used at several Ontario sites in various commercial and industrial applications.

The initial design consisted of an exfiltration gallery located within the NSDF Project site, located downhill from the WWTP. However, hydrogeological conditions at this location are such that the local soils and groundwater regime do not have capacity to accept peak flows from the WWTP at all times. The average WWTP discharge rate is higher than the infiltration capacity of the hosting soils, and the problem is amplified during storm events. Therefore, the current design of the exfiltration gallery cannot support the required flow from the WWTP and is not technically feasible. To address this, additional engineering options were considered including:

- alternative exfiltration locations on the NSDF Project site;
- alternative exfiltration location outside of the NSDF Project site; and
- discharge to an existing legacy liquid dispersal area adjacent to the NSDF Project site.

Alternative Locations on the NSDF Project Site

Space for additional groundwater exfiltration infrastructure on the NSDF Project site is limited due to the size and hydrogeological characteristics of soils at the NSDF Project site as well as wetland areas with environmentally sensitive natural features. Therefore, two additional locations within the NSDF Project site were evaluated. Hydrogeological modelling performed for these two sites indicates that both suffer from inundation challenges similar to that of the original location and will fall short of the required infiltration capacity, and therefore both these options were ruled out.

Alternative Locations off the NSDF Project Site

CNL also evaluated two locations outside the NSDF Project site, located to the northeast of the WWTP. The surrounding area for these locations is across the watershed line which drains to the Ottawa River, unlike the current site location which drains to the Perch Creek and Perch Lake Watershed. The watershed along the Ottawa River is less affected by CRL operations compared to the Perch Creek and Perch Lake Watershed which has been impacted by legacy WMA's and it is desirable to manage all treated effluent within the Perch Creek and Perch Lake Watershed. For this reason, the option was ruled out.

Discharge to Existing Legacy Liquid Dispersal Area

CNL also evaluated the option of discharging the treated effluent to an existing liquid dispersal area located adjacent to the NSDF Project site. This area was used from the 1950s to 2000 to manage untreated low-level liquid waste from CRL operations prior to the expansion of the CRL Waste Treatment Centre. The liquid dispersal area managed up to approximately 100,000 m^3 of low-level liquid waste annually.

Discharge to the existing liquid dispersal area would meet the NSDF Project purpose and could manage the volume of leachate generated from the ECM. However, the discharge of NSDF treated effluent to this dispersal area would generate additional radiologically contaminated groundwater. Due to the existing contamination within the liquid dispersal area, this alternative is not technically feasible.

In summary, based on all the options evaluated above, the sole use of the exfiltration gallery is not sufficient to manage the peak flows from the WWTP at all times. Therefore, the exfiltration gallery on its own is not considered technically feasible. An exfiltration gallery may however be combined with other design options. These combination options are discussed in Section 2.5.7.3 (Co-discharge with NSDF Stormwater System and Discharge to Ground), and Section 2.5.7.6 (Discharge to Ground and Direct Discharge to Surface Water). Combination options were examined for multiple reasons including:

- The use of an exfiltration gallery is consistent with the design approach communicated to stakeholders and Indigenous Peoples.
- The exfiltration gallery will have sufficient capacity during post-closure to handle reduced flows from the WWTP after the ECM is capped.
- The use of the exfiltration gallery as a primary discharge location is beneficial because it provides additional retention time for radioactive decay (e.g., tritium) and returns water to local wetlands

2.5.7.2 Discharge to Surface Water (Perch Creek, Perch Lake or the Ottawa River)

The direct discharge of the treated effluent to surface water would require the construction of a transfer line from the proposed new WWTP (Section 2.5.6.2) to a suitable waterbody. CNL investigated the feasibility of discharging directly to multiple waterbodies including Perch Creek, Perch Lake and the Ottawa River. Each of these discharge locations are discussed further in the sections below and the waterbodies are shown on Figure 2.5.5-1.

2.5.7.2.1 Discharge to Perch Creek

A discharge to Perch Creek was considered. However, the average effluent flow rate is approximately 10% of the low summer flow rate for Perch Creek and the maximum effluent flow rate is approximately 100% of the low summer flow rate for Perch Creek. Direct discharge to Perch Creek would not be expected to be assimilated (i.e., mixed) to the same extent as a larger body of water (e.g., Perch Lake) which could extend the mixing distance down to the Ottawa River depending of flow conditions. Therefore, this alternative was not considered technically feasible and is not evaluated further.

2.5.7.2.2 Discharge to Perch Lake

Constructing a transfer line from the proposed new WWTP to Perch Lake requires the consideration of routing a transfer line through potentially contaminated areas and potential disturbance of wetlands that support critical habitat for designated species at risk. CNL considered two route options:

1) **Transfer line Route 1 –** Transfer line Route 1 would run 1.6 km around the east side of the ECM along the Perch Lake Ring Road to Perch Lake. Pumping would be needed to a high point east of the ECM, from where the water will flow by gravity. This option would require the construction of a small pumping station.
2) **Transfer line Route 2 –** This route option would run 1.3 km around the north and west side of the ECM to Perch Lake. A gravity flow transfer line partly installed by horizontal directional drilling would be required to cross the East Swamp. Unlike Transfer line Route 1, pumping would not be needed.

Both options would be designed to convey the full flow when both treatment trains of the WWTP are operational and can be operated all year.

2.5.7.2.2.1 Technical Feasibility

The use of a transfer line to discharge treated effluent is widely used and effective, and standard mitigation are available to limit adverse effects and provide adequate provisions to protect the environment. Further, CNL currently monitors water quality within Perch Lake and any additional monitoring requirements would be incorporated into the existing monitoring program. Therefore, both route options are considered technically feasible.

2.5.7.2.2.2 Economic Feasibility

The capital and operation cost for the discharge of treated effluent to Perch Lake is expected to represent less than 1% of the costs for the overall project.

2.5.7.2.3 Discharge to Ottawa River

CNL currently discharges treated effluent and surface water via a number of outfalls and streams on the Ottawa River. This alternative considers sending the treated effluent from the WWTP to one of these existing discharge points along the Ottawa River. Any options would require the construction of a transfer line to transport the treated effluent from the WWTP to the ultimate discharge point to the Ottawa River. The transfer line to Ottawa River would be gravity-fed.

2.5.7.2.3.1 Technical Feasibility

There are existing discharge points along the Ottawa River that could handle the proposed discharge volume from the WWTP. The transfer line for some of the discharge points would require construction along the perimeter of the developed CRL site. Although existing underground infrastructure along the perimeter of the developed site adds complexity to construction; construction of a transfer line to the Ottawa River is technically feasible.

2.5.7.2.3.2 Economic Feasibility

The capital and operation cost for the discharge of treated effluent to Ottawa River is expected to represent less than 1% of the costs for the overall project.

2.5.7.3 Co-discharge with the NSDF Project Stormwater System and Discharge to Ground

As described in Section 2.5.7.1, if an exfiltration gallery is used, it must be complemented with other measures. One option considered is to use one or more of the three existing surface water management ponds on-site jointly with the exfiltration gallery. These ponds manage all non-contaminated surface water within the NSDF Project site and discharge to adjacent wetlands and will be dispersed by level spreaders to achieve even flow distribution to the wetland and control erosion.

2.5.7.3.1 Technical Feasibility

The surface water management ponds do not have the capacity to accommodate additional flows from back to back storm events given they were only designed for runoff volumes. The viability of enlarging the existing ponds or adding new ponds was assessed. However, there is insufficient space on the NSDF Project site to accommodate a new pond or enlarging the existing ponds. Therefore, this option was not considered technically feasible.

2.5.7.4 Discharge to Ground and Discharge to Surface Water

This alternative involves the combination of the discharge to ground (Section 2.5.7.1) with the direct discharge to either the Ottawa River (Section 2.5.7.2.3) or Perch Lake (Section 2.5.7.2.2) via a pipeline. For the discharge to Perch Lake, the two pipeline route options discussed in Section 2.5.7.2.3 were investigated as part of this alternative.

2.5.7.4.1 Technical Feasibility

The combination of discharge to ground with a direct discharge to surface water provides an additional discharge option when there is insufficient infiltration capacity at the exfiltration gallery. During post-closure, the ECM will be capped resulting in reduced flows from the WWTP and the exfiltration gallery will have sufficient capacity to manage all flows from the WWTP. As discussed in Sections 2.5.7.2.2 and 2.5.7.2.3, the discharge to either Perch Lake or Ottawa River are considered technically feasible. Further, both transfer line options for the discharge to Perch Lake are considered technically feasible. Therefore, discharge to ground combined with discharge to surface water (i.e., Perch Lake or the Ottawa River) is technically feasible.

2.5.7.4.2 Economic Feasibility

The capital and operation cost for the exfiltration gallery and the discharge of treated effluent to either Perch Lake or Ottawa River are expected to represent less than 1% of the costs for the overall project.

2.5.7.5 No Liquid Discharge (Thermal Evaporator)

Because of public concerns about liquid emissions, options to reduce or eliminate liquid emissions were considered. A thermal evaporator could be installed in the WWTP to evaporate the treated effluent and release it to atmosphere.

2.5.7.5.1 Technical Feasibility

The evaporator would be technically feasible for normal flow conditions but would not have the capacity to manage the flow from back-to-back storm events. It is also noted that this option would not eliminate the need for infrastructure to allow for liquid discharges of treated effluent during storm events. In addition, technology limitations such as fouling of the evaporator would limit the effectiveness of the evaporator and further necessitate the need for a liquid discharge option. This option would also introduce additional emissions to air through evaporation (e.g., tritium and other volatiles) and produce a visible steam plume, which is expected to be a concern to the public. As described in Section 2.5.7.6.1, there was no interest in further consideration of the discharge to air option during the Focus Group on the effluent discharge alternatives in late May 2019.

Based on the above, this option was not considered technically feasible.

2.5.7.6 Environmental Effects

- Based on the review above, three effluent discharge options were considered technically and economically feasible:
- discharge to Perch Lake (Section 2.5.7.2.2);
- discharge to Ottawa River (Section 2.5.7.2.3); and
- discharge to ground and to surface water (Section 2.5.7.4).

The discharge to Perch Lake would require the construction of a new discharge to a waterbody; however, the discharge to the Ottawa River could use an existing outfall where the treated effluent could be combined with an existing discharge to the Ottawa River.

Potential effects to the atmospheric environment considered for all alternatives are related to nuisance noise from construction activities, and increased air and greenhouse gas emissions. Greenhouse gas emissions are expected to be of the same order of magnitude for all alternatives.

Potential effects to groundwater are limited to the option for combined discharge to ground and surface water. The exfiltration gallery would release the treated effluent to ground which would then infiltrate into the groundwater and migrate towards East Swamp Stream and ultimately Perch Lake.

The key pathways related to surface water and aquatic biodiversity include the construction of a new discharge point in a surface waterbody and the release of treated effluent directly to a surface waterbody or via groundwater. The discharge to the Ottawa River alternative includes options to discharge to an existing outfall which limits the construction related effects for the construction of the transfer line. The discharge to Perch Lake would require the construction of a new discharge point within Perch Lake. Design options would need to be considered to limit the resuspension of sediment during operations in Perch Lake due to a thick layer of fine, semi-liquid, highly organic mud lining the bottom of Perch Lake which is susceptible to re-suspension if disturbed. Appropriate mitigation would also be required during construction of the infrastructure to limit adverse disturbances to the Perch Lake shoreline, lakebed, and surrounding watershed.

If only an exfiltration gallery were used (Section 2.5.7.1) an overflow pipe would be required when there is insufficient infiltration capacity at the exfiltration gallery which could result in overland flow of treated effluent. The combination of the exfiltration gallery and discharge to Perch Lake would allow excess flow to be diverted to Perch Lake and eliminate the risk of overland flow at the exfiltration gallery.

All alternatives would result in small changes to surface water quality, which are not expected to result in adverse effects on aquatic biodiversity. The treated effluent will meet effluent discharge targets for protection of the environment and human health.

Discharge to surface water (Perch Lake or the Ottawa River) will require construction of a transfer line from the WWTP to the discharge location. Transfer lines are widely used and standard mitigation measures are available to limit adverse effects on the environment from construction.

A comparison of the environmental effects for the options of direct discharge to surface water compared to the option of discharge to ground combined with discharge to surface water is provided in Table 2.5.7-1.

A comparison of the environmental effects for the options of direct discharge to Perch Lake to the option of direct discharge to the Ottawa River is provided in Table 2.5.7-2.

2.5.7.6.1 Effluent Strategy Focus Group

The NSDF Project team hosted a Focus Group on the effluent discharge alternatives in late May 2019. As a result of feedback on the draft EIS with respect to the effluent management strategy, the NSDF Project chose to further evaluate solutions to manage effluent discharge from the NSDF Project. As a result of the expressed public interest in the protection of the Ottawa River, the NSDF Project decided that a focus group session would be beneficial to the options analysis process and serve as a good forum for members of the public to express their opinions.

Public participation within projects which trigger environmental assessments is critical and CNL considers all input received to ensure good decisions are made with respect to environmental stewardship. At the NSDF Effluent Strategy Focus Group, there was representation from a number of special interest groups including members of the public, local municipalities and non-government organizations. The approach implemented for the Focus Group session included:

- Targeted invite to representatives (or individuals) that expressed an interest in the measures the NSDF Project will take to protect the Ottawa River, as well as the environment in general. In order to ensure an effective and meaningful discussion, the NSDF Project requested for organizations to identify individual to participate who ideally had a background in environmental sciences, familiarity with effluent management practices and a general awareness of the proposed project.
- Provision of relevant background information including general project information, a description of the WWTP, and sharing of the NSDF Project effluent discharge targets as well as several related project links.
- A tour of the proposed NSDF Project site in order to ensure participants were familiar with the setting and environmental baseline conditions.
- Presentations during the focus group session included an overview of leachate treatment alternatives, calculated wastewater quantities, effluent discharge targets and a brief introduction to the alternative means assessment process within CEAA.
- Discussions by the participants were solicited by facilitating two exercises within the focus group session. The first exercise had the participants develop the evaluation criteria through identification of environmental components that were of importance to them followed by a multi-voting process to refine the criteria list as a group. The second exercise had the participants perform a relative evaluation of the effluent discharge options using focus group developed criteria. Participants were broken into two working groups for these exercises and then presented their findings for a round-table discussion.
- Individual survey forms were provided to the participants to provide reflection on their thoughts prior to and following group exercises.

The NSDF Project's intent of the focus group session was to take discussions into consideration for potential improvements to the facility design and incorporation into the final EIS. Although the NSDF Project described and presented the effluent discharge options, the NSDF Project's updated alternative means assessment was not shared with focus group participant so not to influence the discussion. General observations of the discussions included:

- The evaluation criteria developed by the focus group were similar to the NSDF Project developed criteria (presented within Section 2.5.1) thus indicating the NSDF Project's assessment criteria is representative of the public's environmental values. The evaluation criteria developed by the focus group included protection of aquatic life, quantity and quality of effluent discharge, changes in the physical environment as a result of the NSDF Project and public concern.
- During evaluation of the effluent discharge options, both focus groups unanimously rejected the option to discharge to the Ottawa River and scored the discharge to Perch Creek quite low. Additionally there was no interest in further consideration of the discharge to air option. The preferred option was discharge to groundwater although there was recognition this option needed to be in combination with a surface water discharge to Perch Lake due to reduced capacity of the exfiltration gallery under high groundwater elevation conditions during spring.
- Interestingly each focus group suggested additional options which are discussed below:
  - Reduce quantity of leachate and contact-water that requires treatment. A number of design optimizations were suggested in order to achieve this target including the potential to include a weather cover structure over the operating face of the disposal cell.
  - Combination of groundwater exfiltration and an artificial wetland as a receiving environment for the treated effluent.

The discussions from the focus group session are being considered by the NSDF Project team as potential mitigation measures of the NSDF Project's potential effects on the environment. Specifically, the NSDF Project is discussing design options with Ducks Unlimited Canada to incorporate artificial wetland components into the exfiltration gallery and non-contact stormwater discharge systems. The use of the artificial wetland is considered design optimization – that is, the current design of the NSDF is such that objectives for effluent treatment and the stormwater ponds as outlined in the EIS can be met. The use of an artificial wetland could further enhance the current design as an improvement to the proposed treated effluent exfiltration gallery and stormwater ponds, which would further mitigate residual effects predicted on surface water quality as discussed in Section 5.4.2. The artificial wetland, if considered feasible, would be built within the footprint of the NSDF Project.

Additionally, weather cover structure designs are being evaluated for compatibility with the NSDF Project configuration and if feasible, could be implemented as a mitigation measure and operational optimization.

2.5.7.7 Summary

Three effluent discharge options were considered technically and economically feasible and each have comparable potential environmental effects including:

- discharge to Perch Lake (Section 2.5.7.2.2);
- discharge to Ottawa River (Section 2.5.7.2.3); and
- discharge to ground and discharge to surface water (Section 2.5.7.4).

Combined discharge to ground and surface water is beneficial because the exfiltration gallery provides additional retention time for radioactive decay (e.g., tritium) and replenishes water to the local wetlands. For this combined option, the water collected in the ECM as leachate would be treated and returned to the Perch Creek and Perch Lake Watershed (via the exfiltration gallery) consistent with existing conditions. In addition, the exfiltration gallery will have sufficient capacity as a standalone option during post-closure to manage the reduced flows from the WWTP after the ECM is capped.

For both the surface water discharge options (i.e., Perch Lake or Ottawa River), a transfer line would need to be constructed. For the Ottawa River option, the transfer line could connect to an existing outfall where the treated effluent could be combined with an existing discharge to the Ottawa River. Transfer lines are widely used and standard mitigation measures are available to limit adverse effects on the environment from construction.

The treated effluent will meet effluent discharge targets protective of the environment and human health. While both surface water options are protective of environment and human health, direct discharge to the Ottawa River is expected to be perceived unfavourably by the public and Indigenous Peoples. Discharge to Perch Lake is, therefore, the preferred of the two options.

A comparative evaluation of the discharge to surface water versus the discharge to ground combined with a discharge to surface water is provided in Table 2.5.7-1. A comparative evaluation of a discharge to Perch Lake versus Ottawa River is provided in Table 2.5.7-2.

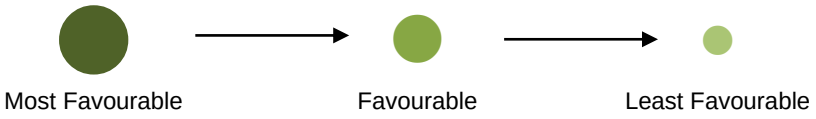

Table 2.5.7-1: Evaluation of Alternatives - Effluent Discharge Options (Discharge to Surface Water vs. Discharge to Ground and Discharge to Surface Water)

Criteria	Alternative 1 – Discharge to Surface Water		Alternative 2 – Discharge to Ground and Discharge to Surface Water	
Technical Feasibility				
Project Purpose	Both alternatives meet the technical requirements.			
Storage Capacity	Neither of the alternatives will limit the storage capacity of the NSDF			
An Example of Best Available Technology	A pipeline and discharge to a surface waterbody is an example of a best available technology and widely used.		A pipeline and discharge to a surface waterbody is an example of a best available technology and widely used. An exfiltration gallery has been used previously but less extensively than a pipeline	
Design Robustness	Pipelines are widely used and standard and effective mitigation and controls are available to limit adverse effects on the environment.		Pipelines are widely used and standard and effective mitigation and controls are available to limit adverse effects on the environment. The exfiltration gallery will also provide additional retention time for radioactive decay (e.g., tritium)	
Monitoring Complexity	Both alternatives may require monitoring requirements; however, these monitoring programs are relatively straight-forward and similar programs are currently in place at the CRL site.			
Economic Feasibility				
Life Cycle Cost	Less than 1% of capital and operating costs of the overall project		Less than 1% of capital and operating costs of the overall project	
Environmental Effects				
Biophysical				
Environmental Setting	Construction of a new outfall structure in Perch Lake.		Construction of a new outfall structure in Perch Lake.	
Atmospheric Environment	Limited air emissions related to construction		Limited air emissions related to construction	
Geological and Hydrogeological Environment	No discharges to groundwater and hence no impacts.		Discharge to ground replenishes local groundwater and the wetlands.	
Surface Water Environment	No radionuclide decay (e.g., tritium) through groundwater.		Tritium discharges to surface water are reduced due to decay of tritium during groundwater transit.	
Aquatic Biodiversity	Small changes to water quality which will not result in adverse effects on aquatic biodiversity.		Small changes to water quality which will not result in adverse effects on aquatic biodiversity.	
Terrestrial Biodiversity	No anticipated difference between alternatives.			
Ecological Health	No anticipated difference between alternatives.

2.5.8 Discharge Type

The total annual volume of contact surface water to be treated and discharged to the Perch Creek and Perch Lake Watershed is approximately 11,000 m^3. This represents less than 1 percent (%) of the annual average total outflow from Perch Lake of approximately 1,700,000 m^3. The current design for the planned discharge, is for treated effluent to be primarily discharged to the proposed exfiltration gallery, with excess volume to be directly discharged to Perch Lake, as necessary. Due to the conditions within the lake, an effective and reliable discharge system is required to distribute treated effluent into Perch Lake. Additionally, mitigation would be put in place for infrastructure associated with the direct discharge to Perch Lake to limit adverse disturbances to the shoreline, lakebed, and surrounding watershed.

To address the need for and effective and reliable discharge system, multiple engineering options were considered including:

- discharge by surface spray onto Perch Lake;
- piped outfall to Perch Lake (submerged outlet in Perch Lake);
- piped outfall to Perch Lake (above water discharge);
- submerged diffuser in Perch Lake (alignment along lakebed); and
- submerged diffuser in Perch Lake (diffuser suspended in water column).

2.5.8.1 Discharge by Surface Spray onto Perch Lake

A discharge by surface spray alternative would involve spraying treated effluent over the lake surface through a series of above-water on-lake or lake periphery discharge units. As such, this discharge option would only be possible in open water conditions (i.e., year-round operation is not possible). The associated infrastructure for this discharge would likely consist of a series of pipes that would extend some distance into the lake.

2.5.8.1.1 Technical Feasibility

The NSDF Project is designed to dispose of up to 1,000,000 m^3 of waste which will generate approximately 11,000 m^3 of treated effluent per year. As noted above, surface spray discharge onto Perch Lake would be viable only in open water conditions. However, there is insufficient capacity on the NSDF Project site to temporarily store treated effluent during the winter months (refer to Section 2.5.7.3 for additional details). Therefore, the selected design option must be able to operate year-round to ensure that the planned storage capacity of the ECM can be met. Therefore, this alternative is not technically feasible and is not carried forward for further analysis.

2.5.8.2 Piped Outfall to Perch Lake (Submerged Outlet in Perch Lake)

Treated effluent would be discharged into the lake below the water line through a single piped outlet. This system could therefore be expected to operate year-round. The pipe would extend some distance along the lakebed to a deeper zone of the lake and would be buried to maintain discharge depth below winter ice and to prevent pipe freezing. A stable lakebed or consolidated sediment would be required below the discharge point and around the pipeline where it extends into the lake below the shoreline and shallow sediment on the lake periphery. As long as the submerged discharge occurs at a suitable depth and treated effluent quality remains within appropriate water quality guidelines and/or site-specific benchmarks, this type of discharge may be undertaken under gravity flow discharge conditions.

2.5.8.2.1 Technical Feasibility

Discharge into Perch Lake through a piped outfall would be operationally simple. However, the installation would be dependent on finding a location in Perch Lake that would support the pipe (i.e., a suitable natural or engineered foundation) and would probably require a winter installation. This would require burial of the discharge pipe below the ice-cover depth at the shoreline and along the lakebed to prevent freezing. Depending on the outlet depth below the lake surface, year-round operation is feasible. Annual inspection and maintenance by divers would be required each spring to check and clear the piped outlet. This option could discharge the required annual volume and meet the discharge rates under gravity flow conditions. Based on the above, this alternative is technically feasible.

2.5.8.2.2 Economic Feasibility

The capital and operation cost for the discharge of treated effluent to Perch Lake via a submerged piped outfall is expected to represent less than 1% of the costs for the overall NSDF Project.

2.5.8.3 Piped Outfall to Perch Lake (Above Water Discharge)

Treated effluent would be discharged onto the lake surface through a pipe outfall, limiting the discharge to open water conditions (i.e., year-round operation is not possible). In this case, the outfall would extend over the lake and be located at or above the water line. Erosion of the shoreline and adjacent lakebed would be mitigated as necessary, depending on the configuration of the outfall structure and its location. The infrastructure to support the piped extension onto the lake may require anchoring within the shoreline and lake periphery (i.e., littoral zone). Anchoring would also require strong bed foundations, which may be limited within the littoral zone of the lake. This type of outfall could be undertaken under gravity flow discharge conditions if the outfall structure was stable and designed to reduce potential erosion risk.

2.5.8.3.1 Technical Feasibility

Similar to the surface spray alternative (Section 2.5.8.1), this alternative cannot operate year-round. Therefore, this proposed alternative is not technically feasible and is not further evaluated.

2.5.8.4 Submerged Diffuser in Perch Lake (Alignment along Lakebed)

A submerged diffuser would be located along the lakebed and anchored to the bed at various points along the submerged pipeline in a well-consolidated zone. This would prevent settlement of the outlet into the sediment layer and limit erosion of the lakebed. Treated effluent would be dispersed into the lake by a series of small-nozzle ports attached to the diffuser pipe by extension pipes. The length of the extension pipes would be determined by the target depth for discharge in the water column to optimize dispersion and reduce the risk of lakebed disturbance by the discharge. A relatively constant discharge is required for this option to actively disperse the discharge through the small discharge ports so as to avoid localized effluent concentrations around the diffuser; therefore, this option requires a pumped discharge condition to provide an appropriate mixing zone. This type of design would be installed within the lake at a depth below the ice cover in winter, allowing for year-round operation. The diffuser would need to be stable to optimize dispersion efficiency, so bed anchoring is critical to limit the potential for sediment mobilization during discharge. Anchors could potentially be placed in the clay layer below the soft sediment substrate.

2.5.8.4.1 Technical Feasibility

This option allows for year-round discharge, as the diffuser would be located in a zone within Perch Lake that is deep enough for the diffuser ports to be below ice and with sufficient water column height to allow maximized mixing within Perch Lake. Installation is considered challenging due to reported soft foundation conditions. This option requires discharge to be pumped to maintain discharge velocity. Annual inspection and maintenance by divers would be required each spring to check and clear the piped outlet, and to verify stability of the lakebed and anchors.

2.5.8.4.2 Economic Feasibility

The capital and operation cost for the discharge of treated effluent to Perch Lake via a submerged diffuser is expected to represent less than 1% of the costs for the overall NSDF Project.

2.5.8.5 Submerged Diffuser in Perch Lake (Diffuser Suspended in Water Column)

Instead of lying along the lakebed as described for Option 3a, this diffuser option extends into the lake with buoyancy support and is suspended in the water column. The buoyancy support for the pipeline extension would limit the application for this option to open water conditions. This diffuser option would also need to be located in a consolidated lakebed zone of Perch Lake, as stable anchoring is necessary along the pipeline and at the diffuser end of the pipe line to keep the diffuser at a constant depth. Anchors could potentially be placed in the clay layer below the sediment substrate.

2.5.8.5.1 Technical Feasibility

As described in Section 2.5.8.1, the selected design option must be able to operate year-round to ensure that the planned storage capacity of the ECM can be met. However, this alternative will be limited to open water conditions; therefore, this alternative is not technically feasible and is not carried forward for further analysis.

2.5.8.6 Environmental

Based on the review above, two effluent discharge options were considered technically and economically feasible including:

- piped outfall to Perch Lake with a submerged outlet (Section 2.5.8.2); and
- submerged diffuser in Perch Lake along the lakebed (Section 2.5.8.4).

Both alternatives are expected to have similar potential environmental effects, with the exception of pathways to surface water and aquatic biota. Within Perch Lake, the construction of either alternative will result in the disturbance of the lakebed sediment during the construction and operations phases. Mitigation will be required to limit resuspension of sediment during the construction and operations phases. The submerged diffuser is expected to result in less resuspension of sediment compared to a submerged piped outlet. Further, the submerged diffuser is expected to provide a more efficient mixing zone compared to a submerged piped outlet.

2.5.8.7 Summary

Two alternatives were considered technically and economically feasible for the discharge of treated effluent to Perch Lake. The comparative evaluation between these alternatives is provided in Table 2.5.8-1. Both alternatives will result in disturbance of the lakebed sediment during construction and operation which will require mitigation. However, the submerged diffuser is expected to limit these effects during operation. The piped outfall will also require regular maintenance to ensure that the outfall stays clear of sediment.

The submerged diffuser will provide a maximized mixing zone at the point of discharge. Based on the above, the submerged diffuser alternative is considered more favourable than the submerged piped outfall.

Note:

2.5.9 Final Grade of the Facility

In relation to the near surface disposal designs referenced in IAEA guidance (SSG-29) (IAEA 2014), CNL considers the NSDF design to be an engineered structure constructed just below the grade but extending above the existing grade. However, variations in the final grade of the facility and the subsequent ECM floor elevation were evaluated as part of the design optimization completed for the NSDF Project (CNL 2016d). Three different final grade alternatives were developed and evaluated to determine the preferred ECM floor elevation including:

1) ECM Below Existing Grade;

2) ECM Above Existing Grade; and

3) Mid-range Grade.

The NSDF Design Requirements (CNL 2019d) also includes the following specific functional requirements of the ECM:

- The overall design of the ECM will be compatible with CRL site topography. The geometric profile and height of ECM shall be designed to ensure that ECM is not visible either from Ottawa River, plant road or CRL campus.
- The base of the ECM (i.e., top of the primary liner) shall be designed to maintain a minimum of 1.5 m above the seasonal high groundwater table.

preferred ECM design, because this alternative is compliant with design requirements and can meet the required storage capacity.

2.6 Conclusion

The recommended alternative for the disposal of LLW based on the Alternative Means analysis is to build a NSDF at the CRL site on the EMR site. The preferred design is that of an ECM along with a new WWTP for leachate treatment. The preferred discharge is a combination of an exfiltration gallery and discharge to Perch Lake with a submerged diffuser. The most favourable alternative means are based upon consideration of technical, environmental and economic factors.

3.0 PROJECT DESCRIPTION

3.1 Introduction

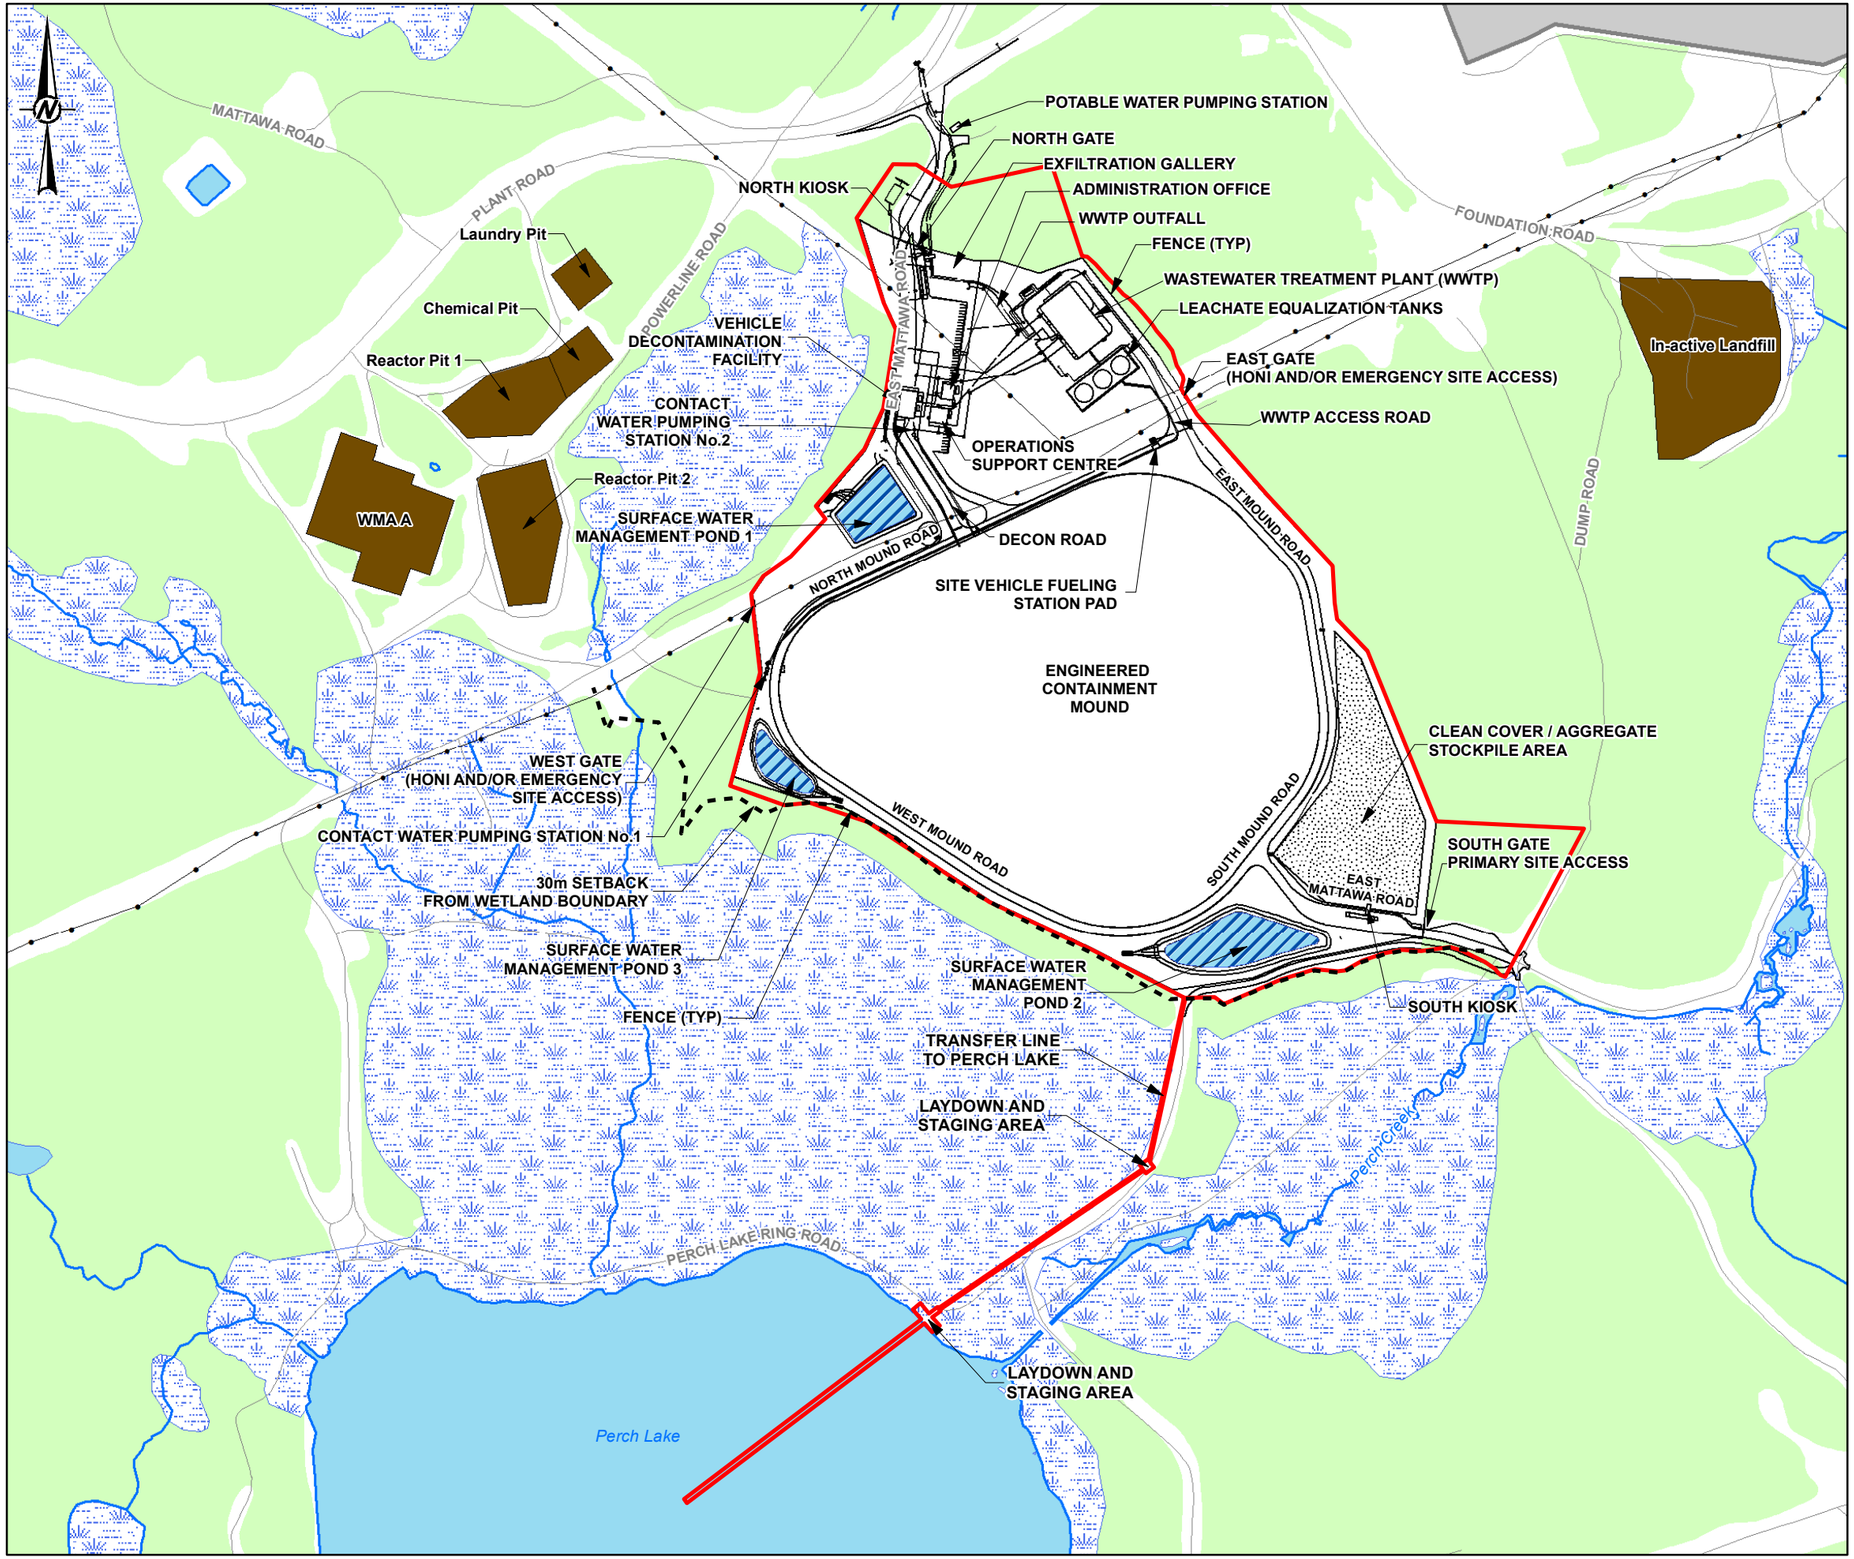
This section provides a description of the main features of the Near Surface Disposal Facility (NSDF) for the disposal of solid low-level radioactive waste (LLW) at Chalk River Laboratories (CRL) (the 'NSDF Project'), and identifies the components (e.g., physical infrastructure such as the disposal facility and roads) and activities (e.g., placement of waste) related to the site preparation and construction, operations, closure, and post-closure phases. The NSDF Project is based on current engineering practice and precedents, and the experience of the engineering and environmental teams. Where components are still being designed, worst-case (i.e., conservative) assumptions have been applied.

3.1.1 Project Overview

The NSDF will be a waste disposal facility in the form of an engineered containment mound (ECM), with similar physical features to a hazardous waste landfill, but designed to nuclear standards. It will contain LLW and will be located within the approximately 4,000 ha Chalk River Laboratories (CRL) site. The CRL site is in Renfrew County, Ontario on the shore of the Ottawa River.

The NSDF will facilitate environmental remediation of the CRL site, which has housed decades of nuclear research and development. The Government of Canada's nuclear legacy liabilities have resulted from the nuclear operations, research and development performed at CNL for approximately 70 years. The majority of these liabilities are located at CRL and consist of shutdown nuclear facilities and radioisotope laboratories, radioactive wastes in interim storage, and contaminated lands. The overall clean-up mission will involve the decommissioning of more than 100 buildings that have reached the end of their useful lives, and the NSDF Project will provide safe disposal for the demolition waste, as well as some wastes from other sources.

The NSDF Project includes components and activities related to site preparation and construction, operations, closure, and post-closure, as well as long-term performance of the ECM for the responsible management of the waste. LLW material is suitable for disposal in engineered near surface facilities that provide robust isolation and containment for periods of up to a few hundred years in alignment with International Atomic Energy Agency (IAEA) standards and guidance. The LLW to be disposed at the NSDF Project will meet the Waste Acceptance Criteria (WAC) established to assure that it is acceptable for disposal at the NSDF Project to meet operational and post-closure safety requirements. The WAC and acceptance process are described in detail in Section 3.3.3.



The ECM will contain ten waste disposal cells to be built progressively over the construction and operations phase of the NSDF Project, with only one active waste cell in operation at a time. The ten cells will have a total waste capacity of up to 1,000,000 m^3. The development of the facility and the placement of waste within the ECM will be completed in two phases. Phase 1 will have a capacity of 525,000 m^3 and will accommodate wastes currently in storage and wastes to be generated over the next 20 to 25 years. Phase 2 will expand the facility by 475,000 m^3 (for a total of 1,000,000 m^3) of wastes to be generated until the expected end of operations at the CRL site in approximately 2070. The NSDF Project has been designed considering best available technologies and industry practices, including those identified by the IAEA, where applicable. The NSDF Project design and related requirements are described in Section 2.4.

While in operation, the NSDF will have a Wastewater Treatment Plant (WWTP) and several support facilities such as an administration building, an operations support center (which includes change rooms), weigh scales and a vehicle decontamination facility. These will be decommissioned and removed following the end of operations. The site will be permanently fenced and contain roads, utilities and surface water management ponds.
The following main physical components (e.g., structures) are to be constructed for the NSDF Project:

- engineered containment mound that will contain the LLW;
- WWTP that will treat leachate (see Section 14, glossary for definition), contact water (see Section 14, glossary for definition), and wastewater from on-going operations;
- support facilities that will enable operation (e.g., administrative buildings); and
- site infrastructure (e.g., utilities).

All physical components will be located within the NSDF Project site (Figure 3.1.1-1). These components and related activities are described in more detail in Section 3.4.

Following its closure, the mound will resemble a grassy outcrop built into an existing hillside. It will be approximately 18 m tall and will occupy a 17 ha footprint on the CRL site. The mound will not be visible from the CRL main campus or the Ottawa River.

3.1.1.1 Alignment of NSDF to Regulatory and International Guidelines

This section provides a summary of how the NSDF Project has been designed to ensure the facility can be built, waste received, handled, and disposed of without undue risk to workers, the public and the environment, consistent with the design principles discussed in Section 2.4. The focus of this section is the safety features associated with the long-term performance of the ECM; however, these safety features are also present during operations.

The key safety features of the NSDF Project have addressed the IAEA design principles for radioactive waste disposal (IAEA 2011) in the following manner:

- **Multiple safety functions** – The ECM is designed with a number of engineered barriers to provide multiple layers of safety to support the long-term containment and isolation requirements. In accordance with the defence-in-depth principle, the safety performance of the NSDF Project is not dependent on any single safety function. The perimeter berm, the HDPE geomembrane cover system, and the double HDPE geomembrane liner system supported by a compacted clay liner contain individual components of natural and synthetic materials designed to work together to mitigate the release of contaminants into the environment for thousands of years. In addition to the engineered barriers, the NSDF Project site is well above the Ottawa River flood levels on a bedrock ridge that naturally forces water to flow in the opposite direction from the river. The NSDF Project design has taken into consideration the CRL site is in a region of minor to moderate seismic activity and will maintain protection of the environment in such events.
- **Containment of radioactive waste** – The ECM is designed to provide containment of the waste. Once the final cover system is installed, the waste material is expected to remain contained for at least the facility design life of 550 years, but likely much longer as demonstrated by the geomembrane testing (R. Kerry Rowe Inc. 2019) as well as natural and anthropogenic analogues. The site of the ECM allows for construction on bedrock and a robust seismic design basis of the perimeter berm contributes to the containment of the waste.
- **Isolation of radioactive waste** – The ECM is designed to isolate the waste from the environment for at least the 550-year design life, but likely much longer as demonstrated by the geomembrane testing (R. Kerry Rowe Inc. 2019). The ECM is designed specifically for the conditions of the NSDF Project site, with special considerations made for seismic design and diversion of precipitation. The siting of the NSDF Project on federally owned lands and the enforcement of land-use restrictions increases confidence that the waste will be undisturbed for hundreds of years after closure.
- **Surveillance and control of passive safety features** – The ECM design incorporates passive safety features. Following facility closure, during the post-closure phase, basic monitoring and inspections of the site will periodically occur to confirm that the facility is performing as expected (e.g., ensuring settlement is complete). The passive safety features perform their containment and isolation functions without intervention, and do not rely on a power source of any kind. The site of the ECM is in the Perch Creek and Perch Lake watershed, which has well-understood hydrogeological properties that lead to a good understanding of how any radionuclides released from the ECM after the design life will move in the environment. The siting of the NSDF Project on federally owned lands and the enforcement of land-use restrictions increases confidence that the waste will be undisturbed for hundreds of years after closure.

Furthermore, as a near surface disposal facility was chosen as CNL's preferred alternative, CNL has also incorporated guidance from IAEA's *Near Surface Disposal Facilities for Radioactive Waste Specific Safety Guide No. SSG-29* (IAEA 2014). SSG-29 provides guidance on the requirements of various NSDF Project activities, including design, waste acceptance, site preparation, construction, operations, closure, post-closure, institutional control, development of monitoring programs, and site security.

CNSC's *REGDOC-2.11 Framework for Radioactive Waste Management and Decommissioning in Canada* (CNSC 2018a) provides the framework for radioactive waste management and decommissioning in Canada. The following three bullets are directly applicable to the proposed long-term management of LLW in NSDF. A description of how the NSDF Project meets the guidance follows each bullet point.

- *Management of waste is commensurate with the hazard: The management of radioactive waste is commensurate with its radiological, chemical and biological hazard to the health and safety of persons and the environment, and to national security.*

The ECM is designed to contain and isolate the wastes from the environment for 550 years, after which, the radioactivity has decreased to levels close to the natural background concentrations. Since the NSDF Project only accepts LLW and most of the radioactivity; thus, the hazard, decays in the first 100 years after closure, the design of the NSDF Project is commensurate with the hazard.

- *The assessment of future impacts of radioactive waste on the health and safety of persons and the environment encompasses the period of time when the maximum impact is predicted to occur.*

The assessment of future impacts from the facility is performed in the Post-Closure Safety Assessment document (Arcadis and Quintessa 2020). CNL followed the guidance of CNSC's *REGDOC-2.11.1 Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* (CNSC 2018b), to determine that a 10,000-year assessment timeframe is appropriate for the facility. This timeframe encompasses the duration of institutional control, the hazardous lifetime of the wastes and the design life of the facility barriers. Peak dose during the most reasonably anticipated evolution of the facility is 0.015 mSv/y at approximately 4100 years. The assessment timeframe is consistent with guidance of IAEA SSG-23 which states that safety assessment studies for near-surface disposal facilities typically consider timeframes of a few thousand years. It is also consistent with the facility being designed to withstand a 1-in-10,000-year seismic event.

- *The predicted impact on the health and safety of persons and the environment from the management of radioactive waste is no greater than the impact that is permissible in Canada at the time of the regulatory decision.*

A near surface design is appropriate since the public dose predicted for all plausible scenarios is less than the 1 mSv/a regulatory dose limit for members of the public, as prescribed in the *Radiation Protection Regulations*. In addition, the Normal Evolution Scenario of the PostSA meets the 0.3 mSv/a dose constraint as recommended by IAEA SSR-5 (IAEA 2011). In the pre-closure phase, the regulatory limit and dose constraint above are also met for public exposure.

The IAEA and CNSC guidance also recognizes that due to the very long time periods involved for a disposal facility, there are uncertainties in the assessment. Ways to enhance confidence in the safety features and provide an understanding of the disposal system include testing and evaluation of barrier materials and the use of anthropogenic and natural analogues.

CNL partnered with Queens University to perform a comprehensive HDPE geomembrane testing and evaluation program (R. Kerry Rowe Inc. 2019). The results of the program demonstrated that candidate HDPE geomembranes are not only expected to meet the 550-year design life of the facility, but is likely to have a design life of up to 2000 years.

Anthropogenic analogues refer to man-made structures that can be used to compare the predicted performance of the NSDF Project with structures that already exist. For example, there is a 13 m earthen mound in Newgrange, Ireland, which was constructed over 5000 years ago. Monks Mound in Collinsville, IL, USA, is a 30 m high earthen mound constructed over 1000 years ago. These structures were built with primitive engineering and construction methodologies, but have retained their structural stability for thousands of years. The NSDF will be constructed with modern construction and design methodologies, and is expected to perform as well or better than these two examples.

Natural analogues can also be used to evaluate the effectiveness of the natural materials contained in the ECM barrier systems. The compacted clay liner in the liner system of the ECM is a completely natural material. Natural deposits of clay have been studied at Cigar Lake in northern Saskatchewan (AECL 1995) with regard to the movement of uranium for the purposes of an HLW repository. The studies demonstrated that clay is an excellent barrier to the movement of water and the radioactive or chemical contaminants. The deposit provides analogue information relevant to the performance of clay-based barriers, and radionuclide migration in clay.

The use of analogues to support long-term safety assessment has its limitations. In particular, the materials and environmental conditions involved are somewhat different in the analogues compared to NSDF and its environment. This is typical of analogues; therefore, NSDF uses the above examples as an additional line of evidence complementing the safety assessments carried out.

3.1.2 Project Schedule

Pending regulatory approvals, Canadian Nuclear Laboratories (CNL) aims to have the ECM operational in 2025. The schedule for the NSDF Project is as follows:

- Site Preparation and Construction Phase = 2022 to 2024;
- Operations Phase = 2025 to 2070;
- Closure Phase = 2070 to 2100; and
- Post-closure Phase, with two discrete periods:
  - Institutional Control Period = 2100 to 2400 (300 years is used for planning purposes however the institutional control period will continue as long as necessary as determined by regulatory agencies); and
  - Post-Institutional Control Period = 2400 and beyond.

Each phase is described in more detail in Section 3.2.

The design life (i.e., the period of useful life intended by the designers) for the ECM is 550 years to meet the required time period to allow for radioactive decay of the waste placed in the facility (i.e., until it has decayed to levels that do not present a risk to the public and environment). The radioactivity concentration in the ECM will decrease about 2,000 times in the first 100 years, and then begin to approach background levels of concentration shortly thereafter. This correlates to design life criteria for similar mounds containing LLW in Canada (e.g., Port Hope and Port Granby Long-Term Waste Management Facilities).

3.1.3 Project Site Overview

The NSDF Project site will be approximately 37 ha, located within the CRL site boundary. The NSDF Project site is almost completely forested, with the western portion containing the Petawawa Research Forest tree plantation that was planted in the 1950s (Figure 1.0-1). The Petawawa Research Forest has confirmed that this plantation has not been active since the 1980s and is no longer required for research purposes.

The legacy Waste Management Area A, and four legacy Liquid Dispersal Areas (Reactor Pit 1, Reactor Pit 2, Chemical Pit and Laundry Pit) are located immediately to the northwest of the NSDF Project site, with the CRL main campus northeast of the NSDF Project site. Waste Management Area B, which is an operating waste management area, is located to the west of the NSDF Project site. There is also a non-radiological landfill to the east (Figures 1.0-1 and 3.1.1-1).

In general terms, the NSDF Project site is located on both sides of the existing East Mattawa Road, which bisects the site crossing north to south. The northern boundary of the NSDF Project site runs along Power Line Road and the southern boundary reaches ER-3 (Emergency Road) and Perch Lake Ring Road. On the western side, there is a 30 m setback from the Perch Lake wetlands that forms the site boundary, except where a proposed discharge line follows existing access roads through this area to reach Perch Lake. The boundary to the east is a local ridge line dividing the Perch Lake and Perch Creek watersheds. North of the NSDF Project site is forested land, a low-lying marsh area is to the west and south, with existing Waste Management Areas A and B further northwest. The East Mattawa Road leads to ER-3 (Emergency Road) and the Perch Creek Ring Road. To the east is forested land that drops down to the CRL main campus on the opposite side of a ridge.

The proposed location of the NSDF Project is within the Perch Creek and Perch Lake watershed, which is a small drainage system along the Ottawa River. The general topography of the NSDF Project site is defined by the ridge feature along the eastern boundary, approximately 197 m above sea level. The ridge slopes down approximately 40 m to the west to relatively flat terrain, which then drains into Perch Lake. The direction of the groundwater and surface water flow reflects the NSDF Project site topography. Groundwater levels range from approximately 0.06 m below ground surface (mbgs) to approximately 16 mbgs (see Section 5.3.2.4.2 for additional information). Surface and groundwater from this basin eventually drain to the Ottawa River, either via Perch Lake and Perch Creek, or directly through Perch Creek. The East Swamp Wetland to the northwest of the NSDF Project site drains via East Swamp Stream to the wetlands located to the south.

The surface geology of the NSDF Project site consists primarily of sands, with underlying dense sandy silt underlain by dense sandy silt till containing cobbles and boulders. Low-lying and wetland areas contain organic soils such as peat.

3.1.4 Project Design Changes

Since the submission of the draft Environmental Impact Statement (EIS) to the CNSC in 2017 March, CNL has continued to refine the design of the NSDF Project. As part of this process and through engagement for the NSDF Project, the waste inventory proposed for disposal in the ECM has been revised to eliminate intermediate level waste. The NSDF Project will now only receive LLW. This design change will reduce the total radiological inventory disposed in the ECM and will reduce potential adverse effects on the environment from the NSDF Project.

CNL also identified that the proposed strategy to discharge all treated effluent to an exfiltration gallery will need to be supplemented due to limited infiltration capacity at the proposed location. The revised NSDF Project design now includes a transfer line and discharge to Perch Lake. This system has been designed and sized to be able to

discharge all treated effluent to Perch Lake and operate year-round. This additional project component will eliminate the risk of overland flow at the exfiltration gallery which was identified as a concern by regulators.

Other design changes include:

- changes to the ECM design to improve the seismic stability of the ECM;
- modifications to the chemical storage in the WWTP to improve industrial safety;
- addition of two large fire water tanks to improve fire response at the NSDF Project;
- addition of hard-wired alarms and interlocks to improve the reliability of systems important to safety;
- modified cell layout; and
- changes to the WWTP storage tank specifications to ensure they would withstand a design-basis tornado.

3.2 Project Phases

The NSDF Project activities are planned to occur in the following phases: site preparation and construction, operations, closure, and post-closure. Regulatory approval will be required for the NSDF Project to progress from one phase to the next. An overview of each phase is provided below.

3.2.1 Construction Phase (including Site Preparation)

3.2.1.1 Site Preparation

Site preparation involves activities required to prepare the NSDF Project site for construction. This includes vegetation clearing (e.g., removal of trees), mobilization of the necessary construction equipment and completing large-scale earth moving activities (e.g., excavation, blasting, hauling of materials, and grading) using conventional earth-moving equipment such as bulldozers and excavators.

Site preparation will begin following receipt of approval of the environmental assessment and licencing decision, and will take approximately four months to complete. The preferred timing for completion of clearing and grubbing of vegetation on the NSDF Project site would be in early spring or fall 2022 to mitigate potential effects to migratory birds and other wildlife species (i.e., outside of sensitive breeding periods). NSDF Project site mobilization of construction equipment would occur in 2022 and the remaining site preparation activities (i.e., soil excavation, hauling and grading) would be completed between late 2022 and early 2023. Equipment required for site preparation will vary during construction. Estimated numbers are shown in Table 3.2.1-1.

Table 3.2.1-1: Estimates of Equipment Required for the NSDF Project Site Preparation and Construction Activities

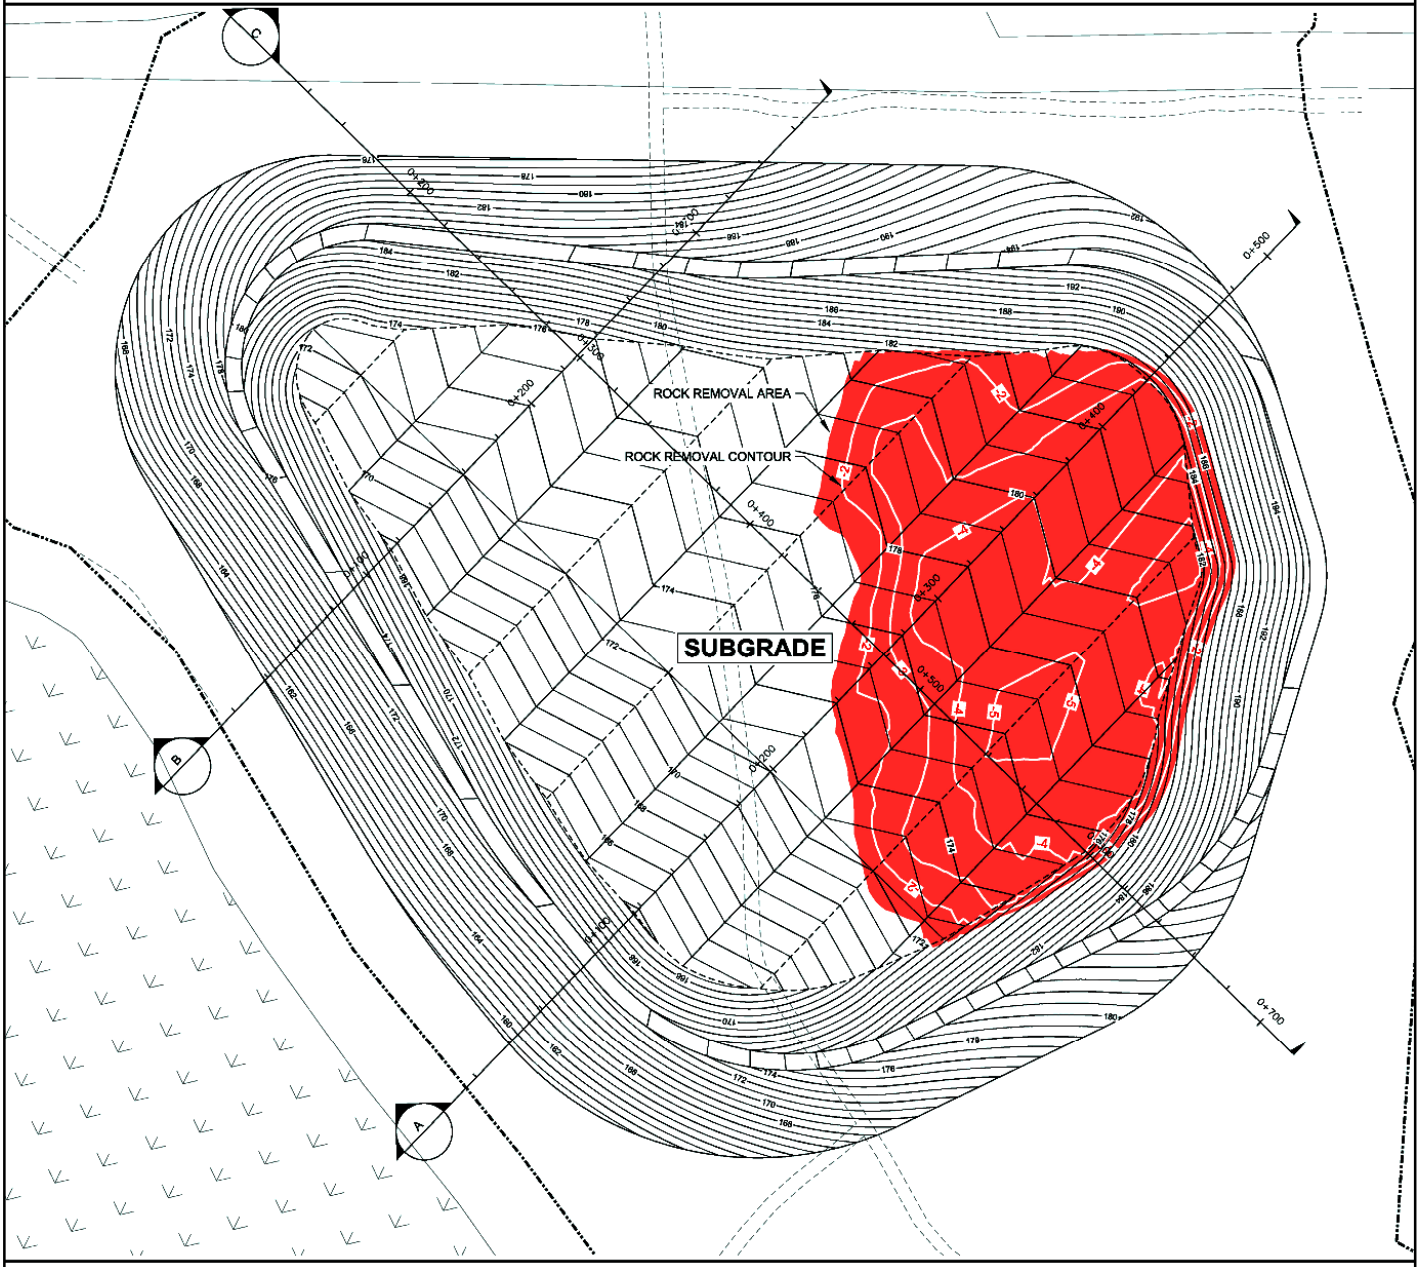
Equipment	Estimated Quantity (units per day)
Rock Truck	10
Waste Transportation Vehicle	25
Water Truck	4
Excavator	10
Bulldozer	8
Grader	3
Roller (Soil Compaction)	4
Roller (Pavement Compaction)	1

Note: This is not an exhaustive list of equipment.

Specific activities associated with the NSDF Project site preparation include the following:

- implementing environmental protection measures as per the Environmental Protection Plan (e.g., silt and erosion fencing, dust monitoring, fuel and lubricants management);
- establishing exclusion and buffer zones (e.g., marking areas, such as wetlands, where activities are not permitted to occur);
- clearing and grubbing of vegetation (i.e., removal of vegetation including brush and trees, as well as the roots that may remain in the soil);
- excavating, removing and stockpiling of topsoil and overburden (e.g., soil and rocks above the bedrock) for later use for the ECM final cover system;
- blasting and excavation for the ECM;
- removal and/or stockpiling of waste rock (e.g., rock that cannot be reused in the construction of the ECM);
- excavating drainage ditches and surface water management ponds; and
- grading (e.g., creating the base) the NSDF Project site, including access roads, WWTP, laydown and stockpile areas, and various other building locations.

A 30 m buffer will be established along identified wetlands near the NSDF Project site; where the buffer cannot be maintained, appropriate measures will be established to address any risk of erosion. In addition to the wetlands buffer, a 5 m tree-line buffer will be established from the NSDF Project site to limit disturbance to vegetation and large tree roots at the tree-line. Buildings and structures will not be located within 5 m of this buffer zone to provide access for equipment around structures. A buffer zone will also be maintained between the ECM and the boundary of the NSDF Project site. This zone provides sufficient area surrounding the facility operations to allow environmental monitoring to be performed, to facilitate maintenance, and to allow implementation of contingency measures during an emergency.



The total land area to be cleared is up to 37 ha, most of which is treed. Sampling has been completed of the vegetation and trees within the NSDF Project site as per CNL's Management of Land and Habitat procedure which confirmed the area is free of radiological contamination (AECL 2017). Roots, stumps, embedded logs and debris will be removed by grubbing and will be mulched, reused or otherwise dispositioned according to existing management practices.

Stripping of the soil will be required to remove topsoil and organic material, where necessary. Radiological surveys of soil and contamination have confirmed that the ECM footprint does not contain radiological concentrations above local background levels (CNL 2017a). The topsoil will be stored in piles for later use as final landscaping of the NSDF Project site, for application elsewhere on the CRL site, or for the ECM final cover system.

Excavation for the ECM, drainage ditches, and the surface water management ponds will be completed once the NSDF Project site has been cleared and topsoil removed. Grading will be completed for the WWTP, other building locations, and access roads.

Rock blasting will be required to complete site preparation activities for the NSDF Project site (Figure 3.2.1-1). Blasting activities will be carried out by qualified personnel, and in accordance with the Blasting Plan (to be developed) indicating the type of explosives to be used and the method of detonation. Additional guidance for the NSDF Project blasting limits will be obtained from the Ontario Provincial Standard Specification (OPSS) in the document *OPSS 120 – General Specification for the Use of Explosives* (OPSS 2014). Blasting activities will follow industry standard Best Management Practices, applicable federal regulations, and Fisheries and Oceans Canada guidelines for use of explosives. Storage and management of explosives will be done in accordance with the *Explosives Act* and supporting *Explosives Regulation, 2013*.

The anticipated quantities of blasted rock are approximately 170,000 m^3. There will also be an allowance made for additional trench blasting that may be required to facilitate utility runs. It is anticipated that most of the blasted rock will be recycled for use within the construction of the ECM. Rock that cannot be recycled for reuse will be stored on the CRL site.

3.2.1.2 Construction Phase

The construction phase (inclusive of the site preparation), is anticipated to start in 2022 pending the receipt of positive environmental assessment and licensing decisions. Construction activities are expected to take approximately two years to complete (i.e., complete by 2024). The construction season is expected to have a duration of approximately nine months per year.

The main components and activities associated with the construction phase include the following:

- vehicle traffic on-site including transportation of construction materials and soil spoils haulage to a soil storage area;
- ECM liner system construction, including construction of a berm that will form the outer boundary for most of the perimeter of the ECM and will function as a containment system;
- development of surface water management infrastructure (i.e., drainage ditches, culverts, ponds);
- management of surface water during construction;
- management of construction wastes (e.g., building materials, domestic wastes, cleaners, aerosol cans);
- on-site road and access development;
- construction and commissioning of the WWTP, including construction of WWTP treated effluent transfer and discharge system including an exfiltration gallery (similar to a septic system) and transfer line to Perch Lake;
- construction of support facilities (i.e., kiosks and vehicle weigh scales, administration building, operations support centre, vehicle decontamination facility, site vehicle refuelling station, and potable water pump station); and
- construction of site infrastructure (i.e., service elements [sanitary sewage disposal system, surface water management and utilities] and support elements [access roads, parking lots, site security, temporary storage area, and stockpile areas]).

The key physical components are the ECM, WWTP, support facilities, and site infrastructure. Construction methods for these will be consistent with the methods used for existing waste management areas, infrastructure, and support facilities on the CRL site.

The contractor will be the Constructor of the NSDF Project and will be responsible per CNL's Occupational Safety and Health Program (described in Section 3.5.2.4) to control or eliminate hazards in the field that may be encountered during NSDF Project site preparation and construction activities. An *Environmental Protection Plan* (AECOM 2018a) will also be implemented to reduce or eliminate environmental effects associated with these activities.

The *Environmental Protection Plan* (AECOM 2018a) will be similar to that in place for other CRL projects and includes measures such as water spraying to control dust, vehicle maintenance standards to reduce emissions, and implementation of erosion and sediment controls. Fuels, lubricants and chemicals required for mechanical construction equipment will be delivered to the NSDF Project site in appropriately qualified vehicles and/or containers and dispensed and used, all in compliance with applicable legislation, codes and practices. Proper handling, storage and disposal of these materials will be achieved through compliance with the Environmental Protection, Waste Management and Occupational Safety and Health Programs (each described in

Section 3.5.2). The use of designated locations for fueling, lubrication and servicing of equipment, inspection requirements, storage requirements and spill clean-up procedures will be included in these procedures.

Based on estimates of truck deliveries to the NSDF Project site during the 24-month construction period, approximately 200 shipments per day are anticipated during the nine-month construction season (i.e., approximately 15 trucks per hour for the daytime period, totalling 200 trucks per day during construction). The additional construction personnel requirements are expected to result in an additional 300 inbound and outbound trips to the site daily. Anticipated equipment required during the construction phase (including site preparation) is shown in Table 3.2.1-1.

The construction materials required for the NSDF Project are described in Section 3.4.1.11. The proposed layout of the facilities to be built is shown on Figure 3.1.1-1.

3.2.2 Operations Phase

The operations phase is anticipated to begin in 2025, following construction, and will end in approximately 2070 (i.e., the facility will be operating for approximately 50 years). Waste to be placed in the ECM will primarily originate from operations and environmental cleanup activities at the CRL site (including legacy radioactive wastes currently stored on the CRL site), from future operations, and from the demolition and decommissioning of structures at the CRL site. Less than 10% of the waste volumes to be placed in the ECM will be from off-site sources (e.g., other Atomic Energy of Canada Limited [AECL] sites such as Whiteshell Laboratories and commercial sources such as hospitals and universities).

The main components and activities associated with the operations phase include the following:

- phased development of disposal cells;
- verification and acceptance of wastes that meet the WAC;
- placement of LLW that meet the WAC in the ECM;
- progressive closure of disposal cells and installation of temporary (i.e., daily and interim) and final cover systems;
- supplementing CRL's existing Environmental Monitoring Program to include the follow-up monitoring program for the NSDF Project;
- operation of the WWTP and discharge of treated effluent;
- surface water management and erosion control;
- domestic waste management;
- petroleum storage and hazardous materials handling; and
- maintenance of infrastructure, facilities, and site services.

The NSDF Project has been designed to operate year-round. Subject to acceptable weather conditions, waste placement in the ECM may cease during periods of inclement weather such as high winds, major precipitation events, extreme cold periods, or inability to compact waste due to frozen conditions. Even if waste placement operations cease, other parts of the NSDF (e.g., the WWTP) may still operate.

It is estimated that there will be approximately 10 trucks per day during operations (i.e., there will be less than one truck per hour during operations for the daytime period). Anticipated equipment required during the operations phase is shown in Table 3.2.2-1.

Table 3.2.2-1: Estimated Typical Equipment Required During the Operations Phase

Equipment	Estimated Quantity (units per day)
Trucks in the engineered containment mound (shuttling full waste containers)	3
Transportation Vehicles (delivering waste to engineered containment mound)	10
Forklifts	2
Water Trucks	2
Track hoes	2
Bulldozer	3
Grader	1
Crane	1
Vehicles	10
Miscellaneous, for example: ■ Pumps, ■ Portable Generators ■ Air Compressors ■ Lights ■ Snow Removal Equipment	Various

Note: Assumes operations involves working in one disposal cell at a time.

The approach used for designing the NSDF Project has been to incorporate waste placement and site stabilization features into routine waste operations so that final closure activities are simplified and streamlined. For example, the interim cover and final cover system placement will progress as disposal cells are filled. The early placement of the final cover system over the disposal cells as they are closed during the operations phase will greatly increase the likelihood that the maximum anticipated settlement of the final cover system in these areas will occur during the operations phase. Closing and covering the disposal cells in phases will provide CNL the opportunity to observe the performance of the portions of cover system placed over time and take appropriate remedial action if required.

3.2.3 Closure Phase

The closure phase includes the following activities:

- installation of any remaining components of the final cover of the ECM;
- decommissioning of infrastructure and support facilities (with the exception of the WWTP and surface water management systems initially);
- remediation and grading of the NSDF Project site;
- continued operation of the WWTP and discharge of treated effluent; and
- on-going, long-term performance monitoring and inspection activities.

Closure activities are expected to start in 2070 and continue through to 2100, after which the NSDF Project will move to the post-closure phase. Most activities will be completed within the initial years of the closure phase, with the continued operation of the WWTP and performance monitoring through to 2100.

Final closure of the NSDF Project site is intended to achieve the following objectives:

- control, limit, or eliminate post-closure escape of radioactive and non-radioactive contaminants, including leachate, to the environment;
- result in an appropriate final cover slope over the ECM to limit settlement and achieve positive drainage off the ECM surface (e.g., water collects and flows to a lower elevation, away from the ECM surface) to limit infiltration, erosion, sediment transport and maintain cover stability;
- be compatible with the anticipated end use(s) and the planned future ownership of the NSDF Project site and surrounding area and the overall CRL site; and
- limit the need for future maintenance.

During the closure phase, decommissioning activities will be limited to those structures and systems not required for the post-closure phase. The preferred approach is to complete decommissioning in two phases. Phase 1 will include the decommissioning of the buildings and facilities that are no longer required once the operations phase is complete (e.g., vehicle decontamination facility). Phase 2 will include the buildings and facilities that are required for a period of time during the closure phase (e.g., WWTP).

Buildings and services will be designated for decommissioning and demolition after NSDF Project site operations deems them of no further use. The general approach for decommissioning and demolition of buildings at the CRL site will be completed in a planned, orderly way to limit impact on shared services and adjacent buildings or services. Structures will be decontaminated to the extent required to allow conventional demolition and enable waste materials to be reused, recycled or disposed of as conventional waste.

Decommissioning of the WWTP and all associated structures will be performed after the leachate quantity is able to be treated using a different technique or it becomes more cost-effective to send leachate to an alternate off-site facility. Once the ECM is closed, the volume of wastewater for treatment in the WWTP will reduce to a substantially smaller flow, as will the quantity of residual solids. The solid wastes generated during the decommissioning of the WWTP will be packaged to meet the future storage or disposal capability. Waste associated with demolition of the WWTP and associated facilities will be disposed of off-site as determined at the time of closure.

Planning for closure is an on-going process, and planning assumptions are expected to change over time. The *Preliminary Decommissioning Plan* (AECOM 2018b) for the NSDF Project is based on current information and describes the intended approach for decommissioning of all infrastructure, facilities, systems and components found on the CRL site. Periodic revisions of the *Preliminary Decommissioning Plan* (AECOM 2018b) for the NSDF will be completed as necessary to reflect changes through the lifecycle of the facility.

A *Closure Plan* (AECOM 2017; analogous to closure plan requirements for provincially regulated disposal facilities) has been developed for the NSDF Project and will be a living document that will be modified as needed to adapt to field conditions, programs, technology updates, and contingencies. An updated and revised Final Closure Plan for the NSDF Project will be prepared at the time of final closure based on actual, verified conditions through the end of the operations phase of the NSDF Project. The Final Closure Plan will have information on

updated remaining waste volumes, projected final contours and associated remaining site life including a detailed implementation schedule. Information that will be considered in the revised/updated Final Closure Plan will include the final inventory disposed in the facility, types of waste, locations of waste, and other relevant information.

At the completion of closure, final radiological surveys of the surface will be performed and documented to demonstrate that the final end state for the site has been achieved in accordance with the criteria specified in the Final Closure Plan.

3.2.4 Post-closure Phase

The post-closure phase has two discrete periods: institutional control and post-institutional control.

The institutional control period includes implementation of controls throughout 2100 to 2400 (i.e., 300 years). During institutional control, inspection and surveillance activities will verify the integrity of the disposal facility system, while environmental monitoring activities will verify that the predicted performance continues to demonstrate compliance with the environmental assessment predictions.

The main components and activities associated with the post-closure phase of the NSDF Project include:

- on-going long-term monitoring to verify facility performance during the institutional control period as long as the appropriate regulatory agency deems necessary; and
- surveillance and inspection activities to verify integrity of the facility as long as the appropriate regulatory agency deems necessary.

The NSDF Project will be maintained during the institutional control period to meet the following performance requirements:

- prevent unacceptable dispersal of radioactive materials through environmental pathways (e.g., protecting groundwater from leachate);
- detect release of radioactivity early;
- confirm the final cover system can withstand damage from degradation over the design life;
- confirm the vegetated topsoil of final cover system does not erode at an unacceptable rate;
- maintain the final cover at an appropriate slope to mitigate the effects of settlement and achieve positive drainage off the ECM surface to limit infiltration, erosion, sediment transport and maintain cover stability;
- confirm that safety is provided by passive means (i.e., no active intervention necessary) during the post-closure phase;
- execute applicable environmental requirements with regard to monitoring, and surface water management systems and drainage features; and
- provide records for facility closure and for regulatory review.

Reporting requirements are subject to change based on changing conditions and regulatory requirements. Changes will primarily be made based on the extent that monitoring data confirms that the site and facilities are performing as projected and as required. This monitoring will be completed in accordance with the operational

control monitoring and effluent verification monitoring program outlined in CNL's procedure for *Management and Monitoring of Emissions* (see Section 3.5.1.3; CNL 2018a).

As the post-closure period progresses, it is expected that much of the environmental sampling will be terminated or reduced, except for groundwater monitoring, which must be carried out to provide data to support long-term effects evaluation. After facility closure, the primary pathway for unintended radionuclide releases from the ECM to the environment would be through the groundwater. The groundwater monitoring program for the operational phase will be continued during the initial period after facility closure, but will gradually be reduced if no radionuclide or chemical constituent migrations are identified.

3.2.4.1 Maintenance

Once closed, the ECM will require regular monitoring and maintenance during the institutional control period to ensure its integrity and performance. During the first year immediately following final closure, post-closure inspection and maintenance activities are expected to be most frequent. Early detection of any concerns or deficiencies will be critical to a successful post-closure program. Inspection and maintenance activities will be designed to identify problems before they develop into a need for corrective action. If deficiencies are found, an appropriate course of action will be determined and executed with expediency to mitigate potential undesired effects. Less frequent maintenance and care is expected to be required as the post-closure period progresses.

Maintenance activities for the ECM will be primarily associated with limiting erosion from surface water runoff and ground settlement within the ECM. The finished surface of the ECM will be elevated from the surrounding terrain, which will limit the quantity of surface water entering the ECM from outside areas. The slopes within the ECM will be sufficient to promote drainage and the ECM surface water collection ditches and related components will be lined with erosion control measures so sediment transport and erosion will be reduced.

Construction, operation, and closure activities of the ECM will be designed to limit settlement (i.e., downward movement of the cover) and water infiltration; however, subsidence (i.e., gradual caving in or sinking) or slope instability could indicate differential settlement beneath the surface. The cover will be inspected for depressions, cracking, or other deformities in the cap shape for evidence of differential settlement.

Trees will not be allowed to establish on the final cover because their root systems could cause damage to the cover layers. For example, if the tree falls over due to wind, roots could disrupt low-permeability layers of the cover, resulting in an increase in their hydraulic conductivity (i.e., the ability for water to flow through the layer). Maintenance activities during the institutional control period will include removal of trees and other deep-rooted type vegetation and conducting physical inspections for animal burrows over the ECM surface. To reduce erosion and protect the ECM cover, the turf will need to be a healthy, uniform, close stand of grass that is free of noxious weeds and surface irregularities, with coverage exceeding 90%. Maintenance activities will use the access roads that are constructed around the perimeter of the landfill and the top of the perimeter berm.

Monitoring during the institutional control period will confirm the performance of the containment system, and if necessary, remedial actions will be taken. Examples of mitigation that would be implemented include:

- If erosion were present, the final cover would be repaired.
- If a localized breach of the final cover were present, the cover would be repaired and the leachate system would be periodically assessed and inspected.
- If there were multiple or and indeterminant number of breach locations in the final cover, another cover / cap system could be installed over the existing cover.

- If the monitoring wells detected abnormal performance results, additional wells could be installed and the monitoring frequency increased.
- Erosion of the perimeter berm would be mitigated by maintaining a healthy vegetation cover.

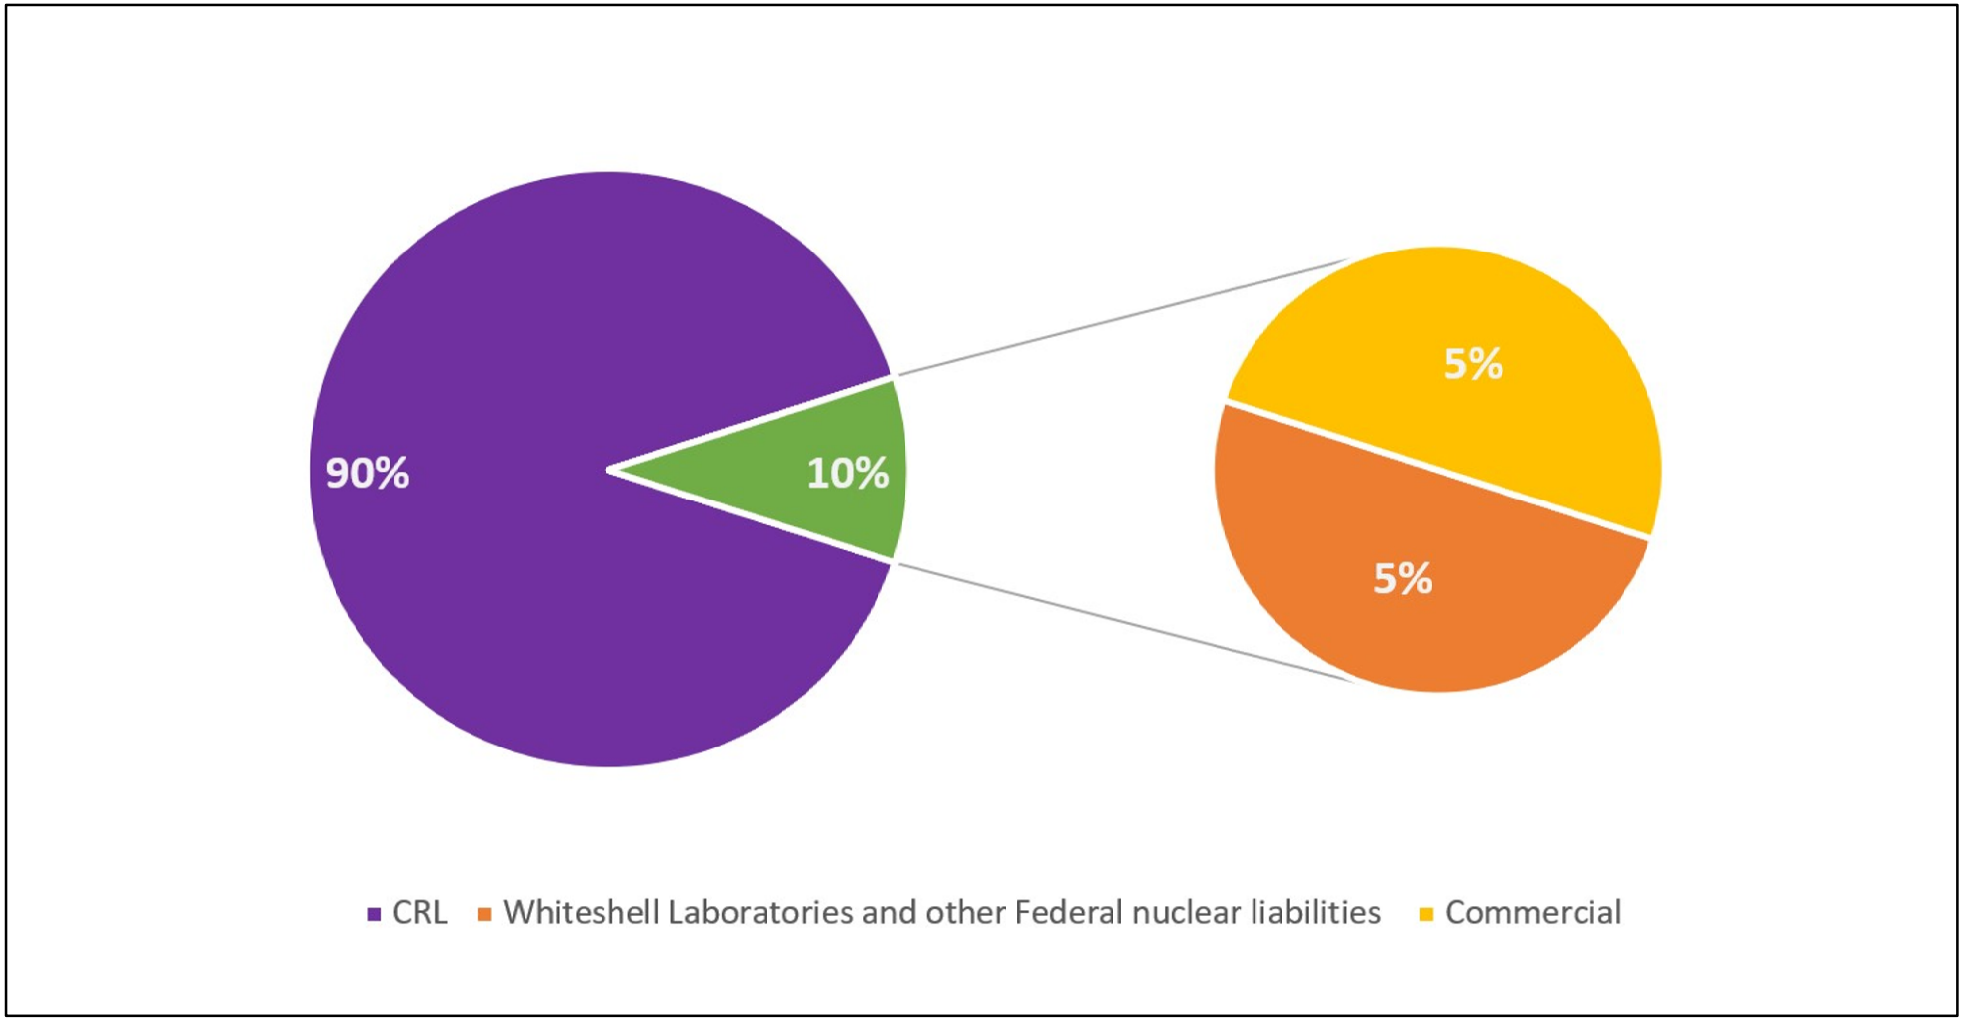
3.2.4.2 Institutional Controls

Institutional controls are anticipated to be required when transitioning from the end of the closure phase (i.e., the year 2100) to the post-closure period. Institutional controls are mechanisms designed to appropriately limit access to or uses of land and facilities, to protect cultural and natural resources, to maintain the physical security of facilities and to prevent or limit inadvertent human and environmental exposure to residual contaminants. Institutional controls include administrative and legal controls, and may also include certain physical controls (e.g., fences and gates).

Institutional controls are important in helping to protect engineered barrier systems by providing a means to ensure that the barriers remain effective, are not showing signs of degradation, and continue to limit the potential for being vandalized or damaged by outside elements (natural or human) in any way. The NSDF Project is designed to promote safety through passive means during post-closure but is complemented by active measures taken by CNL, such as maintenance, security and surveillance. The NSDF Project site security features will include signage, markers, fencing and gate. A chain-link fence will deter intruders and animals from site access. A control gate will be located on the north side of the NSDF Project site to allow personnel access for required maintenance and observation. Features will be maintained and cared for per manufacturer's specifications.

Institutional controls also include methods to preserve knowledge and to inform current and future generations of potential hazards and risks. Such administrative or legal controls help to reduce the potential for human exposure to contamination. The land use designation for the NSDF Project site is as a waste disposal facility. Upon closure, controls will be in place to limit land usage including recognition on the property title or deed to ensure the appropriate zoning restrictions and including buffer or attenuation zones. As the enduring federal entity, and owner of the assets and liabilities of CNL, AECL is committed to controlling and restricting the land use of the NSDF footprint for as long as necessary. While other areas of the CRL site may be reused, the NSDF Project site will continue to be restricted as a waste disposal facility.

Institutional controls work by limiting land or resource use by providing information to modify or guide human behavior at the site. The above are preliminary recommendations of institutional controls for the NSDF Project however these will be reassessed at the time of final closure of NSDF Project and will be updated as necessary during, and at the end of the institutional control period. They will address changes in jurisdiction of authority and changes in other requirements that may occur as they relate to final closure and post-closure care of the NSDF Project.



3.3 Waste Strategy

In the interest of effectively managing AECL's nuclear liabilities, CNL and AECL are working to identify strategies and solutions for waste management of the entire life cycle of all waste classifications from LLW, to intermediate level waste and high level waste. The NSDF Project is the proposed disposal strategy for CNL's LLW. As such, the following sections provide a summary of the waste inventory developed to inform the facility design and various safety assessments, a description of waste types and projected volumes and the WAC that will be employed to keep the facility within its environmental assessment predictions. Additional details regarding CNL's broader integrated waste strategy beyond the NSDF Project is provided in Section 2.2.

3.3.1 Waste Types, Volumes, and Inventory

Sources of the waste to be placed in the ECM will primarily originate from the CRL site and its revitalization plan, which involves the decommissioning of more than 100 buildings that have reached the end of their useful lives. A small percentage of the waste volume will come from off-site sources (e.g., Whiteshell Laboratories, commercial waste sources such as hospitals and universities), as shown on Figure 3.3.1-1.

IF THIS MEASUREMENT DOES NOT MATCH WHAT IS SHOWN, THE SHEET HAS BEEN MODIFIED FROM: ANSI A
0 25mm

The wastes suitable for disposal in the ECM will include a wide range of bulk materials (e.g., demolition debris or soils) and packaged solid wastes (e.g., waste stored in containers or drums). These wastes have or will arise through CNL activities, including:

- demolition of existing and future buildings;
- remediation of contaminated soils and related structures;
- operational and legacy wastes currently in interim storage;
- commercial sourced inventories; and
- wastes from the continuing laboratory operations.

A large portion of the waste inventory planned for disposal from in the ECM will come from waste stored temporarily in the CRL waste management areas (WMA). However, the determination of which WMAs will undergo full remediation (i.e., waste excavated and transferred into the NSDF Project) has not been made. The remediation process, which includes an activity to determine remedial alternatives and select a remedial approach, is captured in CNL's Decommissioning and Demolition Program Description Document (CNL 2018b). In the alternatives evaluation for a specific WMA, a range of alternatives from full remediation to in-situ management through implementation of an engineered cover will be evaluated. This alternatives evaluation would need to demonstrate the preferred remedial approach could satisfy all regulatory and licensing requirements including those specified within REGDOC-2.11.1 Volume III (Assessing the Long-Term Safety of Radioactive Waste Management) (CNSC 2018b).

As per the most recent revision of the Comprehensive Decommissioning Plan (CPDP), the large-scale remediation projects, including the WMAs and impacted areas on the CRL site, are intended to be brought forward to align with the proposed availability of the NSDF Project. For example, the conceptual schedule for the remediation of several WMAs currently impacting groundwater quality on the CRL site (i.e., WMA A, the Liquid Dispersal Area and WMA B sand trenches) have been advanced as much as 10 to15 years from the previous version and strategy. These historic WMAs have none to minimal engineered barriers to contain the inventory. Although the releases and groundwater impact from these WMAs is currently being managed, the risk of future releases and environmental impacts the inventory poses could be substantially reduced through improved containment and isolation of the source term. The NSDF Project is a purpose built disposal facility wherein the ECM design life of 550 years has been established to meet the required time period to allow for radiologic decay of the waste inventory.

Waste characteristic information (i.e., type and volume) is central to determining how waste will be handled, and is the basis for specific waste packaging, handling, and placement practices. In addition, for bulk wastes the waste constituents, such as concrete, wood, brick, and metal, must be described to an extent that allows assessment of waste placement efficiency, stability, and waste segregation strategies.

The expected properties of the future waste streams are based on projections using known wastes that have already been characterized. Waste characterization will continue throughout the operation of the NSDF; however, the waste properties and quantities are sufficiently defined to support the facility design. A range of radiological, chemical, and physical properties have been considered and included in the waste inventory. Only LLW, as defined in the Canadian Standards Association (CSA) standard for the nuclear industry *N292.0-19 General Principles for the Management of Radioactive Waste and Irradiated Fuel (*CSA Group 2019) and IAEA's general

safety guide *GSG-1 Classification of Radioactive Waste* (IAEA 2009), will be accepted for disposal in NSDF. The following sections provide a summary of the waste types and expected volumes for each waste type.

3.3.1.1 NSDF Waste Types

CRL identifies and tracks several hundred waste sources in its waste tracking database. Wastes are categorized into six waste types based on physical characteristics. The six waste types are independent of their radiological and chemical characteristics, which are further defined in Sections 3.3.3.2 and 3.3.3.3. A description of each waste type is provided below:

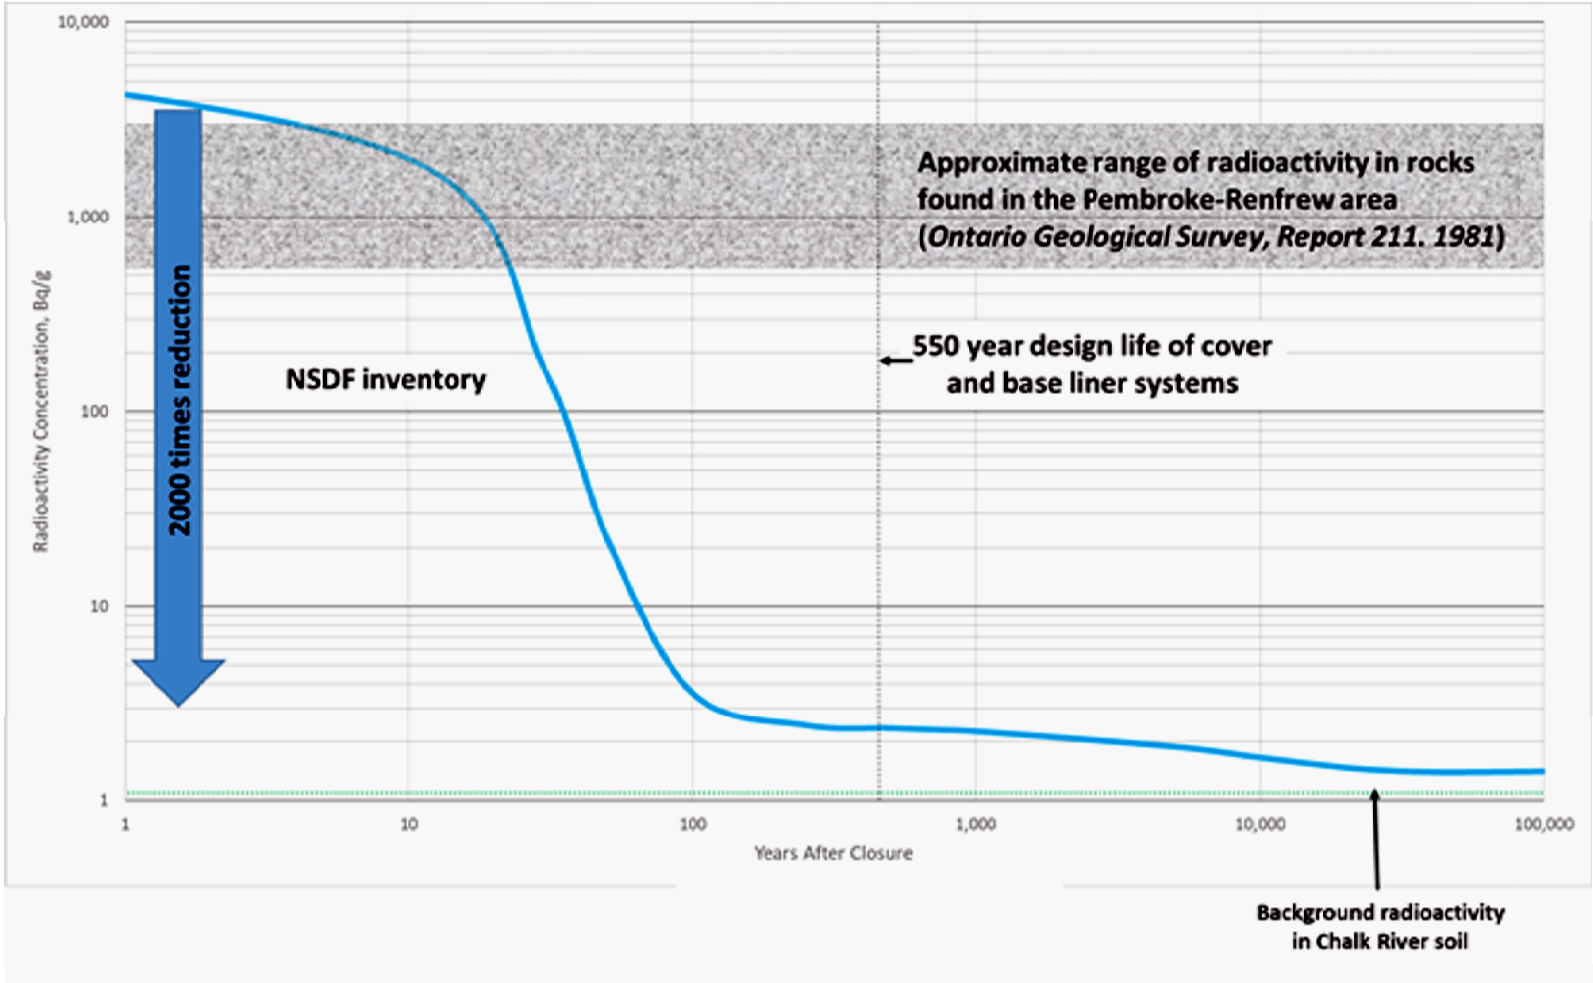
- **Type 1 – Soil and Soil-like Waste:** Type 1 waste includes contaminated soils and other waste materials with characteristics similar to soil that can be placed within the mound with what would be required for the disposal of soil.
- **Type 2 – Comingled Radioactive Waste, Debris, Refuse, Soil, and Soil-Like Waste:** Type 2 waste includes wastes that are anticipated to be at least 50% soil or soil-like in nature.
- **Type 3 – Non-Soil-Like Waste:** Type 3 waste includes materials that can be excavated and handled as bulk materials but do not have the physical characteristics of soil and soil-like materials. These include process wastes, highly organic wastes, highly compressible wastes, flowing wastes and similar waste types.
- **Type 4 – Decommissioning and Demolition Waste:** Type 4 wastes include typical materials used in construction such as: concrete, asphalt, brick, lumber, structural steel, process equipment, piping, wood and other building materials produced by decommissioning and demolition activities.
- **Type 5 – Packaged Waste:** Type 5 waste refers to wastes contained in rigid packages. There are two types of rigid waste packages: Non-Leachate Controlled Waste Packages and Leachate Controlled Waste Packages. Liners and soft-sided waste packages are not considered Type 5 Waste. Non-Leachate Controlled Waste Packages include intermodal containers (e.g., 20-foot ISO container), steel waste boxes (e.g., B-25 boxes) and drums (e.g., 205 L drum). Leachate Controlled Waste Packages provide containment of the waste during the time the disposal cell is not covered with the final cover. Containment can also be provided using approved overpacks or waste processing methods.
- **Type 6 – Oversize Debris:** Type 6 waste includes waste that does not fall within the definition of waste Types 1 through 5, primarily by its size or shape. The Infrequently Performed Operations process is used to approve placement of Type 6 wastes (CNL 2019a).

3.3.1.2 Waste Volumes

Table 3.3.1-1 shows the estimated volume of each type of waste expected to be disposed of at the NSDF. The most abundant waste types by volume are decommissioning and demolition wastes (Type 4) and soil and soil-like wastes (Type 1). Waste types 1,2,3,4 and 6 constitute bulk waste, and type 5 is packaged waste. Approximately 87% of the wastes will be bulk unpackaged wastes and approximately 13% of the wastes will be packaged.

Table 3.3.1-1: Waste Types and Volumes

Waste Type Descriptor	Waste Volume (m^3)	Waste Type (%)
Bulk Waste	866,000	87
Type 1 – Soil and Soil-Like Waste		
Type 2 – Comingled Radioactive Waste, Debris, Refuse, Soil, and Soil-Like Waste		
Type 3 – Non-Soil-Like Waste		
Type 4 – Decommissioning and Demolition Waste		
Type 6 – Oversize Debris		
Packaged Waste	134,000	13
Type 5 – Packaged Waste		
Total	**1,000,000**	**100**



3.3.1.3 Waste Inventory

The NSDF Project will contain only LLW. NSDF will not contain high level radioactive wastes such as used nuclear fuels nor intermediate level waste such as irradiated reactor core components. LLW contains primarily short-lived radionuclides and restricts the amount of long-lived radionuclides; thus, isolation and containment are only required for periods of time up to a few hundred years. Long-lived radionuclides are included in the NSDF inventory as they are intrinsically part of the radiological fingerprints of waste streams at CRL and other CNL sites. It is not practical, technical, or economical, to separate the long-lived radionuclides from the waste streams, especially since many of the waste streams are in the form of soil and building debris. However, the concentrations of long-lived radionuclides that are proposed in the NSDF licensed inventory are limited, consistent with CSA N292.0 (CSA Group 2019) and IAEA GSG-1 (IAEA 2009) guidance. The ECM design life of 550 years has been established to meet the required time period to allow for radioactive decay of the waste inventory, illustrated on Figure 3.3.1-2. The radioactivity concentration in the ECM decreases about 2,000 times in the first 100 years, and begins to approach background levels of concentration shortly thereafter.

The radionuclides currently present on the proposed NSDF footprint are Naturally Occurring Radioactive Material (NORM) such as Potassium-40, Carbon-14, and the uranium and thorium decay chains (CNL 2017a). The natural background also includes Cesium-137 from atmospheric atomic weapons testing.

Although not all radionuclides proposed in the NSDF inventory are NORM, the purpose of comparing the NSDF total radioactivity concentration to the total natural background concentrations is to build confidence that the long-term hazard is acceptably low. This comparison provides an analogy by recognizing that long-lived radionuclides already exist in the environment without being a hazard. There is no requirement to meet background radioactivity levels in a disposal facility. The radiological inventory proposed for the NSDF, combined with the facility design, must ensure that doses to the public and risk to the environment remains below the regulatory limits. Radiological dose and environmental risk as a result of these long-lived radionuclides are discussed in Sections 5.7 and 5.8.

TITLE
RADIOLOGIC DECAY OF THE NEAR SURFACE DISPOSAL FACILITY WASTE INVENTORY

PROJECT NO.	CONTROL	REV.	FIGURE
1547525	0039	FINAL 3	**3.3.1-2**

IF THIS MEASUREMENT DOES NOT MATCH WHAT IS SHOWN, THE SHEET HAS BEEN MODIFIED FROM: ANSI A
25mm
0

An estimation of the total inventory is required for the safety assessments in which the inventory is tested against selected scenarios to determine the long-term consequences of the proposed facility. It also informs design criteria for NSDF Project components such as the WWTP.

The reference inventory (Table 3.3.1-2) establishes a representative radionuclide inventory by considering waste already in storage and waste forecasts from environmental remediation and decommissioning projects data to predict an assumed total volume of waste at the NSDF at time of closure. The NSDF Reference Inventory has been used to inform the design and safety analyses.

In the third iteration of the Post-Closure Safety Assessment (Arcadis and Quintessa, 2020), a recommendation was made to lower the maximum radioactivity of two radionuclides listed in the reference inventory, to support the claim that future public doses in the post-closure phase will be well below the long-term dose acceptance criteria. The Licensed Inventory is a modified reference inventory, and represents a maximum radiological inventory limit for the NSDF. The Licensed Inventory is part of the NSDF safety and licensing basis, and represents a maximum radiological inventory limit for the NSDF. In the Licensed Inventory, the radioactivity of both I-129 and Pu-239/Pu-240 were reduced to 58% of the reference inventory values. All LLW that is expected to be generated has been meticulously described, or “characterized”, before its generation to ensure the cumulative total inventory of the NSDF is tracked against the licensed inventory (Table 3.3.1-2).

Table 3.3.1-2: NSDF Reference Inventory and Licensed Inventory

Radionuclide	Half Life[(a)] (years)	Predominant Decay Emission	Reference Inventory		Licensed Inventory	
			Total Activity (Bq) at Emplacement	Total Activity (Bq) at Closure	Maximum Activity (Bq) at Placement	Maximum Activity (Bq) at Closure
Silver-108m	438	gamma	2.73×10^{10}	2.62×10^{10}	2.73×10^{10}	2.62×10^{10}

(a) Half-Lives are from the IAEA Live Chart of Nuclides (IAEA 2019).

(b) Reported as Pu-239/240 are these radionuclides are generally combined in laboratory analysis.

Bq = Becquerels; Bq/g = Becquerels per gram.

3.3.1.3.1 Non-radiological Waste Inventory

The NSDF will only accept radiologically contaminated material; however, these materials are made of a variety of metals, organics, and chemical compounds. As a land disposal facility, the NSDF will follow the guidelines of Ontario's *Regulation 347, General – Waste Management,* for acceptable quantities and concentrations of metals, organics, and chemical compounds to limit the leaching potential of the facility.

CNL has performed calculations to determine estimates of the amounts of metals, chemical compounds, and organic material present in the waste streams proposed for the NSDF. A summary of discrete metals and organics estimates is presented in Table 3.3.1-3.

Table 3.3.1-3: NSDF Non-radiological Inventory at the Time of Closure

Contaminated Material Type	Calculated Mass in the Facility at Closure (kg)
Aluminum	33,000
Copper	3,520,000
Iron (waste plus package material)	10,442,000
Lead	178,000
Organics (wood and dry radioactive waste, which includes cotton-based materials like mop heads and clothing)	80,339,000

3.3.2 Waste Approval, Verification and Acceptance

Waste generators will be approved through CNL's Waste Programs prior to acceptance of waste for disposal in the ECM. For waste to be accepted for disposal in the ECM, the waste generator will need to characterize the waste, complete and submit a Waste Profile and Waste Management Plan for review and approval, and apply for and receive approval to transport the waste to the NSDF site. Initial discussions between the waste generator and NSDF personnel regarding the waste will be essential to ensure that the waste acceptance process is accurate, complete and meets NSDF requirements.

As part of the waste acceptance process, CNL will verify the NSDF-bound waste against the submitted documentation. The verification may include:

- visual inspection of waste;
- visual inspection of waste package;
- non-destructive assays (e.g., inspection or evaluation); and/or
- destructive sampling and analysis.

Waste that is successfully verified will then be permitted to proceed to the unloading zone.

WAC non-conformances identified through the verification process as well as discrepancies between waste documentation and verification results will be managed through the Waste Certification process. These non-conformances could result in remedial actions ranging from a non-accepted waste shipment with minor anomalies (e.g., missing or incorrect documentation) that would remain in a quarantine area until the required correction is made and the verification and acceptance process can be completed, up to a non-accepted waste shipment with major anomalies (e.g., incorrect packaging) which would be returned to the waste generator's facility to complete the necessary corrective action.

3.3.3 Waste Acceptance Criteria

The NSDF WAC ensures CNL meets its responsibility as the licensee; that all waste received for disposal is in compliance with the design and licensing basis for the facility (CNL 2020c). Specific safety criteria are provided in the *Design Description* (AECOM 2019), this EIS, the *Post-Closure Safety Assessment* (Arcadis and Quintessa 2020) and the *Safety Analysis Report* (CNL 2020b). Compliance with the NSDF safety criteria ensures the short-term and long-term protection of the public, the environment and workers.

Waste shall comply with all of the criteria in the WAC to be considered acceptable for disposal in the ECM. The physical, radiological and chemical characteristics of the acceptable waste are further defined below.

3.3.3.1 Physical Characteristics

The NSDF will only accept solid waste with no free liquids (e.g., liquids that readily separate from the solid portion of a waste) for disposal. Waste that has been solidified via stabilization (e.g., cementation) or pre-treatment may meet this requirement. Such waste will either be delivered to the ECM in the form of:

- Bulk materials (e.g., demolition debris including concrete rubble, masonry, and rebar).
- Packaged wastes (e.g., waste that is stored in containers or drums). The primary objective of waste packaging is to provide contamination control and radiation shielding for worker safety during handling and placement operations. A small percentage of packaging is also credited for containment to limit leachate generation. The properties of each container must be compatible with the enclosed waste.

As summarized in Table 3.3.1-1, the majority of the waste (approximately 87%) to be accepted in the ECM will be bulk materials (i.e., Types 1, 2, 3, 4 and 6), while packaged waste (Type 5) will comprise approximately 13% of the total waste volume. Both forms of waste must meet the WAC requirements for dimension and mass (i.e., size and weight) to assure safe handling and transportation.

3.3.3.2 Radiological Characteristics

LLW includes items such as soils from remediation activities, demolition debris from decommissioning work and general trash such as used personal protection clothing or equipment. These items are considered LLW because they became contaminated at some point with low levels of radioactivity. LLW mostly contains short-lived radioactivity (thus decays relatively quickly) and can be safely handled with limited precautions.

The radionuclide concentration limits for waste are provided in Table 3.3.3-1 below for a single radionuclide. In the case of a mixture of radionuclides, the sum of the component radionuclide limit fractions must not exceed 1 to demonstrate compliance to what is referred to as the “Sum of Fractions” rule. The calculation of the concentration limits shall exclude the mass of packaging and shielding.

Table 3.3.3-1: Radionuclide Concentration Limits in NSDF Waste

Limits for Bulk Waste & Non-Leachate Controlled Waste Packaged Waste	■ 100 Bq/g for alpha emitting radionuclides ■ 1,000 Bq/g for long-lived beta/gamma emitting radionuclides (half life >cesium-137) ■ 10,000 Bq/g for short-lived beta/gamma emitting radionuclides (half life ≤ cesium-137) ■ 100,000 Bq/g for tritium
Limits for Leachate Controlled Packaged Waste	■ 400 Bq/g for alpha emitting radionuclides ■ 10,000 Bq/g for long-lived beta/gamma emitting radionuclides (half life >cesium-137) ■ 10,000 Bq/g for cesium-137 ■ 10,000 Bq/g for strontium-90 ■ 10,000,000 Bq/g for tritium

Bq/g = Becquerels per gram.

Radiation dose rates and surface contamination on containers will meet CNL’s Radiation Protection Program requirements. All waste received at the NSDF must meet the dose rate limits (CNL 2020a) listed in Table 3.3.3-2:

Table 3.3.3-2: Dose Rate Limits and Means of Handling and Transferring

Radiation Type	Dose Rates	Means of Handling and Transferring
Total gamma and neutron	≤0.5 mSv/h near contact **and** ≤0.01 mSv/h at a distance of 1 metre	Manual handling or mechanical means
Total gamma and neutron	>0.5 mSv/h to ≤2 mSv/h near contact **and** >0.01 mSv/h to ≤0.1 mSv/h at a distance of 1 metre	Mechanical means
Total gamma and neutron	>2 mSv/h near contact **or** >0.1 mSv/h at a distance of 1 metre	Handling and transferring is subject to Radiation Protection Programs controls, Infrequently Performed Operations (CNL 2019a) and assessment approval by the NSDF Facility Authority.
Beta	<10 mSv/h near contact	Based on total gamma and neutron dose rates

The maximum non-fixed surface contamination on the accessible surface of each waste package or transportation vehicles, averaged over 300 cm^2, must be less than 3.7 Becquerels per square centimetre (Bq/cm^2) for beta/gamma-emitters, and less than 0.37 Bq/cm^2 for alpha-emitters.

The vast majority of the fissionable material projected for placement in ECM is natural uranium; thus, posing minimal hazard as it exists inherently, or is caused by anthropogenic activities, in soils generated from environmental remediation activities or building materials generated from demolition and decommissioning. A very small amount of other fissionable material will exist in residual, unrecoverable amounts predominately as contamination on waste equipment, demolished structures and in soil as a result of nuclear fuel cycle activities. Concentration limits for fissionable material in the waste have been developed to ensure appropriate controls and mitigations in alignment with CNSC's *REGDOC-2.4.3 Nuclear Criticality Safety* (CNSC 2018c) are in place and to meet the requirements of CNL's Nuclear Criticality Safety Program, such that criticality safety can be assured (see Section 3.5.2.6).

3.3.3.3 Chemical Characteristics

The majority of LLW accepted in the ECM will be on-site building waste from decommissioning and soil and soil-like wastes from environmental remediation. As such, LLW may also contain chemical constituents of potential concern (COPCs), as residual contamination.

Waste placed in the ECM will meet the intent of land disposal and leachate requirements specified in Ontario's *Regulation 347, General – Waste Management*. This is a requirement of the WAC. The acceptance of waste into the ECM will be controlled through waste characterization and utilizing Ontario Regulation 347 limits. Waste that, not considering its radioactive component, is classified as hazardous waste is not permitted for disposal in the ECM, unless the hazardous waste has been treated using methods for land disposal described in Ontario Regulation 347.

3.4 Project Components and Activities

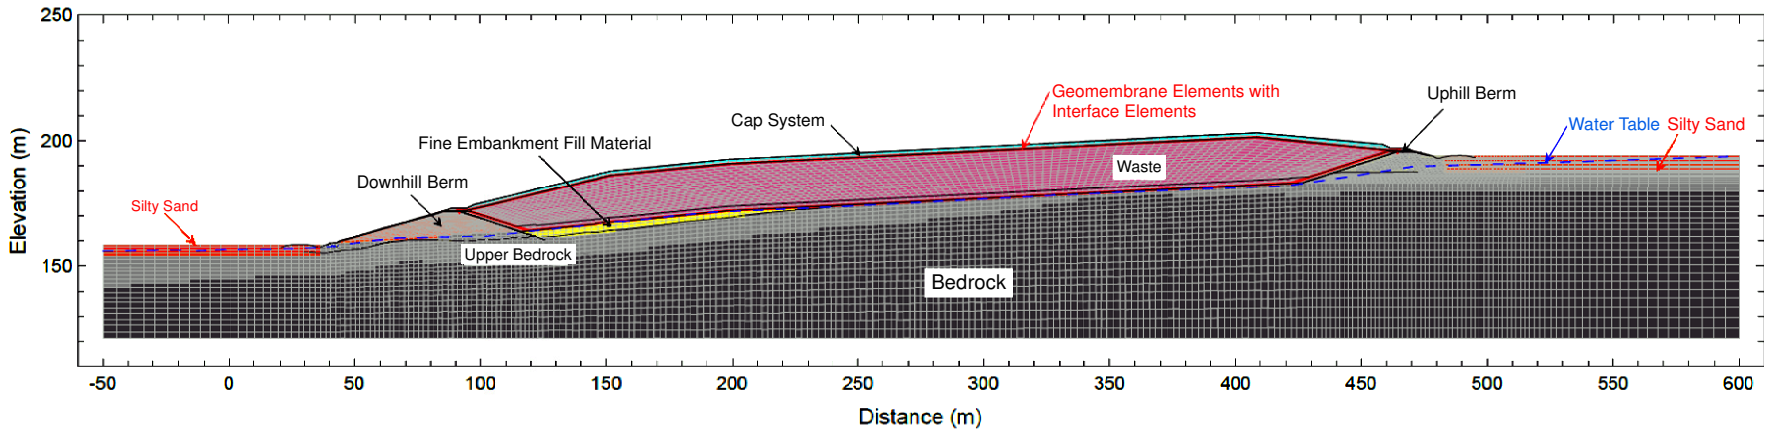
The following sections describe in detail the components and activities anticipated for the NSDF Project. Emphasis is placed on the systems, components, and activities of the NSDF Project that are expected to interact with the environment. All activities will be carried out in compliance with CNL's health, safety and environmental protection requirements.

3.4.1 Engineered Containment Mound

The primary component of the NSDF Project is the ECM, which will contain the wastes and isolate them from the surrounding environment. The ECM relies on passive safety features to provide containment and isolation of the waste. These ensure the safety and protection of individuals, society and the environment. The ECM passive safety features include:

- the base liner (a double-liner system) that provides containment of the waste and the leachate that is generated;
- final cover, that isolates the waste from the environment and human intrusion; and
- perimeter berm, that provides containment of the waste and the leachate that is generated and isolates the waste from the environment and human intrusion.

Containment and isolation of the waste allows radioactive decay to occur and delays the release of any contaminants to the environment. The base liner, final cover and perimeter berm constitute a multiple barrier system because:



- the different materials used in their design and construction have different chemical and physical properties that ensure the long life of these structures; and
- there is no common failure mode that would simultaneously fail all layers of the liner and cover (e.g., subsidence and seismic activity).

The ECM will consist of ten disposal cells, each designed for progressive construction, filling, and closure in sequence. Dividing the entire disposal area into ten cells provides for the preferred operation and closure sequence.

The disposal cells in the ECM will be filled in succession and as each cell is filled to capacity, the next cell will be prepared to accept waste. The average cell area will be 12,000 m^2; however, for the purposes of the modelling, a maximum capacity of 15,000 m^2 was used to calculate a maximum amount of leachate and contact water that could be expected to be generated from any cell. Within the ECM there will also be a 6,000 m^2 temporary waste storage pad for staging waste. The storage pad will be a gravel area that may be used to stage both bulk and packaged waste awaiting disposal.

A cross-section along the east-west axis through the ECM is provided on Figure 3.4.1-1. The figure illustrates the relative elevations of the existing grade, interpreted bedrock surface, ECM subgrade, ECM liner, and ECM final cover. Construction of the ECM will involve excavation below grade in the central portions of the facility, and placement of material above current grade along the exterior berms and in the southern-central portions of the facility. All overburden material will be removed in the area beneath the ECM berm, and the perimeter berm will be constructed on bedrock. Waste will be placed in the ECM between a base liner system and the cover system. Upon completion of the cover, the ECM will reach a maximum elevation of approximately 8 m above existing grade. The ECM will lie on overburden in the northwest region of the footprint. The maximum thickness of overburden underlying the ECM will be approximately 3 m.

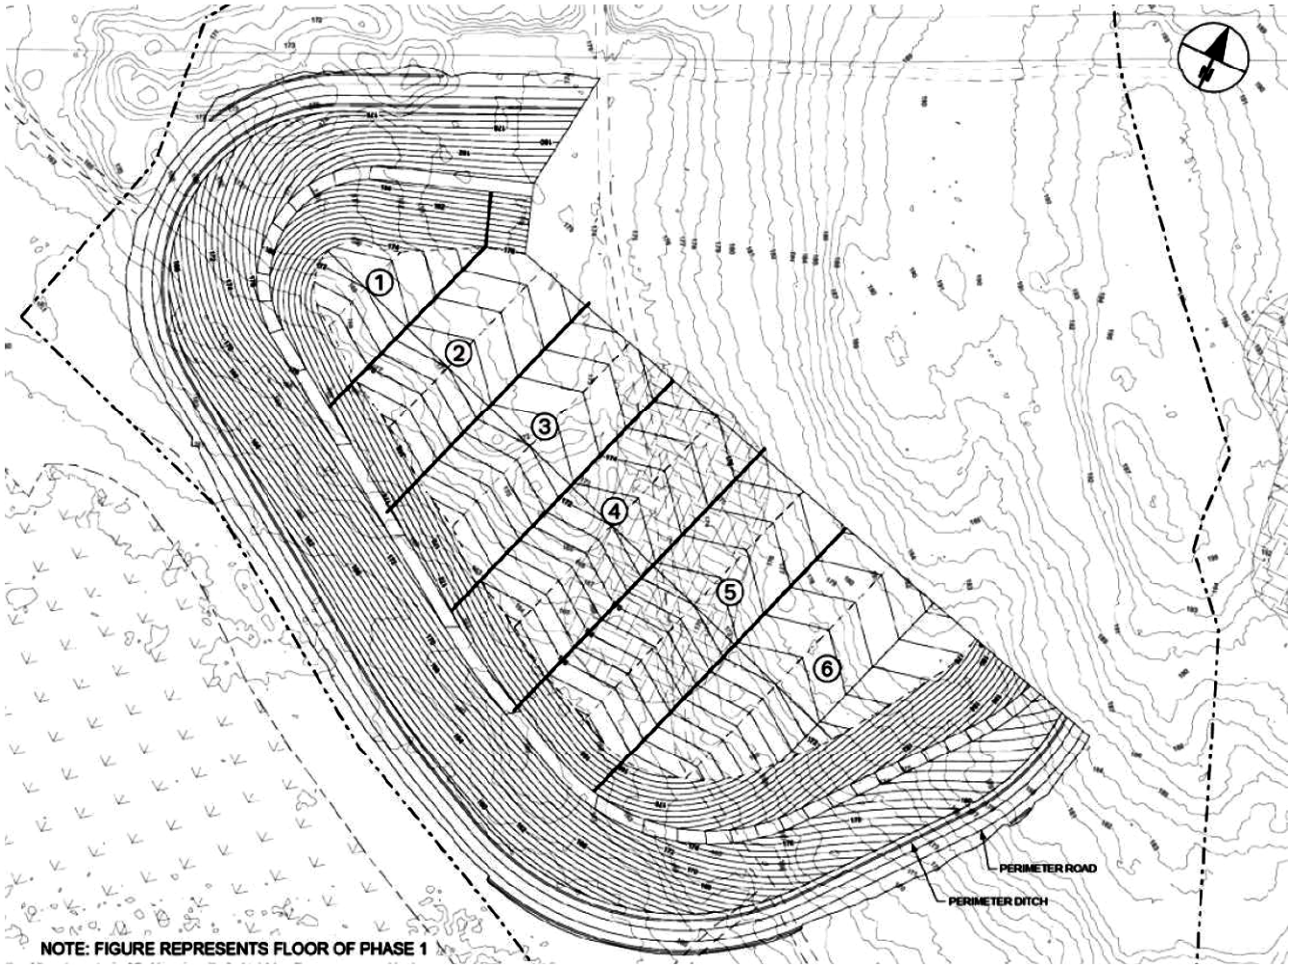
3.4.1.1 Containment Mound Fill Capacity

The construction and operation of the ECM will be accomplished in two phases. Phase 1 will include six cells providing a capacity to accommodate the disposal of 525,000 m³ of waste (Figure 3.4.1-2). Phase 2 will include four cells providing a capacity of 475,000 m³ to accommodate the remainder of the waste (Figure 3.4.1-3). A daily/interim cover (described in Sections 3.4.1.9.1 and 3.4.1.9.2) will use an industry-typical waste-to-soil ratio of 4:1 (i.e., 4 units of waste for every 1 unit of daily/interim cover soil), which will result in a total cover soil volume of 131,250 m³ for Phase 1. As such, the design fill capacity for the Phase 1 mound volume is 656,250 m³ (i.e., 525,000 m³ of waste, plus 131,250 m³ of daily/interim cover soil), and the design fill capacity for Phase 2 is 593,750 m³ (i.e., 475,000 m³ of waste, plus 118,750 m³ of daily/interim cover soil).

The combined total capacity will be 1,250,000 m³ of waste and daily/interim cover soil (i.e., 1,000,000 m³ of waste, plus 250,000 m³ of daily/interim cover soil). The design capacity for the ECM volume, as described above, does not include the final cover volume, base liner volume, or perimeter berm volume.

3.4.1.2 Disposal Cells



The ten contiguous cells will run parallel in rows. The maximum height of fill material, waste, and the final cover will be 18 m. The cells vary in size and have an average surface area of approximately 12,000 m^2. The cell design accounts for shielding requirements, WAC, and are located to provide operational flexibility accounting for variations in waste types and when the waste is produced.

Each cell will operate for approximately five years; however, the fill rate may vary especially during the initial operations. When a cell is nearly full, the subsequent cell will be prepared to receive waste. The filled cells will first be covered with the 0.3-m-thick first layer of the final cover and overlain by a sacrificial liner which allows precipitation falling on these surfaces to be treated as non-contact water (see Section 14 glossary for definition). When the final cover system is ready to be placed on top of the first layer of the final cover, the sacrificial liner will be removed. The final cover, containing a high-density polyethylene (HDPE) membrane, will be constructed in a sequential manner as the cells are filled (see Section 3.4.1.9.3).

3.4.1.3 Base Contours

The base contours for the ECM have been developed using a herringbone design with ridges and valleys to promote leachate transport to the leachate collection system for removal. The herringbone base contours, in conjunction with the spacing of the leachate collection pipes, will allow the drainage path for leachate to reach a collection pipe that is not more than 50 m long.

The base grade at the south end of the NSDF Project site will be a 10% slope, which transitions to a 5% slope over the remainder of the base. This configuration will be used because there is a bedrock plateau near the centre of the mound base and to maximize available volume for waste materials.

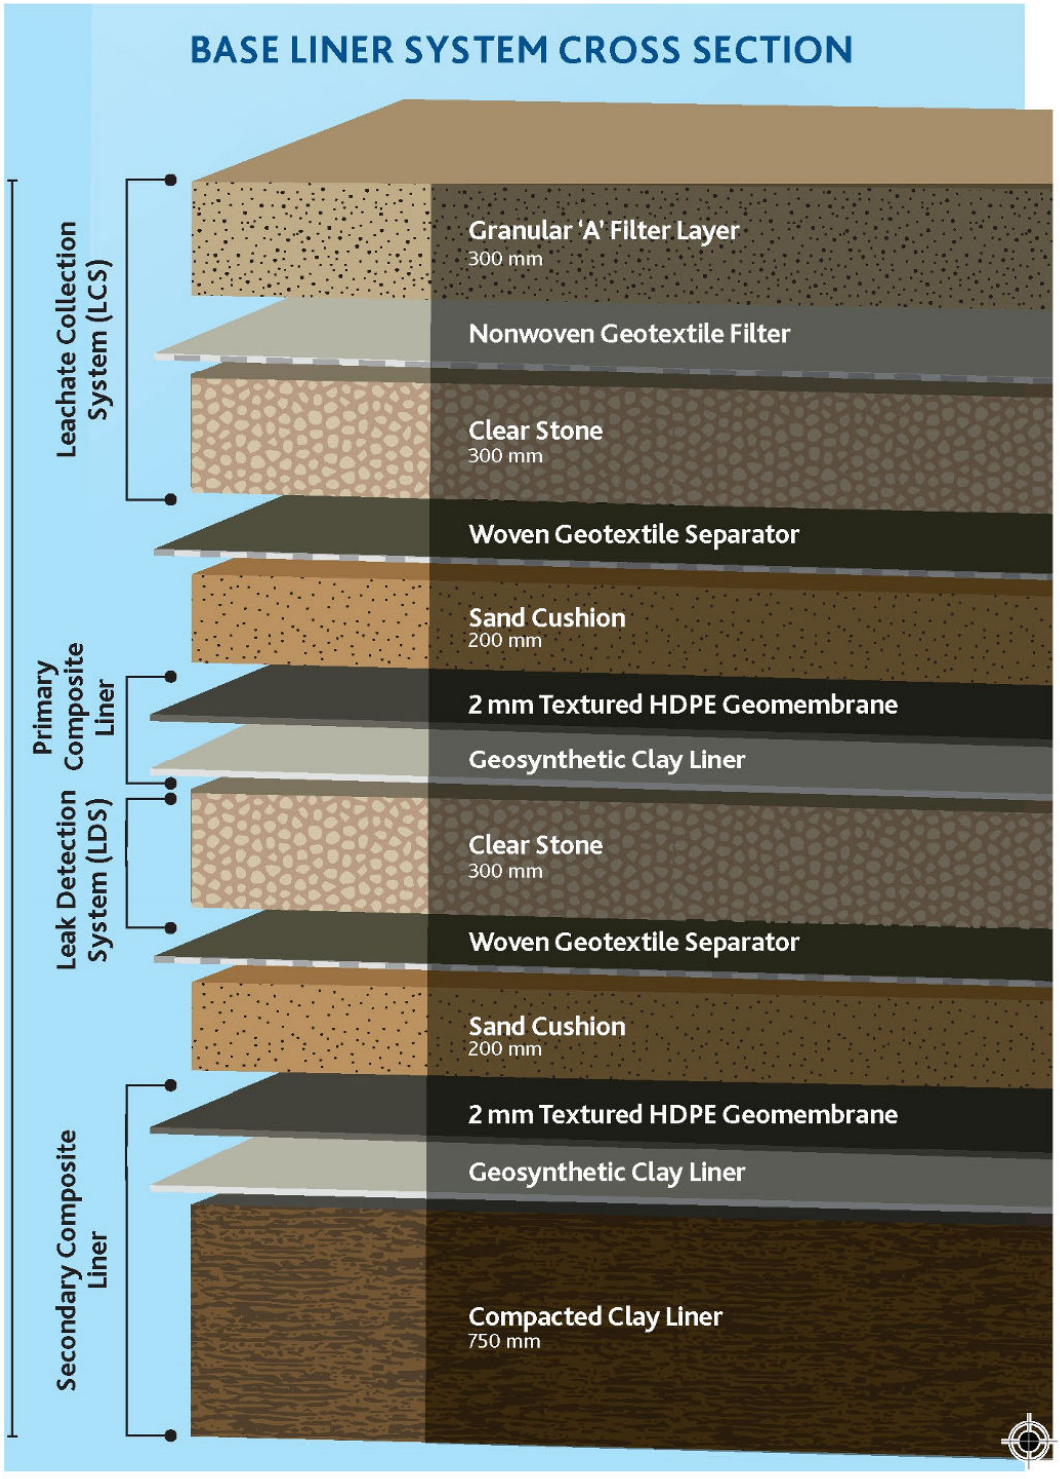
3.4.1.4 Base Liner System

The principle function of the base liner system is to contain leachate generated during and following operation of the ECM; thus, limiting the release of leachate to groundwater.

The base liner system includes both primary and secondary liner systems. The secondary liner system provides redundancy in case of premature degradation of the primary liner. The base liner system includes a combination of natural earthen materials and geosynthetic barrier systems to support the ECM 550-year design life. The combined thickness of the primary and secondary liners is 2.05 m. The base liner system includes the leachate collection system for transferring leachate to sumps and the leak detection system for transferring any primary liner system leakage to sumps.

The base liner system will be positioned on bedrock in the eastern region of the ECM near the bedrock ridge. The top of the ECM cannot be seen from the Ottawa River. Where the base liner is constructed on bedrock, 20 cm of granular bedding will be placed on the bedrock surface to facilitate the construction of the base liner system. Differential settlement may occur because a portion of the ECM will be founded on compacted engineered fill. Differential settlement has been assessed and is not expected to cause cracking of the compacted clay liner component of the base liner system or damage to the leachate collection system.



Component Layers

The schematic showing the base liner system cross-section is provided on Figure 3.4.1-4. Each of the base liner components are described in the following layers (from bottom to top).

- **Secondary Composite Liner and Leak Detection System**– The secondary liner is designed to contain leakage that may occur through the primary liner. It consists of a HDPE liner, geosynthetic clay liner and a compacted clay liner. The secondary composite liner protects the natural environment from leachate migration if the primary liner system fails. The leak detection system (LDS) component of the base liner system is a means of monitoring potential leakage of leachate through the primary liner and transferring leachate and condensate that accumulates to sumps for subsequent removal to the WWTP.
  - **Compacted Clay Liner** – The compacted clay liner provides hydraulic isolation from the geosphere. The compacted clay liner is a minimum 0.75 m thick and will be constructed on top of the finished subgrade to provide an additional layer of protection against the release of leachate to the environment.
  - **Geosynthetic Clay Liner** – geosynthetic clay liner to provide a composite barrier working with the overlying HDPE geomembrane to mitigate defects and/or damage in the HDPE geomembrane that might occur during construction or operations.
  - **Textured HDPE Geomembrane Liner** (2 mm thick [80-mil]) – Textured HDPE geomembrane liner serves as a barrier to the leachate from the granular drainage layer. The high-density polyethylene (HDPE) geomembrane included in the primary and secondary liner system is a proven material with a long design life (R. Kerry Rowe Inc. 2019). Based on the results from several studies conducted to evaluate the service life of HDPE geomembranes, the HDPE geomembranes installed in the final cover and base liner systems of the ECM are expected to perform as an effective barrier for the 550-year design life of the ECM.
  - **Sand Cushion Layer -** The sand cushion layers are included in the design to protect the underlying geomembranes and geosynthetic clay liners.

- **Woven Geotextile Separator -** Separates the clear stone layers from the sand cushions to maintain unobstructed drainage through the stone layers.
- **The Clear Stone Layer –** The clear stone secondary drainage layer will collect and drain leachate that may have leaked through the primary liner system. This layer is part of the LDS.

- **Primary Composite Liner and Leachate Collection System** – The primary liner component of the base liner system is designed to contain waste, collect leachate generated in the ECM and to prevent leakage of leachate to the underlying components of the base liner system. The primary liner will include a leachate collection system (LCS) to drain leachate to sumps. The leachate is then transferred to one of three collection tanks for treatment in the WWTP. The leachate collection and monitoring system design will provide access points for monitoring, inspections, maintenance, repairs and replacements. The top surface of the primary composite liner is designed to be at least 1.5 m above the water table.
  - **Geosynthetic Clay Liner** – See description above.
  - **Textured HDPE Geomembrane** – See description above.
  - **Sand Cushion Layer** – See description above.
  - **Woven Geotextile Separator** – See description above.
  - **Clear Stone Layer** – A clear stone granular drainage layer with a primary function of conveying leachate to one of five lined leachate collection sumps; this layer will form part of the LCS. Perforated collection pipes are also included in the LCS.
  - **Nonwoven Geotextile Filter -** Separates the clear stone layer from the granular A filter layer to maintain unobstructed drainage through the clear stone layer.
  - **Granular "A" Filter Layer** – The granular 'A' sand and gravel filter layer for limiting migration of fines from the overlying waste material into an underlying granular drainage layer.
- **Sacrificial Geomembrane and Cover Layer** – During construction, a temporary sacrificial geomembrane will be installed over the baseline system to divert stormwater to collection ponds in the ECM. A granular 'A' cover layer will be added for frost protection of the constructed base liner system. The sacrificial geomembrane and granular 'A' cover will be removed prior to waste placement.

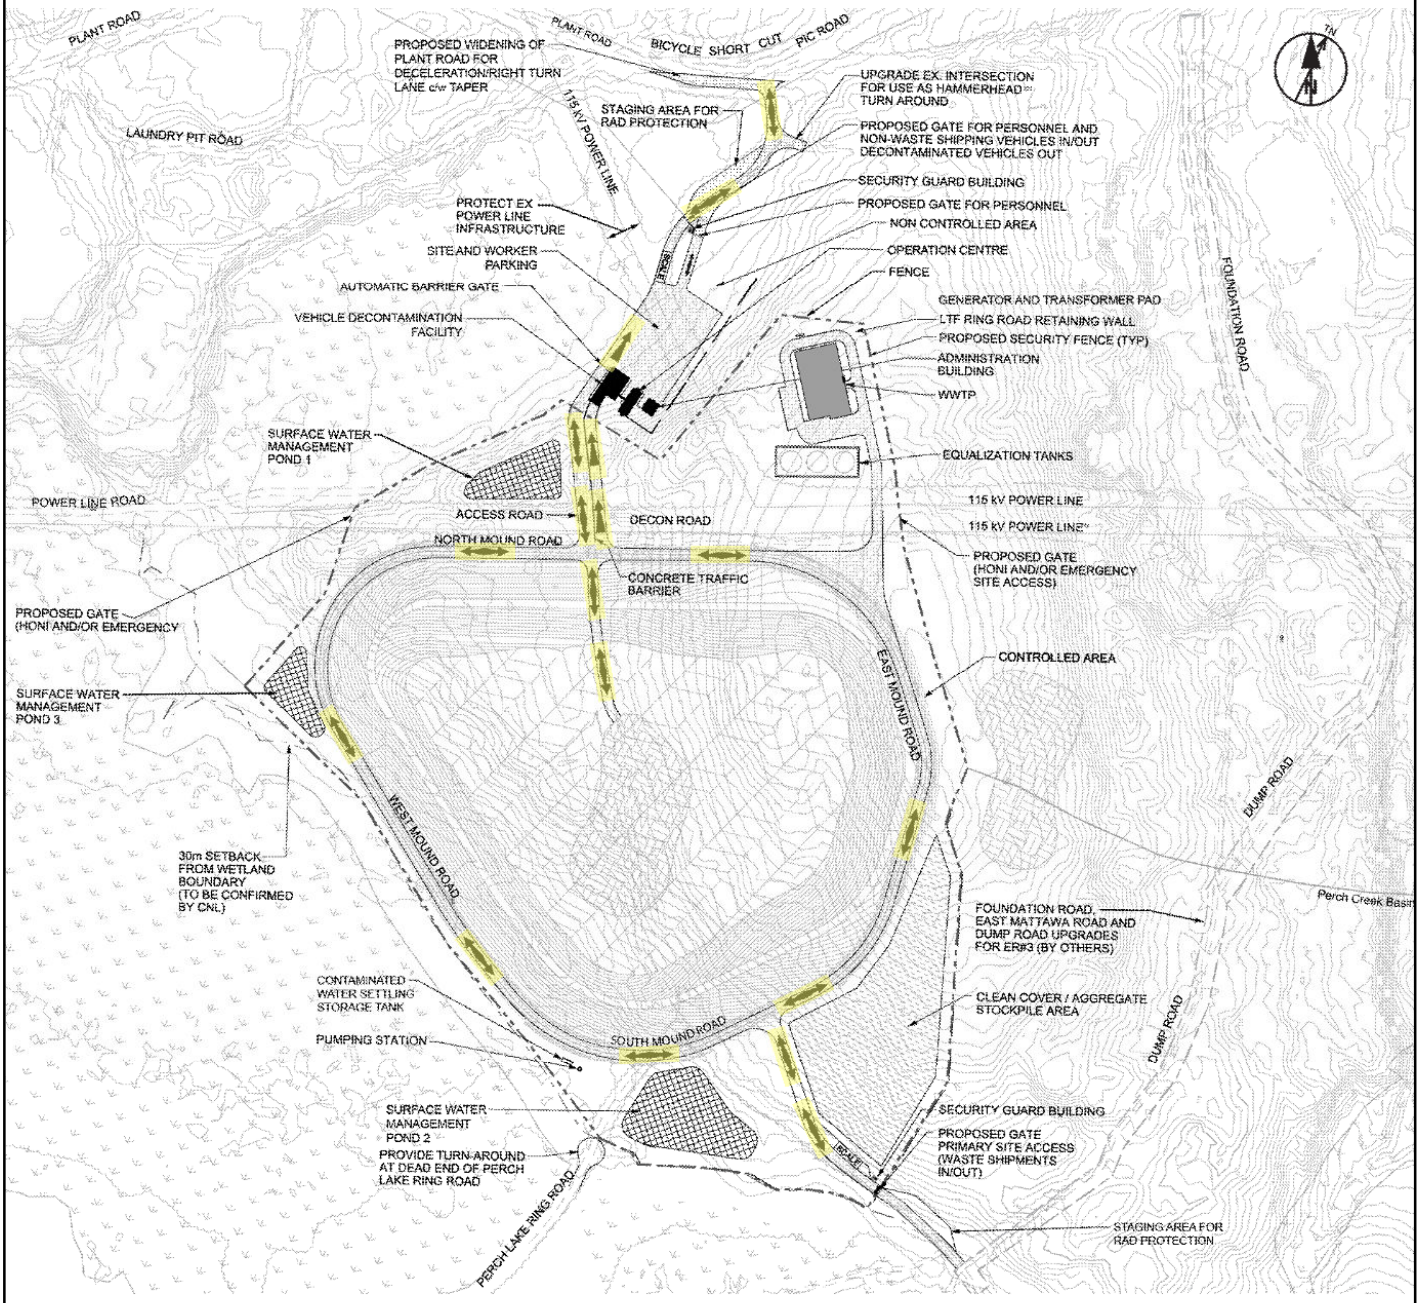
3.4.1.5 Perimeter Berm

The primary function of the perimeter berm is to maintain the integrity of the ECM during operations and throughout the post-closure period. The perimeter berm is a robustly designed, passive safety feature of the ECM. The perimeter berm is a structural component that form the outer boundaries and sidewalls for most of the perimeter of the ECM and is an important part of the ECM containment system, preventing waste and leachate from reaching the environment.

The perimeter berm is constructed on bedrock from compacted free-draining fill (non-liquefiable soil). This construction ensures that no liquefaction will take place, and that the perimeter berm will continue to perform its containment and isolation function during and after the design basis earthquake.

The perimeter berm crest is designed to provide vehicle access to perform operations and monitoring at the ECM. The perimeter berm will provide a physical barrier to divert precipitation away from the ECM.



The perimeter berm side slopes will be 3 horizontal (H) to 1 vertical (V), with a 7 m width at the top. Heights of the perimeter berm will vary from 2 m to 15 m. The perimeter berm height is the height of compacted free-draining fill, and not the ECM perimeter sidewall height that contains the waste. Depending on the location around the ECM, the ECM perimeter sidewall consists of free-draining fill (compacted), bedrock, or a combination of the two. This is due to the sloping terrain and distribution of bedrock.

The perimeter berm will consist of three main geotechnical elements, each contributing to the soundness and integrity of the perimeter berm itself and the whole ECM. The inside of the perimeter berm will be covered with the various liner system layers (described in Section 3.4.1.4), while the outside will be covered with an intrusion barrier rockfill over HDPE geomembrane, geotextile cushion and geogrid. The top of the perimeter berm will be covered with a layer of granular A material, an HDPE geomembrane and geotextile cushion, with the top layer granular A becoming the top of perimeter berm road. A Slope Stability Analysis was completed and confirmed that the slope designs will satisfy minimum factor-of-safety requirements for stability.

3.4.1.6 Transfer of Waste to ECM

The Transportation Plan (Figure 3.4.1-5) for Phase 1 of the ECM involves waste transport vehicles entering the ECM from the south. The vehicles coming in will be weighed at the south kiosk and then will unload the waste into the active cell. After unloading, the vehicles will be scanned for radiation in a clean area of the ECM. Clean vehicles will exit the ECM to the south; however, contaminated vehicles will be routed to the north to the vehicle decontamination facility and exit to the north following decontamination. The vehicles will be weighed at either the north or south kiosk prior to leaving the site. This operation is anticipated to be very clean and most of the waste transport vehicles will be able to enter and exit to the south, without requiring decontamination.

After the first five cells are filled, the berm on the south side of the ECM will be constructed for finishing the 525,000 m^3 capacity ECM. Once this berm is constructed, the access to the ECM on the south will be closed. The only entrance into the ECM will then be from the north. After unloading, the vehicles will follow the same scanning and exit procedures as described above.

3.4.1.7 Waste Placement

Waste will be placed in the active cell in the ECM using dedicated equipment intended to operate in contaminated areas. The dedicated waste placement equipment will include haul vehicles, cranes, bulldozers, compaction equipment, and other heavy equipment. The waste placement equipment used will depend on the types and quantities of wastes to be placed in the ECM. Methods of placement will include either: 1) the use of dedicated haul vehicles to transfer bulk waste directly into the cells, spread by bulldozers or other heavy equipment, and compacted by rollers or other compactors, or 2) the use of heavy equipment (e.g., a crane or forklift) to unload and place large debris waste components or waste packages directly into the cells.

Placement of waste will typically be from a clean ramp. Dedicated equipment, such as a bulldozer, within the cell will spread and compact the waste. This method will limit the potential to contaminate the vehicles bringing waste to the ECM.

Compaction equipment may include soil compactors, sheepsfoot rollers, or similar heavy equipment for Type 1, soil and soil-like waste, and Type 3, non-soil-like waste. A landfill compactor (similar to a Caterpillar 826) may be used for compaction of Type 2, comingled radioactive waste, if the waste is highly variable (heterogeneous) or contains large amounts of refuse or debris waste.

Water trucks will be used for moisture adjustment and dust control, as required.

A Waste Placement Mapping Plan will be developed to ensure accurate record-keeping and documentation of the cell and ECM development, as well as the placement locations of different wastes in the cells. This plan will specify a three-dimensional waste location recording system and methods for maintaining proper spacing of waste placed within the ECM. As waste is placed in the ECM, the locations/elevations will be documented, mapped and updated on a regular basis during the ECM operation.

3.4.1.7.1 Waste Placement Procedures

The waste placement procedures will be developed to maximize in-place density and to reduce void space, reducing the potential for future differential settlement of waste. Waste placement is planned on a year-round basis, subject to acceptable weather conditions. Waste placement may cease during periods of inclement weather such as high winds, major precipitation events, extreme cold periods, or inability to compact waste due to frozen conditions. A decision by CNL to curtail waste placement operations may be based on considerations for safety of workers and the public, the potential for release of contaminants, and the ability to meet engineering requirements for waste placement or compaction.

Initial Select Waste Layer

As each cell is constructed, the initial waste is placed as a 1 m-thick select waste layer that will consist of homogeneous Type 1 soil and soil-like waste. Select waste is waste that is free of large stones/boulders or other foreign materials and is relatively free draining (e.g., free of silts and clays). The purpose of the select material layer is to protect the leachate collection system and underlying composite base/sidewall liner components during subsequent waste placement. Equipment used to place the select waste layer will work from the perimeter of the cell, toward the center and only on top of previously placed waste. To prevent damage to the collection layer or other components of the composite base/sidewall liner, no equipment is permitted to operate directly on the surface of the leachate collection system layer.

Only low-ground-pressure equipment is used for construction, operations, and maintenance until the initial 1 m select waste layer is in place. Placement of debris, large bulky items, or packaged waste is not permitted within approximately 10 m of the sidewall slopes or within 1 m of the leachate collection and final cover systems.

Subsequent Waste Layers (Layer Thickness/heights)

Waste placement in each cell will proceed initially by unloading waste at the cell perimeter and grading it into position directly with bulldozers or similar heavy equipment. Waste is placed in operational layers of 3 m thickness against the berm sidewalls of the cell with the waste compacted in approximately 0.3 m layers. The initial operational layer is developed to a width of approximately 20 m from the sidewall of the cell and a minimum of 50 m in length. A second operational layer may be started on top of this. Waste placement continues in this manner until approximately five operational layers are placed, including the final 1 m select waste layer immediately under the final cover. The configuration of the ECM will allow almost parallel and symmetrical operational layers to be developed, since the design of the final cover parallels the floor in the major area of the landfill.

Actual fill sequence and placement procedures may vary based on the volume and type of incoming waste during the operations phase. As operations proceed, multiple ECM access roads and waste transfer areas are developed to support the multiple work faces of the operational layers. Waste handling or placement restrictions may be required due to the presence of contaminants in the waste material.

One of the main objectives of waste placement is to reduce empty space to limit the potential for the future differential settlement of the waste. Waste materials of high compressibility will not be placed in concentrated areas but are spread in thin layers over larger areas. Materials with no compressibility (such as demolition debris) will also be placed to avoid concentrated areas. Each layer of waste is graded to provide surface runoff from the waste within the disposal cell. Contact water and non-contact water is managed in accordance with the surface water management system (Section 3.4.4.5).

Dust Control during Waste Placement

Dust control is conducted to support waste placement operations in accordance with the *Dust Management Plan* (AECOM 2018c) during loading, transportation, placement and compaction operations. Work areas that have the potential for generating dust will require dust suppression techniques and monitoring. The primary dust control method will be water spraying or misting techniques (e.g., water trucks). Water application is controlled to avoid generation of free liquids. Water for dust suppression will be applied only to combat release of dust during operations. Care will be taken not to apply excessive water to the waste for dust suppression since water applied may become contact water that would need to be treated in the WWTP.

Fixatives (e.g., chemical suppressant) may also be used for dust control, or as daily/interim cover. The use of fixatives is reviewed prior to application for potential effects on leachate and contact water generated by the ECM.

Air quality is monitored for dust that may contain radiological and hazardous constituents to support worker and environmental protection as described in the *Environmental Protection Plan* (AECOM 2018a). Waste placement activities may be restricted or suspended if unacceptable amounts of dust are generated due to winds or other site conditions. All excavating, loading, hauling, and placement operations are suspended when wind speeds exceed the specified criterion.

Specific Waste Placement Requirements by Waste Type

The waste materials planned for disposal in the ECM have unique characteristics for unloading, placement, and compaction. Specific waste placement requirements pertaining to the six different waste types (as defined in Section 3.3.1.1) have been developed based on the individual characteristics of the waste. The handling and placement procedures are developed to ensure safe and secure placement of the waste so that it does not affect the integrity and long-term performance of the ECM.

3.4.1.8 Temporary Storage and Stockpiling Areas

During the operations phase both wastes and construction materials will need to be temporarily staged and/or stockpiled as they are placed within the ECM.

3.4.1.8.1 Temporary Storage, Waste Receiving and Processing Area

The TSWRPA is constructed within the footprint of the active cell or adjacent cell, and includes the drum and waste unloading platform (Figure 3.4.1-6). The TSWRPA facilitates the safe unloading and transfer of bulk and packaged waste for storage and or processing. The TSWRPA is constructed at grade, consisting of aggregate material provided to limit dust generation and facilitate contamination control. Dedicated vehicles will be used to transfer drummed wastes inside the ECM.

The temporary storage, waste receiving and processing area will be moved as necessary for the sequencing of the cells.

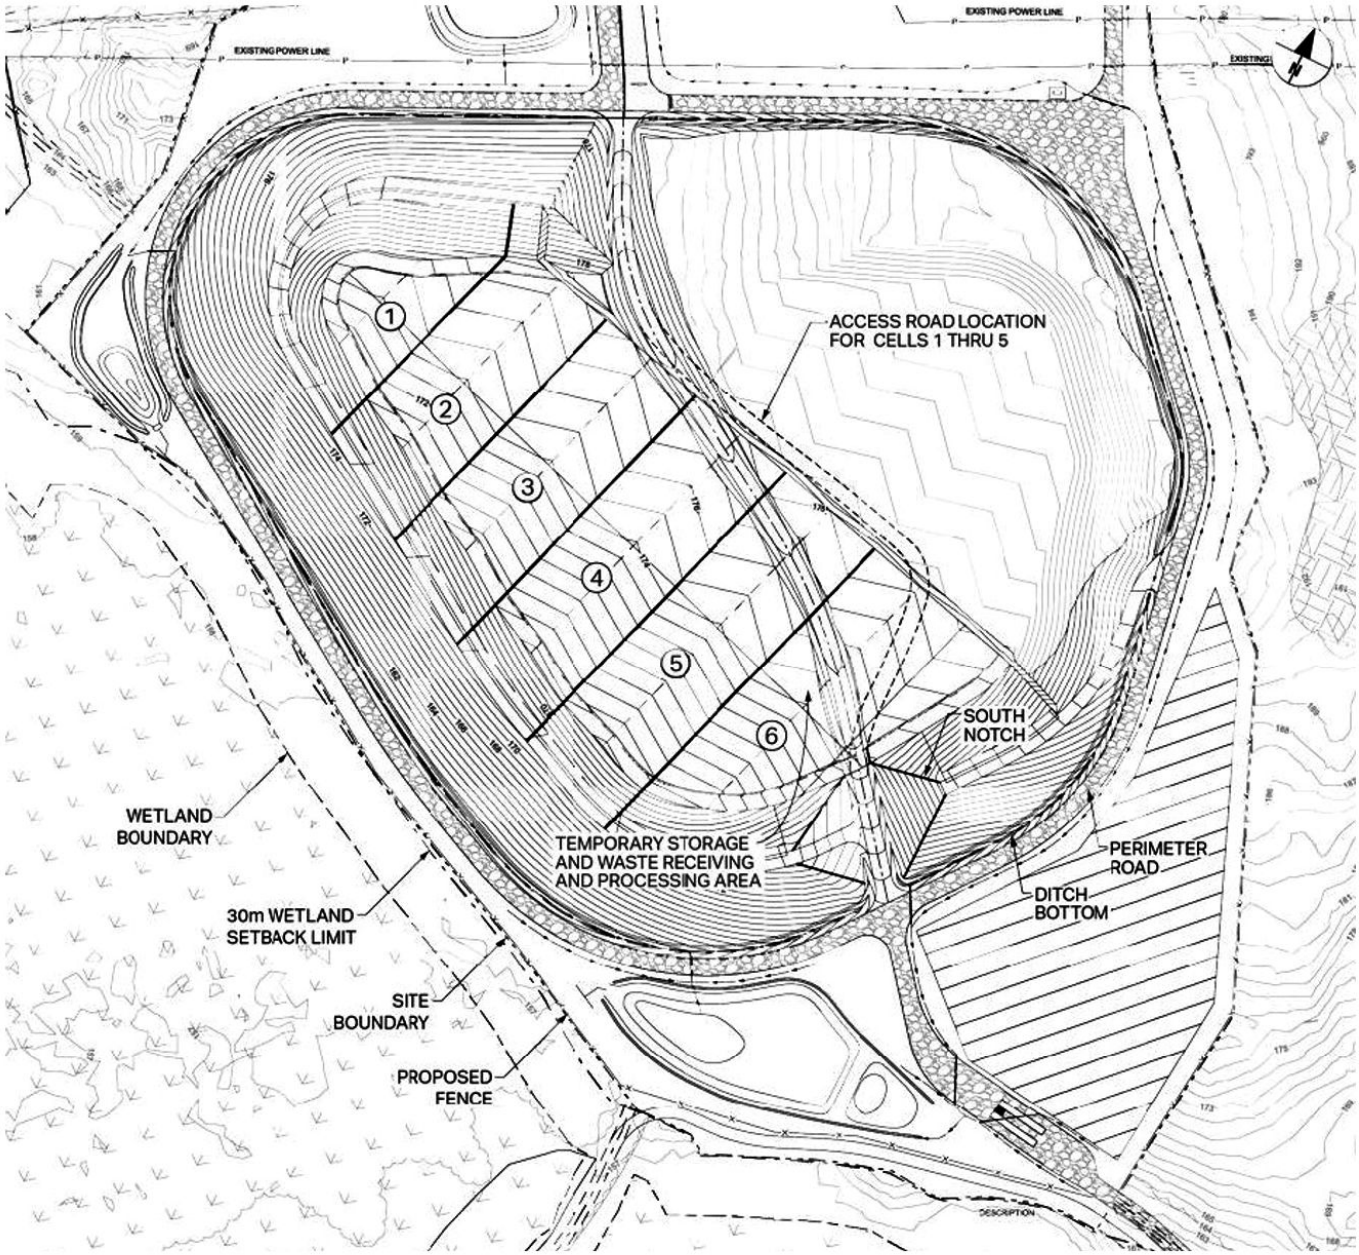
The TSWPRA will normally store wastes, and stored waste shall be placed in the ECM disposal cell within one year. The TSWRPA stores 800 m3 of waste, and is sized to promote efficient unloading between the dedicated site vehicles and waste transport vehicles, to minimize handling, and to limit the potential of dust generation.

No uncontained waste is stored in the TSWRPA. All waste is either in its transportation container or disposal container, or covered with daily cover. The only processing that is performed is staging of waste or container preparation for grouting in the ECM.

3.4.1.8.2 Clean Cover and Aggregate Stockpile Area

Clean cover/aggregate stockpile areas will be established both within and outside of the ECM to support waste placement operations. The clean cover/aggregate areas will be large enough to accommodate cell construction and waste operations including adequate space for haul vehicles and waste loading equipment to operate. They will also be large enough to store overburden removed during construction and to stage soil used for cover purposes. Erosion and sediment control measures will be applied to clean cover/aggregate areas.

Excavation of the ECM will generate approximately 560,000 m^3 of excavated soil. Approximately 365,000 m^3 of this amount will require interim or permanent storage during construction. The soil will be stored at a location on the CRL site managed by CRL Waste Operations.



3.4.1.9 Disposal Cell Cover

Cover materials are used to reduce personnel radiation exposure or contact with contaminated materials, to control the release of fugitive dust from the surface of the waste, to promote non-contact surface water run-off, and minimize precipitation infiltration into the waste material. These cover materials include daily cover, interim cover and the final cover system. The time spent on the working face is limited and the working distance from the waste is maximized to the extent practical to maintain worker exposures As Low As Reasonably Achievable (ALARA). These approaches to reduce worker exposure are discussed in greater detail in Section 3.5.2.1.

3.4.1.9.1 Daily Cover

Daily cover is applied at the end of each work day over the active disposal area or the placed waste working face, to control the release of fugitive dust from the surface of the waste. Daily cover also fulfills a number of other functions such as reducing erosion of placed waste, reducing blowing litter, reducing odour, discouraging insect and vermin activity, improving equipment access to the active disposal area, and maintaining a more aesthetically pleasing site appearance.

The daily cover consists of 0.150 m layer of clean soil or an alternative daily cover material that is pre-approved for use including tarpaulin, fixative (crusting agent), or similar temporary cover system material. The daily cover, 0.150 m layer of soil, provides fire protection for the placed waste, from wind-blown sparks or embers released from a fire. If a tarpaulin or fixative is used as an alternate daily cover material, the tarpaulin or fixative must be fire rated, and classified as "fire proof". Prior to using any fixative as an alternative daily cover material, the fixative must be verified to not adversely affect the WWTP treatment processes.

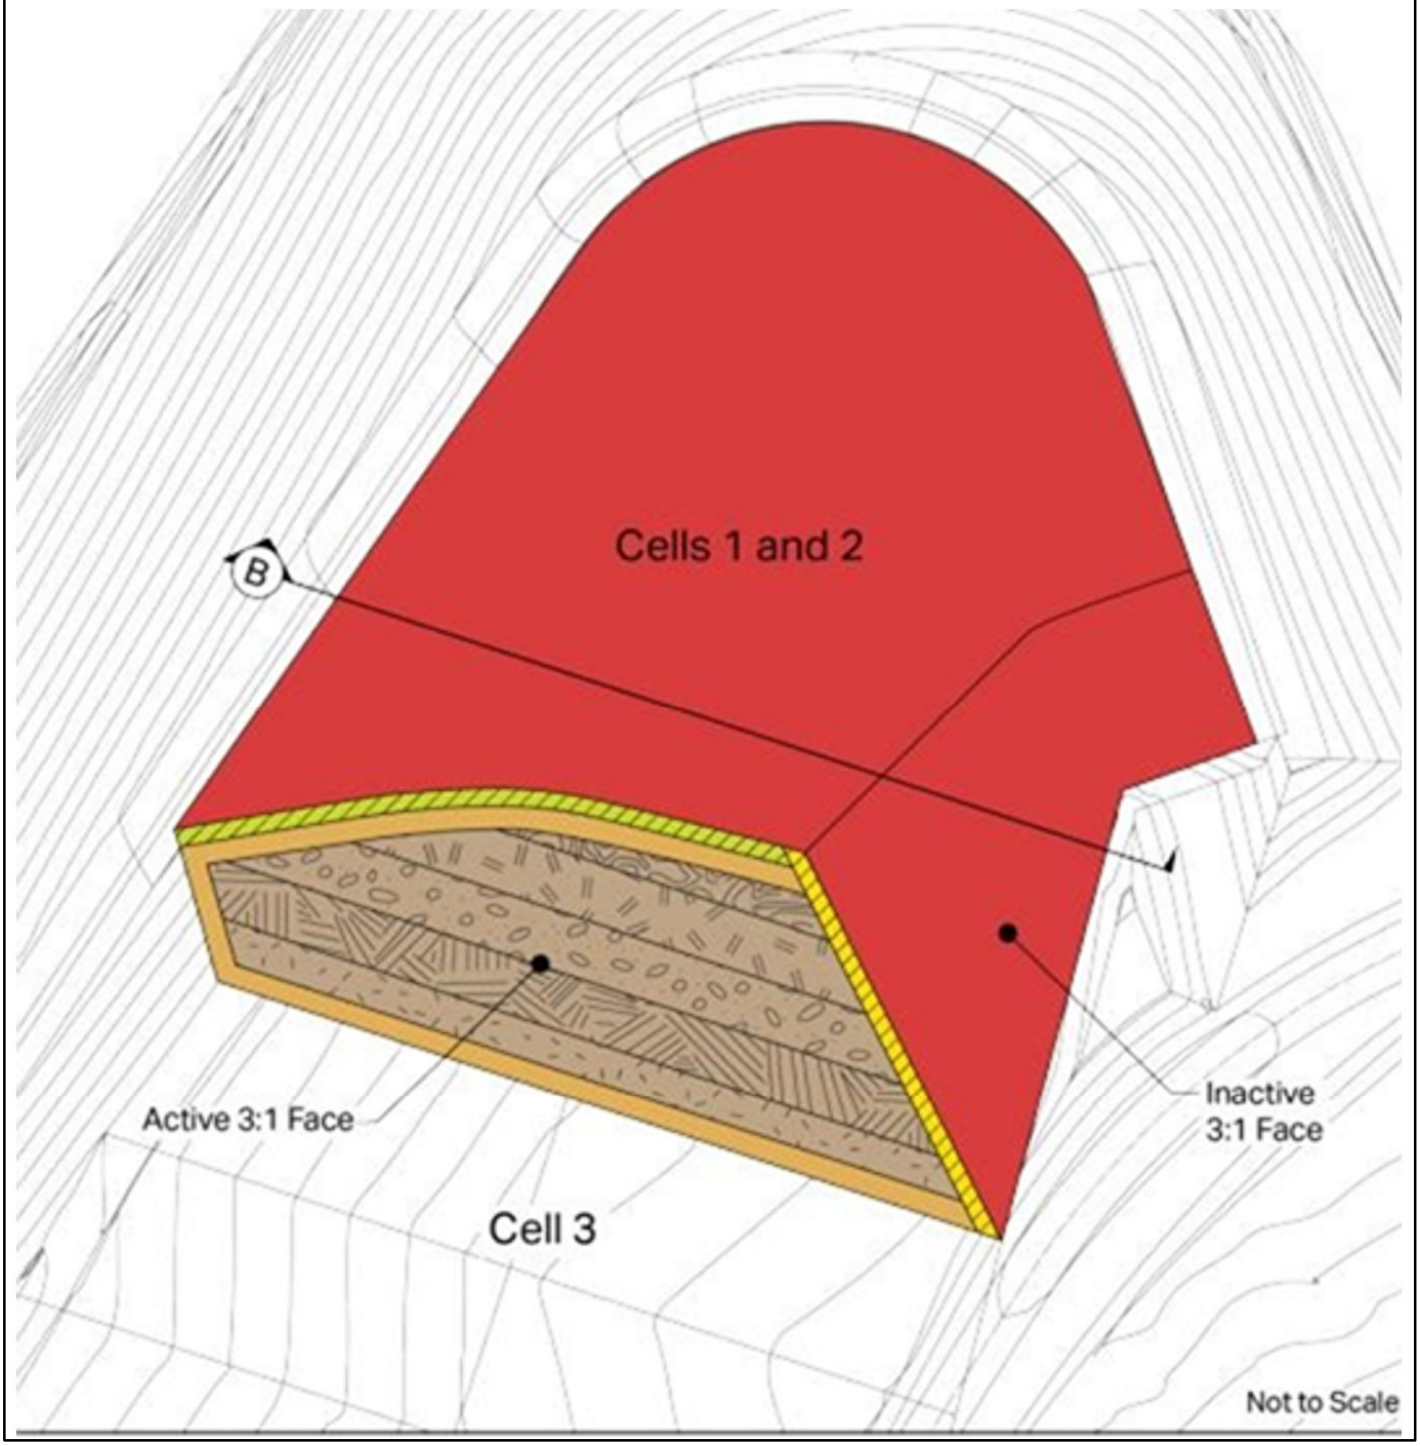
3.4.1.9.2 Interim Cover

The interim cover consists of 0.3 m layer of clean soil or clean sand that is overlain by a sacrificial liner to promote non-contact surface water run-off, and minimize precipitation infiltration into the waste material. The interim cover is applied to:



- Waste disposal areas that will remain inactive for more than 30 days and are not considered part of the active disposal area, but are scheduled to receive waste in the future.
- Waste disposal areas that have reached the design waste fill grade, and are not scheduled to receive additional waste and are awaiting installation of the final cover system.

The sacrificial liner is a 1.0 mm (40 mil) thick, double-sided, textured, white-surfaced (top side only) linear low-density polyethylene (LLDPE) geomembrane that is adequately anchored to prevent uplift by wind. In addition, the sacrificial liner is to be durable, have a suitable coefficient of expansion and be resistant to ultraviolet radiation damage.

Figure 3.4.1-7 shows the interim covers on waste disposal areas (inactive 3:1 face) that will remain inactive for more than 30 days and waste disposal areas (cell 1 and cell 2) that have reached the design waste fill grade.

The interim cover consisting of 0.3 m layer of clean soil overlain by a sacrificial liner is applied to waste disposal areas that will remain inactive for more than 30 days. The interim cover, including the clean soil layer and sacrificial liner, are removed prior to the resumption of waste placement, to the extent practical, to promote hydraulic connection between waste lifts.

The interim cover consisting of 0.3 m layer of clean sand overlain by a sacrificial liner is applied to waste disposal areas that have reached the design waste fill grade, and are awaiting installation of the final cover system. The interim cover is installed on the 1 m layer of select waste. The primary function of the sacrificial liner is to protect the 0.3 m layer of clean sand, first layer of the final cover system, against erosion, promote non-contact surface water run-off, and limit precipitation infiltration into the sand layer and underlying wastes prior to the installation of the remaining layers of the final cover system. The sacrificial liner is removed during the installation of the final cover system. The 0.3 m clean sand layer of the interim cover is not removed for the installation of the final cover system, and is regraded to eliminate low areas.

Legend:

- 0.3 m sand layer of the Interim Cover
- 0.3 m soil layer of the Interim Cover
- 1 m Select Waste layer
- Waste layers
- Sacrifical Liner of the Interim Cover

3.4.1.9.3 Final Cover

A final cover system has been designed for the entire surface of the completed containment mound to limit leachate generation. The final cover system will consist of an engineered multi-layer system with a minimum thickness of 2.05 m. A schematic of the cross-section of the final cover system is shown on Figure 3.4.1-8 and the cell sequencing plan is shown on Figure 3.4.1-2 and Figure 3.4.1-3. The final cover is designed to limit water infiltration, to direct infiltration and surface water away from the ECM waste placement area, and to resist degradation by surface geologic processes and biotic activity (e.g., prevent burrowing of animals) and inadvertent intruder attempts to access or excavate the waste cell. A series of drainage control features will be installed in conjunction with placement of final cover over the ECM.

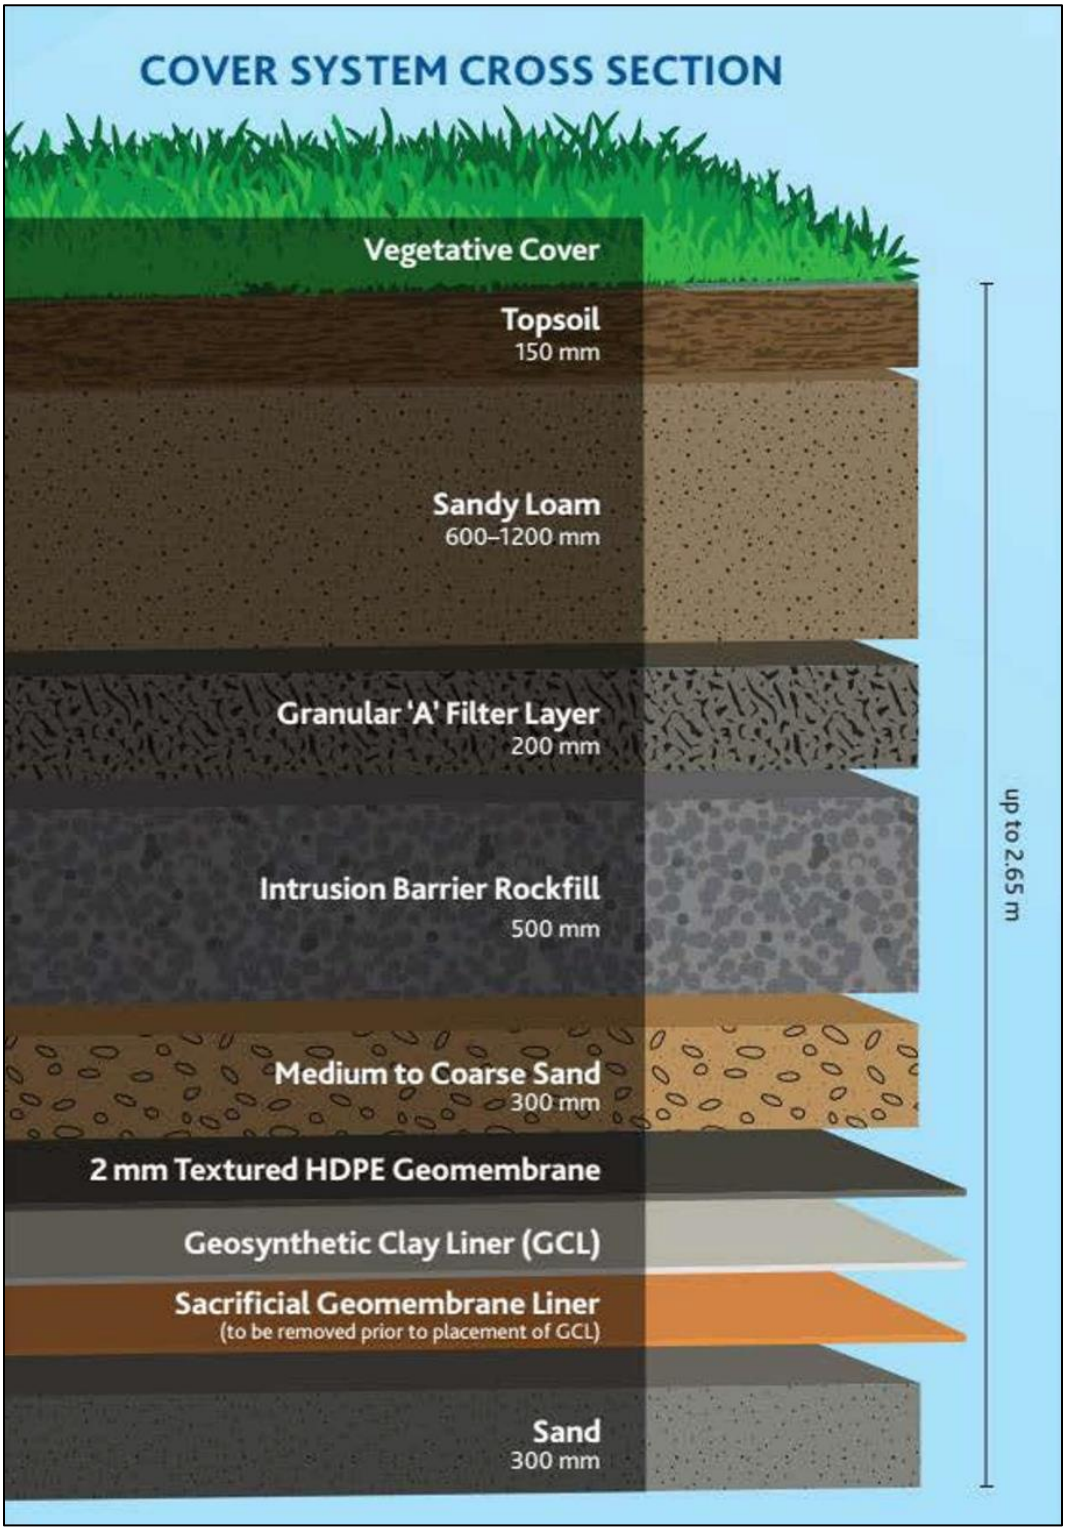

Figure 3.4.1-8: Proposed Cross Section of the Final Cover System

Component Layers

The final cover system incorporates the following layers (from bottom to top).

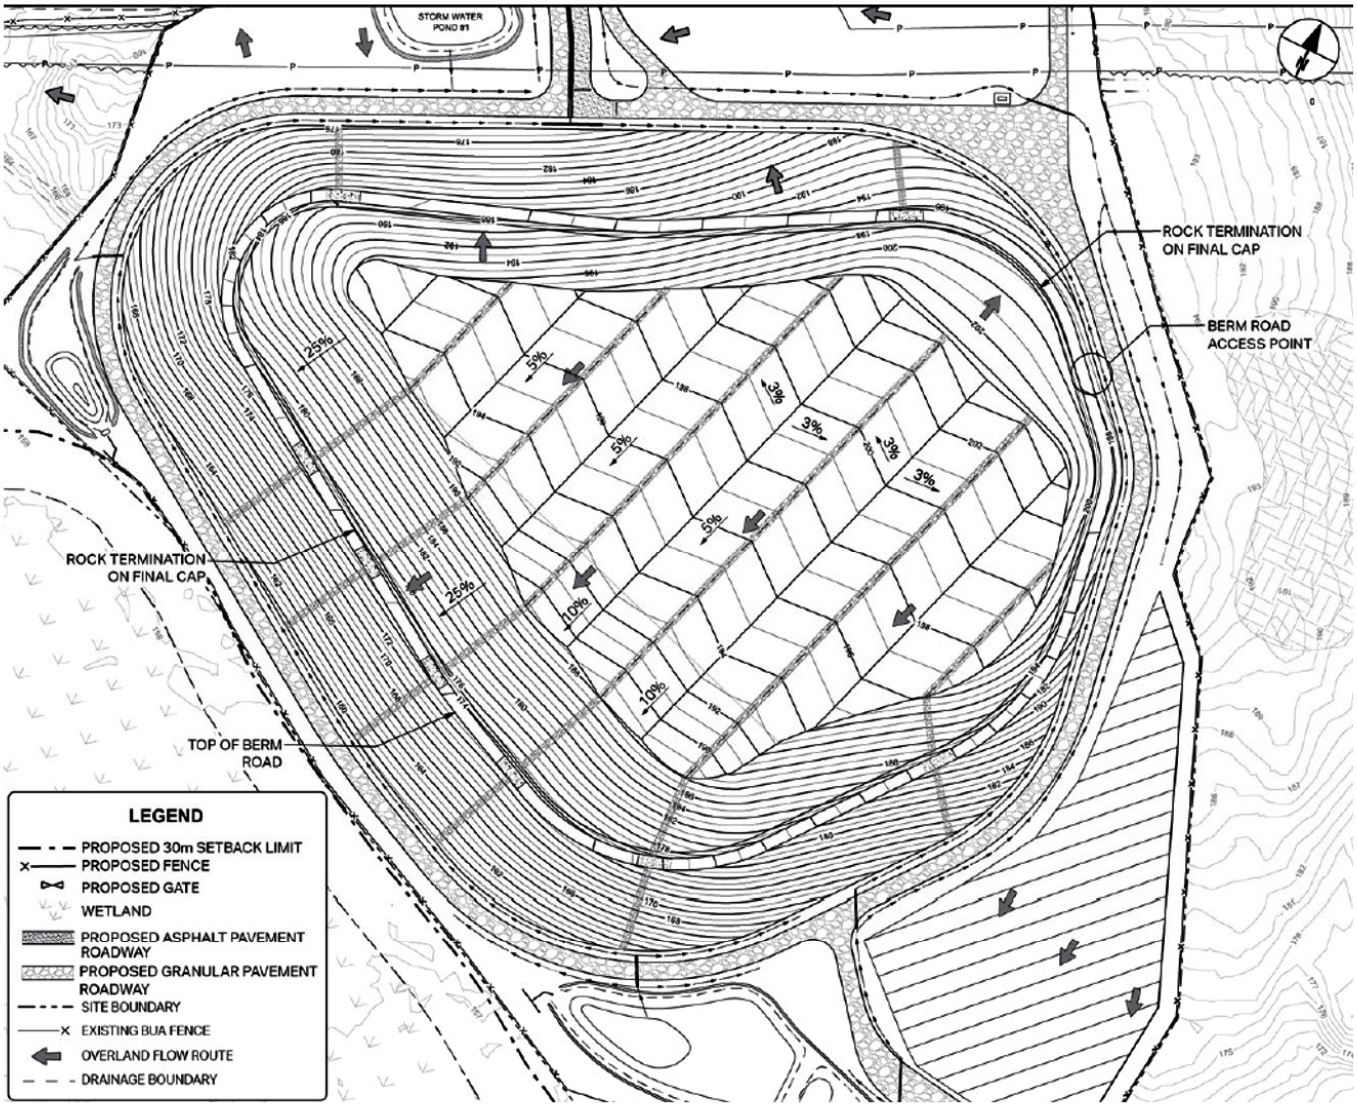
- **Sand** – A sand cover layer will be installed directly above the waste material to provide for a smooth, firm base surface for installation of the infiltration barrier component layers. This layer protects the infiltration barrier from damage by waste materials, such as exposed stones and demolition waste and provides a layer to promote lateral venting of landfill gas.
- **Sacrificial geomembrane liner** – In areas of the cell where top-of-waste final contours have been achieved, a sacrificial liner will be placed overtop the first layer of final cover until a sufficient area has been reached to warrant commencement of construction of the rest of the final cover system in this area. When the rest of the final cover system is ready to be placed on top of the first layer of the final cover, the sacrificial liner will be removed (prior to placement of the geosynthetic clay liner).
- **Infiltration barrier** – Two HDPE geomembrane components will be installed:
  - **Geosynthetic clay liner** – The first is a composite HDPE geomembrane/geosynthetic clay liner to provide an additional means of restricting infiltration, which is less susceptible to significant damage from freeze-thaw or potential long-term differential settlement.
  - **2 mm textured HDPE geomembrane** – The second is a textured, HDPE geomembrane liner to serve as the upper (primary) barrier against infiltration through the cover into the buried wastes.
- **Medium to coarse sand** – A cushion/drainage layer, consisting of medium to course sand will be installed above the HDPE geomembrane to provide, in conjunction with the underlying HDPE geomembrane. It provides lateral drainage of water that percolates through the upper layers of the final cover.
- **Intrusion barrier rockfill** – An intrusion barrier rockfill layer to deter burrowing animals and roots from deeper-rooted plant species reaching and possibly damaging the final cover lining system. It will also inhibit the roots from penetrating into and transporting contaminants from the waste fill. This rockfill layer would also help deter inadvertent future intrusion into the buried wastes by humans.
- **Granular ‘A’ filter layer** – The principal function of the Granular A (i.e., high-stability graded sand and gravel) filter layer above the intrusion barrier layer is to provide a natural filter layer to limit the possibility of fines migrating downward; reducing the potential for future clogging of the barrier layer. It also allows for some degree of lateral flow diversion within the cover system.
- **Vegetative cover / erosion protection** – Includes three main components:
  - A **sandy loam layer** to provide moisture retention for plant uptake and evapotranspiration. This layer also provides additional gamma radiation shielding, additional confining stress for the final cover lining system, and an insulating layer to help limit freeze-thaw effects.
  - A **topsoil layer** consisting of loam, sandy loam and/or sandy clay loam, augmented with nutrients to promote growth of a healthy stand of hardy grasses.
  - A **vegetative cover** to provide an aesthetically pleasing surface, enhance evapotranspiration and reduce the potential for erosion. The vegetation will be limited to grass species that are maintenance free and drought resistant. Maintenance activities during the institutional control period will include removal of trees and other deep rooted type vegetation, as well as conducting physical inspections for animal burrows over the ECM surface.

Sequencing

Any cell that has reached top-of-waste final contours and has received the initial layer of the final cover system, including a sacrificial liner, is considered non-radiological. Any precipitation falling on the top of this inactive area is then considered non-contact water and is routed to the appropriate surface water management pond for release to the ground and surface water.

When waste placement in cell 2 reaches the northwestern boundary of cell 1, the sacrificial liner will be removed. The first layer of the final cover will be re-graded to eliminate low areas and the remaining layers of the final cover will be placed on cell 1. This final cover sequencing scenario will continue through all six cells in Phase 1. Final cover placement and sequencing for Phase 2 cells will continue the same scenario as Phase 1, with final cover being placed on each cell as the waste is brought up to bottom of the final cover elevation with the placement of the 1 m select waste layer, to the cell boundary.

3.4.1.9.4 Landfill Gas Venting System



A passive landfill gas (LFG) venting system will also be installed in conjunction with the final cover construction as part of the final closure activities. The LFG venting system is designed to prevent excessive gas pressure under the low-permeability barrier components of the final cover, as excessive gas pressure could result in damage or disruption of the final cover system. LFG monitoring probes will be installed around the perimeter of the ECM and will be monitored periodically during the ECM post-closure phase to detect evidence of potential LFG migration away from the ECM.

3.4.1.10 Final Grading and Drainage Plan

The ECM Final Grading and Drainage Plan also includes collection ditches along the top of the ECM berm road to collect side slope drainage. The runoff from the collection ditches will be routed to the perimeter. Figure 3.4.1-9 provides the Final Grading and Drainage Plan for the ECM final cover system.

The final cover system will be sloped between 5% and 25%. The top slope also has a herringbone pattern similar to the base. This promotes surface water runoff, reduces infiltration into the ECM and minimizes erosion and sediment transport.

The perimeter road ditch will route the runoff it receives to one of three surface water ponds located outside the ECM perimeter road. These runoff controls are designed to minimize ponding of water into the closed ECM, erosion of the cover and underlying waste materials, destabilization of the ECM structure, and damage to access roads. The ECM surface water runoff controls will be maintained until the end of the institutional control period. Additional details on the surface water management plan for the NSDF Project site is provided in Section 3.4.4.5.

3.4.1.11 Construction Materials

It is estimated that approximately 600,000 m^3 of various soil and granular materials (e.g., clay, sand, gravel and stone), plus an estimated 1,500,000 m^2 of geosynthetic products such as geomembranes (e.g., impervious synthetic sheets typically used for linings and covers), geotextiles (e.g., synthetic non-biodegradable fabrics), and geosynthetic clay liners (e.g., fabricated barriers consisting of bentonite clay or similar material supported by geotextiles or geomembranes) will be transported to the NSDF Project site. These will be used for construction of the ECM base liner (Table 3.4.1-1).

Table 3.4.1-1: Estimated Material Requirements for the Engineered Containment Mound Base Liner

Engineered Containment Mound	Clay (m^3)	Drainage Media (m^3)	Geomembrane (m^2)	Geotextile (m^2)
Phase 1	71,000	82,000	182,000	225,000
Phase 2	38,000	54,000	125,000	135,000
Total	109,000	136,000	307,000	360,000

A final cover system has been designed for the entire surface of the completed ECM. The estimated material requirements for the final cover are provided in Table 3.4.1-2. Final cover construction will result in similar delivery requirements as needed during the construction period.

Table 3.4.1-2: Estimated Material Requirements for the Engineered Containment Mound Final Cover – Phase 1

	Topsoil (m^3)	General Fill Soil (m^3)	Geotextile (m^2)	Coarse Stone (m^3)	Sand (m^3)	Geomembrane (m^2)	Geosynthetic Clay Liner (m^2)
Total	16,400	110,000	110,000	22,000	22,000	110,000	110,000

While other aspects of the ECM construction will involve additional materials, their quantities are generally not substantial relative to those associated with the base liner and final cover. An exception will be the requirement for the granular and earth fill materials for the perimeter berm and access road construction, which will total approximately 500,000 m^3 (approximately half this volume for Phase 1, and half for Phase 2).

The transportation route of NSDF Project site preparation and construction equipment and materials will be by public roads to the CRL site (e.g., Highway 17) and will pass through the Village of Chalk River. Based on estimates of truck deliveries to the NSDF Project site during the 24-month construction period, approximately 200 shipments per day are anticipated during the nine-month construction season (i.e., approximately 15 trucks per hour for the daytime period, totalling 200 trucks per day during construction). The additional construction personnel requirements are expected to result in an additional 300 inbound and outbound trips to the site daily. Transportation of equipment and construction materials will be scheduled during normal business and daylight hours to the greatest extent possible to limit inconvenience to local residents. Construction materials (e.g., processed granular materials and gravel, geosynthetic products and clay) will be transported to the NSDF Project site using standard highway haul vehicles. Within the CRL site, transport of site preparation and construction equipment, and construction materials to the NSDF Project site will be by Plant Road, which leads to the main site access road.

It is estimated that the entire amount of soil that will be excavated is 560,000 m^3. The sum of clean fill requiring interim or permanent storage during NSDF construction is 365,000 m^3, while the sum of topsoil is estimated at 47,000 m^3. In addition to the final cover system, the active cells will be temporarily covered on a daily basis and

areas scheduled to receive additional waste at some future time will receive interim cover. This volume of excavated soil will be sufficient to meet the soil volume requirements for the daily/interim cover and for placement of the final cover. The expected volumes of soil to be redeployed is 130,000 m^3 of clean fill and 18,000 m^3 of topsoil. The transport of this excavated soil to the soil storage area on the CRL site and back to the NSDF Project site is expected to result in approximately 55,000 trips of close to 10 km (i.e., 5 km to the soil storage area and back). The impact of this interim management of soil spoils on the atmospheric environment is further clarified in Section 5.2.

3.4.1.12 Leachate Collection and Removal

The LCS immediately overlying the top (primary) liner component of the base lining system collects and removes leachate from the ECM throughout the operations phase and following final closure of the ECM. The LDS immediately overlies the bottom (secondary) composite liner. The LDS allows for the timely detection, collection, and removal of leachate that leaks through the primary liner system and/or condensate that might accumulate in the LDS during the operations phase or during the post-closure phase following final closure of the ECM.

Leachate will be removed from the LCS and LDS sumps and along with the contact water will be transferred to the collection tanks, from which it will be periodically transferred to the WWTP for treatment (see Section 3.4.2).

3.4.1.12.1 Leakage Rates and Leachate Flows

During the operations phase of the ECM, the maximum leachate generation rates are expected to occur. During this period, the ECM is open and is actively receiving waste. It was also assumed that contact water is generated from the temporary waste storage pad within the active cell.

It is expected that of the generation of leachate in the ECM will eventually trend toward zero over time. Residual moisture present within the buried waste material will drain to the LCS and LDS sumps and be removed. Before the WWTP is shut down, the long-term treatment needs for any leachate derived from the ECM will be evaluated. Low-flow mobile leachate removal equipment is expected to be adequate to remove leachate from the LCS and LDS sumps once the WWTP is shut down.

3.4.1.12.2 Leachate Monitoring

During the operations phase, flow rates of leachate removed from the LCS and LDS sumps will be measured, totalized and recorded. The integrity of the ECM primary liner system will be monitored by reviewing the rate of leachate collection in the LDS sumps and comparing it to baseline measurements of leachate collection in the LDS sumps.

3.4.1.12.3 Leachate Sampling and Analysis

An ECM leachate Sampling and Analysis Plan will be developed to collect baseline information to determine the profile for liquid that will be transferred to the WWTP for treatment. Sampling will allow for changes in leachate quality through time to be identified. The latter information will be used to inform and update the groundwater monitoring program for the ECM.

3.4.2 Wastewater Treatment

This section describes the facilities to be constructed and processes implemented to treat wastewater associated with the operation of the ECM. The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses best available technology that is economically achievable, and capable of meeting regulatory requirements. The WWTP for the NSDF Project will be a new, stand-alone facility with a new discharge. The design life for the WWTP is approximately 50 years. If the WWTP is required beyond its design life, the unit would be refurbished to enable continued treatment of leachate or other treatment options would be investigated.

3.4.2.1 Wastewater Quantity

Wastewater requiring treatment comes from three general sources at the NSDF Project: 1) leachate, 2) contact water and 3) wastewater from on-going operations at the WWTP, vehicle decontamination facility (see Section 3.4.3.4) and operations support centre facilities (see Section 3.4.3.3).

Leachate quantities were estimated based on a water balance calculation completed with the Hydrologic Evaluation of Landfill Performance model. The model estimates the amount of water infiltrating the ECM using information on soil characteristics, precipitation, temperature and humidity, site area, slopes and slope lengths. The Hydrologic Evaluation of Landfill Performance model was used to model the active open cell period, when the infiltration is greatest. Following active operations, each cell will be covered and infiltration will be reduced. Results from the one cell that was modelled are applied to each additional cell in succession to model the wastewater generation rate throughout the 50-year lifetime of the ECM.

Contact water is managed separately from non-contact water (discussed in Section 3.4.4.5) in the ECM during operations to minimize the quantity of water that needs to be treated in the WWTP. Contact water is collected in temporary contact water ponds or equivalent structures on a lined portion of the cell floor. The contact water pond has sufficient capacity to contain the volume of contact water generated during back-to-back 100-year, 24-hour storm events. The contact water ponds are moved within the ECM as necessary to support operations.

The average cell area is 12,000 m^2; however, for the purposes of the modelling, an upper bound capacity of 15,000 m^2 was used to provide a conservative amount of leachate and contact water that could be generated from any cell. Within the ECM there is a 6,000 m^2 temporary waste storage pad for staging waste. The storage pad is a gravel area that may be used to stage both bulk and packaged waste awaiting disposal. Precipitation that falls on the temporary storage pad will be treated as contact water and routed to the WWTP. Water that infiltrates through the storage pad will eventually flow into the leachate collection system, where it mixes with leachate from the active and closed waste cells. In addition, a combined total of 100 m^3/yr is included in the wastewater volume to account for vehicle and personnel decontamination facilities.

During the first year of operation, the ECM will have one active disposal cell and the temporary storage pad producing leachate and contact water. The average annual volume of wastewater expected to require treatment is about 11,000 m^3. Once Cell 1 has been closed, Cell 2 will be operational and will begin generating both leachate and contact water. This process will continue until all 10 cells have been developed and finally closed. The maximum average annual wastewater volume (11,230 m^3) will be produced during the years 45 to 50, when Cells 1 through 9 are filled and closed with final cover, and Cell 10 is active (Table 3.4.2-1). At the end of the 50-year operational life (and into the post-closure phase), the total leachate expected to be generated from the ECM is 45 m^3/yr.

Table 3.4.2-1: Average Annual Wastewater Volumes Generated Over the Life of the Engineered Containment Mound

n/a = not applicable.

Another important design consideration for the WWTP is the maximum wastewater flow rate to be received and processed by the WWTP. Leachate and decontamination wastewater are produced at relatively low rates compared to contact water, especially during major precipitation events. The projected average leachate flow from a single closed cell with final cover is 0.0017 m^3/hr. The projected average annual flow rate of decontamination wastewater is approximately 0.01 m^3/hr. The maximum flow rate was determined by evaluating the expected contact water volume that would be produced during back-to-back 100-year, 24-hour storm events. It is estimated that back-to-back 100-year, 24-hour storm events would produce a contact water volume of 4,710 m^3 at a maximum rate of 75 m^3/hr.

3.4.2.2 Wastewater Quality

Wastewater quality was predicted taking into consideration the WWTP flow rates, waste inventory and the design and behaviour of the ECM. The wastewater quality is managed by controlling what wastes are placed in the ECM. The WAC were developed to ensure only waste with acceptable physical, radiological, and chemical characteristics will be placed in the ECM (see Section 3.3.3).

The radiological and non-radiological constituents of potential concern (COPC) concentrations in leachate were calculated using a partitioning model that assumes that the ratio of the contaminant concentration in the waste to the contaminant concentration in the leachate is constant. Partitioning models are commonly used in radiological assessments to determine leaching characteristics of radionuclides and metals in soil and soil-like wastes. The partitioning factors were taken from the CSA Standard *N288.1-14 Guidelines for Calculating Derived Release Limits for Radioactive Material in Airborne and Liquid Effluents for Normal Operation of Nuclear Facilities* (CSA Group 2014). These factors conservatively estimate the leachate characteristics with the intention to avoid underestimating release rates and leachate concentrations.

Packaged wastes are assumed to initially contribute little to the leachate characteristics (i.e., packaged wastes are any wastes that are permanently disposed in containers such as drums or metal boxes). Some waste packages (5%) are assumed to fail immediately following placement in the ECM; these waste packages will no longer effectively isolate their contents from infiltrating water and will contribute to leachate quality. As time progresses, waste containers are assumed to fail at a rate of 1% per year due to corrosion. As more waste packages fail, more waste is available to contact infiltrating water and influence the leachate characteristics. The 1% annual degradation rate is based on measured corrosion rates of metal buried in moist soil.

The contact water is assumed to have very low COPC concentrations compared to the leachate because of the effects of daily waste cover and water management practices within the disposal cell. Precipitation that falls in the active cell will be routed away from waste in active disposal areas to the extent practicable to reduce contamination of the contact water. Decontamination wastewater from NSDF support facilities is assumed to have the same radiological and chemical characteristics as the wastewater from the ECM.

In the absence of quantitative information for some non-radiological COPCs, an alternative approach was taken using initial estimates of leachate concentrations based on the estimated upper limit of leachate characteristics predicted from groundwater modelling data at the CRL site and from information gathered from other sites. These values present a reasonable and conservative estimate of concentrations in wastewater, which provide a design basis for the WWTP.

The effluent concentrations were compared to effluent discharge targets based on protection of the environment and human health and are described in Section 3.4.2.5.1 (CNL 2019b). The effluent discharge targets were used to identify those constituents that may require treatment at the WWTP. Table 3.4.2-2 and Table 3.4.2-3 summarize the projected concentrations in wastewater for radionuclides and non-radiological COPCs, respectively. A comparison of projected wastewater concentrations and effluent release criteria shows that two radionuclides, strontium-90 and cobalt-60, are predicted to be present in wastewater at levels that exceed the respective effluent discharge targets. These two radionuclides will require treatment prior to discharge to meet the proposed effluent discharge targets (Table 3.4.2-2). Several non-radionuclide COPCs in the untreated effluent exceed or approach effluent release criteria, including aluminum, boron, cobalt, iron, manganese, anthracene, chloroform, chrysene, ethylene dibromide, and fluoranthene (Table 3.4.2-3). The majority of these constituents will require treatment prior to discharge to meet the proposed effluent discharge targets.

The maximum predicted concentrations in wastewater are derived from the contaminant inventory and are designed to be conservative. For a number of constituents such as nitrite, nitrate and sulphate, maximum predicted concentrations in untreated wastewater marginally exceed effluent discharge targets. Further, carbonaceous 5-day biochemical oxygen demand may require treatment to meet the proposed effluent discharge target. If sampling of wastewater during operations demonstrates that the concentrations of contaminants are approaching levels that need to be treated, the operation of the WWTP can be adjusted so that effluent discharge targets are met (for example by including the appropriate resin in the ion exchange columns).

Table 3.4.2-2: Radionuclide Concentrations in Wastewater and Effluent Discharge Target

Radionuclide	Maximum Predicted Concentration in Wastewater (Bq/L) Prior to Treatment	Effluent Discharge Target (Bq/L)	Treatment Required?

1) The concentration of nitrates and nitrites in the final effluent is predicted based on conservative assumptions and the actual concentration of the nitrate and nitrite in the effluent is expected to be less than the predictions. The flexibility of the WWTP design allows CNL to modify our treatment approach based upon the actual wastewater characteristics. CNL will sample the leachate before treatment begins and at several times during the treatment process to ensure that the treatment processes are working as expected. If they are not, CNL can make adjustments to the treatment strategy to deal with the unexpected waste constituents through the use of different ion exchange resins or chemistry changes. The treated effluent goes to a Final Effluent Tank where it is sampled and the sample is analysed prior to discharging the treated effluent. If the treated effluent does not meet the effluent discharge targets, it would be returned to the beginning of the WWTP process and go through the treatment process again to remove the species that exceed the effluent discharge targets. For sulphate, nitrate and nitrite, an anion exchange resin would be used to remove these species.
2) Similar to Note 1, the predicted concentration of phosphorus is based on conservative assumptions and the general discussion of the WWTP treatment approach applies to phosphorus. Specifically for phosphorus, it will be removed during the chemical precipitation step by the ferric chloride that is part of the normal treatment strategy. In the event that higher than normal phosphorus concentrations are observed in the wastewater feed to the WWTP treatment processes, the chemical precipitation step using ferric chloride can be optimized for phosphorus removal at this time. If the concentration of phosphorus in the Final Effluent Tank prior to discharge exceeds the discharge criterion, this liquid would be returned to the beginning of the process and undergo further treatment to remove it.
3) The Chromium (total) effluent discharge target is based on the Canadian Water Quality Guideline for Chromium (VI).

* = no limit established.

** = Present at an elevated concentration in groundwater used to estimate leachate characteristics; not expected to be present in excess in effluent limit in leachate.

*** = Not expected to be present in significant concentrations based on projected bulk waste characteristics.

+ May be present at concentrations exceeding the discharge requirement based on preliminary bulk waste characteristics.

Note: Additional constituents may be identified. Effluent discharge targets for these would be defined as required.

3.4.2.3 Leachate and Contact Water Transfer System

The leachate and contact water transfer system is comprised of gravity drains and two pumping stations. Sources of wastewater at the NSDF Project site include the ECM (generates leachate and contact water), the vehicle decontamination facility (generates decontamination wastewater), the operations support center (generates decontamination wastewater) and the WWTP (process related drains). Wastewater is transferred by gravity drain to one of two pump stations, which then pumps to the WWTP's collection tanks for eventual treatment.

The pump stations are cylindrical HDPE structures that provide dual containment by means of a 2,400 mm diameter cylindrical tank (carrier wall) installed inside of a 3,000 mm diameter cylindrical tank (containment wall). There is a leak detection system between the carrier wall and containment wall. If the leak detection system detects moisture, an alarm is generated and the tanks will be inspected.

A pipe in a pipe approach is used to provide dual containment between the pump station and the WWTP collection tanks.

3.4.2.4 Wastewater Treatment Plant and Process

The WWTP building houses the process systems for treating wastewater. The major processes, and other design features of the WWTP are described in the following sections. Process treatment technologies were selected based on a determination of best available technology that is economically achievable. A general description of the operating strategy for the WWTP process is summarized below.

- **Collection system** – This system provides initial storage for wastewater and is designed to contain a volume of contact water that could be produced from the largest cell of the ECM during a back-to-back, 100-year, 24-hour precipitation event, as well as leachate from closed cells, and wastewater produced from on-going site operations.
  - Three above-grade, covered collection tanks will be installed to provide the required volume. The collection tanks will be installed within a concrete secondary containment area designed to contain 110% of the volume of a single tank.
  - The accumulated dilute wastewater is sampled. If it meets all requirements for discharge, it may be transferred directly from the collection tank to the final effluent tank(s). If certain COPCs exceed discharge requirements, the wastewater will then be treated using some or all of the processes in the WWTP, depending on the specific COPCs in the wastewater.
- **Chemical precipitation system** – The purpose of this system is to precipitate COPCs so they can be filtered from the wastewater. Chemical precipitation has been identified by the U.S. Environmental Protection Agency as best available technology that is economically achievable for multiple radionuclides.
  - Each treatment train will include two chemical precipitation tanks operated in series (four tanks in total).
  - Ferric chloride, sodium sulphide, sodium hydroxide and sulphuric acid can be added to each chemical precipitation tank. Chemicals will be stored in segregated rooms within containment areas based on chemical compatibility, to avoid the mixing of incompatible chemicals in the event of a spill.
- **Membrane filtration system** – Membrane filtration provides nearly complete removal of suspended solids from the wastewater that has been treated in the chemical precipitation system. Recognized by the US Environmental Protection Agency to provide enhanced removal of multiple radionuclides; it was determined to be best available technology that is economically achievable for the WWTP.
  - Concentrated solids will be periodically pumped from the process tanks to the residuals storage and conditioning tanks. Each tank will have a capacity of approximately 80 m^3.
- **Polishing treatment system** – The system is designed for removal of radionuclides and metals that remain in the wastewater after the chemical precipitation and filtration system.
  - Each train of the polishing treatment system includes a pH adjustment tank, polishing system feed tank, three types of polishing filter media, a final pH adjustment tank, and an effluent storage tank.
  - The final effluent storage tanks enable the final effluent to be sampled prior to discharge, when operating the WWTP in batch mode. Final effluent will be discharged to the Perch Creek and Perch Lake Watershed either through an exfiltration gallery or by a transfer line discharge to Perch Lake (Section 3.4.2.6).

3.4.2.4.1 Residuals Management System

The residuals management system is designed for handling and dewatering of residuals produced as a by-product of wastewater treatment. Two types of residuals will be produced by the WWTP: dewatered residuals produced by the chemical precipitation process, and spent granular activated carbon (GAC) and ion exchange resin from the polishing system. For the liquid residuals, a filter press system will be used to remove the water and the dewatered residuals will be transported to the ECM for disposal.

When GAC and ion exchange resin are spent they must be replaced. Spent GAC and ion exchange resin are removed from the vessel using water to slurry the materials into a container for dewatering. The removed water will be discharged to the collection tanks for re-processing. After the water has been removed, the need for additional treatment or processing of spent GAC and ion exchange resin will be determined. Based on the results of sampling and analysis, solidification may be required to meet the WAC prior to disposal in the ECM.

The annual quantity of dewatered residuals is expected to be approximately 42 m^3/yr, and the annual quantity of spent GAC and ion exchange resin is expected to be approximately 47 m^3/yr. The amount of radionuclides in the dewatered residuals, and spent GAC and ion exchange resin, is expected to be well below the definition of LLW and will be acceptable for disposal in the ECM.

3.4.2.5 Treated Effluent Discharge Concentrations

3.4.2.5.1 Effluent Discharge Targets

Effluent discharge targets were developed for the WWTP and are based on protection of human health and the environment. The surface water quality assessment (Section 5.4.2) provides an assessment of the impact of WWTP effluent discharges on surface water quality.

Radiological Constituents

The WWTP effluent discharge targets for radionuclides are the maximum acceptable concentrations for drinking water and are derived using Health Canada Guidelines for Canadian Drinking Water Quality (Health Canada 2019). The use of drinking water concentrations for radionuclides is considered conservative as there is no public access to the Perch Creek and Perch Lake watershed where WWTP effluent discharges will occur. The method for calculation of the maximum acceptable concentrations is provided in Health Canada Guidelines for Canadian Drinking Water Quality (Health Canada 2019).

Due to the impracticality of treating the wastewater to remove tritium, CNL has instead placed stringent limits on the total amount of tritium that can be placed in the NSDF (see Table 3.3.1-2) and on the tritium concentration in individual waste shipments (see Table 3.3.3-1). By placing stringent controls on the amount of tritium being placed in the NSDF, emissions from the WWTP will meet the tritium effluent discharge targets. The discharge target for tritium of 360,000 Bq/L is based on maintaining tritium concentrations in Perch Creek which discharges to the Ottawa River, below the drinking water guideline of 7,000 Bq/L. Thus, no treatment method is necessary to reduce the activity of tritium in the wastewater since it is instead controlled through means to isolate the source.

Non-Radiological Constituents

The effluent discharge targets for non-radioactive constituents are based on the protection of aquatic life and may be lower or higher than drinking water criteria. The effluent discharge targets are gathered from a variety of sources including the Canadian Council of Ministers of the Environment (CCME) and Ontario Provincial Water Quality Objectives (PWQOs). If both federal and provincial criteria were available, the lower value was used to define the discharge target. The CCME guideline values are for the protection of aquatic life; the PWQOs were developed to ensure that water quality is satisfactory for aquatic life and recreation. Other reference documents were used when CCME or PWQOs were not available.

3.4.2.6 WWTP Treated Effluent Discharge Systems

The NSDF's WWTP treated effluent discharge systems are designed for the peak flow from the WWTP. The preferred option is to discharge the treated effluent from the WWTP to the exfiltration gallery as this provides a longer transit time to the Ottawa River then discharge to Perch Lake. Under high groundwater elevation conditions, discharge to the Exfiltration Gallery is not possible and the treated effluent will be routed to Perch Lake. Figure 3.1.1-1 shows the two potential discharge locations. The estimated annual volume of the treated effluent to be discharged is approximately 11,000 m^3.

The exfiltration gallery design and transfer line to Perch Lake are described in Sections 3.4.2.6.1 and 3.4.2.6.2 below.

Groundwater monitoring in proximity to the exfiltration gallery has indicated that the groundwater elevation under spring conditions is near ground level. Groundwater flow modelling has also indicated that under high seasonal groundwater conditions discharge to the exfiltration gallery will result in flooding at the exfiltration gallery. It is therefore anticipated that under spring conditions all effluent will be discharged to Perch Lake to ensure that the water table remains below grade at the exfiltration gallery and there is no flooding. Under summer conditions when the water table is lower and the volume of wastewater generated is lower, effluent will be routed to the exfiltration gallery.

Real time groundwater monitoring wells will be installed in proximity to the exfiltration gallery and provide water table elevation. The water table elevation data will be used to determine when the treated effluent can be discharged to the exfiltration gallery.

3.4.2.6.1 Exfiltration Gallery

An exfiltration gallery has been designed at the discharge outlet to disperse the treated effluent into the local groundwater. The treated effluent, once discharged to ground, would be returned to the adjacent wetlands and eventually discharge to Perch Lake and the Ottawa River. The vegetation in the wetland will provide a level of tertiary treatment for non-radionuclide COPCs, through plant uptake, before discharge to the Perch Lake and Perch Creek receiving systems.

The location and footprint of the exfiltration gallery is maximized to approximately 1,000 m^2. The exfiltration gallery has been designed to operate year-round. Subject to acceptable weather conditions, waste placement in the ECM may cease during periods of inclement weather such as high winds, major precipitation events, extreme cold periods, or inability to compact waste due to frozen conditions. Even if waste placement operations cease, other parts of the NSDF (e.g., the WWTP) may still operate. Winter conditions have been accounted for by doubling the calculated required design area of the gallery in line with the *Stormwater Management Planning and Design Manual* (MOE 2003).

The average flow rate from the WWTP is 27.8 m^3/day of continuous flow, whereas the existing East Swamp Wetland average flow rate is 233 m^3/day. As such, the average flow rate discharged from the WWTP to the exfiltration gallery is roughly 12% of the existing average flow rate from the East Swamp Wetland.

3.4.2.6.2 Transfer Line Discharge to Perch Lake

In the event that the exfiltration gallery does not have sufficient capacity to manage the treated effluent (e.g., under high groundwater elevations), a portion of the treated effluent will be discharged directly to Perch Lake through a submerged diffuser. The transfer line to Perch Lake has the capacity to discharge all treated effluent to Perch Lake and operate year-round.

The discharge transfer line, which will be constructed using HDPE pipe, will extend south for approximately 1 km from the WWTP along the perimeter of the ECM and existing access roads before entering Perch Lake from the southeast (Figure 3.1.1-1). Horizontal directional drilling may be required to cross select areas during construction to minimize disturbance to wetlands. Pumps located within the WWTP will be used to discharge the treated effluent to Perch Lake.

The dual containment HDPE piping system includes leak detection stations. These stations are spaced at approximately 100 m intervals.

The transfer line will extend from the road through approximately 30 m of riparian marsh before open water. The total length of required pipe extending across riparian and open water areas of Perch Lake is 340 m. A shallow trench (2 m depth) will be excavated/dredged within the riparian/shoreline area for the installation of the discharge transfer line, and a foundation to support the discharge transfer line and diffuser will be installed with consideration of reducing any disturbance to the soft sediments. The treated effluent will be discharged through a submerged diffuser positioned in the deepest location near the centre of the lake and will be dispersed through the lake before discharging downstream via the Perch Lake weir.

3.4.3 Support Facilities

The NSDF Project will require various support facilities during construction, operation and maintenance. The facilities makeup will consist of both modular and permanent structures with associated construction features required for their use or installation. Support facilities will be designed for year-round operation.

The main support facilities consist of six structures of varying types and sizes including:

- north and south kiosks;
- administration building;
- operations support center;
- vehicle decontamination facility;
- site vehicle refueling station; and
- potable water pump station.

The facilities have been designed considering Leadership in Energy and Environmental Design principles and building for energy efficiency. Other support facilities, such as the Fire Water Pump station, will provide the remaining necessary services to the NSDF Project.

3.4.3.1 North and South Kiosks

The NSDF Project site will have two weigh scales, one on the north side and one on the south side (Figure 3.1.1-1). The south kiosk will be used for most incoming loaded waste transport vehicles for both loaded weight and empty weight. The north kiosk will be used by the trucks coming from Plant Road for loaded weight and empty weight. A kiosk will be located at each scale with computerized waste quantity tracking equipment. After unloading the waste, the waste transport vehicles will be monitored for contamination and decontaminated, if necessary.

3.4.3.2 Administration Building

The administration building is positioned off the main site access road. It will serve dedicated NSDF Project site personnel (non-construction workers) during operation and maintenance. The administration building includes office space, a meeting room, a records room, a washroom facility and a lunch room. The administration building will also include necessary minimum first aid equipment, per CNL's Occupational Health and Safety program and Canadian Labour Code requirements.

3.4.3.3 Operations Support Centre

The operations support centre building includes the necessary spaces required for the decontamination of the personnel working on-site and shower facilities after work. The building provides contaminated and clean change rooms and decontamination showers. The decontamination water is directed to the active drainage system and returned to the WWTP for processing. Service rooms for the facility (e.g., mechanical, electrical, janitorial and storage) are located outside of the contaminated zone. This facility will also house secondary first aid equipment to provide quick access for workers requiring decontamination.

3.4.3.4 Vehicle Decontamination Facility

The vehicle decontamination facility provides equipment and facilities for decontamination of vehicles and facility personnel when required. A support office, washroom and mechanical room to carry out light maintenance activities are also present in the building. The vehicle decontamination hall is separated from the rest of the building to prevent transmission of contamination. Contaminated water is transferred by the active drainage system to the WWTP for processing. The facility is sized to accommodate the decontamination of on-site vehicles and highway-legal vehicles. The vehicle decontamination facility will be enclosed, as NSDF Project waste placement activities are required to occur year-round, subject to acceptable weather conditions.

3.4.3.5 Site Vehicle Refueling Station

Located next to the northern ECM perimeter road at the WWTP Access Road the site vehicle refueling station will store bulk diesel for use in ECM construction equipment. It will be an unattended station with an automated fuel pump capable of metering fuel and logging consumption. The fueling area has been designed to protect the natural environment from fuel-related spills.

3.4.3.6 Potable Water Pump Station

The potable water pump station will be located at the north end of the NSDF Project site. This building will house a 15 m^3 potable water tank which is fed from a watermain delivering potable water from the CRL site. The building will also include potable water booster pumps, and a re-chlorination station.

3.4.4 Site Infrastructure

The design of the site infrastructure and support facilities will accommodate year-round operation during the NSDF Project construction and operations, and for the long-term monitoring and maintenance activities during the closure and post-closure phases.

The site infrastructure systems consist of the following:

- access roads;
- site security, including site perimeter fencing and boundary setbacks;
- Sanitary Sewage Disposal System (collection, conveyance, treatment and discharge);
- Surface Water Management (collection, conveyance, treatment and discharge); and
- utilities, including natural gas, power, telecommunication, data, and domestic water pump and distribution (e.g., potable water supply and fire water supply).

3.4.4.1 Access Roads

The NSDF Project site transportation network consists of primary and secondary access roads. Primary access roads provide two-way traffic. Secondary access roads facilitate both one- and two-way traffic.

There are two primary access roads to the site (Figure 3.1.1-1). The main waste shipment access road is from the ER-3 (Emergency Road)/East Mattawa Road intersection south of the NSDF Project site boundary. This road is proposed to be comprised of a granular pavement structure. This road will be used for waste shipments arriving to the NSDF Project site, as well as transport vehicles leaving the NSDF Project site, providing that vehicle decontamination is not required.

The other primary access road to the NSDF Project site is from Plant Road to the site boundary. This road is proposed to be an asphalt pavement structure from the Plant Road to the site boundary to limit dust generation in the vicinity of Plant Road. A right-turn/deceleration lane is proposed at the intersection with Plant Road to allow for slower moving vehicles to turn into the NSDF Project site without impeding eastbound traffic to the CRL main campus. This primary access road will be used for occasional waste deliveries to the NSDF Project site, but is mainly intended for employee access to the support facility buildings and material and equipment deliveries to the site.

Secondary site access roads generally consist of perimeter roads around the ECM and the WWTP. The secondary roads are proposed with granular pavement structures and are sized to facilitate two-way vehicular traffic around the site. Decon Road, linking the ECM to the vehicle decontamination facility, is proposed as an asphalt road and will be used by waste shipment vehicles or equipment that require decontamination.

3.4.4.2 Site and Worker Parking

Site and worker parking will be positioned near the administration office and the vehicle decontamination facility. This area will be large enough to accommodate vehicles from on-site personnel, visitors, and CRL site security. Parking areas will be constructed of granular material.

3.4.4.3 Site Security

The NSDF security will follow CRL's site security requirements and physical security plans. Access to the NSDF Project site will be exclusively from within the CRL site boundary and access to the CRL site is strictly controlled by security personnel. In addition, a security fence will be installed around the entire perimeter of the NSDF Project site to prevent unauthorized personnel from entering, and limit animal injury and contact during construction and waste placement operations. The perimeter fencing will be 2.4-m high, typically offset 1.0 m inside the NSDF boundary. A swing gate area will be provided at secondary access points (i.e., connections to maintenance roads and/or hydro transmission corridors) and automated gates are provided at the north and south entrances with security features to control access to and within the site. Fencing is anticipated to be chain-linked and include a below-ground portion, which will prevent turtle migration into the site.

3.4.4.4 Sanitary Sewage Disposal System

The NSDF's sanitary sewage disposal system has been designed to transfer the peak sewage flows generated by up to 65 full time employees at the NSDF Project site. The NSDF sanitary sewage will be managed through a gravity sewer network connected to a sewage disposal system. This system is completely separate from the ECM leachate and contact water transfer system for the on-site WWTP.

Two site sewage disposal systems are proposed to service the NSDF Project site, including:

- one primary sewage disposal system located at the north entrance to the NSDF Project site east of East Mattawa Road; and
- one secondary sewage disposal system adjacent to the South Entrance Kiosk to support only the South Kiosk.

Each of these two systems will contain a pump station, precast concrete septic tank and polyvinyl chloride piped leach field. The sanitary system uses a network of gravity sewers to convey sewage from the Vehicle Decontamination Facility, the Operations Support Center, the Administration Building, the North Kiosk, and the WWTP to a sanitary pumping station located near the north entry to the site. At the South Kiosk, sewage will discharge from the Kiosk through a septic tank to a septic field near the kiosk. There are no tie-ins to the CRL system. Sewage discharges to the sewage disposal systems will conform to CNL's Environmental Protection Program procedure, *Acceptability Criteria for Routine and Non-Routine Discharge of Liquids on the CRL Site* (CNL 2015).

3.4.4.5 Surface Water Management Collection, Conveyance, Treatment and Discharge

The surface water management system for the NSDF Project is designed to control non-contact water including limiting surface water from uncontaminated areas discharging into contaminated areas. Contact water that is collected from within the ECM is transferred to the WWTP for treatment (Section 3.4.2). The design of the surface water management system considers the accumulation of 1 m of snowfall in advance of a design storm event.

The surface water management system consists of four main elements:

- collection (i.e., site grading, inlets, catch basins);
- conveyance (i.e., internal ditches, sewers, culverts and external flow diversion ditches);

- treatment (i.e., settling/detention ponds); and
- outlet to receiving waters (i.e., East Swamp wetland).

The design of the surface water management system for the NSDF Project site is to achieve the following objectives:

- to mitigate erosion and intercept sediment during the construction phase to avoid transport off-site during wet weather events;
- to control the quantity of surface water discharge from the NSDF Project site to maintain pre-development peak flow rates; and
- to provide quality treatment of non-contact water from the ECM to meet the requirements of the Ontario Ministry of the Environment, Conservation and Parks by facilitating the settling of suspended sediment and ultimately protecting receiving watercourses and waterbodies.

During the construction phase, erosion and sediment control measures will be in place to mitigate the effects of sediment transport. The measures will include the use of erosion control blankets, as needed on steep slopes, check dams in ditches and swales, and the three proposed surface water management ponds that will be constructed to serve as interim sediment control facilities during construction, and then as stormwater management facilities during the operations, closure and post-closure periods. The ECM surface water runoff controls will be maintained until the end of the institutional control period. The ECM and external areas, including the WWTP, parking lots, administrative and maintenance buildings, and laydown areas will be subject to erosion and sediment control measures during construction.

During the construction phase, CNL anticipates an average water use of approximately 110 m^3/day to 150 m^3/day for construction activities (e.g., dust suppression, clay mixing and fire protection). Construction water use is expected to peak at approximately 750 m^3/day. Water usage will be lower during the winter season (December through to March) when construction will be less active. The water may also be used for commissioning activities including hydrostatic testing of the WWTP storage tanks, the leachate collection, and piping systems. Construction water will be sourced from the Ottawa River using an existing intake structure to fill temporary storage containers.

Site operations include surface water management for the ECM and all external areas. Surface water from all external areas will be transferred by drainage ditches, swales and culverts to surface water management ponds that will address water quality and water quantity criteria established for the wetland receiving waters and, ultimately, Perch Creek. Contact water drainage from the active cells of the ECM will be to the WWTP unless sampling and analysis demonstrates that the water in the contact water pond is suitable for discharge as non-contact water. Non-contact water drainage will be directed by gravity to the external surface water management system, or to temporary holding ponds within the ECM and then pumped to the external system and the three surface water management ponds.

3.4.4.5.1 ECM Surface Water Management

Contact and non-contact water ponds will be kept independent from each other by the ridge and valley configuration (herringbone-shape) in the base liner and use of temporary berms. The cells are oriented so that the ridge and valleys will naturally direct water to ponds located at the low point of each cell. The ponds will be positioned along the south edge of the ECM for Phase 1 as shown in Figure 3.4.4-1. In addition, berms will be installed along the cell ridges in the area of the ponds to provide the necessary pond structure, volume and provide separation for:

- Active disposal cell from the adjacent contact water pond;
- Contact water pond from the adjacent non-contact water ponds; and
- Each of the non-contact water ponds.

Phase 2 will be separated from Phase 1 by the ECM access road which keeps Phase 2 independent from Phase 1 and prevents inflow of contact water. Phase 2 non-contact water will drain to an internal control pond located at the north west corner of the ECM.

Non-contact water ponds will avoid contamination from adjacent operations by means of the following design features:

- Ponds will be positioned at the low points of each cell to provide a predictable drainage path;
- Ponds have been sized for the back to back 100-year, 24 hr storm event with 0.5 m freeboard based on the maximum cell area to prevent overtopping;
- Berms between ponds have been designed with a 3:1 slope to provide the necessary containment structure; and
- Ponds will be individually lined with an additional 2 mm geomembrane anchored to the berms to form a water tight structure for each cell.

The non-contact water collected in the ECM non-contact water ponds is pumped to the ECM perimeter ditches and drains to surface water management ponds 2 and 3 which are discussed in subsequent sections.

The purpose of the contact water pond is to receive contaminated water from the waste handling area as well as the adjacent waste disposal cell. The design and waste placement objectives (AECOM 2019b) promote flow to the contact water pond by:

- Installation of the sacrificial liner in the waste handling cell;
- Compacting the surface of the waste to maximize its in-place density to reduce infiltration; and
- Grading the waste in the active waste cell (minimum 2% slope), towards the contact water pond.•

As discussed in Section 3.4.2 the contact water collected in the ECM contact water ponds is pumped to the WWTP for treatment prior to discharge to the environment.

3.4.4.5.2 Surface Water Management Ponds

The three surface water management ponds are provided to address the proposed layout and drainage patterns (Figure 3.4.4-2).

- Surface water management pond 1 is at the north end and will receive runoff from proposed buildings and parking lots. The outlet will be via channel and dispersion outlet (spreader), to the East Swamp wetland.
- Surface water management pond 2 is to the south and will receive runoff from the post-closure ECM and adjacent laydown/stockpile area. The outlet will be via channel and dispersion outlet (spreader) to the Perch Lake Swamp wetland complex.
- Surface water management pond 3 is to the west and will receive runoff from the post-closure ECM. The outlet will be via channel and dispersion outlet (spreader) to the Perch Lake Swamp wetland complex.

An internal control detention pond will be used during Phase 1 operations. This pond will be located along the northwest corner of the ECM in the Phase 2 area and will attenuate peak flows before transferring to surface water management pond 3.

The surface water management pond footprints reflect the overall storage required to control post-closure flows to predevelopment levels for the 2-year through to 100-year rainfall events at the site. This volume also contains the storage required for sediment control during construction and water quality control during operations. The design footprints typically assume a maximum 100-year operating water level at a 3 m depth with 1 m of freeboard that includes allowance for climate change impact projections and rain on snowmelt.

IF THIS MEASUREMENT DOES NOT MATCH WHAT IS SHOWN, THE SHEET SIZE HAS BEEN MODIFIED FROM: 25mm 0

S:\Clients\Canadian_Nuclear_Laboratories\NSDF\99_PROJ\1547525_NSDF_EIS\40_PROD\0004_EIS_Section_3\1547525-0004G-0007.mxd

The target non-contact water quality objective is provided by Ministry of the Environment, Conservation and Parks Ontario Ministry of the Environment, Conservation and Parks in their *Stormwater Management Planning and Design Manual* (MOE 2003), which suggests a 60% total suspended solids (TSS) removal that provides a basic water quality treatment for discharge to a receiving wetland. Surface water management pond 1 will provide 80% TSS removal, surface water management pond 2 will provide 76% TSS removal and surface water management pond 3 will provide 60% TSS removal.

Mitigation measures will be implemented upstream and downstream of the surface water management ponds to minimize sediment loading. These will include:

- Design of the facility to resist heavy erosion during severe storm events. Conveyance structures such as ditches and swales will be vegetated, lined in rip-rap and contain check-dams and similar structures to trap sediment and reduce flow velocity.
- The impervious area of the SWMP catchments during operation and post-closure is relatively small. Geotextile and granular liners as well as vegetation cover will reduce the amount of solids entering the system from these surfaces. In addition, operational practices such as sweeping sand off asphalt surfaces, granular sealing of road shoulders and gravel surfaces and various dust suppression measures will reduce solids loading into the SWMP influent.

The surface water management pond outfall structures are within the NSDF site boundary and provide for approximately 35 m of dispersed overland flow and infiltration before the stormwater reaches the edge of the wetland. The edge of the wetlands are forested and only seasonally wet, providing additional distance for the stormwater to travel, pond and infiltrate before reaching East Swamp Stream located 200 m from SWMP 3 outfall and Perch Creek located 150 m from SWMP 2 outfall.

The surface water management ponds will be monitored for total suspended solids as described in Table 11.0-1 to ensure compliance with Environmental Protection Program requirements for total suspended solids in effluent discharge.

Road, sidewalk and parking lot winter maintenance activities that may release road salt to the environment, include snow plowing/shoveling and de-icing practices, salt and sand storage, and snow stockpiling, removal and disposal. The current winter maintenance practices outlined in the CRL *Salt Management Plan* (AECL 2013) provide effective measures to manage salt use within the NSDF Project site. The application of road salt on the NSDF Project site is to be minimized as salt residual within contact water and/or leachate may compromise the treatment effectiveness of the WWTP systems. Instead, alternative products such as a sand-stone mixture are being considered.

For each surface water management pond, the water level will be monitored to estimate the inflow and outflow of each pond. Visual inspections of the ponds will be completed to confirm that inlets and outlets are clear of debris and to confirm that there are no major erosion issues at the inlet or outlet. The berms and outlet structures will be visually inspected to identify any animal burrowing activity or active soil erosion. Inspections will also include an annual sediment level monitoring component to identify sediment clean-out requirements. Sediments will be extracted by excavation equipment and will be disposed of based on sediment sampling, testing, and classification according to Ministry of the Environment, Conservation and Parks standards or stockpiled, de-watered and reused on-site for ECM cover operations. The sediment removal assessment follows procedures identified in the *Stormwater Management Planning and Design Manual* (MOE 2003).

3.4.4.5.3 Drainage Ditches and Swales

All roads, including the perimeter road, have ditches that convey not only road drainage, but drainage from adjacent lands, to the surface water management ponds. These have been designed to convey the 25-year post-development peak design flow. Annual maintenance activities will identify any erosion problems. A maintenance review will be completed on a regular basis to confirm there are no major erosion issues.

3.4.4.5.4 Culverts and Sewers

Where drainage crosses roads, culverts are sized to convey the 25-year design event without road overtopping. A 900 mm storm sewer has been sized to convey the 100-year flow plus climate change to surface water management pond 1 in the vicinity of the administration building because adjacent land use, property and road limits preclude the use of a ditch. Annual maintenance activities will identify any erosion or blockage problems. A maintenance review will be completed on a regular basis to confirm there are no major erosion or blockage issues at the culvert and sewer inlet or outlet.

3.4.4.5.5 Flowpaths

Major system (i.e., 100 year) flow routes follow the road system and ditches to the relevant surface water management ponds. The probable maximum precipitation flow generally follows the major system route using the road, related ditches and adjacent lands. Even when the probable maximum precipitation flow will exceed the surface water management ponds attenuation capacity, one of the design objectives is that inlet and emergency outlet structures adjacent to the surface water management ponds will be able to convey this flow safely.

3.4.4.5.6 Outlets

The major flow system for all three surface water management ponds will discharge to adjacent wetlands and will be dispersed by level spreaders to achieve even flow distribution to the wetlands. Current surface water management pond outlet locations are limited by the site boundary (greater than 5 m separation required) so that there is no discharge from the spreader directly to the wetlands. Local topography between the level spreader and the wetlands, as well as any setbacks, has influenced the location of the level spreaders on-site. Annual maintenance activities will identify any erosion problems. In addition, a maintenance review will be completed on a regular basis to confirm there are no major erosion issues at the dispersion outlets.

3.4.4.6 Utilities

The following site utilities will be required to facilitate the NSDF Project construction, operation and maintenance:

- potable water service for human consumption and staff decontamination facilities;
- service water for vehicle decontamination facilities, and WWTP operations if required;
- electricity for site facilities for lighting; ventilation and air conditioning; and other power uses;
- natural gas for heating; and
- telephone and internet access for communication and CNL surveillance equipment (such as security cameras).

The water distribution system is designed to supply water to meet the potable and service water demands at the NSDF Project site and supply and maintain sufficient pressures to meet the NSDF's operational requirements. All buildings and facilities, with the exception of the south kiosk, will be provided with potable water service for various uses, which include but are not limited to showers, toilets, eyewash stations, faucets, floor/equipment

wash down, and process applications. The south kiosk is serviced by a water storage tank within the kiosk. The NSDF's watermain will tie into the CNL potable water network. All watermains will be equipped with cathodic protection on all metal appurtenances; cathodic protection monitoring stations and tracer wire will be supplied. The watermain will be provided frost protection by locating it below the frost line.

Fire protection at the NSDF Project site will be provided through two on-site underground fire water holding tanks. The tanks have been designed and will operate in a duty/standby manner. Each tank will have a capacity of 403 m^3. This capacity will be sufficient to provide 2 hours of fire water supply through a dry fire main system to on-site hydrants.

3.4.5 Management of Waste Generated by the Project

All wastes that arise as a result of the construction, operations, and closure phases will be safely managed and in accordance with CNL's Waste Management Program. The CNL Waste Management Program prescribes that management of waste at CNL-operated sites is completed in a safe and environmentally responsible manner that meets or exceeds CNL's Safety and Health Policy, CNL's Environment Policy, as well as applicable regulations and standards, and limits current and future environmental effects and liabilities. Facilities and activities within these sites are planned, developed and operated or conducted in a manner that reduces both the volume and the level of hazard of all wastes that are generated during the entire life cycle of the facility or activity. Under the Waste Management Program, wastes are managed in accordance with CNL's procedure for *Management of Waste* (CNL 2019d).

3.4.6 Human Resource Requirements

The construction, operations, closure and post-closure phases of the NSDF Project will require administrative and supervisor staff, engineering and environmental monitoring personnel, technical support staff and construction workers. Table 3.4.6-1 summarizes the expected averaged labour requirements during construction, operations, closure and post-closure, including contractors. The construction is planned over two years and has a variable labour force depending on the number of parallel activities being performed. The averaged labour force over the duration of the construction phase is approximately 225 full time equivalents, with the peak labour force expected to be close to 300 personnel (Table 3.4.6-1).

Limited maintenance and inspection will occur in off-shift hours. Operations occur over a 50-year period, with an average labour force of 65 full time equivalents (although this will be adjusted based on operational demand). Closure and Post-closure labour force requirements will be substantially less than requirements for the operations phase.

Table 3.4.6-1: Summary of Labour Force Requirements for the Near Surface Disposal Facility Project During Construction and Operation

Project Phase	Labour Force	Types of Positions
Construction	Peak manpower of 300 personnel over a 2-year period	■ Administrative and Supervisor Staff ■ Construction Management ■ Engineering/Technical Support Staff ■ Equipment Operators ■ Skilled Trades ■ General Labour ■ Environmental Monitoring ■ Owner Representatives ■ Truck Drivers
Operations	65 full time equivalents (although this will be adjusted based on operational demand)	■ Administrative and Supervisor Staff ■ Mechanical/Technician ■ Engineering/Technical Support Staff ■ Equipment Operators ■ Environmental Monitoring ■ Truck Drivers (transport of waste)

3.5 Application of Existing Policies, Objectives, and Programs

The following sections outline CNL's existing health, safety, security and environmental policies, objectives and programs that will be applicable to all phases of the NSDF Project. CNL will implement these policies on the NSDF Project through project-specific plans and procedures (e.g., Environmental Protection Plan, Radiation Protection Plan, Blasting Plan).

3.5.1 Existing Policies and Procedures

3.5.1.1 Environmental Policy

CNL has an *Environment Policy* (CNL 2017b) that considers the protection of the environment as an integral component of its decision-making in all phases of its business activities, including product development, project planning, project implementation, operations and decommissioning. CNL also focuses its environmental efforts on limiting nuclear legacy obligations for future generations. CNL's *Environmental Policy* (CNL 2017b) applies to all aspects of CNL's activities as following:

- To practice responsible environmental management.
- To be committed to pollution prevention.
- To set environmental objectives and targets to support continual improvement of their environmental performance.
- To set sustainability objectives and targets for energy efficiency, clean energy utilization, waste management and conservation of resources to support continual improvement of their performance.
- To comply with environmental laws, requirements and recognized standards and guidelines applicable to their activities.
- To review the impacts of their activities, facilities, projects, services and products on the environment.
- To seek to develop and improve technologies to advance environmental protection and clean air solutions.
- To promote public and employee awareness of this policy and their environmental performance.

3.5.1.1.1 Environmental Plan

The *Environmental Plan* is a report that is issued annually (CNL 2019e). It describes the strategic environmental objectives for CNL sites. The *Environmental Plan* currently includes the following initiatives (CNL 2019f).

- Manage legacy radioactive waste.
- Upgrade or construct new infrastructure related to current operations.
- Manage and monitor emissions.
- Build new infrastructure.
- Implement sustainability/green initiatives for energy management, waste management and conservation of resources to continually improve performance.

3.5.1.2 Safety Policies and Objectives

CNL has established several corporate policies relevant to employee, public and environmental safety. The following policies will be followed for all NSDF Project activities:

- Quality (June 2019);
- Safety and Health (February 2019);
- Environment (March 2018);
- Nuclear Safety (March 2018); and
- Security (June 2019).

The following safety objectives will be followed for all NSDF Project activities:

a) Radiation exposures to facility staff, on-site personnel, and the off-site public resulting from the normal facility operation, Anticipated Operational Occurrences and credible accidents are:
   - below the regulatory limits, as per the *Radiation Protection Regulations*;
   - As Low As Reasonably Achievable, social and economic factors taken into account (ALARA); and
   - as per CNL's Radiation Protection Requirements.

b) Radioactive releases and radiation exposures to the facility staff, on-site personnel, and the most exposed group of the off-site public resulting from abnormal events will be addressed with the defence-in-depth philosophy. Doses will be:
   - first prevented;
   - mitigated; and
   - accommodated through design, operating procedures, training, and administrative controls.

c) Releases of radiological substances to the environment will be first prevented, then mitigated, and then accommodated such that exposures are limited and are ALARA.

3.5.1.3 Procedure for Management and Monitoring of Emissions

Emissions and effluents from the NSDF Project during the construction, operations, and closure phases will be managed according to CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018a). This procedure defines the key requirements, responsibilities, and processes for the management of radioactive and non-radioactive emissions at CNL operated sites. This document expands on regulatory requirements for the effective management of these emissions, and involves the following activities:

- identification and assessment of emission pathways;
- control and treatment of emissions;
- operational control monitoring; and
- effluent verification monitoring.

Identification and assessment of emission pathways involves identifying routes by which radioactive and non-radioactive contaminants are likely to be emitted to the atmosphere, wastewaters, ground or groundwater, or to off-site municipal sewer systems from CRL facilities during routine and non-routine events. The type and quantities of these contaminants to be emitted are characterized, and subsequently assessed for the likelihood of exceeding regulatory and internal emissions limits, the magnitude and likelihood of effects to the public, the potential for adverse effects to the environment, and the potential for public concern.

Control and treatment of emissions includes identifying mitigation to prevent, reduce, or limit release of emissions to the environment. To the extent practical, airborne and waterborne effluent containing contaminants are managed separately from non-contaminated effluent. Preventive maintenance programs are implemented to reduce the likelihood of system failures, and appropriate systems are in place to provide timely warning in the event of a failure or degradation of control and treatment systems. Operational control monitoring is completed to evaluate whether emission control and treatment systems are functioning as intended.

Effluent verification monitoring is intended to verify that emissions are below regulatory limits and includes measuring or estimating nuclear substances and hazardous substances being released into the environment by a site or facility. An effluent verification monitoring program is established for the monitoring of radioactive and non-radioactive emissions. The overall effluent verification monitoring program for the CRL site is applicable to the NSDF Project; specifically, the Air Verification Monitoring Program and Liquid Verification Monitoring Program will be expanded to include the NSDF Project.

As well, a passive LFG venting system will be constructed during installation of the ECM final cover system and will be monitored periodically during the ECM post-closure phase to detect evidence of potential LFG migration away from the ECM (described in Section 3.4.1.9.4).

Monitoring of the treated effluent discharge from the WWTP will be completed in accordance with CNL's procedure for *Management and Monitoring of Emissions*. The Operational Control Monitoring Program for the CRL site will be expanded to include the NSDF Project, and will achieve the following objectives:

- to provide feedback to facility operators on system performance with respect to emissions to the environment within a time frame consistent with routine operational control decisions;
- to confirm the adequacy of controls on emissions from the source;

- to provide timely indication to facility operators of abnormal emissions that may be in excess of emission limits to initiate corrective action, incident reporting, quantitative monitoring, investigations or emergency actions as appropriate; and
- to differentiate sources of abnormal emissions where there is more than one facility, system or subsystem that discharges to the environment through a single or common effluent stream.

Leachate monitoring will be conducted at the ECM. The leachate monitoring program will be designed to characterize the leachate quality as the ECM is operated, and to ascertain unique indicator constituents that are representative of the leachate characteristics.

Environmental monitoring is performed to assist in determining the effect of emissions in the environment surrounding a site or facility and consists of measuring or estimating nuclear substances and hazardous substances present in the environment. CNL's maintains a comprehensive Environmental Monitoring Program for the CRL site to verify that radiation doses to members of the public as a result of radioactive releases from the CRL site remain ALARA. The program demonstrates that releases from the CRL site do not exceed regulatory limits and serves to verify that radioactive and non-radioactive releases do not pose hazards to human health and the environment. Monitoring is completed through routine collection and analysis of environmental samples from numerous locations within the CRL site, as well as in the surrounding communities. The Environmental Management Plan (EMP) for the CRL site will be expanded to include monitoring and sampling locations for the NSDF Project.

3.5.2 Existing Health, Safety, Security and Environmental Programs

To demonstrate compliance with regulatory commitments related to health, safety and security, CNL has developed a number of programs outlining corporate expectations.

The following presents an overview of CNL's existing programs related to environment, safety and security. CNL is responsible for and committed to providing for the health and safety of its employees and the public and the protection of the environment. These programs include, but are not limited to:

- Radiation Protection Program.
- Environmental Protection Program.
- Waste Management Program.
- Occupational Safety and Health Program.
- Emergency Preparedness Program.
- Nuclear Criticality Safety Program.
- Physical Security Program.
- Nuclear Materials and Safeguards Management Compliance Program.
- Fire Protection Program.
- Quality Assurance Program.
- Human Performance.
- Transportation of Dangerous Goods.

The above-mentioned programs will be implemented during all phases of the NSDF Project. A brief description of each program is provided in the following sections.

3.5.2.1 Radiation Protection Program

CNL's Radiation Protection Program is designed and implemented so that CNL complies with, or exceeds, the level of radiation safety that is required by the relevant regulations pursuant to the *Nuclear Safety and Control Act* and CNL's Health and Safety Policy.

The fundamental objectives of the CNL Radiation Protection Program are to:

- limit the doses to less than the regulatory limits;
- limit doses to employees and members of the public to levels as low as reasonably achievable, social and economic factors being taken into account (ALARA principle); and
- prevent detrimental non-stochastic (deterministic) health effects caused in employees and members of the public by CNL's use of radiation. At all CRL facilities, these objectives are achieved through facility design, staff training, administrative exposure control procedures, contamination control requirements, and work planning and supervision. A combination of Action Levels and dose management tools are used to keep radiation doses to employees below regulatory limits and ALARA.

CNL's ALARA program takes into consideration CNSC's regulatory guide to the ALARA principle (CNSC 2004) in the design of the NSDF Project. This program is used for the planning and control of radiological work, and includes guidelines and procedures for initiating, analyzing, planning, scheduling, executing and closing out radiological work so that radiation exposures and the risk of unplanned exposures are kept ALARA. All new and non-routine activities (activities that will introduce any new or non-routine radiological aspects, hazards or safety concerns) require analysis by CNL's ALARA review process.

The ALARA principle for the NSDF Project design will be achieved by implementing zoning and access control measures, providing process equipment segregation, establishment of radiation alarms and through operator training and approved procedures. Further reduction in operating staff doses is achieved by limiting releases through periodic inspection and preventive maintenance of equipment. This principle applies throughout the life cycle of the NSDF Project, from design to decommissioning.

3.5.2.2 Environmental Protection Program

CNL's Environmental Protection Program provides compliance with applicable environmental regulatory requirements and requirements that CNL has adopted as a matter of policy. The program is registered under ISO 14001 and is designed to provide for the protection of the environment and the public in relation to CNL's activities. The Environmental Protection Program incorporates the following key elements of the ISO 14001 Environmental Management System Standard:

Planning

- Identification and determination of significance of those environmental aspects associated with CNL's activities.
- Establishment of environmental objectives and targets.
- Development of appropriate plans and/or programs to achieve the objectives and targets.

Implementation and Operation

- Defining and documenting appropriate roles and responsibilities.
- Establishment and maintenance of operational controls over environmental aspects.

Checking and Corrective Action

- Monitoring to verify environmental performance and compliance.
- Maintaining non-conformance and corrective and preventative action procedures.

Management Review

- Periodic review by CNL's management to ensure the on-going suitability, adequacy and effectiveness of the Environmental Management System.

CNL maintains a comprehensive EMP at the CRL site. The EMP operates under the direction of CNL's Environmental Protection Program to achieve the following primary objectives:

- To assess the level of risk on human health and safety, and the potential biological effects in the environment of the contaminants of concern arising from the facility.
- To demonstrate compliance with limits on the concentration and/or intensity of contaminants and physical stressors in the environment or their effect on the environment.
- To check, independently of effluent monitoring, on the effectiveness of contaminant and effluent control, and provide public assurance of the effectiveness of containment and effluent control.
- Provide an indication of unusual or unforeseen conditions that might require corrective action or additional monitoring.
- To verify predictions made in the Environmental Risk Assessment, Derived Release Limit model, and/or environmental assessments, refine the models used, and reduce the uncertainty in predictions made by these assessments and models.

The EMP is also designed to provide data required to support site remediation programs, site operations, or to plan for future stages of the site lifecycle (e.g., decommissioning); to provide resources and data that can be of value during the response to an accident or upset, and in the recovery from such an event; to demonstrate due diligence; and to meet stakeholder commitments. The design of the EMP takes into account the facilities and processes at the CRL site, actual emissions from the site at present and in the past, the environmental pathways leading to radiation dose to critical groups, as well as various other scientific, historic, and public considerations. The EMP for the CRL site will be expanded to include monitoring and sampling locations for the NSDF Project.

The NSDF Project Environmental Protection Plan will establish guidelines for safe and environmentally sound management of the facility during construction. During operations, this plan will establish guidelines to prevent unacceptable dispersal of radioactive and non-radioactive materials through environmental pathways and provides mechanisms for early detection of releases of radioactivity, as well as monitoring for both radioactive and non-radioactive emissions. This plan will also include information on how long-term behaviours of the waste are evaluated with respect to environmental protection.

3.5.2.3 Waste Management Program

Waste Management Program includes requirements and processes to ensure that CNL activities that involve planning for, handling, transporting, processing, storage and disposal of wastes are performed in a manner that complies with applicable regulatory and licence requirements and protects workers, the public and the environment. This Program will integrate the requirements for waste producers and Waste Operations authorities. The Waste Management Plan at CRL includes identification of waste inventory and the characteristics of the waste (radiological and hazardous non-radiological), waste segregation waste packaging and transfer requirements, and the plan for storage or disposal of the wastes. The Waste Management Plan developed for the NSDF Project provides the plan for managing the waste generated during the construction, operations, and decommissioning of the NSDF in accordance with CRL waste management requirements.

3.5.2.4 Occupational Safety and Health Program

CNL's Occupational Safety and Health Program is designed to provide for the protection of workers and public health and safety in relation to CNL activities. CNL and its contactors will meet all applicable health and safety legislative requirements. CNL requires that contractors and their subcontractors maintain a level of safety equivalent to that of CNL employees while on-site.

All activities related to the NSDF Project construction will be performed according to the contractor's approved Health, Safety, Security and Environment Plan, which will be compliant with the *Occupational Health and Safety Act*. An Integrated Work Control process for all non-routine work involving potential health and safety hazards ensures that hazards are evaluated and appropriate protective measures are taken.

3.5.2.5 Emergency Preparedness Program

Emergency Preparedness Program comprises planning and response elements to provide that processes are in place to control and mitigate the consequences of an emergency (whether related to a nuclear/radiological or conventional incident) both on- and off-site. In accordance with the Ontario Nuclear Emergency Plan, the program includes infrastructure, assigned response staff and other resources, and periodic exercises to test and demonstrate emergency preparedness. The Emergency Preparedness Program takes into consideration guidance provided in the CNSC's *REGDOC-2.10.1 Nuclear Emergency Preparedness and Response* (CNSC 2016).

3.5.2.6 Nuclear Criticality Safety Program

Nuclear Criticality Safety Program is intended to prevent criticality accidents through appropriate design, analysis, operations, and decommissioning of facilities involving fissionable materials. The program applies to activities involving the use, processing, transfer, storage and disposal of fissionable materials. It requires that criticality safety analysis be conducted and that processes and procedures be established to provide assurance that a sufficient safety margin is established. The Nuclear Criticality Safety Program takes into consideration recommendations and guidance provided in the Federal Nuclear Emergency Plan (Health Canada 2014).

3.5.2.7 Physical Security Program

Physical Security Program is intended to provide continuous security coverage of the CRL site, in compliance with *Nuclear Safety and Control Act* legislation and federal government security policy. The program provides physical protection against unauthorized access and malicious damage to nuclear facilities, non-nuclear facilities, and specified nuclear materials used, processed, stored or possessed by CNL at the site.

3.5.2.8 Nuclear Materials and Safeguards Management Compliance Program

Nuclear Materials and Safeguards Management Compliance Program is intended to manage and safeguard nuclear materials in CNL's custody, in compliance with applicable laws and standards. The program provides assurance that CNL's activities are meeting Canada's commitment under the Nuclear Non-proliferation Treaty.

3.5.2.9 Fire Protection Program

Fire Protection Program is dedicated to the delivery of a compliant Fire Protection program that will provide the highest level of fire and life safety to all CNL employees and facilities. The objectives of the Fire Protection Program include preventing fire losses, providing responsible fire protection management, demonstrating compliance to applicable fire protection codes and standards, and providing reliable facilities from a fire protection perspective. The Fire Protection Program provides services including developing fire prevention processes and conducting fire safety inspections. Fire hazard analyses, code compliance reviews and fire protection screenings are also conducted as part of the program.

3.5.2.10 Quality Assurance Program

The Quality Assurance Program is designed to enable CNL to provide effective and efficient product delivery in full compliance with applicable statutory and regulatory requirements through the provision of quality services. The quality services range from:

- The deployment of Quality Assurance Representatives (QARs) to support Project and Operational activities throughout their lifecycle.
- The assessment, evaluation and on-going oversight to existing or prospective supplier's quality assurance programs.
- The provision of personnel, separate from the executing organization, to perform independent inspection and verification activities to the applicable quality code or standard.
- The provision of various quality programs such as Calibration, Real-Time programmable Electronic Systems, Analytical, Scientific and Design Software Program, Counterfeit, Fraudulent, and Suspect Items Program, or Foreign Material Exclusion Program.
- The planning and execution of quality audits to ensure industry standard requirements applicable to CNL's Management System are met. Additionally, the responsible group also act as the point of contact for 2nd/3rd-party audits/assessment by certification/accreditation bodies and customers.

CNL is committed to conducting all operations in a safe and responsible manner in compliance with the CNL Management System.

3.5.2.11 Human Performance

The Human Performance Program assists all employees to anticipate, manage, and monitor the effects of variability in human performance on organizational outcomes. The Human Performance Program supports the implementation of and promotes the CNL Nuclear Safety Policy and the *Institute of Nuclear Power Operations Traits of a Healthy Nuclear Safety Culture* (INPO 2013). The guiding principles of the Human Performance Program are that:

- organizational values influence individual behaviours;
- performance is based on reinforcement and self-motivation;
- people are fallible, and even the best make mistakes; and
- error-likely situations are predictable and preventable, only if they are recognised.

Goals of the Human Performance Program are to:

- improve the understanding of the effect that Human Performance has on event rates;
- aid management in reducing the frequency and severity of adverse events resulting from human error;
- support employees in recognizing error-likely circumstances and applying measures to reduce the likelihood of significant events;
- meet human performance licensing requirements and assist CNL in achieving and sustaining a healthy nuclear safety culture; and
- increase engagement of all Lines to promote the internalization of Human Performance principles.

Employees receive appropriate training on the application of the principles of Human Performance through the Human Performance Fundamentals course that is a required course and offered in the New Employee Orientation.

3.5.2.12 Transportation of Dangerous Goods

The Transportation of Dangerous Goods Program is intended to provide an operational framework for the safe transport of dangerous goods by conforming to all applicable laws, regulations, company policies and procedures. It enables an effective, consistent and comprehensive application of international standards. The Transportation of Dangerous Goods Program applies to all modes of transport and all locations where CNL is responsible as the consignor (shipper), consignee (receiver), carrier or material owner of dangerous goods off-site. Dangerous goods include explosives, gases, flammable liquids, flammable solids, oxidizing substances and organic peroxides, toxic and infectious, radioactive material, corrosives and miscellaneous.

This page intentionally left blank

4.0 PUBLIC AND STAKEHOLDER ENGAGEMENT

Public and Indigenous engagement is a key component of the environmental assessment process and reflects the corporate social responsibility of Canadian Nuclear Laboratories (CNL). Indigenous engagement for the Near Surface Disposal Facility (NSDF) for the disposal of solid low-level radioactive waste at Chalk River Laboratories (CRL) (the 'NSDF Project') is discussed in Section 6.2 of the Environmental Impact Statement (EIS). Section 4.0 summarizes CNL's past and proposed public and stakeholder engagement initiatives, including documentation of meetings, presentation materials, discussion topics and outcomes, and relevant agreements. These activities are intended to fulfil the requirements for public engagement under the *Canadian Environmental Assessment Act, 2012* and the *Nuclear Safety and Control Act.* This section describes past, on-going and proposed public and stakeholder engagement activities and events in accordance with the Generic EIS Guidelines developed by the Canadian Nuclear Safety Commission (CNSC 2016), which state:

> *…the EIS will describe the ongoing and proposed participation activities that the proponent will undertake or that it has already conducted on the project. It will describe efforts made to distribute project information, as well information and materials that were distributed during the public consultation process. The EIS will indicate the methods used, where the consultation was held, the persons and organizations consulted, the concerns voiced and the extent to which this information was incorporated in the design of the project as well as in the EIS. The EIS will provide a summary of key issues raised related to the Project and its potential environmental effects, as well as describe any outstanding issues and ways to address them.*

In addition, CNSC and Canadian Environmental Assessment Agency guidance documents require that the following topics are to be included as part of public engagement activities:

- current Project information (CNSC 2016 Section 2.3);
- alternative means (The Agency 2015);
- Valued Components (VCs; CNSC 2016 Section 5.2.1);
- spatial and temporal boundaries (CNSC 2016 Section 5.2.2); and
- follow-up monitoring program (CNSC 2016 Section 12).

This section summarizes the public engagement activities undertaken for the NSDF Project that fulfill the requirements above.

4.1 Engagement Objectives

CNL is required to ensure that NSDF Project information is made available to local and host communities and stakeholder groups through a variety of mechanisms to ensure accessibility of information. Communication activities are conducted in support of this requirement; CNL's specific engagement objectives include:

1) initiating and maintaining two-way communication channels between CNL and host communities and stakeholder groups, determining the best methods for communicating NSDF Project information and facilitating input at appropriate junctures in the NSDF Project schedule, so that stakeholder feedback can be integrated into the NSDF Project planning and design, as appropriate;

2) developing meaningful, user-friendly information and communication products geared for host communities and stakeholders, ensuring accessible and current information on NSDF Project activities;

3) demonstrating CNL's long-term commitment and approach to safely and responsibly managing radioactive waste and decommissioning activities for the benefit of the future generations;

4) informing and educating host communities and stakeholders about nuclear decommissioning, environmental remediation and radioactive waste management; and

5) meeting all regulatory-based communication and engagement requirements.

CNL has employed a variety of methods and activities to achieve the stated objectives.

CNL has completed three stakeholder engagement reports representing the various time periods that the NSDF Project has spanned (Stakeholder Engagement Technical Supporting Documents [TSDs] 1, 2, 3; CNL 2017a,b, 2019a). These TSDs detail the engagement methods and activities through which the engagement objectives described above were achieved. These methods and activities provided valuable feedback for the NSDF Project to incorporate, as presented in Section 4.3. Their respective identification and period of applicability are defined below.

1) Environmental Assessment Stakeholder Activities Report – NSDF and NPD Closure Projects, March 2017 (August to December 2016) (CNL 2017a).

2) Stakeholder Activities Report – Near Surface Disposal Facility (NSDF), November 2017 (January to July 2017) (CNL 2017b).

3) Stakeholder Engagement Report – Near Surface Disposal Facility (NSDF), October 2019 (August 2017 to June 2019) (CNL 2019a).

4.1.1 Evaluation

The engagement objectives discussed above in Section 4.1 are used to measure the effectiveness of communication activities as well as the evolving nature of the communication strategy of the NSDF Project through events and activities. CNL evaluates several public engagement indicators including: level of participant satisfaction, audience representation, level of engagement with subject matter experts, level of understanding of the NSDF Project, and level of increased project understanding of community and stakeholder issues.

Through the use of various flexible modes of communication and public engagement, CNL has been able to engage a wider audience (demographically and geographically) who may have a stake in the development of the NSDF Project. By enabling two-way dialogue and implementing these accessible engagement mechanisms in the planning of the NSDF Project, CNL was able to adapt and respond to stakeholders' changing need for information. The NSDF Project's routine self-assessment of its public engagement activities, as well as public feedback, will enable CNL to continuously evaluate the effectiveness of its engagement efforts.

CNL has provided a summary evaluation of the NSDF communication program against each of the objectives in Section 4.1.

Objective 1: Initiating and maintaining two-way communication channels between CNL and host communities and stakeholder groups, determining the best methods for communicating project information and facilitating input at appropriate junctures in the project schedule.

CNL has initiated and maintained a progressive number of communication channels between CNL host communities and stakeholder groups.

Since CNL first initiated dialogue on the Near Surface Disposal Facility (NSDF) at an Environmental Stewardship Council (ESC) meeting in 2015 October, CNL has adapted and evolved techniques for communicating project information and facilitating input.

Two early techniques included providing regular updates at ESC meetings and hosting public information sessions in local communities.

Updates to the ESC have been consistently maintained at each of the three annual ESC meetings over the past four years.

In response to public feedback, public information sessions which were originally held in seven local communities in 2016, were expanded geographically to include two more communities, Arnprior and L'Isle-aux-Allumettes (Chapeau).

Finally, the format of the public information evolved in 2018 into an online webinar, held on a quarterly basis. This adaption was in response to continued interest in having more information available in French, in Quebec and in the Ottawa-Gatineau region. The newer online webinar format ensures accessibility for stakeholders in a wide range of places and for both French and English speaking stakeholders.

Other feedback on engagement techniques emphasized the need to create on-going channels of communications with the local community of scientific experts. In response, CNL established semi-monthly Breakfast Briefings in Deep River and more recently Pembroke, as well.

CNL has also coordinated a focus group on effluent discharge to evaluate the project’s plan.

CNL has started to offer one on one meetings with intervenors, with simultaneous translation if applicable.

The feedback that was used to evolve these techniques was obtained through both comments on the draft EIS and through feedback shared directly with CNL, through surveys, email and the online feedback forms.

Both hard copy and online feedback forms have been provided while email has also been a common tool used by stakeholders to engage with CNL and the NSDF Project. Feedback continues to be provided through CNL’s ever-expanding email distribution list (used to disseminate information, project milestones and timeline activities), social media, media, telephone, ESC, Ottawa Valley Economic Development, council meetings, meetings with Service Clubs and at public events.

CNL continues to receive, track and assess feedback for future planning.

Objective 2: Developing meaningful, user-friendly information and communication products geared for host communities and stakeholders, ensuring accessible and current information on project activities.

CNL has developed a variety of simple, user-friendly communications products that are accessible and meaningful to a broad audience in both official languages.

One example of this is the first NSDF overview infographic, which was posted online in 2017 and still has the highest number of downloads of all online NSDF content, after the draft EIS. This was developed to address public concern that messaging around the NSDF was too technical. The infographic helped to simplify an overview of the NSDF Project.

Due to the popularity of this infographic, CNL produced three additional infographics to help tell the story of the proposed NSDF.

The use of video was also essential to user-friendly and accessible communications. Online webinars were posted to YouTube. CNL created three videos on themes that were discerned from public feedback, including a video on what would happen to water effluent. One way CNL tested that the video – Water Management within the NSDF – was accessible, was by showing it to the ESC as a focus group to determine how useful and user-friendly the product was.

Another innovative way that CNL has communicated the NSDF Project includes the use of physical models. CNL had three different physical models created to support stakeholder understanding of the facility. In 2017, scale models of both the base and cover liners were created and used at public information sessions, public events and CNL's Open House in 2017. A third model, which was a 3D rendition of the proposed facility, went on a "tour" through the local communities with a residency at municipal offices in Deep River, Laurentian Hills and Petawawa, where the public could view what the proposed facility would look like.

In order to address accessibility feedback, document repositories have been functionally created by providing the EIS at local libraries and municipal offices.

Online content has also been updated and continually refreshed and reorganized, while at the same time maintaining old content to ensure transparency with stakeholders. CNL has consistently been responsive to feedback on online content. One comment early in the NSDF Project was that the posters used at public information sessions should be made available online. All public open house posters are now posted to CNL's external website.

To ensure ease of understanding and user-friendliness and provision of meaningful information, CNL also adheres to internal and external standards on communications. Communications products like presentations align with CNL Corporate Branding Guidelines. Communication activities are audited annually through CNL's environmental protection program's ISO: 14001 certification.

Objective 3: Demonstrating CNL's long-term commitment and approach to safely and cost-effectively reducing Canada's nuclear legacy liabilities.

To demonstrate CNL's long-term commitment and approach to safely and cost-effectively reducing Canada's nuclear legacy liabilities in relation to the NSDF Project, CNL has focused on refining its messaging.

To this end, CNL has attempted to share the story of why the NSDF is needed and how it is part of the solution to safely reducing Canada's nuclear legacies. To this end, some communication focused on the relationship between the revitalization of the Chalk River Laboratories and its connection with the necessary remediation of the site and the NSDF Project.

In the context of the NSDF Project, CNL has provided more information on existing waste management practices and planned initiatives (such as the Integrated Waste Strategy) to communities and stakeholder groups than ever before.

Information on current waste storage and waste management has been woven into presentations, posters and online content related to the NSDF Project.

Site tours related to the NSDF Project, that have included members of the public, elected officials and media, visit legacy waste management areas as well as the proposed NSDF site, to provide perspective that the NSDF Project is an enabling facility to help with remediation of impacted areas at the CRL site.

Objective 4: Informing and educating host communities and stakeholders about nuclear decommissioning, environmental remediation and radioactive waste management.

At both a basic level and a technical level, CNL has informed and educated host communities and stakeholders about environmental remediation and radioactive waste management.

In particular, presentations prepared for stakeholder groups have included detail on existing waste management practices at CNL as well as information on what types of waste are proposed to be disposed of in the NSDF.

An infographic CNL produced (which is available online) also responds to questions on what kinds of waste is destined for the proposed NSDF.

CNL has also shared information on what specific impacts the NSDF would have on the public in terms of radiation dose. This has been achieved with a user-friendly "peak dose" graphic used in presentations with stakeholder groups and other communications products.

Some public feedback on the NSDF Project has showed that project communications and information need to be simple and clear enough for non-technical audiences to understand. CNL has strived to make language and communications tools as accessible as possible. For instance, the use of video and infographics has encouraged wide understanding of the NSDF Project.

Another way that CNL attempts to share information with a broad audience is through annual public events and activities. CNL regularly attends events like DownTown Connect in Pembroke and Petawawa Showcase, the Ottawa Valley's largest home show.

Local high school students get a chance to learn about CNL's waste management practices and how the proposed NSDF fits into the long-term plan on the annual Take Our Kids to Work Day event at Chalk River Laboratories. At annual public events in the community, CNL representatives regularly share updates on the NSDF Project and use communications products, such as the base and cover liner models and 3D models.

There has also been public feedback that has shown a strong interest in having technical and scientific information about the NSDF Project made available to the public.

One way that CNL has addressed this is to have third party expertise provide information on the NSDF Project. Dr. Kerry Rowe from Queen's University was invited to share details on the testing his laboratories performed on the material used for construction of the liners. Dr. Rowe shared a presentation at one of the semi-monthly Breakfast Briefings in Deep River. A video with Dr. Rowe discussing the NSDF was also posted online to the NSDF webpage and CNL's YouTube channel.

Objective 5: Meeting all regulatory-based communication and engagement requirements.

CNL has aligned its stakeholder engagement strategy with regulatory requirements.

CNL began stakeholder engagement in support of the NSDF Project in 2015 October when CNL leadership introduced the NSDF Project at the final ESC meeting for that year. By the end of 2016, engagement activities were fully underway. For more than four years CNL has modelled its engagement on the regulatory requirements found in REGDOC 3.2.1 Public Information and Disclosure as well as other CNSC guidance, such as the Generic Guidelines for the Preparation of an Environmental Impact Statement. The goals of CNL's stakeholder engagement program, outlined in the Near Surface Disposal Facility Stakeholder Engagement Report (CNL 2019a), are aligned with both the REGDOC 3.2.1 and CNL's Public Information and Disclosure Program (CNL 2021).

4.2 Engagement Methods and Activities

Engagement activities commenced on October 29, 2015, with the introduction of CNL's near- and longer-term plans, including high-level introduction to the NSDF Project, to the CNL Environmental Stewardship Council (ESC; Section 4.2.1.1). This section details Project-specific engagement methods and activities, which include the following:

- presentations to various stakeholders (members of the public, industry, elected officials and employees);
- publishing and updating Project-specific webpage content;
- posting and publishing Project-specific fact sheets;
- publishing and distributing *Contact* community newsletter;
- conducting NSDF Project site visits;
- conducting Project-specific public information sessions
- conducting Project-specific employee information sessions;
- publishing and distributing *Voyageur* CNL internal newsletter;
- participation in public events;
- increased transparency with interested members of the media – hosted journalists on-site for interviews and presentations on the NSDF Project (i.e., Radio-Canada's Decouvertes, Presse Canadienne, Carleton Master's Journalism students);

- “detect and correct” media relations (i.e., letters to the editor aimed at correcting inaccurate statements in articles, disseminating factual information);
- increased use of social media, including webinars, posting Project-specific videos to YouTube;
- advertising campaign in support of public information sessions (online, intranet, newspapers, flyer insert, radio public service announcement, social media, paid Facebook advertising);
- distribution of factsheets and comment cards to local municipal offices in Ontario and Quebec, to function as an information repository and support public input; and
- emails to stakeholders including notifications of the draft EIS submission and responses to questions submitted.

Project materials were prepared and distributed in both French and English. The following subsections outline specific engagement methods and activities already undertaken for the NSDF Project up to June 20, 2019. Engagement activities will continue as part of the environmental assessment process. The final EIS or the Commission Member Document (prepared to support the Commission Hearing) will include an update on public engagement activities and feedback.

4.2.1 Presentations / Site Tours

CNL uses presentations to help inform and educate stakeholders on the NSDF Project. These presentations have triggered discussion that help to inform the NSDF Project through the regulatory process.

As part of its Public Information Program (CNL 2021), CNL periodically hosts stakeholder visits to the NSDF Project site. These visits provide an opportunity for information sharing and open dialogue about the NSDF Project between CNL and stakeholders. These visits are used as one of several means of engaging with stakeholders.

4.2.1.1 Environmental Stewardship Council Meeting – October 2015

Established in 2006, the ESC meets three times annually with the objective of building working relationships and creating opportunities for open dialogue between various stakeholder groups, local communities and CNL. These conversations are integral in providing CNL with a wide range of viewpoints. During independently facilitated meetings, ESC members are presented with information about CNL and CNL’s environmental practices, and have the opportunity to ask questions and discuss the information presented. Each meeting is documented (i.e., presentations and actions) and members are asked to take meeting information back to their respective constituents, organizations and communities.

On October 29, 2015, the NSDF Project was first introduced to the members of the ESC as a part of a Decommissioning and Waste Management update. The ESC has received regular NSDF Project updates at subsequent meetings since October 2015.

See Stakeholder Engagement TSD 1 (CNL 2017a).
Stakeholder(s): Local elected officials, local environmental organizations, and local non-governmental organizations (NGO)s.

4.2.1.2 Environmental Stewardship Council Meeting – June 2016

ESC members were given an NSDF Project overview presentation, which included alternative means assessment and site selection considerations. Members also visited the proposed NSDF Project site and had the opportunity to ask questions related to the NSDF Project.

See Stakeholder Engagement TSD 1 (CNL 2017a).
Stakeholder(s): Local elected officials, local environmental organizations and local NGOs.

4.2.1.3 World Nuclear University Site Visit – July 2016

The World Nuclear University is an organization that provides training to young professionals in the nuclear industry. The World Nuclear University brings an international industry perspective with participants from more than 20 countries.

Every year during its six-week summer session, the World Nuclear University arranges tours of the local nuclear institutions in the host country. In 2016, the World Nuclear University was hosted in Ottawa, and on July 15, 2016, 80 nuclear industry representatives / students toured CNL's Chalk River Laboratories (CRL) and Nuclear Power Demonstration (NPD) sites. Students were able to tour the NSDF Project site where subject matter experts presented on the proposed facility. Comment cards on the NSDF Project were provided to this group to receive international nuclear industry feedback.

See Stakeholder Engagement TSD 1 (CNL 2017a).
Stakeholder(s): Industry.

4.2.1.4 Non-governmental Organizations Site Visit – July 2016

Northwatch, the Canadian Environmental Law Association and the Concerned Citizens of Renfrew County represent three stakeholder groups interested in the environmental assessment activities for the NSDF Project. Northwatch and Canadian Environmental Law Association also participated in the CNSC request for comments on the NSDF Project description and provided their comments.

The group visited the NSDF Project site and had the opportunity to discuss their questions and concerns with subject matter experts.

See Stakeholder Engagement TSD 1 (CNL 2017a).
Stakeholder(s): NGOs.

4.2.1.5 Organization of Canadian Nuclear Industries Suppliers' Day – September 2016

On September 8, 2016, the Organization of Canadian Nuclear Industries Suppliers Day was held at the CRL site. This event was open to Organization of Canadian Nuclear Industries members and local non-member companies and provided an opportunity for CNL to engage representatives from more than 45 companies in the Canadian nuclear supply chain. A presentation on CNL decommissioning and waste management initiatives informed the industry participants about the plan for the NSDF Project.

See Stakeholder Engagement TSD 1 (CNL 2017a).
Stakeholder(s): Industry.

4.2.1.6 Nuclear Waste Management, Decommissioning and Environmental Restoration Conference Presentation – September 2016

At this industry conference, hosted by the Canadian Nuclear Society (CNS) and held in Ottawa, between September 11 and 14, 2016, a presentation on the NSDF Project was given. This presentation was an opportunity to inform, educate and receive feedback within the nuclear industry.

See Stakeholder Engagement TSD 1 (CNL 2017a).
Stakeholder(s): Industry, local elected officials.

4.2.1.7 Canadian Nuclear Society Site Visit – September 2016

A group of 19 individuals from the CNS Conference on Nuclear Waste Management, Decommissioning and Environmental Restoration visited the CRL site on September 15, 2016. The site visit provided an opportunity to elicit feedback on the NSDF Project from a cross-section of the nuclear industry. The site visit included a tour of the NSDF Project site.

See Stakeholder Engagement TSD 1 (CNL 2017a).
Stakeholder(s): Industry.

4.2.1.8 Environmental Stewardship Council Meeting – October 2016

On October 13, 2016, the ESC was briefed biodiversity findings and mitigation, archaeological findings, waste types and waste acceptance criteria, design updates and project schedule. Following these updates, members had the opportunity to seek clarification and raise any concerns they had with the NSDF Project.

See Stakeholder Engagement TSD 1 (CNL 2017a).
Stakeholder(s): Local elected officials, local environmental organizations and local NGOs.

4.2.1.9 Near Surface Disposal Facility Industry Day – November 2016

On November 8, 2016, the NSDF Project team hosted an industry day in Ottawa to introduce the NSDF Project and plans to construction companies so they could gain understanding of the NSDF Project and possible future construction opportunities.

See Stakeholder Engagement TSD 1 (CNL 2017a).
Stakeholder(s): Construction industry representatives.

4.2.1.10 Renfrew County Council Meeting, Presentation and Site Visit – December 2016

On December 12, 2016, CNL hosted the Renfrew County Council. The meeting included an overview presentation of CNL, as well as a specific presentation on the NSDF Project and a site tour. It provided an opportunity to offer updated information to council and answer questions.

See Stakeholder Engagement TSD 1 (CNL 2017a).
Stakeholder(s): Local elected officials.

4.2.1.11 Local Elected Officials Meeting and Presentation – December 2016

On December 12, 2016, CNL hosted the local elected officials for a site tour and presentation. The meeting included an overview presentation of CNL, as well as a specific presentation on the NSDF Project. It provided an opportunity to offer updated information to local elected officials and answer questions.

See Stakeholder Engagement TSD 1 (CNL 2017a).
Stakeholder(s): Local elected officials.

4.2.1.12 Ottawa Valley Economic Development Meeting – December 2016

The Ottawa Valley Economic Development Committee is composed of economic development officers from the local municipalities, as well key regional employers, for example, Canadian Forces Base Petawawa, CNL and Algonquin College. Ottawa Valley Economic Development holds bi-monthly meetings to discuss economic issues and opportunities throughout Ottawa Valley and Eastern Ontario. On December 15, 2016, CNL hosted a meeting which included a presentation on the NSDF Project.

See Stakeholder Engagement TSD 1 (CNL 2017a).
Stakeholder(s): Municipality, Industry.

4.2.1.13 Meeting and Project Briefing with Pontiac Member of Parliament – December 2016

At the request of the Pontiac Member of Parliament (MP), CNL attended a meeting at the MP's constituency office in Campbell's Bay, Quebec. The meeting, held on December 21, 2016, briefed the MP on the NSDF Project and enabled the MP to discuss the NSDF Project with CNL.

See Stakeholder Engagement TSD 1 (CNL 2017a).
Stakeholder(s): Local elected officials.

4.2.1.14 Technical Discussion Meeting – January 2017

A meeting to discuss technical aspects of the NSDF Project with former employees (alumni) and other members of the local scientific community was held on January 19, 2017, in Deep River, Ontario. This meeting was planned in response to a request from a local community member, who assisted in coordinating the discussion.

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Public within local community, industry.

4.2.1.15 Presentation and Meeting with Renfrew County Council – January 2017

On January 25, 2017, CNL representatives met with the Renfrew County Council. The meeting included more in-depth updates on the NSDF Project. It also provided CNL with an opportunity to answer questions.

See the Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Local elected officials.

4.2.1.16 Presentation to the Town of Deep River – January 2017

On January 25, 2017, CNL representatives presented to the Deep River Town Council at an open council meeting. The presentation was an overview of CNL activities with specific updates on the NSDF Project. It also provided an opportunity to answer questions from local government and members of the public.

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Local elected officials, public within the local and host communities.

4.2.1.17 Presentation to the Upper Ottawa Valley Chamber of Commerce – January 2017

On January 27, 2017, CNL representatives presented to the Upper Ottawa Valley Chamber of Commerce at the organization's annual general meeting in Pembroke, Ontario. The presentation was an overview of CNL activities with specific updates on the NSDF Project. It also provided an opportunity to answer questions from the local business community and share information on CNL's economic impact.

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Public within local and host communities.

4.2.1.18 Presentation to the Eastern Ontario Wardens' Caucus – January 2017

On January 31, 2017, CNL representatives attended the Rural Ontario Municipal Association conference and presented to the Eastern Ontario Wardens' Caucus on CNL's activities, with a specific look at the NSDF Project. It led to a presentation to the United Counties of Prescott Russell in February 2017.

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Local elected officials.

4.2.1.19 Presentation to the United Counties of Prescott Russell – February 2017

CNL representatives attended the United Counties of Prescott and Russell's council meeting, by invitation, on February 8, 2017. The presentation included an overview of CNL, with a focus on the NSDF Project and the NPD Closure Project.

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Local elected officials, media.

4.2.1.20 Presentation to Pontiac Regional County Municipality – February 2017

CNL representatives attended the council meeting of the Pontiac Regional Municipal Council (*Municipalité régionale de comté* [MRC]) on February 14, 2017. The presentation included an overview of CNL, with a focus on the NSDF Project and the NPD Closure Project.

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Local elected officials.

4.2.1.21 Environmental Stewardship Council Meeting – March 2017

On March 23, 2017, one of the three annual ESC meetings was held. Members were briefed on highlights of the draft EIS submission, design progress and next steps, waste inventory and waste acceptance criteria. Following these updates, members had the opportunity to seek clarification and raise any concerns they had with the NSDF Project.

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Local elected officials, local environmental organizations and local NGOs.

4.2.1.22 Sheenboro Municipal Council Meeting and Presentation – April 2017

CNL representatives attended the Municipality of Sheenboro's council meeting on April 3, 2017. The presentation included an overview of CNL, with a focus on the NSDF Project and the NPD Closure Project.

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Local elected officials, members of the public.

4.2.1.23 Pembroke City Council Meeting and Presentation – April 2017

CNL representatives attended the City of Pembroke's council meeting on April 18, 2017. The presentation included an overview of CNL, with a focus on the NSDF Project and the NPD Closure Project.

See the Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Local elected officials, members of the public.

4.2.1.24 Laurentian Hills Town Council Meeting and Presentation – April 2017

CNL representatives attended the Town of Laurentian Hill's council meeting on April 19, 2017. The presentation included an overview of CNL, with a focus on the NSDF Project and the NPD Closure Project.

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Local elected officials, members of the public.

4.2.1.25 Arnprior Town Council Meeting and Presentation – April 2017

CNL representatives attended the Town of Arnprior's council meeting on April 24, 2017. The presentation included an overview of CNL, with a focus on the NSDF Project.

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Local elected officials, members of the public.

4.2.1.26 Petawawa Town Council Meeting and Presentation – May 2017

CNL representatives attended the Town of Petawawa's council meeting on May 1, 2017. The presentation included an overview of CNL, with a focus on the NSDF Project and the NPD Closure Project.

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Local elected officials, members of the public.

4.2.1.27 L'Isle-Aux-Allumettes Town Council Meeting and Presentation – May 2017

CNL representatives attended the Town of L'Isle-Aux-Allumette's council meeting on May 2, 2017. The presentation included an overview of CNL, with a focus on the NSDF Project and the NPD Closure Project.

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Local elected officials, members of the public.

4.2.1.28 Environmental Stewardship Council Meeting – June 2017

On June 22, 2017, the ESC was briefed on CNSC/CNL administrative protocol update, review of alternative means, NSDF benchmarking, biodiversity and archeological field activities, communication and engagement activities. Members were also given a second presentation detailing the NSDF waste acceptance criteria. Following these updates, members had the opportunity to seek clarification and raise any concerns they had with the NSDF Project.

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Local elected officials, local environmental organizations and local NGOs.

4.2.1.29 Pontiac Regional County Municipality Council Site Visit – July 2017

On July 11, 2017, the MRC Pontiac council visited the CRL site and had a presentation on the NSDF Project and site visit. Following the presentation and tour, members had the opportunity to seek clarification and raise any concerns they had with the NSDF Project.

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Local elected officials.

4.2.1.30 Old Fort Williams Cottagers' Association Meeting and Presentation – July 2017

On July 15, 2017, CNL staff gave a presentation on the NSDF Project to members of the Old Fort Williams Cottagers' Association. Following the presentation, members had the opportunity to seek clarification and raise any concerns they had with the NSDF Project.

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Concerned members of the public.

4.2.1.31 Bloc Québécois Leader Mme Ouellette Presentation and Site Visit – August 2017

On August 10, 2017, Mme Ouellette came to the CRL site for a CNL overview presentation with a focus on the NSDF Project and NPD Closure Project. Following the presentation, Mme Ouellette had a tour of site and had the opportunity to seek clarification and raise any concerns the Bloc Québécois had with the NSDF Project. A reporter with the Canadian Press also attended and reported on the meeting.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Elected official, media.

4.2.1.32 Nuclear Energy Agency Presentation and Site Visit – October 2017

On October 3, 2017, Nuclear Energy Agency staff came to the CRL site for a CNL overview presentation with a focus on the NSDF Project and NPD Closure Project. They had a tour of site and the opportunity to seek clarification and raise any concerns they had with the NSDF Project.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Nuclear industry.

4.2.1.33 Environmental Stewardship Council Meeting – October 2017

On October 26, 2017, the ESC was briefed on the NSDF design completion, and the removal of Intermediate Level Waste from the NSDF. A second presentation was giver to members on the proposed valued components of the NSDF Project. During this meeting, members took a walking tour of the Chalk River campus to gain an understanding of the buildings that would be demolished and destined for the prosed NSDF if they meet the new waste acceptance criteria. Following these updates, members had the opportunity to seek clarification and raise any concerns they had with the NSDF Project.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Local elected officials, local Indigenous Peoples, local environmental organizations and local NGOs.

4.2.1.34 Take Our Kids to Work Day – November 2017

CNL participates annually in Take Our Kids to Work Day for students in grade nine to introduce them to different careers and areas of work. Approximately 80 students come to the CRL site. On November 1, 2017, a presentation and tour component were included about the NSDF Project.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Employees, general public (students).

4.2.1.35 Ottawa Riverkeeper Presentation and Site Tour – November 2017

On November 16, 2017, Ottawa Riverkeeper, a charitable organization advocating for the Ottawa River watershed, came to the CRL site for a tour with presentations on the NSDF Project. Attendees had the opportunity to seek clarification and raise any concerns they had with subject matter experts available to answer their questions.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Local environmental organizations.

4.2.1.36 Near Surface Disposal Facility Technical Discussion Meeting Day 1 – December 2017

A meeting to discuss technical aspects of the NSDF Project with former employees (alumni) and other members of the local scientific community was held on December 6, 2017, in Deep River, Ontario. This meeting was planned in response to a request from a local community member, who assisted in coordinating the discussion.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Concerned public, industry, alumni, elected officials.

4.2.1.37 Near Surface Disposal Facility Technical Discussion Meeting Day 2 – December 2017

A meeting to discuss technical aspects of the NSDF Project with former employees (alumni) and other members of the local scientific community was held on December 14, 2017, in Deep River, Ontario. This meeting was planned in response to a request from a local community member, who assisted in coordinating the discussion.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Concerned public, industry, alumni, elected officials.

4.2.1.38 Meeting with Hull-Aylmer Member of Parliament Greg Fergus – February 2018

At the request of MP Fergus, NSDF Project staff met with him on February 26, 2018, to discuss the NSDF Project. This gave him the opportunity to gain understanding of the NSDF Project and seek clarification on issues his constituents had brought up to him.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Government officials.

4.2.1.39 Town Hall with Hull-Aylmer Member of Parliament Greg Fergus – March 2018

At the request of MP Fergus, CNL staff presented at a town hall meeting in Gatineau on March 5, 2018. This gave Gatineau constituents the opportunity to gain understanding of the NSDF Project and seek clarification on areas they had concerns with.

See Stakeholder Engagement TSD 3 (CNL 2019).
Stakeholder(s): Government officials, members of the public.

4.2.1.40 Nuclear Footprints Program Presentation and Site Tour – March 2018

As a part of an international program, participants travelled to different nuclear facilities in Canada to learn about Canada's nuclear industry. Participants had a tour and presentation on March 6, 2018, to discuss the NSDF Project. On March 7, 2018, the participants had a breakfast panel with local elected officials and members of CNL staff to further discuss the projects and gain perspective from host community leaders.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): International industry, local elected officials.

4.2.1.41 Member of Ontario Provincial Parliament John Yakabuski Site Visit – April 2018

MPP Yakabuski attended a meeting at the Deep River offices of CNL on April 3, 2018, to learn about the NSDF Project and NPD Closure Project. He had the opportunity to speak directly with subject matter experts about concerns constituents had raised to him and gain understanding of the projects and CNSC processes that are being adhered to for the proposed projects.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Government official.

4.2.1.42 Member of Parliament Will Amos Site Visit – April 2018

MP Amos attended the CRL site on April 4, 2018, to learn about the NSDF Project and NPD Closure Project. He had the opportunity to tour the NSDF Project site and speak directly with subject matter experts about concerns constituents had raised to him. He also had the opportunity to gain understanding of the projects and CNSC processes that are being adhered to for the proposed projects.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Government official.

4.2.1.43 Environmental Stewardship Council Meeting – April 2018

On April 5, 2018, the ESC was briefed on the updated NSDF Project schedule, completion of stage 3 and 4 archeological assessments, design improvements based on feedback and key stakeholder issues relevant to the NSDF performance assessment. Following these updates, members had the opportunity to seek clarification and raise any concerns they had with the NSDF Project.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Local elected officials, local environmental organizations and local NGOs.

4.2.1.44 Canadian Nuclear Workers Council (CNWC) Presentation – June 2018

On June 19, 2018, members of the CNWC (collective voice of organized labour in Canada's Nuclear Industries) were given a presentation on the NSDF Project. Following the presentation, members had the opportunity to seek clarification and raise any concerns they had with the NSDF Project.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Industry.

4.2.1.45 Environmental Stewardship Council Meeting – June 2018

On June 21, 2018, the ESC was briefed on common themes identified from the federal and public comments submitted on the draft EIS, these included proximity to the river, waste acceptance criteria, international standards, facility design and follow-up monitoring programs. During this presentation, an ESC action was addressed on comparing the NSDF to similar facilities that have been capped/closed for over ten years. Following these updates, members had the opportunity to seek clarification and raise any concerns they had with the NSDF Project.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Local elected officials, local environmental organizations and local NGOs.

4.2.1.46 Eastern Ontario Water Works Association Conference – October 2018

On October 24, 2018, CNL staff attended the Eastern Ontario Water Works Association Conference to present on the NSDF Project and the NPD Closure Project. The presentation offered attendees information about both projects and the opportunity to gain understanding of what is being proposed as well as opportunity to ask questions.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Municipal water works professionals.

4.2.1.47 Environmental Stewardship Council Meeting – October 2018

On October 18, 2018, the ESC was briefed on the NSDF Project timeline and planning basis, treated effluent transfer design with a review of considerations and benefits of the proposed change. Following these updates, members had the opportunity to seek clarification and raise any concerns they had with the NSDF Project.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Local elected officials, local environmental organizations and local NGOs.

4.2.1.48 Carleton University Journalism Master's Students Presentation and Site Visit – November 2018

On November 28, 2018, two master's students, who were writing a piece for the media, from Carleton University were given a CNL overview presentation with a focus on the NSDF Project and the NPD Closure Project. Following the presentations, the students went on a site tour and had the opportunity to seek clarification and raise any concerns they had with the projects.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Academia (media).

4.2.1.49 Warden Jane Toller and Pontiac Regional County Municipality Staff Presentation and Site Visit – December 2018

On December 11, 2018, Warden Jane Toller and MRC Pontiac staff were given a CNL overview presentation with a focus on the NSDF Project and the NPD Closure Project. Following the presentations, they went on a site tour and had the opportunity to seek clarification and raise any concerns they had with the NSDF Projects.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Local elected officials.

4.2.1.50 Renfrew and Pontiac Counties Elected Officials Information Day – February 2019

On February 15, 2019, local elected officials from both Renfrew and Pontiac counties were invited to the CRL site for updates and presentations on CNL and the NSDF Project and NPD Closure Project. Officials were also invited to tour the CRL site. Throughout the day, officials had the opportunity to seek clarification and raise any concerns they had with the projects and ask questions about CNL.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Local elected officials.

4.2.1.51 Meeting with Representatives of the Government of Quebec – February 2019

On February 28, 2019, CNL staff from the NSDF Project and the NPD Closure Project went to Quebec City to meet with representatives from the Government of Quebec to discuss the NSDF Project and NPD Closure Project. Throughout the day, representatives had the opportunity to seek clarification and raise any concerns they had with the projects.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Government of Quebec officials.

4.2.1.52 Carleton University Civil and Environmental Engineering Students Presentation and Site Tour – March 2019

On March 8, 2019, students from Carleton University visited the CRL site for a tour and presentations on CNL and the NSDF Project and NPD Closure Project. Throughout the day, the students had the opportunity to seek clarification and raise any concerns they had with the projects and ask questions about CNL.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Academia (engineering students).

4.2.1.53 Environmental Stewardship Council Meeting – March 2019

On March 28, 2019, the ESC was briefed on geomembrane testing program, enabling activities including the final archeological assessment and turtle road mortality plan. During this presentation two ESC actions were covered on the revised NSDF study area and the detailed inventory of the NSDF. ESC members were the first audience for the NSDF water video which detailed how risk from precipitation would be mitigated. Following these updates, members had the opportunity to seek clarification and raise any concerns they had with the NSDF Project.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Local elected officials, local environmental organizations and local NGOs.

4.2.1.54 Breakfast Briefing – April 2019

Bi-monthly Breakfast Briefings were introduced in 2019 April. The Breakfast Briefings offer an opportunity for Alumni and interested members of the public to gain a further technical understanding of the NSDF Project. On April 24, 2019, the NSDF team presented on *Factors affecting radioactive waste disposal decisions,* and attendees had the opportunity to seek clarification and raise any concerns they had with NSDF Project subject matter experts.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Alumni, Interested members of the public, local elected officials.

4.2.1.55 Presentation to Laurentian Valley Township Council – May 2019

On May 07, 2019, project staff attended the Laurentian Valley Township's council meeting and gave a presentation on the NSDF project. Council members had the opportunity to seek clarification and raise any concerns they had with the NSDF Project.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Local elected officials.

4.2.1.56 NSDF Effluent Discharge Alternatives Focus Group – May 2019

On May 10, 2019, CNL invited members of different interest groups to participate in a focus group discussing effluent discharge alternatives for the proposed NSDF. Members input and discussion was used to determine options and path forward for the proposed effluent discharge options analysis process.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Alumni, local environmental organizations.

4.2.1.57 Hill Times Journalist Presentation and Site Visit – May 2019

On May 27, a journalist from the Hill Times was given an overview presentation with a focus on the proposed NSDF Project. Following the presentation, the journalist had the opportunity to interview project staff for a piece and had the opportunity to seek clarification and ask any questions he had about the NSDF Project.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Media.

4.2.1.58 Moderated Forum with City of Gatineau Councillor Duggan – May 2019

On May 30, at the invitation of Mike Duggan, City Councillor for the City of Gatineau, CNL attended a moderated forum for the public in Gatineau, Quebec, to share information about CNL, in particular, the proposed NSDF and the NPD Closure Project. Council members and members of the public had the opportunity to seek clarification and raise any concerns they had with the NSDF Project. NSDF Project subject matter experts were in attendance.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Members of the public, elected officials

4.2.1.59 Environmental Stewardship Council Meeting – June 2019

On June 20, 2019, the ESC was briefed on ESC actions that had been addressed. They were then given project update, project justification and CRL clean-up plan presentations. Following these updates, members had the opportunity to seek clarification and raise any concerns they had with the NSDF Project.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Local elected officials, local environmental organizations and local NGOs.

4.2.1.60 Breakfast Briefing – June 2019

The bi-monthly Breakfast Briefings offer an opportunity for Alumni and interested members of the public to gain a further technical understanding of the NSDF Project. On June 26, 2019, Dr. Kerry Rowe (Queen's University) presented on *A barrier system for a 550 design life,* and attendees had the opportunity to seek clarification and raise any concerns they had with NSDF Project subject matter experts.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Alumni, Interested members of the public.

4.2.2 Webinars

Beginning in October 2018, webinar sessions were introduced as another way to increase accessibility and to disseminate information to the public and answer their questions (Table 4.2.2-1). Webinars are the evolution of the Public Information Sessions (see Section 4.2.2.1), as turnout to the face to face poster sessions was limited. CNL remains available to provide a community based public information session when there is an expressed interest from stakeholders. The webinars were conducted from the CRL site, but they were accessible to anyone with internet access. The webinar updates were designed to provide an overview and quarterly updates of the NPD Closure Project and the NSDF Project. They provided updated information and addressed questions from the public, based on the themes from public review of the draft EIS. Webinar sessions also provided access for members of the public to ask their questions directly to the staff members taking part in the webinar through an online forum. Beginning in March 2018 webinars were conducted in both official languages. All videos were uploaded to the CNL YouTube channel after broadcast.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): General public

Table 4.2.2-1: Webinars on the Near Surface Disposal Facility Project to Date

Date	NSDF/NPD	NSDF Topics
October 17, 2018	NSDF/NPD	▪ Engineering and Design ▪ Waste Acceptance Criteria ▪ Long-term Performance ▪ Protection of the Ottawa River
March 20, 2019	NSDF/NPD	▪ Justification for the NSDF Project ▪ Proposed Inventory ▪ Geomembrane Performance ▪ Archeological Significance

4.2.2.1 Public Information Sessions

Public information sessions were conducted in June/July 2016, October 2016 and April/May 2017 to help CNL inform, educate and solicit feedback from members of the local and host communities surrounding the NSDF Project site.

The topics presented at the public poster board sessions began with a description of the NSDF Project and facility (including an area map), the proposed NSDF Project timeline, Valued Components (VCs) (soliciting feedback from visitors on which VCs are important to them) and an overview of the environmental assessment process and regulatory approvals required.

As sessions progressed and feedback was received, the poster boards and presentation materials were developed to address the questions and concerns that were heard and to present the additional NSDF Project information that was available. For example, to-scale model tubes depicting the base layers and top cover layers of the engineered containment mound were created to help the public visualize what the layers will be. A significant effort was made to share updated information that responded to specific areas of interest and to provide a broader context of how the NSDF Project fits into CNL's overarching goals.

Subject matter experts in different areas of interest such as groundwater monitoring, species at risk and project design were available at the sessions to answer questions and engage in one-on-one dialogue with event guests. See Stakeholder Engagement TSD 3 (CNL 2019a) for a complete list of subject matter experts.

The locations of the public information sessions were chosen based on proximity to the NSDF Project site and population size, with a few sessions also added in specific locations where they were requested. Dates and locations of public information sessions are summarized in Table 4.2.2-2.

Table 4.2.2-2: Public Information Session Dates and Locations

Date	Location	Date	Location
June 20, 2016	Rapides-des-Joachims	October 26, 2016	Chalk River
June 21, 2016	Deep River	October 27, 2016	Petawawa
June 22, 2016	Stonecliffe	April 20, 2017	Deep River
June 29, 2016	Sheenboro	April 24, 2017	Stonecliffe
July 6, 2016	Pembroke	April 25, 2017	Chalk River
July 7, 2016	Petawawa	April 26, 2017	Rapides-des-Joachims
July 12, 2016	Chalk River	May 1, 2017	Petawawa
October 17, 2016	Rapides-des-Joachims	May 2, 2017	Sheenboro
October 18, 2016	Deep River	May 3, 2017	Pembroke
October 19, 2016	Stonecliffe	May 9, 2017	Arnprior

See Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): Local and host communities, local elected officials.

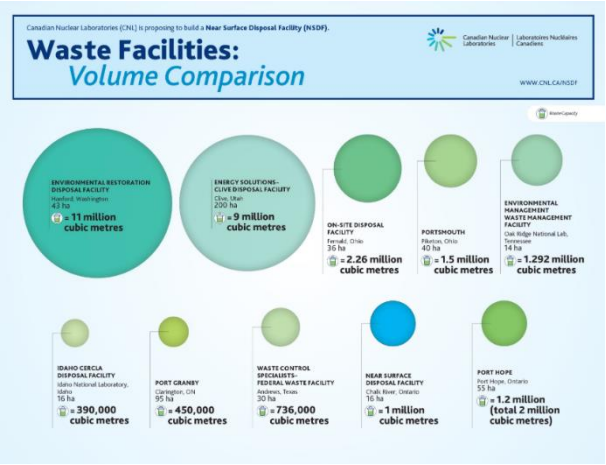
4.2.2.2 Poster Boards

The poster boards were created with content specific to the NSDF Project. They were developed with the intent to educate and prompt discussion about the NSDF Project. The poster boards were used to support tactics such as presentations, public information sessions, employee information sessions, site visits and public events.

Throughout the iterations of the information sessions CNL created several new informational poster boards with updated information to share with the local communities. The posters were set out to describe the narrative of why CNL is planning the NSDF Project and how CNL is proposing to execute the NSDF Project. As the NSDF Project evolved the content of the poster boards also evolved to convey updated information and address different issues as they became prevalent as areas of concern for the public. The poster boards were a versatile tactic used in conjunction with other tactics such as presentations, videos, visual and tactile examples. The poster boards have been used during public information sessions, the employee information sessions, site visits and community events, such as the Petawawa Showcase.

Poster board topics included:

- CRL site revitalization;
- What will the facility look like?
- a safe solution;
- the EIS;
- proposed waste solution;
- disposal site selection;
- safe by design;



- waste streams;
- cultural resource management;
- What you told us;
- CNL protecting the environment;
- CNL regulatory oversight;
- Project description;
- disposal facility graphic representation;
- proposed disposal facility locations;
- VCs;
- biodiversity; and
- What is an environmental assessment?

See the Stakeholder Engagement TSD 2 (CNL 2017b).
Stakeholder(s): General public

4.2.2.3 Communications Materials at Public Information Sessions

Communications materials at the public information sessions were provided in several formats:

- informational poster boards;
- Project factsheets/infographics;
- Project description;
- environmental monitoring reports;
- informational videos;
- visual aids (to scale tubes, sample pieces of liners); and
- feedback forms.

Example of a Near Surface Disposal Facility Infographic

4.2.3 Employee Engagement

To reach internal stakeholders, a variety of tactics were employed to disseminate information to employees, including employee information sessions, articles and videos on myCNL (intranet site), all-staff meetings and presentations held for the NSDF Project.

Stakeholder(s): Employees.

Canadian Nuclear Laboratories Staff Member Answering Questions at an Internal Information Session

4.2.3.1 Employee Information Sessions – June 2016

On June 21 and 24, 2016, employee information sessions were held in Deep River and at the CRL site, respectively, for employees to learn about the NSDF Project and NPD Closure Project. These internal events were similar to the public information sessions, with the same communications products used and a similar level of access with subject matter experts for the NSDF Project.

See Stakeholder Engagement TSD 2 (CNL 2017b).

4.2.3.2 Employee Information Sessions – November 2016

On November 16 and 17, 2016, employee information sessions were held in Deep River at the CRL site, respectively, for employees to learn about the NSDF Project and NPD Closure Project. These internal events were similar to the public information sessions, with the same communications products used and a similar level of access with subject matter experts for the NSDF Project.

See Stakeholder Engagement TSD 2 (CNL 2017b).

4.2.3.3 Canadian Nuclear Laboratories All-Staff Meeting – March 2017

On March 28, 2017, CNL hosted an all-staff meeting in the CRL cafeteria with live feeds to all other site locations to present to staff about the NSDF Project. Following the presentation, members of staff had the opportunity to seek clarification and raise any concerns they had with the NSDF Project.

See Stakeholder Engagement TSD 2 (CNL 2017b).

4.2.3.4 myCNL TV – Near Surface Disposal Facility – May 2018

In a similar fashion to the webinars (Section 4.2.2.1), on May 18, 2018, a broadcast was done through the CNL intranet to provide staff with an update on the NSDF Project. Staff had the opportunity to gain understanding of the NSDF Project and send in questions to be answered during the broadcast.

See Stakeholder Engagement TSD 3 (CNL 2019a).

4.2.3.5 Near Surface Disposal Facility 3-D Model – February 2019

A 3-D model of the NSDF Project site was built and put on display on the CRL site along with informational banners and a video to increase staffs understanding of the NSDF Project.

See Stakeholder Engagement TSD 3 (CNL 2019a).

4.2.3.6 New Employee Orientation – On-going

All CNL employees take part in a week-long orientation when they start their roles. As a part of the orientation, a presentation is given that introduces three major projects (one being the NSDF Project) to the employees. This gives new employees a firsthand introduction to the projects and the ability to ask any questions they have directly.

4.2.4 Community Events and Conferences

One tactic to support the stated communications objectives of initiating two-way communications and informing and educating was to have CNL representatives attend community events local to the NSDF Project site as well as industry conferences to expand the reach of stakeholders beyond the local community. Attendance at each event is described in the following sections.

Stakeholder(s): General public, local elected officials, industry, local environmental organizations and local NGOs.

4.2.4.1 Rotary Club of North Renfrew – Annual Dinner – July 2016

CNL was invited to present at the Rotary Club of North Renfrew's Annual Dinner. The President and CEO presented on CNL's Vision 2026 with a focus on the NSDF Project on July 20, 2016. There were no questions and comments related to the NSDF Project.

See the Stakeholder Engagement TSD 1 (CNL 2017a).

4.2.4.2 Petawawa Showcase – September 2016

CNL attended Petawawa Showcase September 23 – 25, 2016. It is the Ottawa Valley's largest spring and fall home, consumer and leisure show in September. The event drew approximately 10,000 visitors from across the Ottawa Valley and western Quebec. To ensure visibility, CNL secured a 20 by 20-foot exhibitor space. Informational posters on the NSDF Project were displayed and subject matter experts described NSDF Project activities, facilitated discussion about the NSDF Project and responded to public inquiries.

4.2.4.3 Canadian Nuclear Association Annual Conference – February 2017

CNL has a presence at the Canadian Nuclear Association conference every year. At the conference held on February 22 – 24, 2017, CNL had information on the company and both the NSDF Project and NPD Closure Project on interactive touch screens, as well as informational handouts on both projects at the booth.

4.2.4.4 Petawawa Showcase – April 2017

On April 28 – 30, 2017, CNL had an exhibit booth at Petawawa Showcase. CNL annually attends Spring Showcase, as it is one of the largest community events in the Ottawa Valley. The event gives CNL a direct means to discuss CNL and the NSDF Project and NPD Closure Project with members of the general public who otherwise may not engage with the company. General questions, concerns and rumours can be addressed directly with those who have an interest.

4.2.4.5 Canadian Nuclear Society Annual Conference – June 2017

CNL has a presence at the CNS conference every year. At the conference held on June 4 – 7, 2017, CNL had information on the company and both the NSDF Project and NPD Closure Project on interactive touch screens, as well as informational handouts on both projects at the booth.

4.2.4.6 Canadian Nuclear Laboratories Open House – August 2017

On August 12, 2017, CNL hosted an Open House on the CRL site. The Open House had over 2,000 people register and as a part of the day presentations and site tours of the NSDF Project site were offered. Interested attendees could learn about the NSDF Project, see the proposed site and seek clarification from subject matter experts.

4.2.4.7 Renfrew County Plowing Match – September 2017

On September 16, 2017, CNL attended the Renfrew County Ploughing Match. Interested attendees could learn about the NSDF Project and seek clarification from subject matter experts with regard to their concerns. Additionally, informational handouts were available at the booth.

4.2.4.8 Canadian Nuclear Association Annual Conference – February 2018

CNL has a presence at the Canadian Nuclear Association conference annually. At the conference on February 21 – 23, 2018, CNL had information on both the NSDF Project and NPD Closure Project on interactive touch screens, as well as informational handouts at the booth.

4.2.4.9 Waste Management Symposium – March 2018

On March 18 – 22, 2018, CNL attended the Waste Management Symposium and had information on CNL and both the NSDF Project and NPD Closure Project on informational handouts at the booth. Subject matter experts also attended to discuss the projects as part of conference sessions. A paper titled "*Identification of Waste Streams and Chemicals of Concern for CNL's Near Surface Disposal Facility"* was presented as a part of the conference proceedings.

4.2.4.10 Petawawa Showcase – April 2018

On April 27 – 29, 2018, CNL had an exhibit booth at Petawawa Showcase. CNL annually attends Spring Showcase, as it is one of the largest community events in the Ottawa Valley. The event gives CNL a direct means to discuss CNL and the projects with members of the general public who otherwise may not engage with the company. General questions, concerns and rumours can be addressed directly with those who have an interest.

4.2.4.11 CNL Downtown Connect Pembroke – May 2018

On May 11 – 12, 2018, CNL had an exhibit booth at Downtown Connect Pembroke. CNL annually attends Downtown Connect as it is one of the largest community events in the Ottawa Valley. CNL The event gives CNL a direct means to discuss CNL and the projects with members of the general public who otherwise may not engage with the company. General questions, concerns and rumours can be addressed directly with those who have an interest.

4.2.4.12 Canadian Nuclear Society Annual Conference – June 2018

CNL has a presence at the CNS conference every year. At the conference held on June 3 – 7, 2018, CNL had information on the company and both the NSDF Project and NPD Closure Project on interactive touch screens, as well as informational handouts on both projects at the booth.

4.2.4.13 Canadian Nuclear Association Annual Conference – February/March 2019

CNL has a presence at the Canadian Nuclear Association conference annually. At the conference on February 28 – March 02, 2019, CNL had information on both the NSDF Project and NPD Closure Project on interactive touch screens, as well as informational handouts at the booth.

4.2.4.14 Near Surface Disposal Facility 3-D Model – February/March 2019

A 3-D model of the NSDF Project site was built and put on display in the Deep River Town Hall for two weeks along with informational banners and a video to give members of CNL's "host community" more information on the NSDF Project. At the Deep River location, NSDF Project staff were available Monday to Friday during lunch hours.

4.2.4.15 Near Surface Disposal Facility 3-D Model – March/April 2019

A 3-D model of the NSDF Project site was built and put on display in the Laurentian Valley for two weeks along with informational banners and a video to give community members more information on the NSDF Project.

4.2.4.16 NSDF 3D Model – May 2019

A 3-dimensional model of the proposed NSDF and proposed CRL site location was constructed and put on display in the Town of Petawawa office for two weeks along with informational banners and a video to give community members more information on the NSDF Project.

4.2.4.17 Downtown Connect Pembroke – May 2019

On May 10 – 11, 2019, CNL had an exhibit booth at Downtown Connect Pembroke. CNL annually attends Downtown Connect Pembroke as it is one of the largest community events in the Ottawa Valley. It gives CNL a direct means to discuss CNL and the proposed NSDF Project with members of the general public that otherwise may not engage with us. General questions, concerns and rumours can be addressed directly with those that have an interest.

4.2.4.18 Canadian Nuclear Society (CNS) Conference – June 2019

CNL has a presence at the CNS conference every year. At the conference held on June 23 – 27, 2019, CNL had information on the company and both the NSDF Project and NPD Closure Project on interactive touch screens, as well as informational handouts on both projects at the booth. CNL

4.2.5 Webpage Content

CNL has established a Project-specific webpage: www.cnl.ca/NSDF. Quick links have been added to the landing page, raising Project visibility and making it easier to access the appropriate pages. Since August 2016, updated information has been added to the NSDF Project webpage, and webpage activity continues to be tracked and analyzed using Google Analytics.

See Stakeholder Engagement TSD 3 (CNL 2019a).

The webpage has been updated with new content as it becomes available. Frequently asked questions, Project infographics, informational videos, a Project description, the draft EIS, poster boards, quick facts, the Project timeline and public comments on the draft EIS broken down into themes have all been added to the NSDF Project webpage.

In an effort to improve EIS supporting document access and transparency CNL continues to post key EIS technical support documents and any revisions and updates to these documents as they become available. In addition, starting March 2019 CNL has committed to posting all external project presentations to the NSDF Project webpage.

On the NSDF Project webpage, there are mechanisms for the user to share feedback on the NSDF Project through an online submission form and a “mailto” hyperlink that sends an email into the CNL Corporate Communications general mail box. All submissions are recorded as a part of public feedback and receive a reply from a CNL representative.

See Stakeholder Engagement TSD 3 (CNL2019a).
Stakeholder(s): All stakeholders.

4.2.6 Infographics/Fact Sheets

Two infographics, or fact sheets, were created and made available online and in hard copy to better convey information in a succinct digestible format for members of the public. The first was 10 facts about the proposed NSDF and the second was a volume comparison to put the proposed amount of waste in perspective.

The infographics are published on the webpage and has been used at Public Information Sessions, Open Houses, and many other community events. The NSDF Project infographics have proven to be an effective method for relaying some technical aspects of the NSDF Project in a simplistic format that the general public can understand.

In addition, copies of the fact sheets have been sent to seven local municipal offices to function as an information repository, as recommended by the CSA (CSA Group 2014), and to support greater awareness in local host communities.

See Stakeholder Engagement TSD 1 (CNL 2017a) and TSD 3 (CNL 2019a).
Stakeholder(s): All stakeholders.

4.2.7 Newsletters

CNL’s *Voyageur* newsletter is an internal newsletter that is distributed across all CNL sites monthly. When applicable, NSDF Project updates and articles have been included. The newsletter is available in hard copy and through the CNL intranet site.

See Stakeholder Engagement TSD 3 (CNL 2019a).
Stakeholder(s): Employees.

CNL’s *CONTACT* newsletter is published and mailed to approximately 55,000 residences in the Renfrew and Pontiac counties and is available on www.cnl.ca. This publication informs the reader on activities undertaken at CNL’s various sites and profiles CNL’s community activities.

The Summer 2016 issue of *CONTACT* focused on CNL’s major projects, including the NSDF Project, and related environmental assessment activities.

Each subsequent newsletter has had a NSDF Project update included in it.

See the Stakeholder Engagement TSD 1 (CNL 2017a) and TSD 3 (CNL2019a).
Stakeholder(s): Local and host communities.

4.2.8 Email

Emails have been used to connect with internal and external stakeholders, as well as with NGOs. In particular, emails were sent out to promote different events, to advise of the public comment period on the draft EIS and to provide responses to questions submitted electronically. Stakeholders are encouraged to be added to an email distribution list to receive notices of upcoming events related to NSDF (webinars, breakfast briefings, etc.).

See the Stakeholder Engagement TSD 3 (CNL2019a).
Stakeholder(s): Local and host communities, local elected officials, media, Indigenous Peoples.

4.2.9 Advertising

As different events and engagement opportunities were planned, CNL utilized advertising to announce and increase awareness of the events. Advertising is undertaken in specific regions that would have an interest due to their proximity to the CRL site. Different forms of advertising have been utilized to reach the interested public through their preferred method of intake.

4.2.9.1 Advertising Methods

- advertisements posted on CNL.ca landing page and the Project-specific webpage (www.cnl.ca/nsdf);
- advertisements included in online version of CNL's *Contact* newsletter when applicable;
- newspaper advertisements (see Table 4.2.9-1 for circulation of main newspapers utilized);
- radio advertisements – CNL has dedicated public service announcement spots on Star 96.7, when applicable, it was used to advertise specific project events; and
- paid Facebook advertising via a "boosted post" (see Section 4.2.9).

Table 4.2.9-1: Newspaper Circulation Numbers

Newspaper	Circulation
North Renfrew Times	4,000
Pontiac Journal (bi-weekly)	9,400
Shawville Equity	4,046
The Valley Gazette	2,300
Eganville Leader	6,200
Renfrew Mercury	13,394
Arnprior Chronicle	8,130
Petawawa Post	13,225
The News	29,000
Daily Observer	3,000
Flyer Insert	30,000

4.2.9.2 Public Service Announcements

CNL has had dedicated spots on the local radio station, Star 96.7, based in Pembroke, ON, for over 10 years. CNL utilizes these to promote local events and not-for-profit organizations; however, when there are events such as public information sessions, public service announcements are used for advertising. The public service announcements run on the radio station four times a day and reach an average of 35,000 listeners.

See Stakeholder Engagement TSD 3 (CNL 2019a).

4.2.9.3 Intranet – myCNL

The internal website has been used to communicate with internal stakeholders with updates on the NSDF Project and publicizing events related to the NSDF Project. Updates and events on the NSDF Project were shared on myCNL to educate, inform and provide updates on the NSDF Project to employees.

See Stakeholder Engagement TSD 3 (CNL 2019a).

4.2.10 Social Media

Social media is used to inform, educate, promote awareness for all CNL activities including NSDF Project events and to receive feedback on the NSDF Project. CNL has used web-based analytics to determine how online users utilize different CNL company social media platforms. This enables CNL to assess which platforms are more effective in engaging the largest audience (followers) and the widest geographic reach (location) while also evaluating the overall usefulness of social media as a medium of public dialogue. Seven videos covering topics such as “why the NSDF?”, “responsible water management” and NSDF Project updates have been uploaded to YouTube. The videos have been added in an effort to make information and technical information more accessible. Facebook is CNL’s largest platform, where the company sees the strongest engagement through “comments, shares and likes” of posts. When CNL wished to raise the profile of project events or information, “boosted” posts were used to target by location and demographics. “Boosted” posts are paid posts through Facebook. Twitter has not been used as broadly as Tweets have been found to receive very little traction, and CNL has a comparatively much larger Facebook following. While numbers are significantly larger on LinkedIn, the demographics are far more industry based, rather than general public. Therefore, CNL utilizes LinkedIn, but in a much lower capacity than Facebook to ensure engagement is a balanced approach with general public in comparison to those actively part of the nuclear industry. See Table 4.2.10-1 for follower/subscriber numbers.

CNL’s social media channels continue to gain followers and build communication through multiple social media accounts, including recently adding an Instagram account.

Table 4.2.10-1: Canadian Nuclear Laboratories Social Media Account Details

Social	Link	Followers
Facebook	www.facebook.com/CanadianNuclearLaboratories	3,306
Twitter	www.twitter.com/CNL_LNC	1,046
YouTube	www.youtube.com/channel/UC2GCEfZQgsURh4t_QZ-JwCw	271
Instagram	www.instagram.com/canadiannuclearlaboratories/	147
LinkedIn	www.linkedin.com/company/canadian-nuclear-laboratories/	10,296

Followers as of October 28, 2019.

See Stakeholder Engagement TSD 3 (CNL 2019a).

4.2.11 Media

During the summer of 2017 coverage of the NSDF Project grew significantly with detractors of the project gaining traction in their messaging. However, CNL began actively utilizing a “detect and correct” method in sending in responses to articles that held misinformation. This method proved effective in getting more factual information out and overall has lead to more balanced coverage with some media outlets now reaching out to CNL for information about the NSDF Project before printing articles.

CNL has responded to and sought media coverage much more actively. Through this more active approach there has been a decline in negative/inaccurate coverage of the NSDF Project.

See Stakeholder Engagement TSD 3 (CNL2019a).

4.2.12 Document Repository

Canadian Nuclear Laboratories made four hard copies of the draft EIS publicly available, functionally creating a document repository for the draft EIS volumes. One hard copy of the draft EIS was available at the Deep River Public Library, two copies were made available through two separate branches of the Laurentian Hills Public Library and a French version of the draft EIS was made available through the Rapides-des-Joachim municipal offices. CNL commits to providing hard copies of the final EIS in the same locations.

4.2.13 Release of Documents

When requested supporting documents were provided to different groups and individuals to aid in their review of the draft EIS. An email was sent to more than 200 individual and group stakeholders offering information on the NSDF Project upon request.

To ease accessibility and transparency of the NSDF Project, supporting documents were uploaded onto the NSDF pages of www.cnl.ca. These technical documents are available for any interested member of the public to download.

See Stakeholder Engagement TSD 3 (CNL2019a).

4.2.14 Participant Funding

The CNSC offered participant funding through its Participant Funding Program to assist members of the public, Indigenous Peoples and other stakeholders in participating in the environmental assessment, licence application review and CNSC hearing processes for the NSDF Project. Recipients provide value-added and relevant information that contributes to a better understanding of the anticipated effects of the NSDF Project. Recipients also participate in the CNSC’s proceedings for this NSDF Project. The CNSC’s decision on who has received funding to participate is available in the CNSC Participant Funding Program Decision: CNL NSDF Project. Information on participant funding for the NSDF Project is available online: http://nuclearsafety.gc.ca/eng/the-commission/participant-funding-program/opportunities/pfp-funding-for-near-surface-disposal-facility-project.cfm.

Information on the CNSC Participant Funding Program is relevant to CNL’s stakeholder engagement efforts as it identifies individuals or groups who have expressed interest in the NSDF Project and a desire to proactively learn more. CNL has made it a priority to engage directly with recipients of participant funding due to their expressed interest in the NSDF Project.

4.3 Feedback

The engagement activities discussed in this section provide CNL with an opportunity for dialogue with public on their concerns with respect to the NSDF Project. This feedback helps CNL gauge public views and points out areas where CNL can improve elements of the NSDF Project or EIS on current project information, alternative means, valued components, spatial and temporal boundaries and follow-up monitoring program. This section summarizes the key themes that have been raised during outreach activities, including web inquiries and formal feedback on the draft EIS. It also demonstrates how CNL has responded and, when possible, incorporated this feedback into the development and design of the NSDF Project as well as the final EIS. Additionally, the NSDF Project has posted these key themes and how they will be incorporated into the final EIS on the NSDF Project webpage.

Table 4.2.14-1 presents a comparison of the themes identified through public engagement (informal feedback) and those identified through formal public comments during review of the draft EIS. At a high level, public engagement feedback tends to be informal and based around general areas of interest such as “what and why,” whereas the formal feedback centred more on technical aspects of the NSDF Project such as “how.”

Table 4.2.14-1: Theme Comparison

Themes from Public Engagement	Themes from Formal Public Comment Period on Draft EIS
	Justification of the Project
Waste acceptance criteria	Waste Inventory
Origins of material for disposal in the NSDF facility	
Engineering containment mound construction materials	Design/engineering
	Long-term accountability
	Alternative means assessment (including site selection)
Future impact of natural disasters and climate change on the Project	Environmental events (e.g., flooding, earthquakes)
Seismic qualifications vs. seismic activity	
Water quality monitoring for groundwater and the Ottawa River	Protection of the Ottawa River

EIS = Environmental Impact Statement.

4.3.1 Informal Public Engagement Feedback

The Stakeholder Engagement TSDs (CNL 2017a, CNL 2017b and CNL 2019a) summarize feedback received during NSDF Project public engagement outreach activities. Table 4.3.1-1 provides input from NSDF Project engagement activities that was used to identify the key issues raised during the informal engagement process and demonstrates how the public influenced the scope of the environmental assessment. The relevant interests raised during public engagement activities are also recognized within the respective environmental analysis of Section 5.

Table 4.3.1-1: Summary of Interest Raised During Public Engagement Activities that Influenced the Scope of the Environmental Assessment

Interest Expressed During Public Engagement	Incorporation of Public Key Issues into the Final EIS
Information on monitoring air contamination, including dust.	The monitoring program proposed for air quality includes monitoring of fugitive dust emissions and is described in Section 5.2.1. Fugitive Dust Monitoring is captured through the implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and air verification monitoring. In addition, the *Dust Management Plan* (AECOM 2018) to be implemented for the NSDF Project will include information on dust mitigation and monitoring for the NSDF Project.
Potential for changes in groundwater quality to affect uses downstream of the ECM	Potential changes in groundwater quality from the NSDF Project were evaluated in the hydrogeology assessment described in Section 5.3.2 and included potential changes from construction activities (e.g., erosion and blasting activities), changes from treated effluent discharge from the WWTP and leakage from the ECM during the post-closure phase following decommissioning of the WWTP.
Treatment of leachate and wastewater	The design of the NSDF includes capture and treatment of wastewater (including leachate) from the ECM as described in Section 3.4.2. The potential changes in groundwater and surface water quality, as well as the ambient radioactivity in the environment, as a result of the treated effluent discharges are discussed in Sections 5.3.2, 5.4.2 and 5.7 respectively.
Potential leakage of leachate from the ECM	Potential leakage of leachate from the ECM during operations will be mitigated through the design and implementation of a composite base liner system, a leachate detection system and a leak collection system as discussed in Section 3.4.1. Potential leakage from the ECM during the operations and post-closure phases is considered in the hydrogeology assessment (Section 5.3.2) as well as the human and ecological health assessments (Sections 5.7 and 5.8).
Long-term monitoring of groundwater	A conceptual long-term monitoring program for the NSDF Project as it relates to groundwater has been developed and evaluated in the hydrogeology assessment described in Section 5.3.2. A detailed monitoring program will be provided in the follow-up monitoring report to be submitted as a part of the license application.
Potential for contamination in the Ottawa River from the NSDF Project.	The original spatial boundaries of the surface water assessment in the draft EIS were selected to include consideration of potential effects to the Ottawa River. As described in Section 5.4.2 surface water quality modelling was completed to estimate contaminant concentrations within the Perch Creek basin, which flows directly into the Ottawa River. Meeting effluent discharge targets within the Perch Creek basin is considered to be protective of the Ottawa River. In response to comments received from the public, the Regional Study Area for surface water in the final EIS was expanded further to include a reach of the Ottawa River extending 8 km downstream of the CRL site. Additionally, in response to public concerns, receptors downstream of the CRL site in Sheenboro and Ottawa-Gatineau were explicitly modeled in the PostSA and the results summarized in Section 5.8.
Effects to fish from potential for contamination in the Ottawa River from the NSDF Project.	The original spatial boundaries of the surface water assessment in the draft EIS were selected to include consideration of potential effects to the Ottawa River. As described in Section 5.4.2 surface water quality modelling was completed to estimate contaminant concentrations and compared to aquatic quality guidelines. As discussed in Section 5.5 meeting aquatic quality guidelines within the Perch Creek and Perch Lake Watershed is considered to be protective of fish in the Ottawa River. In response to comments received from the public, the Regional Study Area for surface water in the final EIS was expanded further to include a reach of the Ottawa River extending 8 km downstream of the CRL site. Therefore, effects to fish within the Regional Study area is consider in the human and ecological health assessments (Sections 5.7 and 5.8).
Potential for radioactivity from gases from the capped facility	Potential changes in air quality from the NSDF Project were evaluated in the human and ecological health assessment (Sections 5.7 and 5.8) during the pre-closure and post-closure phases.

Table 4.3.1-1: Summary of Interest Raised During Public Engagement Activities that Influenced the Scope of the Environmental Assessment

Interest Expressed During Public Engagement	Incorporation of Public Key Issues into the Final EIS
Inclusion of migratory birds in the assessment	Because of their ecological importance and because they are protected by federal legislation (*Migratory Birds Convention Act, 1994* [MBCA]), the suite of migratory birds with the potential to be affected by the NSDF Project was included as a terrestrial biodiversity VC in Section 5.6. Some individual migratory bird species that are federally listed species at risk were also included as VCs assessed at the species level.
Inclusion of bird and other species at risk in the assessment	The species-level assessment in Section 5.6 focused on species identified on Schedule 1 of the federal *Species at Risk Act* (SARA). Species at risk evaluated in the assessment include Canada warbler, eastern whip-poor-will, eastern wood pewee, wood thrush and golden-winged warbler, bats, Blanding's turtle, eastern milksnake and monarch butterfly. Most of the species-level VCs identified for the terrestrial biodiversity assessment are also useful indicators for broader groups of species.
Concern over the conversion of terrestrial habitat	Sections 5.6 includes an evaluation of the change in habitat availability and habitat distribution in the vicinity of the NSDF Project is completed for each of the wildlife species selected as VCs.
Concern with road mortality to Blanding's turtle and what can be done to reduce this risk	Increased risk of injury/mortality of Blanding's turtle on roads is a key interaction evaluated as part of the residual effects assessment in Section 5.6. Mitigation to be implemented to reduce this risk is described and monitoring programs are recommended for Blanding's turtle.
Indigenous and non-Indigenous interest expressed in relation to potential effects on fish and fish harvesting due to concerns of potential contamination or radioactive seepage into Perch Creek, the Ottawa River and other waterbodies from the NSDF Project.	The original spatial boundaries of the land use assessment in the draft EIS were selected to include consideration of potential effects on water quality and include the aquatics study areas. CNL continues to monitor the aquatic environment extensively, specifically Perch Creek. The NSDF Project has used recent modelling to understand the potential for effects within the Perch Creek basin. Existing land use with regards to fishing is described in Section 5.9.4.1.3.2 (outdoor tourism and recreation) and existing traditional land use with regard to fishing is described in Section 6.4.4.1. Potential effects on these VCs are assessed in Section 5.9.5 and Section 6.4.5. CNL conducts monitoring of fish in the Ottawa River for radioactive contamination as part of its Environmental Monitoring Program. In response to concerns received the Regional Study Area for the land use assessment in the final EIS was expanded further to include a reach of the Ottawa River extending 8 km downstream of the CRL site. To address potential future safety concerns of Indigenous Peoples, the PostSA explicitly modeled a Self Sufficient Indigenous Group receptor and is summarized in Section 6.6.
Interest expressed in relation to potential effects on recreational activities (i.e., boating and swimming) due to concerns of potential contamination or radioactive seepage into the Ottawa River and other waterbodies from the NSDF Project.	The land use assessment included outdoor tourism and recreation as a VC. The spatial boundaries for the land use assessment include consideration of potential effects to the aquatic environment, and specifically include the aquatics study areas. CNL continues to monitor the aquatic environment extensively. The NSDF Project has used recent modelling to understand the potential for effects within the Perch Creek basin. CNL conducts environmental monitoring for tritium and other radionuclides in environmental media including fish from the Ottawa River. Outdoor tourism and recreation is addressed in Section 5.9.4.1.3. In response to comments received from the public, the Regional Study Area for the land use assessment in the final EIS was expanded further to include a reach of the Ottawa River extending 8 km downstream of the CRL site. Additionally, in response to public concerns, receptors downstream of the CRL site in Sheenboro and Ottawa-Gatineau were explicitly modeled in the PostSA and the results summarized in Section 5.8.

Table 4.3.1-1: Summary of Interest Raised During Public Engagement Activities that Influenced the Scope of the Environmental Assessment

Interest Expressed During Public Engagement	Incorporation of Public Key Issues into the Final EIS
Will consideration be given to provide jobs or buy material, such as sand that could be delivered by barge, to the closest full-time residents to the site, in Sheenboro QC?	▪ Industries throughout the County of Renfrew and the Ottawa area in Ontario and the Region of Outouais in Quebec, are anticipated to supply the NSDF Project with many of the required goods and services (e.g., manufacturing, wholesale, transport) be. CNL will competitively procure material and services for the NSDF Project (see Section 5.10.6.2.1). ▪ The construction workforce is anticipated to be sourced from firms within the County of Renfrew and the Ottawa area in Ontario and the Region of Outaouais (which includes the Municipality of Sheenboro and City of Gatineau) in Quebec. Canadian Nuclear Laboratories employment opportunities that may arise due to NSDF Project activities will be posted on the vendor portal at www.cnl.ca website (see Section 5.10.6.2.1).

WWTP = Wastewater Treatment Plant; ECM = engineered containment mound; EIS = Environmental Impact Statement; CRL = Chalk River Laboratories; VC = valued component; PostSA = Post-closure Safety Assessment.

4.3.2 Formal Public Comments Feedback

In addition to the informal feedback that the public engagement outreach and activities offer, the environmental assessment process provides an opportunity for formal feedback from the public. This process began with the formal public and Indigenous comment period on the NSDF Project Description in May 2016. Followed by a formal public and Indigenous comment period on the draft EIS for the proposed NSDF Project from May 2017 until August 2017. Comments from members of the public, Indigenous Peoples and non-governmental organizations on the draft EIS were consolidated by the CNSC (as the responsible authority) and received by CNL. The CNL prepared responses to the formal comments which will be submitted to the CNSC and posted on the CEAA Registry under project #80122. Through analysis of all formal public comments, key themes were identified. Table 4.3.2-1includes a summary of the key themes and how they were incorporated into the final EIS.

Table 4.3.2-1: Incorporation of Public Key Issues into the Draft Environmental Impact Statement

Themes from Formal Public Comment Period on Draft EIS	Incorporation of Public Key Issues into the Final EIS
Justification for the Project	Section 2.3 (Purpose of the Project) has been revised to improve the clarity on the justification for the project. The development of a near surface disposal facility for solid low-level radioactive waste at the CRL site will reduce potential risks associated with AECL's legacy wastes liabilities. The NSDF Project would enable the remediation of historically contaminated lands and legacy waste management areas, as well as the decommissioning of outdated infrastructure to facilitate the CRL site revitalization. The current CRL waste management practice is to safely store radioactive waste on-site in individual facilities in accordance with current licence conditions. However, appropriate nuclear waste management includes full life cycle management from generation to disposal. The NSDF Project will accommodate the permanent disposal of current and future low-level radioactive waste at the site.

Table 4.3.2-1: Incorporation of Public Key Issues into the Draft Environmental Impact Statement

Themes from Formal Public Comment Period on Draft EIS	Incorporation of Public Key Issues into the Final EIS
Waste inventory	▪ The original inventory proposed for NSDF Project in the draft EIS included a small fraction of intermediate-level waste. In response to comments received from the public, CNL made a commitment to limit the inventory to solid low-level radioactive waste only. This change has been reflected in the final EIS (Section 3.3), as well as supporting modeling and assessments such as the PostSA, and the revised Waste Acceptance Criteria. ▪ Consistent with IAEA classification of radioactive waste (GSG-1), low-level waste contains primarily short-lived radionuclides and restricts the amount of long-lived radionuclides thus requiring isolation and containment for periods of time up to a few hundred years. The engineered containment mound design life of 500 years has been established to meet the required time period to allow for radiologic decay of the waste inventory. ▪ Low-level waste includes items such as soils from remediation activities, demolition debris from decommissioning work and general trash such as used personal protection clothing or equipment. These items are considered low-level waste as they have become contaminated at some point with low levels of radioactivity. Low-level waste mostly contains short-lived radioactivity (thus decays relatively quickly) and can be safely handled with limited precautions. ▪ An estimation of the total inventory is required to inform the safety assessments where the inventory is tested against selected scenarios to determine the long-term consequences of the proposed facility. It also informs design criteria such as the Wastewater Treatment Plant (WWTP). ▪ The reference inventory identified in Section 3.3.1 establishes a representative radionuclide inventory by extrapolating waste already currently in storage, as well as waste forecasts from environmental remediation projects and decommissioning projects data to an assumed total volume of the NSDF at time of closure. All waste that is expected to be generated is meticulously described, or “characterized” before its generations to ensure the cumulative total inventory of NSDF is tracked against the licensed inventory.
Design/engineering	▪ At the time of submission of the draft EIS, CNL had completed the preliminary design of the NSDF. Since then, CNL has continued development of the design of the engineered containment mound, WWTP and supporting facilities. While the overall design has generally remained the same, several improvements have been made in many cases as a result of the decision to include only low-level radioactive waste, but also in response to valuable public and Indigenous input. An increase in detail and explanation of the engineered containment mound and wastewater treatment plan has been included in Section 3. CNL has also made the NSDF Design Description available for download on the NSDF Project website as well as summarized the intended operation of the NSDF in the YouTube video “NSDF Responsible Water Management”. ▪ A number of comments were received questioning CNL’s confidence in the 550-year design-life of the engineered containment mound, a key component of which is are the High Density Polyethylene (HDPE) Geomembranes (GMB). Dr. Kerry Rowe, a globally recognized expert in geomembrane systems based at Queens University has undertaken testing of the NSDF geomembrane and provided the scientific evidence to demonstrate with confidence that 550-year service-life will be met. Methods for testing and data analyses were performed in accordance with applicable standards and have been published in a number of peer-reviewed journals. ▪ To ensure the integrity of the HDPE materials and quality of installation, the NSDF Project will apply a Construction Quality Assurance (CQA) program. The CQA Program will include confirmatory tests and inspection by qualified personnel prior to and during liner installation. The design also includes systems to monitor and detect any leakage.
Long-term accountability	As discussed in updates to Section 3, as the owner of the CRL site and of the associated liabilities, Atomic Energy of Canada Limited (AECL) - a federal Crown corporation - will ensure that the site is safely managed and controlled for as long as necessary.

Table 4.3.2-1: Incorporation of Public Key Issues into the Draft Environmental Impact Statement

Themes from Formal Public Comment Period on Draft EIS	Incorporation of Public Key Issues into the Final EIS
Alternative means assessment (including site selection)	The revised EIS will have an expanded Alternative Means in Section 2 to better clarify the process that was followed to determine the NSDF location and design features. Based on questions and comments received, a summary of some of key information is provided below. ■ *Why the Chalk River site?* Chalk River Laboratories is the most suitable host site as more than 90% of the waste to be managed in the NSDF is already on the CRL site. This location for the facility avoids the time, cost and risk in transporting the waste to another location and reduce the unnecessary generation of tons of greenhouse gas emissions. ■ *Why the East Mattawa Road Location on the Chalk River Site?* The chosen East Mattawa Road (EMR) site is closest to the CRL main campus and therefore closest to the mandatory support services (e.g., electricity, water, heat). It is located within the Perch Lake drainage basin, which has been impacted by other historic waste management practices. Groundwater flow and contaminant migration at CRL site has been studied for over six decades and the Perch Lake Basin is well understood, better enabling CNL to mitigate any potential impacts from the NSDF facility. Placing the NSDF at the EMR site allows us to consolidate it within an area that is currently affected by historic and on-going operations. The Alternate site is in a largely undeveloped area, which means it is an unaffected, natural site. There are no pre-existing plumes or contamination from waste storage in the vicinity of the Alternate site. CNL and AECL would prefer to retain the Alternate site as a largely undeveloped area, providing protected habitat for species at risk such as the Blanding's Turtle and bats. ■ *Why a near surface disposal facility?* Near surface disposal facilities, as proposed for the NSDF Project, are suitable for the disposal of low-level waste as noted by IAEA guidance. An engineered containment mound design is a best available technology in consideration of the proposed waste stream which the vast majority is impacted soils and demolition debris. NSDF has been sited and designed to provide features that are aimed at the isolation of the radioactive waste from people and the environment.
Environmental events (e.g., flooding, earthquakes)	Section 10 (Effects of the Environment on the Project) describes how the design basis of NSDF has considered all environmental events that are likely to occur within the assessment timeframe. Other disruptive environmental events have been further analyzed in the safety assessments, considering both during the operations phase (SAR) and post-closure (PostSA). ■ Earthquakes: The analysis has shown that the design of the engineered containment mound is robust and can withstand a 1:10,000-year earthquake. Design changes to the engineered containment mound have been made to mitigate liquefaction potential. A replacement of the liquefiable soils with graded granular material from the bedrock excavation at site was considered as an optimal solution and included in the design of the engineered containment mound. ■ Tornadoes: The design of the WWTP has been made more robust to withstand potential tornadoes and high winds. ■ Precipitation: The design basis increases the capacity for the collection tanks for the WWTP to accommodate for 100-year back to back storm events. ■ Flooding: The base of the proposed NSDF is located approximately 163 metres above sea level, which is approximately 50 metres above the current water levels of the Ottawa River. Local residents can be assured that the proposed site is situated well outside of a flood plain. The Ottawa River posed no flooding threat to the Chalk River Laboratories site or its operations during the 2019 high-water conditions, nor would it have impacted the NSDF.

Table 4.3.2-1: Incorporation of Public Key Issues into the Draft Environmental Impact Statement

Themes from Formal Public Comment Period on Draft EIS	Incorporation of Public Key Issues into the Final EIS
Protection of the Ottawa River	▪ As discussed in Section 3 (Project Description), the proposed facility has been designed to ensure leachate and wastewater are controlled as well as treated to meet effluent discharge targets that have been developed to be protective of the public and environment health. Additionally, waste emplacement plans have been developed to minimize the generation of wastewater during operation of the engineered containment mound. CNL has also summarized the intended operation of the NSDF in the YouTube video “NSDF Responsible Water Management”. ▪ A state of the art WWTP has been designed to remove both radiological and chemical contaminants. CNL has performed pilot testing of the proposed wastewater treatment process utilizing simulated wastewater representative of what we expect to collect and treat when the NSDF is in operation. Through pilot testing we have demonstrated that we can achieve the effluent discharge targets. Furthermore, the plant is designed for batch releases, which means all liquid effluent must be sampled and proven to meet our targets before discharge. ▪ CNL is providing the necessary evidence and the science-based explanation that supports placing the facility at the Chalk River location as captured in updates to Sections 5.4.1 (Hydrology), 5.4.2 (Surface Water Quality), 5.5 (Aquatic Environment), 5.9 (Land and Resource Use) and 6.0 (Indigenous Interests) of the EIS. In response to concerns received the Regional Study Area for the land use assessment in the final EIS was expanded further to include a reach of the Ottawa River extending 8 km downstream of the CRL site. In response to comments received from the public, receptors downstream of the CRL site in Sheenboro and Ottawa-Gatineau were explicitly modeled in the PostSA and the results summarized in Section 5.8. ▪ Lastly CNL’s environmental and effluent monitoring program will be expanded to include the NSDF WWTP effluent, surface water in the Perch Lake Basin, and groundwater to confirm performance of the engineered containment mound and on-going monitoring of the Ottawa River.

AECL = Atomic Energy of Canada Limited; CRL = Chalk River Laboratories; PostSA = Post-closure Safety Assessment; EIS = Environmental Impact Statement; IAEA = International Atomic Energy Agency; HDPE = High Density Polyethylene; EMR = East Mattawa Road; SAR = Safety Analysis Report.

Through the wide range of communications strategies undertaken, the NSDF Project has continued to collect valuable input from stakeholders on current project information, alternative means, valued components, spatial and temporal boundaries, follow-up monitoring program and has incorporated informal and formal feedback into the final EIS. The NSDF Project is continually developing and strives to maintain transparency and open communication with the general public as the NSDF Project moves forwards. Feedback will continue to be tracked, collected and incorporated (when possible) as a part of the engagement activities into the future.

4.4 Planned Future Engagements

CNL has additional engagements planned throughout the environmental assessment process for which the records and feedback will be summarized in the final revision of the EIS (or Commission Member Document). Planned future engagements may include but are not limited to the following:

- annual conferences;
- annual public events (i.e., Petawawa Showcase, Downtown Connect);
- Renfrew County Municipal Councils – Project overview/updates;

- quarterly Project update webinars;
- quarterly website review and content update (note: new information will be updated as it becomes available);
- CRL ESC meeting – Project updates;
- CNL corporate kiosk/storefront – Project information;
- NSDF Project update letter/ invitation to intervenors;
- bi-monthly Project breakfast briefings;
- CONTACT newsletter; and
- informational videos.

4.5 Conclusions

Methods employed to date have helped to inform, educate and discuss the NSDF Project with stakeholders, and have enabled the public to provide valuable feedback into the NSDF Project. CNL will continue stakeholder engagement efforts to support growth in awareness and understanding of the NSDF Project.

There will always remain those in the public whose perception of nuclear waste remains negative and whose perception of the actual risk posed by the NSDF will remain grossly out of skew. CNL understands that it is an impossible task to convince all publics that the NSDF represents a safe and modern facility for the management of low-level nuclear liabilities at CNL sites. This however will not stop CNL from continuing to educate the public on the safe management of nuclear waste now and into the future, because it is the right thing to do.

CNL makes it a priority to build public awareness, understanding and a supportive appreciation of the laboratories value and relevance to Canadians. CNL works to ensure that the general public, Indigenous Peoples, news media, and other stakeholders are informed about the on-going activities at all CNL sites. While there is a stigma/fear of nuclear present in the general public, CNL continues to develop relationships and programs, as a part of the Public Information Program, to educate different demographics of the population about the perceived risk vs. the actual risk of nuclear.

CNL has proactively addressed the key issues raised by stakeholders, in many cases resolving those concerns. However, there remain persistent negative issues including the perception of a potential negative effect of the NSDF Project on the Ottawa River and other off-site effects. Follow-up monitoring will be used to verify predictions made in the final EIS, which will be communicated through CNL's Public Information Program (CNL 2021). CNL will continue with these efforts to inform the public on the NSDF Project and address the perception of risk.

Continuing to provide information as it becomes available will encourage transparency, and further feedback, which can assist CNL in understanding and incorporating stakeholder perspectives into NSDF Project planning, future communications and the environmental assessment process.

5.0 ENVIRONMENTAL EFFECTS

5.1 Environmental Assessment Approach

The environmental assessment process is an important tool for integrating environmental and social factors into project planning and decision making. The goals of the environmental assessment process are to:

- promote sustainable development;
- engage Indigenous Peoples, the public and government agencies; and
- identify appropriate mitigation to reduce the overall biophysical, economic, social, heritage and health effects of the Near Surface Disposal Facility (NSDF) Project.

More specifically, environmental assessment is a process used to predict environmental effects of proposed initiatives before they are carried out. An environmental assessment:

- identifies potential adverse environmental effects;
- proposes measures to mitigate adverse environmental effects;
- predicts whether there will be significant adverse environmental effects after mitigation measures are implemented; and
- includes a follow-up monitoring program to verify the accuracy of the environmental assessment and the effectiveness of the mitigation measures.

This section describes the scope and approach of the environmental assessment implemented for the NSDF Project. The environmental assessment approach applied to disciplines (e.g., atmospheric environment, hydrogeology, terrestrial biodiversity, human health and socio-economic environment) includes the following main activities (where applicable), with further detail on each provided in Sections 5.1.1 to 5.1.9 and Section 6.0:

- **Step 1** – Define the scope of the assessment, including input received from regulatory agencies and engagement activities.
  - Identify the Valued Components (VCs) for each discipline that the assessment will focus on, and the associated measurement indicators and assessment endpoints for VCs.
  - Define spatial (e.g., geographic extent of the project activities and effects) and temporal (e.g., timelines for the project phases and effects) boundaries, and assessment cases used to evaluate effects.
- **Step 2** – Describe the existing conditions, including the cumulative effects of previous and existing developments for each VC.
- **Step 3** – Evaluate Project interaction and mitigation by conducting a pathway analysis to identify Project components or activities with a potential to create a residual effect, and describe the mitigation developed for removing pathways or limiting effects. In the assessment for some disciplines, no primary pathways for effects are identified, and the assessment proceeds directly to Step 7.

- **Step 4** – Conduct an analysis for each VC to predict residual effects from the NSDF Project.
  - Conduct an assessment for each VC to predict the cumulative effects of previous and existing projects and activities, the NSDF Project and potential future projects that have been proposed but not yet approved (if applicable).
- **Step 5** – Evaluate and describe the level of certainty that can be placed on predicted residual effects and the methods used to manage uncertainty.
- **Step 6** – Classify and determine the significance of predicted residual effects, including cumulative effects from the NSDF Project and potential future projects that have been proposed but not yet approved (if applicable).
- **Step 7** – Identify monitoring and follow-up programs to confirm the effects predictions and address uncertainty.
- **Step 8** – Present a consolidated summary of conclusions and outcomes of the assessment.

Generally, this approach is consistently applied across disciplines, with some modifications, where appropriate. For example, VCs are defined for all disciplines, and there is consistency in the determination of spatial and temporal boundaries for the effects analysis. Similarly, the methods for identifying interactions that link the NSDF Project to potential effects on VCs are consistent. Details specific to each discipline are provided in their respective sections of the Environmental Impact Statement (EIS).

In contrast, the methods for analyzing, classifying (e.g., magnitude and duration) and predicting environmental significance of residual effects can differ among disciplines. For example, human effects from a specific project are difficult to isolate from the on-going processes of interdependent social, cultural and economic change. Evolving social trends, government policy and programming decisions and individual choice all have effects that will be concurrent with potential NSDF Project effects. Biophysical disciplines (e.g., hydrogeology, aquatic environment and terrestrial environment) are influenced simultaneously by natural and human-related factors. However, for many biophysical disciplines, effects specific to the NSDF Project can be quantified (e.g., incremental changes to ground and surface water quality, air quality and fish and wildlife habitat). Because the socio-economic status of different communities, subpopulations and individuals may vary, a socio-economic effect may have both positive aspects and negative aspects, whereas an effect on a biophysical discipline is typically constrained to being negative or positive.

5.1.1 Scope of the Assessment

As described in Section 1.4, the *Generic Guidelines for the Preparation of an Environmental Impact Statement* (Generic EIS Guidelines) developed by the Canadian Nuclear Safety Commission (CNSC 2016) provides an outline of the information to be included in the EIS, along with a high-level description of the methods to be implemented for the environmental assessment.

The scope of the environmental assessment, where applicable, incorporates input received from regulatory agencies, Indigenous Peoples (Section 6.0) and the public (Section 4.0) through the review of the draft EIS and advice provided in guidance documents relevant to environmental assessment practice (Section 1.4).

Input from engagement for the NSDF Project is used to identify the key issues that were raised during the engagement process (Section 4.0 and 6.0). Issues identified during community information sessions and considered in the development of the EIS are summarized in CNL's Indigenous Engagement Report (CNL 2021) and CNL's Stakeholder's Activity Reports (CNL 2017a,b, 2019). Comments received, the responses prepared and the degree to which these comments are considered resolved are also presented in CNL's Indigenous Engagement Report (CNL 2021) and CNL's Stakeholder's Activity Report – Near Surface Disposal Facility (CNL 2019). These issues and the response to these issues are presented under the "Scope of the Assessment" heading within each discipline section, and helped to guide the scope and development of the assessment for each discipline.

The EIS also relies on multiple key technical support documents as described in Section 1.5 (Structure of this Document) and as shown on Figure 1.5.1-1.

5.1.2 Valued Components

VCs refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018a). Because this assessment is for a designated project, as described in the *Canadian Environmental Assessment Act, 2012* (CEAA 2012), and is regulated by the CNSC, VC selection considered guidance from Appendix A of the CNSC's *REGDOC-2.9.1 Environmental Protection: Environmental Principles, Assessments and Protection Measures* (CNSC 2017). The selection of appropriate VCs allows the assessment to be focused on those aspects of the natural and human environment that are of greatest importance to society and species conservation.

The list of VCs selected for the NSDF Project considered a number of factors, including:

- presence, abundance and distribution within or relevance to the area associated with the NSDF Project;
- potential for interaction with the NSDF Project and sensitivity to effects;
- species conservation status or concern (e.g., rarity, sensitivity and uniqueness);
- ecological and socio-economic value to communities, government agencies and the public;
- traditional, cultural and heritage importance to Indigenous Peoples; and
- experience with similar projects, including the EIS completed in 2010 for the National Research Universal Reactor Long-term Management Project at the Chalk River Laboratories (CRL) property (SENES 2010).

VCs were selected with due consideration of the results of baseline studies and subsequent consultation, with a focus on criteria used to evaluate the potential significance of residual effects. The rationale for discipline-specific VC selection is described in Sections 5.2 to 5.10, under the "Valued Components" subheading. The final list of VCs and rationale for inclusion in the effects assessment for the NSDF Project is provided in Table 5.1.2-1. Accidents and malfunctions for the NSDF Project are discussed separately in Section 7.0 and are not listed in Table 5.1.2-1 below.

Table 5.1.2-1: Valued Components Selected for the Effects Assessment

Discipline	Valued Component	Rationale for Selection
Atmospheric Environment	Air Quality	■ Air quality is selected as a VC as emissions from the NSDF Project activities have the potential to alter the existing air quality regime. ■ Changes in air quality can affect human health, aquatic and terrestrial biodiversity.
	Greenhouse Gases	■ This VC, assessed through incremental changes in emissions of a group of gases, considers the potential of the NSDF Project to contribute to climate change.
Geological and Hydrogeological Environment	Geology*	■ Characteristics of geology, such as soil quality and quantity, bedrock and geomorphology, are important components that interact with other VCs (e.g., hydrogeology, hydrology and surface water quality) and if changed by NSDF Project activities, these characteristics could affect terrestrial and aquatic biodiversity.
	Groundwater quantity* and quality*	■ Characteristics of hydrogeology, such as groundwater quantity and quality are important components that interact with other VCs (e.g., hydrology and surface water quality) and if changed by NSDF Project activities, these characteristics could affect terrestrial and aquatic biodiversity, and human health including future use (e.g., human intrusion).
Surface Water Environment	Hydrology*	■ The NSDF Project may affect existing availability of the spatial and temporal distribution of water quantity for aquatic and terrestrial biodiversity, which can in turn affect land and resource use. ■ Societal values concerning changes in water quantity (i.e., watersheds) are an important consideration in understanding potential effects of the NSDF Project.
	Surface Water Quality*	■ Water quality to support aquatic and human health is defined by the concentration or value of various physical and chemical constituents[(a)] of water, such as temperature, suspended particulate matter, major ions (e.g., chloride, potassium), nutrients (e.g., nitrogen, phosphorus), metals, and trace organic compounds, and radiological compounds that occur in dissolved or soluble form (e.g., aluminum and iron) and suspended matter (comprising inorganic or organic material). ■ Changes in the quality of water can affect aquatic and terrestrial sustainability and biodiversity, and the use of water for recreational purposes or as a drinking water source for people and wildlife. ■ Societal values concerning changes in water quality (i.e., Ottawa River) are an important consideration in understanding potential effects of the NSDF Project.
Aquatic Environment	Perch Creek and Perch Lake Watershed Fish Habitat (i.e., Fish Habitat)[(a)]	■ Wetlands, lakes, streams and rivers provide a diversity of functions for life history stages of fish species and forage fish species. ■ The NSDF Project may affect existing availability of the spatial and temporal distribution of habitat, which can subsequently affect land and resource use.
	Perch Creek and Perch Lake Watershed Fish Community (i.e., Fish Community)[(a)]	■ Up to 15 species have been documented within the Perch Creek and Perch Lake Watershed, some of which may use habitat in the Ottawa River at the mouth of Perch Creek. ■ Species in potentially affected waters are protected under the *Fisheries Act*., for example, Northern Pike (*Esox lucius*), Brown Bullhead (*Ameiurus nebulosus*) and supporting forage fish species. ■ Societal values concerning changes in local fisheries species are an important consideration in understanding potential effects of the NSDF Project.

Table 5.1.2-1: Valued Components Selected for the Effects Assessment

Discipline	Valued Component	Rationale for Selection
Aquatic Environment	Perch Creek and Perch Lake Watershed[(a)] Brown Bullhead	■ Brown Bullhead (*Ictalurus nebulosus*), a species of 'bullhead catfish', is a warm water native species to Ontario and resident of Perch Lake where it is a dominant species in the fish community. ■ Brown Bullhead is a valued species by local Indigenous communities.
	Fish Species of Conservation Concern	■ The Lake Sturgeon (*Acipenser fulvescens*) population in the Ottawa River is designated as Threatened by COSEWIC; threats to the Lake Sturgeon include overexploitation, dams, habitat degradation, contaminants and introduced species; commercial fishing was the most significant factor that caused the historical decline of populations. ■ American Eel (*Anguilla rostrata*) is designated as Threatened by COSEWIC; threats include dams which can impede upstream migration of juvenile eels; impeded access to the Ottawa River, Lake Ontario and Lake Champlain resulted in substantial cumulative loss of formerly productive rearing habitat in the St. Lawrence River watershed. ■ The Northern Brook Lamprey (*Ichthyomyzon fossor*) population in the Ottawa River is designated as special concern under Schedule 1 of SARA; lampricide (chemical used to target lamprey larvae) use to manage invasive Sea Lamprey (*Petromyzon marinus*) is the main threat for Northern Brook Lamprey. ■ River Redhorse (*Moxostoma carinatum*) is designated as special concern under Schedule 1 of SARA; principal threats are habitat degradation through siltation, agricultural and urban pollution, and instream barriers such as dams, which restrict access to spawning areas and can change flow regimes during spawning periods.
Terrestrial Environment	Vegetation communities	■ This VC broadly captures effects on terrestrial biodiversity. ■ The NSDF Project is associated with footprint effects that will remove vegetation and result in physical losses of some vegetation communities (and related wildlife habitat).
	Migratory birds	■ Migratory birds and their nests are protected under the federal MBCA. ■ There are numerous migratory bird species that breed, nest or could be present year-round in the vicinity of the Project. There is the potential for migratory birds to be indirectly and directly affected by the Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads or loss of eggs in nests during tree clearing). ■ Comment on the Project Description received by a member of the public specifically requested assessment of this VC.
	Canada warbler	■ Canada warbler (*Cardellina canadensis*) is federally listed as Threatened under SARA and is protected under the MBCA. It has legal individual and habitat protection provisions under SARA and individual and nest protection under the MBCA. ■ The CRL site is federally owned; therefore, this species is afforded protection of critical habitat because it is listed as Threatened on Schedule 1 of SARA. Critical habitat has not yet been defined for this species in the federal recovery strategy. ■ There is the potential for Canada warbler to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads or loss of eggs in nests during tree clearing). ■ Canada warbler is an avian species VC recorded within the LSA that represents a guild of early successional habitat specialists requiring coniferous, deciduous, moist mixed forest and regenerating habitats.

Table 5.1.2-1: Valued Components Selected for the Effects Assessment

Discipline	Valued Component	Rationale for Selection
Terrestrial Environment	Eastern whip-poor-will	■ Eastern whip-poor-will (*Antrostomus vociferus*) is federally listed as Threatened under SARA and is protected under the MBCA. It has legal individual and habitat protection provisions under SARA and individual and nest protection under the MBCA. ■ The CRL site is federally owned; therefore, this species is afforded protection of critical habitat because it is listed as Threatened on Schedule 1 of SARA. Critical habitat has been partially defined for this species in the federal recovery strategy (ECCC 2018a). ■ There is the potential for eastern whip-poor-will to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads or loss of eggs in nests during tree clearing). ■ Eastern whip-poor-will is a keystone avian species VC recorded within the LSA that represents a guild of aerial insectivores requiring open forest/edge habitat in drier deciduous and coniferous habitats.
	Eastern wood-pewee	■ Eastern wood-pewee (*Contopus virens*) is federally listed as Special Concern under SARA and is protected under the MBCA. It has legal individual and nest protection under the MBCA. ■ The CRL site is federally owned; therefore, Section 65 of SARA requires that habitat is managed for conservation of this species because it is listed as Special Concern on Schedule 1 of SARA. ■ There is the potential for eastern wood-pewee to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads or loss of eggs in nests during tree clearing). ■ Eastern wood-pewee is an avian species VC recorded within the LSA that represents a guild of forest edge habitat species.
	Golden-winged warbler	■ Golden-winged warbler (*Vermivora chrysoptera*) is federally listed as Threatened under SARA and is protected under the MBCA. It has legal individual and habitat protection provisions under SARA and individual and nest protection under the MBCA. ■ The CRL site is federally owned; therefore, this species is afforded protection of critical habitat because it is listed as Threatened on Schedule 1 of SARA. Critical habitat has been partially defined for this species in the federal recovery strategy. ■ There is the potential for golden-winged warbler to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads or loss of eggs in nests during tree clearing). ■ Golden-winged warbler is a keystone avian species VC recorded within the LSA that represents a guild of edge habitat specialists.

Table 5.1.2-1: Valued Components Selected for the Effects Assessment

Discipline	Valued Component	Rationale for Selection
Terrestrial Environment	Wood thrush	■ Wood thrush (*Hylocichla mustelina*) is federally listed as Threatened under SARA and is protected under the MBCA. It has legal individual and habitat protection provisions under SARA and individual and nest protection under the MBCA. ■ The CRL site is federally owned; therefore, this species is afforded protection of critical habitat because it is listed as Threatened on Schedule 1 of SARA. Critical habitat has not yet been defined for this species in the absence of a federal recovery strategy due to recent (2017) listing. ■ There is the potential for wood thrush to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads or loss of eggs in nests during tree clearing). ■ Wood thrush is an avian species VC recorded within the LSA that represents a guild of deciduous and mixedwood forest habitat specialists.
	Bats ■ Little brown myotis ■ Northern myotis ■ Tri-colored bat	■ Little brown myotis (*Myotis lucifugus*), northern myotis (*Myotis septentrionalis*) and tri-colored bat (*Perimyotis subflavus*) have observation records within the LSA. All three bat species are federally listed as Endangered and have legal individual protection provisions under SARA. ■ The CRL site is federally owned; therefore, these bat species are afforded protection of critical habitat because they are listed as Endangered on Schedule 1 of SARA. Critical habitat has only partially been defined for hibernacula (i.e., overwintering sites), as the largest threat to these species is associated with that habitat. The destruction of maternity roosts is also a potential threat to bat populations. Hibernacula have not been found in the study areas and are unlikely to occur in the SSA. Maternity roosts are likely present and have the potential to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (i.e., loss of roosting bats during tree clearing). ■ There is the potential for bats to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss (loss of roost trees) and mortality (i.e., loss of pre-volant juveniles in maternity roosts during tree clearing). ■ The bats VC represents small mammal species recorded in the LSA that rely on standing dead trees (e.g., snags) for part of their life history (maternity roosting, diurnal roosting and evening roosting).

Table 5.1.2-1: Valued Components Selected for the Effects Assessment

Discipline	Valued Component	Rationale for Selection
Terrestrial Environment	Blanding's turtle	■ The Great Lakes / St. Lawrence population of Blanding's turtle (*Emydoidea blandingii*) is federally listed as Threatened and has legal individual and habitat protection provisions under SARA. COSEWIC (2016) has assessed the population as Endangered. ■ The CRL site is federally owned; therefore, this species is afforded protection of critical habitat because it is listed as Threatened on Schedule 1 of SARA. Critical habitat has been identified within the CRL site based on the partial definition in the recovery strategy (ECCC 2018b). Grid squares that have been identified as containing critical habitat for Blanding's turtle are intersected by the NSDF Project (ECCC 2017). ■ There is the potential for Blanding's turtle to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads and overwinter mortality from changes in the hydrology in wetlands). ■ The Blanding's turtle is represented through effects on species at risk in the terrestrial environment. This species further acts as an indicator species representing reptile species (e.g., snapping turtle) that use a variety of wetland habitats for hibernation, mating, foraging, thermoregulation, staging prior to nesting and for movement. They use upland, relatively open areas with suitable substrate for nesting, overland migration, thermoregulation and foraging. Blanding's turtles display fidelity to their overwintering sites and nesting sites (i.e., use the same habitat year after year). ■ Comments and questions raised at public information sessions unambiguously expressed value of the Blanding's turtle.
	Eastern milksnake	■ Eastern milksnake (*Lampropeltis triangulum*) has not been observed within the LSA but is potentially present because it has been confirmed elsewhere on the CRL site. It is federally listed as Special Concern on Schedule 1 under SARA. ■ There is the potential for eastern milksnake to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads). ■ The CRL site is federally owned; therefore, Section 65 of SARA requires that habitat is managed for conservation of this species because it is listed as Special Concern on Schedule 1 of SARA. ■ Eastern milksnake represents reptile species that use a variety of microhabitats. The eastern milksnake is known to congregate in hibernacula over winter.
	Monarch butterfly	■ Monarch butterfly (*Danaus plexippus*) has not been observed within the LSA but is potentially present because it has been confirmed elsewhere on the CRL site. It is federally listed as Special Concern and is considered Endangered by COSEWIC. ■ There is the potential for the monarch butterfly to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads or loss of individuals during vegetation clearing). ■ The CRL site is federally owned. Although species listed as Special Concern are not afforded the same degree of legal protection as higher threat levels, Section 65 of SARA requires that a management plan be developed that includes measures for the conservation of the species and their habitats. ■ The iconic migratory butterfly relies on milkweed and represents other insects that use a variety of open habitats during the summer and early fall.

Table 5.1.2-1: Valued Components Selected for the Effects Assessment

Discipline	Valued Component	Rationale for Selection	
Ambient Radioactivity and Ecological Health	A list of VCs was developed from those documented to occur in the vicinity of the SSA, have potential for exposure, play a key role in the food web, and represent a variety of habits and trophic levels. To determine the potential effect of radiological emissions on the environment, a smaller group of indicator species was chosen to represent VCs selected for assessment. The indicator species listed below includes those species identified and assessed for terrestrial and aquatic biodiversity effects.		
	Valued Component	**Indicator Species**	**Justification for Inclusion in Exposure Assessment**
	Crustaceans	■ Benthic invertebrates	■ Indicator species for changes in sediment quality
	Crustaceans	■ Zooplankton	■ Indicator species for changes in water quality
	Fish and Fish Habitat (Small Pelagic forage [omnivores])	■ Bluntnose Minnow	■ Present in Perch Creek, represents small pelagic fish
	Fish and Fish Habitat (Small -Benthivorous)	■ Black Bullhead	■ Present in Perch Creek, represents small benthivorous fish
	Fish (Large - Carnivorous)	■ Northern Pike	■ Present in Perch Lake, represents Large Carnivorous fish
	Vegetation Communities (Aquatic)	■ Reed (food for predators)	■ Present in the wetlands in the LSA, represents aquatic vegetation communities, food chain
	Vegetation Communities (Terrestrial)	■ Red maple	■ Present in the LSA, represents terrestrial vegetation communities
	Pollinator	■ Monarch butterfly	■ Present in the LSA, represents Pollinators
	Terrestrial Invertebrate	■ Earthworm	■ Indicator species for changes in soil quality
	Bats (Small - Insectivores)	■ Little brown myotis	■ Present in the LSA, represents small insectivores
	Small – Herbivore	■ Meadow vole	■ Present in the LSA, represents small herbivorous mammals
	Large – Herbivore	■ White-tailed deer	■ Present in the LSA, represents large herbivorous mammals, public interest
	Large - Herbivore	■ Moose	■ Present in the LSA, make use of aquatic habitat, represents large herbivorous mammals, Indigenous interest
	Small – Omnivorous	■ Short-tailed shrew	■ Present in the LSA, represents small omnivorous mammals
	Large – Omnivorous	■ Black bear	■ Present in the LSA, represents large omnivorous mammals, public interest
	Large - Carnivorous	■ Eastern wolf	■ Present in the LSA, represents large carnivorous mammals, public interest
	Turtle (Semi-terrestrial)	■ Snapping turtle	■ Present in the LSA, represents semi-terrestrial reptiles (turtle)
	Snake (Semi-terrestrial)	■ Common watersnake	■ Present in the LSA, represents semi-terrestrial reptiles (snake)

Table 5.1.2-1: Valued Components Selected for the Effects Assessment

Discipline	Valued Component	Rationale for Selection	
Ambient Radioactivity and Ecological Health	**Valued Component**	**Indicator Species**	**Justification for Inclusion in Exposure Assessment**
	Snake (Terrestrial)	■ Eastern milksnake	■ Present in the LSA, represents terrestrial reptiles (snake)
	Frog (Semi-aquatic)	■ Green frog	■ Present in the wetlands in the LSA, represents semi-aquatic amphibians
	Migratory birds (Small – Insectivores)	■ Canada warbler	■ Present in the LSA, represents small insectivore birds
	Migratory birds (Large Insectivores)	■ Eastern whip-poor-will	■ Present in the LSA, represents large insectivore birds
	Migratory birds (Small Omnivores)	■ Purple finch	■ Present in the LSA, represents small omnivore birds
	Large Omnivores	■ Ruffed grouse	■ Present in the LSA, represents large omnivore birds
	Small Carnivores	■ Belted kingfisher	■ Present in the LSA, represents small carnivore birds
	Raptors (Large Carnivores)	■ Bald eagle	■ Present in the LSA, represents large carnivore birds, public interest
	Waterfowl (Small semi-aquatic)	■ Mallard	■ Present in the LSA, represents small semi-aquatic birds, public interest
	Large semi-aquatic	■ Great blue heron	■ Present in the LSA, represents large semi-aquatic birds, public interest
Human Health	Worker	■ Potential external and internal radionuclide exposure; potential non-radionuclide exposure from the NSDF Project.	
	Public ■ Residential ■ Seasonal	■ Potential exposure to airborne and waterborne radiological emissions; potential non-radionuclide exposure from the NSDF Project.	
	Self Sufficient Indigenous Peoples	■ Potential exposure to airborne and waterborne radiological emissions; potential non-radionuclide exposure from the NSDF Project. ■ This group represents Indigenous Peoples, including adults and children, using area that surrounds the ECM, including Perch Creek and the Ottawa River, for hunting and gathering during the Post-closure phase. ■ This receptor was assessed as part of the Sensitivity Analysis Case in the Post-Closure Safety Assessment (Arcadis and Quintessa 2020).	
Socio-economic Environment	Labour Market	■ Local workforce and communities are interested in long-term employment opportunities that will be generated through the NSDF Project. ■ Income generation is perceived as a Project benefit by local workforce, businesses and communities.	
	Economic Development	■ The NSDF Project will contribute to local and regional economies, through direct procurement, as well as indirect investment in other business activities.	
	Government Finances	■ The NSDF Project will generate incremental tax revenues for all levels of government.	
	Housing and Accommodations	■ Potential in-migration of workers (and families) for the NSDF Project could increase the demand for permanent housing or temporary accommodations.	

Table 5.1.2-1: Valued Components Selected for the Effects Assessment

Discipline	Valued Component	Rationale for Selection
Socio-economic Environment	Services and Infrastructure	■ Potential in-migration of workers (and families) for the NSDF Project could increase the demand for community services (i.e., schools, community health, protection and emergency services) and community infrastructure (i.e., water supply and traffic).
	Quality of Life	■ Project activities (i.e., changes in air quality, ambient noise, increases in traffic volume and visual disturbances) could affect worker and local public quality of life.
	Public Safety	■ Public safety is a concern near the NSDF Project. Hazards include transport of heavy equipment and supplies to the site and other hazards typical of industrial facilities.
Land and Resource Use	Land Tenure and Other Registered Interests	■ Project construction and operation must demonstrate compatibility with existing land use direction as expressed by responsible authorities based on a qualitative comparison of the Project with established land and resource designations in plans, policies and bylaws. ■ Land users and responsible authorities need to understand if the Project will affect access routes / access to commercial land and resource use areas (e.g., for existing mining, forestry and agriculture). ■ Land users and responsible authorities need to understand if the Project will affect the availability of commercial land and resource use opportunities.
	Outdoor Recreation and Tourism	■ The Project has the potential to affect the access to outdoor tourism and recreational land and resource use opportunities associated with parks and protected areas, fishing, hunting, trapping and non-consumptive tourism and recreation. ■ The Project has the potential to affect the quality and quantity of outdoor tourism and recreation land use opportunities.
	Archaeological Sites	■ Archaeological sites are an important aspect of the cultural heritage of Indigenous Peoples. Archaeological sites are the focus of the archaeology discipline as archaeological sites are identified and protected by the *Ontario Heritage Act*.
Indigenous Interests - Traditional land and resource use	Traditional land and resource use by Indigenous Peoples	■ Trapping, hunting, fishing and gathering where traditional and are modern day land and resource use activities are practised by Indigenous Peoples in the Ottawa Valley. These activities provide important links to cultural continuity and traditional way of life. These activities are protected under Section 35 of the *Constitution Act*, which identifies that existing Indigenous and treaty rights of the Indigenous Peoples of Canada are recognized and affirmed. For Métis people, the rights were affirmed in the courts in 2003 (R. v. Powley) confirming that Métis can assert Indigenous rights under Section 35 of the *Constitution Act*. ■ Indigenous Peoples place a high degree of value on specific sites of cultural, historical, spiritual, social or ecological significance. These sites may have broader cultural significance related to the practice of formal or informal ceremonies at or near these sites.

Note: VCs denoted with an '*' indicate a valued component that does not have an assessment endpoint.

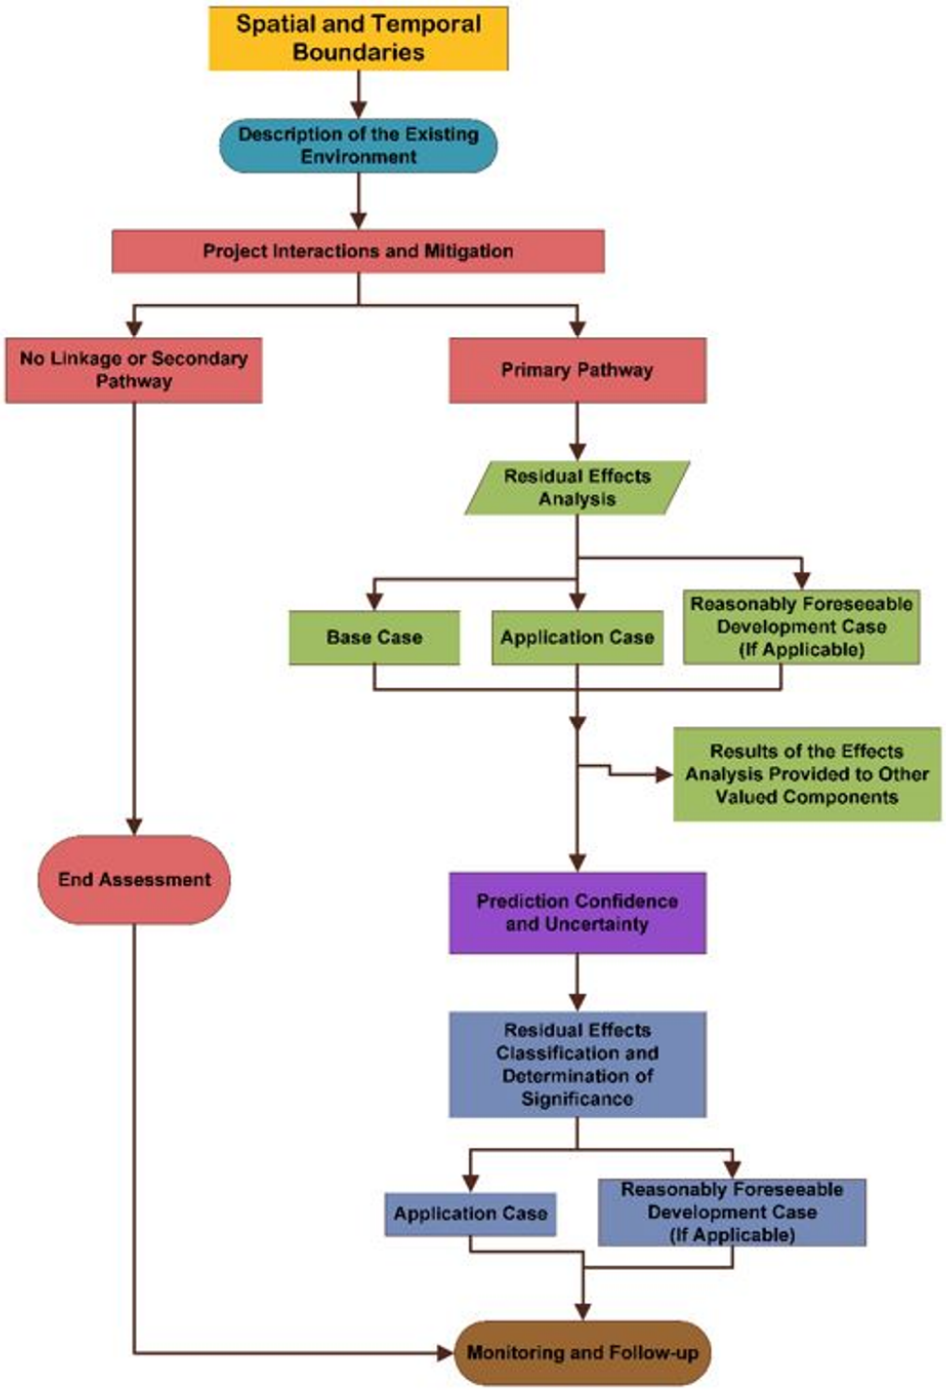
(a) The surface water quality assessment addresses only the non-radiological constituents of water; the assessment of radiological constituents is provided in Section 5.7 Ambient Radioactivity.

(b) Includes contributing watercourses and waterbodies within the Perch Creek and Perch Lake Watershed, including Perch Lake, Perch Creek, East Swamp Stream, and Main Stream.

R. v. Powley [2003] 2 SCR 207, 2003 SCC 43. https://scc-csc.lexum.com/scc-csc/scc-csc/en/item/2076/index.do?r=AAAAAQAGcG93bGV5AAAAAAAAAAQ

VC = valued component; NSDF = Near Surface Disposal Facility; CRL = Chalk River Laboratories; LSA = local study area; RSA = regional study area; SARA = *Species at Risk Act*; SSA = site study area; MBCA = *Migratory Birds Convention Act, 1994*; COSEWIC = Committee on the Status of Endangered Wildlife in Canada.

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future human generations (i.e., incorporating sustainability). For example, self-sustaining and ecologically effective fish and wildlife populations, continued land use opportunities and protection of archaeological resources may be assessment endpoints for fish and wildlife, land use and tenure and archaeological resources, respectively. Assessment endpoints are typically not quantifiable and require the identification of one or more measurement indicators that can be directly linked to the assessment endpoint.



Measurement indicators represent properties of the environment and VCs that, when changed, could result in or contribute to an effect on assessment endpoints. Measurement indicators may be quantitative (e.g., concentrations of metals in surface water) or qualitative (e.g., movement and behaviour of wildlife from disturbance to habitat). Measurement indicators also provide the primary factors for discussing the uncertainty of effects on VCs and, subsequently, are key variables for study in potential follow-up and monitoring programs.

The significance of effects from the NSDF Project on VCs is evaluated by linking **changes** in measurement indicators to **effects** on the assessment endpoints. For example, changes in habitat quantity and quality (measurement indicators) are used to assess the significance of residual effects from the NSDF Project on the ability of a wildlife population to remain self-sustaining and ecologically effective (an assessment endpoint).

All VCs have measurement indicators, but not every VC has an assessment endpoint. For example, VCs such as geology, hydrogeology and surface water quality are considered as measurement indicators for other VCs, and do not have an assessment endpoint (i.e., they may be referred to as pathway or intermediate components). Intermediate components are considered to be important aspects of the natural and human environment, and are evaluated in the EIS to determine how they may influence assessment endpoints. The evaluation includes an analysis of changes in measurement indicators for the intermediate components. The results of the analysis are provided to other disciplines (e.g., aquatic and terrestrial environment and human health) for inclusion in their residual effects analysis.

VCs with no assessment endpoint are still analyzed for Project-specific and cumulative (if applicable) changes in measurement indicators. The changes are characterized in terms of magnitude, duration and geographic extent, but are not classified using rankings for effects criteria. For example, the magnitude of change in hydrological flows may be described as the relative change from baseline, but this change would not be classified (or ranked) as low, moderate, or high. This ranking would be reserved for the classification of residual effects and determination of significance for those VCs with assessment endpoints.

In summary, the same systematic and rigorous approach is applied to VCs with and without assessment endpoints, except that effects on VCs without explicit assessment endpoints are not classified using effects criteria or evaluated for significance. The environmental assessment approach for VCs with assessment endpoints is illustrated on Figure 5.1.2-1, and the approach for VCs with no assessment endpoints is illustrated on Figure 5.1.2-2. The assessment approach is described further in Sections 5.1.3 to 5.1.9.

5.1.3 Assessment Boundaries

Assessment boundaries define the geographic and temporal limits of the analysis of effects from the NSDF Project on the environment. These boundaries encompass the areas within which (spatial boundaries) and times during which (temporal boundaries) the NSDF Project, and in combination with previous, existing and reasonably foreseeable developments, is expected to interact with the VCs.

5.1.3.1 Spatial Boundaries

Defining the geographic extent of the study areas for each discipline is a key element of the environmental assessment process. Spatial boundaries are selected to be appropriate for each discipline (e.g., hydrogeology, surface water environment, terrestrial biodiversity and socio-economics), and associated VCs, using the following criteria:

- physical extent of the NSDF Project;
- physical extent of Project-related effects; and
- physical extent of key environmental systems (e.g., watershed boundary of potentially affected streams).

Individuals, populations and communities function within the environment at different spatial and temporal scales (Wiens 1989). In addition, the response of physical, chemical and biological processes to changes in the environment can occur across several spatial scales at the same time (Holling 1992; Levin 1992).
This environmental assessment has adopted a multiscale approach for describing baseline conditions (existing environment) and predicting effects from the NSDF Project on VCs because the responses of physical, biological, cultural and economic properties to natural and human-induced disturbance will be unique and will occur across different scales.

For this EIS, data collected at the NSDF Project site and within the CRL site were used to provide measures of baseline environmental conditions and predict the direct and indirect changes from the NSDF Project on VCs (e.g., changes to terrestrial habitat from the physical footprint). Data collected at larger scales (i.e., outside of the CRL site) were used to measure broader-scale baseline environmental conditions. These data also provide regional context for the maximum predicted geographic extent of combined direct and indirect effects from the NSDF Project on VCs (e.g., changes to downstream water quality, or changes to regional employment and incomes). Cumulative effects from the NSDF Project in combination with previous, existing and reasonably foreseeable developments are assessed at the regional spatial scale.

Consistent with the Generic EIS Guidelines (CNSC 2016), the following spatial scales are considered by each discipline.

- **Site Study Area (SSA):** The SSA is the NSDF Project footprint (i.e., where NSDF Project activities would be undertaken, including the NSDF Project's proposed facilities, buildings and infrastructure).
- **Local Study Area (LSA):** The LSA is selected in consideration of the NSDF Project footprint and the spatial extent of potential direct effects of the NSDF Project on the VCs. The LSA is selected to represent an area that is likely to be directly affected by the Project, helping to identify Project-specific effects (rather than cumulative effects of the NSDF Project in combination with other projects in the region).
- **Regional Study Area (RSA):** The RSA is defined as the area within which the maximum geographical extent of potential indirect effects of the NSDF Project may interact with the effects of other existing or reasonably foreseeable developments.

The spatial boundary for the study areas considered by each discipline and the rationale for their selection are identified in Sections 5.2 through 5.10 under the “Assessment Boundaries” heading. The study areas are illustrated on maps of appropriate scale that are also included in Sections 5.2 through 5.10 under the “Assessment Boundaries” heading.

5.1.3.2 Temporal Boundaries

Temporal boundaries (i.e., project phases) establish the timeframe during which NSDF Project effects are assessed. The temporal boundary represents the timeframe during which project activities are actively occurring, and does include the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a Project activity or stressor (which is related to the project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the NSDF Project (e.g., a residual effect that lasts for thousands of years). The following phases were identified for the NSDF Project.

- **Construction phase**: This phase includes site preparation and all activities associated with the construction of the NSDF Project. This phase includes activities such as installing the necessary supporting and/or ancillary facilities and infrastructure to facilitate NSDF Project operations, inactive commissioning and systems testing and transportation of construction materials. Construction activities are expected take place from 2022 to 2024.
- **Operations phase**: This phase includes all activities associated with waste placement, water management, Wastewater Treatment Plant (WWTP) operations, vehicle movements into and from the SSA and maintenance activities. Operations activities are expected to last approximately 50 years (i.e., 2025 to 2070).
- **Closure phase**: This phase includes activities necessary to complete the installation of the final cover and implementation of long-term monitoring. Closure activities are expected to start in 2070 and continue through to 2100, after which the NSDF Project will transfer into the post-closure phase.
- **Post-closure phase**: This phase has two discrete periods: institutional control and post-institutional control. The institutional control period includes implementation of controls throughout 2100 to 2400 (i.e., 300 years). During institutional control, environmental monitoring will be completed as required to confirm that the final cover is functioning as intended and to demonstrate compliance with the environmental assessment predictions. Post-institutional control occurs after year 2400 and continues indefinitely.

Baseline studies associated with each VC identify temporal variation (e.g., annual or seasonal changes in water flow or habitat use, or trends over time in populations and employment) and other biophysical constraints relevant to the assessment of the NSDF Project. The final selection of temporal boundaries is discipline-specific and includes consideration of the phases described above. For some VCs, residual effects are assessed for all phases of the NSDF Project but not necessarily for each specific phase. For example, effects on wildlife begin during the construction phase with the removal and alteration of habitat (i.e., results in direct and indirect changes) and continue through the operations phase and for a period after the closure phase until reversed, unless determined to be irreversible or permanent. Therefore, effects on wildlife are analyzed and predicted from construction through closure phases, which generates the maximum potential spatial and temporal extent of effects, and provides confident and ecologically relevant effects predictions.

Alternatively, for some VCs, the assessment was completed for those phases of the NSDF Project where predicted effects would be expected to peak (e.g., most air quality effects from emissions occur during construction) or at several key points in time. These points in time may include several periods within or among

NSDF Project phases. For example, evaluating surface water quality predictions at specific times that represent key milestones throughout the life of the NSDF Project. For other VCs, the assessment of effects may continue beyond the closure phase.

The temporal boundaries identified for cumulative effects assessments are specific to the VCs being assessed. Temporal boundaries include the duration of residual effects from previous and existing developments that overlap with residual effects of the NSDF Project and the period during which the residual effects from reasonably foreseeable developments (RFDs) will overlap with residual effects from the NSDF Project. The temporal boundaries considered by each discipline are identified in Sections 5.2 through 5.10 under the “Assessment Boundaries” heading.

5.1.3.3 Assessment Cases

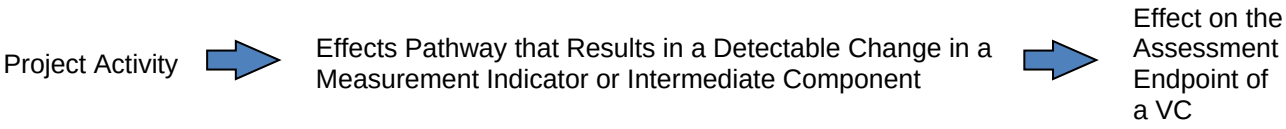
This section provides a brief description of the assessment cases considered in the EIS. The assessment cases are discipline-specific and consist of the following:

- **Base Case**: This scenario represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural, mining and residential and recreational development. Current effects from the existing CRL facilities and operations, for example, are considered part of the Base Case.
- **Application Case**: This scenario represents predictions of the effects of the Base Case combined with the effects that may result from the NSDF Project.
- **Reasonably Foreseeable Developments (RFD) Case**: This scenario represents predictions of the cumulative effects of the Application Case, which includes the Base Case, plus projects that are currently under application review or that have officially entered a regulatory application process and are, therefore, considered reasonably foreseeable. In addition, effects from the future decommissioning and environmental remediation activities to be completed at the CRL site are also considered as part of the RFD Case.

5.1.4 Description of the Environment

To provide a basis for evaluating potential changes of the NSDF Project, the “Description of the Environment” subsection for each discipline assessment includes a description of the baseline conditions. Baseline studies are completed to develop an understanding of the existing physical, biological and social conditions that may be influenced by the NSDF Project and are used to prepare a Base Case. The Base Case includes the cumulative effects from all previous and existing developments in the study area of a VC. Existing environment or baseline conditions represent the historical and current environmental selection pressures that have shaped the observed patterns in VCs. Environmental selection pressures include natural (e.g., weather, predation and competition) and human-related factors (e.g., mineral development, forestry and traditional and sport hunting and fishing).

Existing conditions are described recognizing that conditions typically fluctuate depending on which selection pressures are currently driving changes to the VC and system. The fluctuations are generated by variation in natural factors (natural variation) and variation associated with human influences. The Base Case thus describes the existing environment without the implementation of the NSDF Project, and is used to provide an understanding of the physical, biological and social conditions that may be influenced by the NSDF Project.



Information sources included published and unpublished material and baseline and other monitoring data collected by CNL. This information was reviewed and analyzed to determine the presence of data gaps. Baseline field studies were then planned and carried out to fill the identified gaps. Relevant existing data from

previous studies and the results of the recent baseline field programs are presented in the discipline-specific sections. Traditional knowledge, including Indigenous traditional knowledge, if available, was included in the baseline information.

The methods and results of the data collection described above that are directly relevant to the assessment of NSDF Project effects are summarized in the “Description of the Environment” subsections in Sections 5.2 through 5.10.

5.1.5 Project Interactions and Mitigation

Interactions (linkages) between NSDF Project components or activities and the corresponding potential changes to measurement indicators are identified by a pathway analysis that is then used to focus the residual effects assessment for the VCs. The first part of the analysis is to identify all pathways by which a Project component or activity could cause a potential effect. Each pathway is initially considered to have a linkage to potential effects on VCs. For an effect to occur, there has to be a Project component or activity that results in a detectable change to the measurement indicators and a correspondent effect on a VC.

The development of the potential pathways is followed by the screening of potential pathways to determine if mitigation is required, and if so, the development of environmental design features and mitigation that can be incorporated into the NSDF Project to remove a pathway (i.e., eliminate the potential effect) or limit (i.e., mitigate) adverse effects on VCs. Environmental design features and mitigation include engineering design elements, environmental best practices, management policies and procedures and spill response and emergency contingency plans. The description of environmental design features and mitigation will be specific to each discipline and the associated VCs. Any uncertainty associated with the effectiveness of proposed mitigation actions will be noted.

The purpose of the pathway analysis is to focus the residual effects analysis on linkages that require a more comprehensive assessment of effects on VCs, or those pathways that are likely to result in residual effects on a VC. Pathways are determined to have no linkage, a secondary (minor) linkage, or a primary linkage using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features. Each potential pathway is evaluated and described as follows:

- **No linkage**: Analysis of the potential pathway reveals that there is no valid linkage between the NSDF Project and the VC, or the pathway is removed by environmental design features or mitigation so that the NSDF Project would not be expected to result in a measurable environmental change and would therefore have no residual effect on a VC relative to existing conditions or guideline values.
- **Secondary**: The pathway could result in a measurable minor environmental change, but would have a negligible residual effect on a VC relative to existing conditions or guideline values, and is not expected to contribute to effects of other existing, approved, or reasonably foreseeable developments to cause a significant effect.

- **Primary**: The pathway is likely to result in an environmental change that could contribute to residual effects on a VC relative to existing conditions.

Pathways with no linkage to a VC, either because there was no linkage initially or because environmental design features or mitigation will remove the pathway, are not advanced for further assessment. Pathways that are assessed to be secondary and demonstrated to have a negligible residual effect on a VC through simple qualitative or semi-quantitative evaluation of the pathway are also not advanced for further assessment. In summary, pathways determined to have no linkage to a VC or those that are considered secondary are not expected to result in environmentally significant effects on the assessment endpoint of VCs, individually or cumulatively. Primary pathways require further effects analysis and classification to determine the environmental significance of the NSDF Project effects on VCs. Appendix 5.1-1 presents a matrix summarizing NSDF Project–environment interactions for each VC that are determined to be no linkage, secondary, or primary, after consideration of environmental design features and mitigation.

5.1.6 Residual Effects Analysis

The residual effects analysis is based on the NSDF Project–environment interactions that are determined to be primary in the pathway analysis. For primary pathways that require a residual effects analysis, the concept of assessment cases is applied to estimate the incremental and cumulative effects from the NSDF Project, as well as previous, existing and reasonably foreseeable developments. The residual effects analysis is completed for the Application Case and the RFD Case.

5.1.6.1 Application Case

This Application Case represents predictions of the cumulative effects of the existing environment combined with the effects that may result from the NSDF Project. The residual effects analysis for the Application Case is based on residual Project-specific (incremental) effects that are evaluated to be primary in the pathway analysis. The environmental design features and mitigation identified in Section 5.1.5 will be described in this section. Thus, the residual effects analysis will consider all primary pathways that will likely result in detectable changes in measurement indicators, and subsequent residual effects on VCs, after implementing environmental design features and mitigation. The Application Case represents effects predictions of the projects represented in the existing environment (Base Case) combined with the effects that may result from the NSDF Project.

The Application Case represents predictions of the cumulative effects of the developments in the Base Case combined with the effects from the NSDF Project. Where relevant, this case was used to identify the incremental changes from the NSDF Project that are predicted to occur between the Base Case and the Application Case. The residual effects analysis considers the proposed environmental design features and mitigation identified in Section 5.1.5.

The temporal boundary of the Application Case begins with the anticipated first year of construction of the NSDF Project, and continues until the predicted effects are reversed. For several VCs, the temporal extent of some effects likely will be greater than the lifespan of the NSDF Project because the effects will not be reversible until after closure. For other VCs, the effects may be determined to be irreversible within the temporal boundary of the Application Case. Such effects may be permanent or the duration of the effect may not be known, except that it is expected to be extremely lengthy (i.e., more than 100 years past closure).

Results of the effects analyses for the Application Case are used to describe the magnitude, duration and geographic extent of the predicted changes to measurement indicators and residual effects on VC assessment endpoints. Expected changes are expressed quantitatively (i.e., numerically), wherever possible. For example,

the magnitude of the effect may be expressed in absolute or percentage values above or below baseline conditions or a guideline value. The duration, including reversibility, of the effect typically is described in years relative to the phases of development of the NSDF Project and the spatial extent of effects is typically expressed in area or distance from the NSDF Project. In addition, the direction, frequency, reversibility, probability and context of effects are described, where applicable. Rankings such as short-term duration or moderate magnitude are not used in the effects analysis. These rankings are applied to the classification of effects and determination of significance, where definitions of these rankings are provided.

Effects on social, economic and cultural properties include positive and negative changes to employment, training and education, family income, traditional land use, family and community cohesion and long-term social, cultural and economic sustainability. Some of these measurement indicators can be analyzed quantitatively (e.g., number of jobs created and estimated income levels). Other indicators such as community cohesion and traditional land use are more difficult to quantify, and involve information from public engagement, literature, examples from similar projects under similar conditions, and scientific knowledge and experience. The effects analysis considers the interactions among the unique and common attributes, challenges and opportunities related to social, cultural and economic measurement indicators.

5.1.7 Prediction Confidence and Uncertainty

The purpose of an environmental assessment is to predict the future conditions of the biophysical and human environments as a result of a proposed project or development. Because the biophysical and human environment changes naturally and continually through time and across space, most assessments of effects embody some degree of uncertainty. The purpose of the uncertainty sections of the assessment is to identify the key sources of uncertainty and to discuss how uncertainty is addressed to increase the level of confidence that effects will not be worse than predicted. Confidence in effects analyses can be related to many elements, including the following:

- adequacy of the baseline data for providing an understanding of the existing conditions and future changes unrelated to the NSDF Project (e.g., rate and extent of future developments, climate change or catastrophic events);
- model inputs (e.g., changes in chemical concentration in water over time and space);
- understanding of Project-related effects on complex ecosystems that contain interactions across different scales of time and space (e.g., how and why the NSDF Project will influence wildlife);
- limited knowledge and experience with the type of effect in the system;
- knowledge of the effectiveness of the environmental design features for reducing or removing effects (e.g., environmental performance of the base liner);
- uncertainties associated with the exact location, physical footprint and activity level of the NSDF Project, as well as the timing, nature and rate of future developments in the RFD Case; and
- uncertainties in the direction, magnitude and spatial extent of future fluctuations in ecological, cultural and socio-economic variables, independent of effects from the NSDF Project and other developments.

Uncertainty in these elements can decrease confidence in the prediction of environmental significance. Discipline studies use quantitative methods, such as sensitivity analyses, or qualitative discussion to assess prediction confidence to the extent reasonable. Assumptions for statistical tests, and details on models that were used as part of the assessment, are discussed within each discipline of study. Where possible, methods are used to reduce uncertainty and increase the level of confidence in effects predictions, as shown in the following examples:

- using the results from several models and analyses to help reduce bias and increase precision in prediction; and
- using data from effects monitoring programs and literature as inputs for models rather than strictly hypothetical or theoretical values.

In addition, a conservative approach was implemented when information is limited so that effects are typically overestimated (e.g., defining the key input variables so that the result is a conservatively high effects prediction). Where appropriate, residual uncertainty is addressed by additional mitigation and in monitoring and follow-up programs. Each discipline of study includes a discussion of how uncertainty is addressed and provides a qualitative evaluation of the resulting level of confidence, which is included in the residual effects classification and determination of significance discussions.

5.1.7.1 Reasonably Foreseeable Development Case

The RFD Case includes the Application Case plus additional RFDs in the region that have not yet been approved. Developments and activities that are currently under application review or have officially entered a regulatory application process were considered reasonably foreseeable. This section describes the general methods used to predict whether the cumulative effects from the NSDF Project, in combination with previous, existing and reasonably foreseeable developments and activities are likely to result in environmental, social, economic, heritage and health effects, taking into account the mitigation actions proposed in the EIS.

The CEAA 2012 requires that each environmental assessment of a designated project take into account any cumulative environmental effects that are likely to result from the designated project in combination with the environmental effects of other physical activities that have been or will be carried out (The Agency 2015). Cumulative effects such as those that are likely from a reviewable project, combined with the effects from previous, existing and reasonably foreseeable future developments that are sufficiently certain to proceed. Therefore, the RFD Case represents predictions made about the cumulative effects of the Application Case, which includes the Base Case, plus projects that are currently under application review or that have officially entered a regulatory application process, and are therefore, considered reasonably foreseeable.

The RFD Case includes the predicted duration of residual effects from the NSDF Project, plus other previous, existing and future developments and activities. Thus, the minimum temporal boundary for the Application Case and the RFD Case is the expected lifespan of the NSDF Project, which, like the Base Case, includes a range of conditions over time. The difference between the Application Case and the RFD Case is that the Application Case considers the incremental effects from the NSDF Project in isolation of potential future land use activities.

The VCs requiring an analysis under the RFD Case are determined by understanding whether the residual effects from the NSDF Project and one or more additional developments (or activities) overlap or interact with the temporal or spatial distribution of the VC. Where potential cumulative effects from the RFD Case are identified for these VCs, these effects will be assessed using the same approach used for the NSDF Project-specific effects analysis (Section 5.1.6.1).

The analysis for the RFD Case is quantitative where possible and qualitative where necessary. The analysis is quantitative for those future projects that could be assigned a location, a physical footprint (i.e., known or hypothetical) on the landscape and information about project emissions (e.g., to air and water). The analysis is qualitative for developments that did not have this information. For all RFDs, the EIS uses the most current information available for the location, size and type of activity associated with a project.

5.1.8 Residual Effects Classification and Determination of Significance

5.1.8.1 Residual Effects Classification

The purpose of the residual effects classification is to describe the residual incremental and cumulative adverse effects from the NSDF Project and other developments on VCs using a common set of criteria. The classification criteria provide definitions that permit a clear, thorough and unambiguous classification of residual effects such that reviewers and readers can follow and apply the logic used in the assessment and reach the same classification for a given residual effect. The residual effects classification is then used to make significance determinations. The intent of the environmental assessment is to predict if the NSDF Project is likely to cause a significant adverse (i.e., negative) effect on the environment or to cause public concern.

The classification of residual adverse effects and the determination of significance are completed for those VCs that have assessment endpoints, and where residual adverse effects are predicted. The residual effects classification takes into consideration additional mitigation identified (if applicable) in the residual effects assessment. The results of the classification are used to determine the significance of predicted adverse effects.

Effects are classified using the criteria listed below, which follow the Generic EIS Guidelines (CNSC 2016) and the Agency's *Determining Whether a Designated Project is Likely to Cause Significant Adverse Environmental Effects under the Canadian Environmental Assessment Act, 2012* (The Agency 2018b). Specific definitions for the classification criteria have been developed for each VC or discipline of study.

Direction: Direction indicates whether the residual effect on a VC is negative (i.e., less favourable), positive (i.e., improvement), or neutral (i.e., no change). Neutral and positive changes are not assessed for significance.

Magnitude: Magnitude is a measure of the intensity of a residual effect, or the degree of change caused by the NSDF Project (and other developments, if applicable) relative to baseline conditions, guidelines, or threshold values. Magnitude is typically classified into three scales: negligible to low, moderate and high. The scales of magnitude are specific to each VC or discipline of study, and incorporate the geographic extent and duration of residual effects in context of the properties of VC assessment endpoints. Where possible, magnitude is reported in absolute and in relative terms.

Geographic extent: This criterion refers to the spatial extent of the effect, and is different from the spatial boundary (i.e., study area) for the residual effects analysis. The spatial boundary for the residual effects analysis represents the maximum area used for the assessment, and is related to the spatial distribution and movement of VCs. The geographic extent of residual effects can occur on multiple scales within the spatial boundary of the assessment. Geographic extent refers to the area affected, and is often categorized into three scales of local, regional and beyond regional.

Duration: Duration is defined as the amount of time (usually in years) from the beginning of a residual effect on when the residual effect to a VC is reversed and is expressed relative to NSDF Project phases. Duration has two components. It is the amount of time between the start and end of a Project activity or stressor (which is related to Project development phases), plus the time required for the residual effect to be reversed.

Reversibility: After removal of the NSDF Project activity or stressor, reversibility is the likelihood that the NSDF Project will no longer influence a VC in a future predicted period. Reversibility usually has only two alternatives: reversible or irreversible. The period is provided for reversibility (i.e., duration) if a residual effect is reversible. Permanent residual effects are considered irreversible.

Frequency: Frequency refers to how often a residual effect will occur and may be expressed as isolated, periodic, or continuous. Frequency is explained more fully by identifying when the residual effect occurs (e.g., once at the beginning of the NSDF Project). Timing was not included as a separate criterion. If the frequency is periodic, then the length of time between occurrences and the seasonality of occurrences (if present) is discussed.

Likelihood: Likelihood is the probability of an effect occurring and is described in parallel with uncertainty. This criterion may be influenced by a variety of factors, such as the likelihood of disturbance occurring or the likelihood of mitigation being successful. Four classification categories are typically used: unlikely, possible, likely and highly likely.

The specific definitions applied to the above classification criteria for each VC or discipline of study are based on the ecological or socio-economic processes and properties of the VC or discipline of study. Although some professional judgement or experienced opinion is inevitable in determining the scales for effects predictions, the residual effects, to the extent possible, are classified using scientific principles, established guidelines, thresholds or target values, and supporting evidence.

5.1.8.2 Determination of Significance

The residual effects classification of primary pathways and the associated predicted changes in measurement indicators provide the foundation for determining the significance of incremental and cumulative effects from the NSDF Project and other previous, existing and reasonably foreseeable developments on VC assessment endpoints. For some VCs, there may be no RFD Case and the assessment is limited to determining the significance of residual effects from the NSDF Project and previous and existing developments (i.e., Application Case). For those VCs that may be influenced by forecasted future developments, the assessment includes classifying and determining the significance of cumulative effects from all previous, existing and reasonably foreseeable developments, including the NSDF Project (i.e., RFD Case). The classification of residual adverse effects and the determination of significance are completed only for those VCs that have assessment endpoints. Although the neutral and positive residual effects associated with the NSDF Project are reported in this section, they are not assessed for significance.

Magnitude is the primary criterion used to determine the significance of effects on VCs. Where possible and appropriate, established guidelines, thresholds and screening values are used to support the classification of the predicted amount of change in measurement indicators and associated effects on VC assessment endpoints. For some disciplines and VCs, such as aquatic health effects to fish, guideline or threshold values are known with reasonable certainty, which increases confidence in effects predictions and significance determinations. For other VCs of the biophysical and human environments, social and ecological benchmarks or effects thresholds are not known with reasonable certainty, which decreases confidence in determining the significance of predicted effects. For example, critical thresholds and screening levels for measurement indicators such as habitat quality, quantity and connectivity and ecologically effective population sizes are frequently not available for plant, fish and wildlife species. Because of the uncertainty regarding the effects of development on VCs, magnitude classification is conducted conservatively to increase confidence that effects will not be under-estimated. Furthermore, the determination of significance considers the level of confidence in the effects predictions.

Magnitude also considers the geographic extent and duration of residual effects that are specific to VC assessment endpoints. For example, the magnitude of an effect on a fish or wildlife VC from changes in habitat availability and connectivity depends on the spatial extent (e.g., amount of area or proportion of the population) and duration of the changes in habitat (e.g., how long populations using that habitat may be adversely affected). Duration includes consideration of reversibility; a reversible effect from development does not result in a permanent adverse effect and therefore may be considered to be of lower magnitude. The duration of residual effects to VCs with high resilience (ability to recover from disturbance) would be expected to be shorter relative to VCs with lower resilience to disturbance.

Frequency is considered a modifier when determining significance, where applicable. For example, the magnitude of the effect from the loss of individuals from a wildlife population due to collisions with vehicles will depend partially on how often animal-vehicle collisions occur over the life of a project. For some effects, such as the physical loss of habitat from the NSDF Project, the likelihood is high and has little influence on the significance of effects (i.e., the decline in habitat is certain and significance depends on the amount of change over space and time [magnitude]). Alternately, the magnitude of an effect may vary from low to high depending on the probability of different projected outcomes of climate change and the degree of success in actions implemented to mitigate effects from climate change. Likelihood is also considered a modifier, but it is applied after significance is determined.

The evaluation of significance for biophysical VCs considers the entire set of primary pathways that influence a particular assessment endpoint; thus, significance is not explicitly assigned to each pathway. Rather, the relative contribution of each pathway is used to determine the significance of potential adverse effects of the NSDF Project and other developments on an assessment endpoint. This approach is known as a “weight of evidence” approach (i.e., an evaluation of the persuasiveness of the collective evidence). For example, a pathway with a high magnitude (which would include a large geographic extent and a long-term duration) is given more weight in determining significance relative to pathways with smaller scale effects. The relative effect from each pathway is discussed; however, pathways that are predicted to have the greatest influence on effects to assessment endpoints are assumed to contribute the most to the determination of significance. This method is used to identify predicted residual adverse effects that have sufficient magnitude, duration and geographic extent to result in significant adverse effects on VC assessment endpoints.

Classification of residual effects and determination of significance for the human environment generally follow the methods used for biophysical VCs. However, there are some differences in the selection and definition of effects criteria. For socio-economic VCs, direction, magnitude, geographic extent and duration are the criteria used to classify effects and evaluate the significance of changes to assessment endpoints. The assessment of significance considers the scale of these criteria (e.g., low magnitude, regional geographic extent and long-term duration) and scientific knowledge and experience, which is based on the context of the communities involved, and the informed value and judgement of interested and affected organizations and specialists. The level of significance takes into consideration the effectiveness of the proposed mitigation (i.e., policies, practices and investments) and benefit enhancement programs to limit negative effects and foster positive effects on the continued persistence of long-term sustainable social, cultural and economic features of the human environment.

Details on the approach and methods for classifying residual effects and determining significance on VCs of the biophysical and human environments are provided in the applicable discipline sections of the EIS. The definition of a significant effect is specific to each discipline and will be provided in each discipline section. Significance is determined for the residual adverse effects of the NSDF Project overall, for the cumulative residual adverse effects from the NSDF Project and previous and existing developments (Application Case), and for the NSDF

Project and previous, existing and reasonably foreseeable developments (RFD Case). The following is a summary of some of the key factors considered in the determination of significance on VCs of the biophysical and human environments:

- Magnitude is the primary criterion used to determine significance, with geographic extent and duration (which implies reversibility) providing important context for assigning magnitude.
- Frequency and likelihood act as modifiers for determining significance, where applicable.
- The degree of uncertainty in the effects estimates also influences the classification of magnitude and the determination of significance. Where uncertainty was high and the effect from the NSDF Project might be either significant or not significant, the assessment conservatively identified the effect as significant and provided additional follow-up actions to reduce uncertainty.

5.1.9 Monitoring and Follow-up

In the EIS, monitoring programs are proposed to address the uncertainties associated with the effects predictions and the performance of mitigation. In general, monitoring is used to verify the effects predictions, identify any unanticipated effects and provide for the implementation of adaptive management to limit these effects. Typically, monitoring includes one or more of the following categories, which may be applied during the development of the NSDF Project:

- **Compliance monitoring**: monitoring activities, procedures and programs undertaken to confirm the implementation of approved design standards, mitigation and conditions of approval and company commitments (e.g., inspecting the installation of a silt fence).
- **Environmental monitoring**: monitoring to track conditions or issues during the development lifespan of the NSDF Project, and to subsequently provide for the implementation of adaptive management (e.g., monitoring of treated wastewater discharge quality and volumes).
- **Follow-up monitoring**: programs designed to test the accuracy of effects predictions, reduce or address uncertainties, determine the effectiveness of mitigation, or provide appropriate feedback to operations for modifying or adopting new mitigation designs, policies and practices (e.g., monitoring of downstream lakes for aquatic effects). Results from these programs can be used to increase the certainty of effect predictions in future environmental assessments.

Proposed monitoring and follow-up programs are discussed in each discipline section of the EIS and, upon NSDF Project approval, will be included in CNL's Environmental Protection Program or other appropriate CNL management, monitoring, or reporting programs. Where relevant, conceptual monitoring programs will be proposed to deal with the uncertainties associated with the effect predictions and mitigation.

5.2 Atmospheric Environment

This section of the Environmental Impact Statement (EIS) for the Canadian Nuclear Laboratories (CNL) Near Surface Disposal Facility (NSDF) Project seeks to understand and characterize potential residual effects of the NSDF Project and other previous, existing, and reasonably foreseeable developments on the atmospheric environment. As part of the assessment, the following subsections present an assessment of the atmospheric environmental effects of the NSDF Project. Section 5.2.1 focuses on air quality and Section 5.2.2 focuses on greenhouse gas (GHG) emissions. Radiological emissions are not included within this section and instead are discussed in Section 5.7 Ambient Radioactivity and Ecological Health.

There are no sensitive receptors[1] in the vicinity of the NSDF Project that would experience nuisance effects from the construction and operations phases of the NSDF Project due to noise and vibration. The nearest dwelling to the NSDF Project site is located approximately 3 km away. The *NSDF Project Construction-Related Road Traffic on Human Receptors* (Golder 2018) was completed to understand the potential for indirect effects of noise from NSDF Project traffic on adjacent land users; the results are discussed in Section 5.10 Socio-economic Environment. A discussion of potential indirect effects from noise and vibrations and supporting information is also provided in Sections 5.5 Aquatic Environment and 5.6 Terrestrial Environment.

5.2.1 Air Quality

5.2.1.1 Scope of the Assessment

The air quality assessment focusses on predicting changes in indicator compound emissions and comparison of these changes to the applicable guidelines and standards (see Section 5.2.1.4). The indicator compounds relevant to the NSDF Project include suspended particulate matter (SPM), particles nominally smaller than 10 µm in diameter (PM_{10}), particles nominally smaller than 2.5 µm in diameter ($PM_{2.5}$), carbon monoxide (CO), sulphur dioxide (SO_2), nitrogen oxides (NO_x) expressed as nitrogen dioxide (NO_2). Emissions of particulates (SPM, PM_{10}, and $PM_{2.5}$), CO, SO_2, and NO_x have the potential to affect aquatic, human, and terrestrial wildlife health. Particulates emissions, which are also referred to as fugitive dust, can be a nuisance issue of concern to the public. In addition to the indicator compounds noted above, hydrogen sulfide (H_2S), vinyl chloride (C_2H_3Cl), lead (Pb), mercury (Hg), and odour emissions have been considered as indicator compounds. Acrolein (C_3H_4O) was included to represent volatile organic compounds (VOCs) from combustion at the request of Canadian Nuclear Safety Commission (CNSC). Radiological indicator compounds are not included in this assessment and instead have been evaluated in Section 5.7 Ambient Radioactivity and Ecological Health.

The air quality assessment follows the overall environmental assessment approach and methods described in Section 5.1 Environmental Assessment Approach. The assessment was completed following the key steps listed below:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries, and assessment cases** for the air quality assessment (refer to Sections 5.2.1.2 Valued Components and Section 5.2.1.3 Assessment Boundaries). The VCs, assessment endpoints, and measurement indicators used to assess Project-related changes to air quality are described, along with the spatial and temporal boundaries at which the assessment occurred; and the assessment cases considered.

[1] Consistent with *O. Reg. 419/05 Air Pollution – Local Air Quality*, the air quality assessment considers the following places as 'sensitive receptors': a health care facility; a senior citizens' residence or long-term care facility; a child care facility; an educational facility; a dwelling; or a place specified by the Director in a notice under subsection (9) as a place where discharges of a contaminant may cause a risk to human health.

- **Step 2 – Describe the existing conditions** (refer to Section 5.2.1.4 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation). The existing conditions provide a reference, to which the effects of the NSDF Project can be compared.
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 5.2.1.5 Project Interactions and Mitigation). Project components and/or activities with the potential to affect air quality are identified and mitigation developed to limit or avoid effects is presented. A pathways analysis is then used to focus further assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects to air quality after incorporating mitigation are carried forward to Steps 4 for further analysis and residual effects characterization.
- **Step 4 – Present the methods and results of the residual effects analysis** (refer to Section 5.2.1.6 Residual Effects Analysis). This section outlines the methods used to predict and characterize residual effects to air quality from primary effects pathways. The analysis results are also presented including the characterization of incremental effects from the NSDF Project, as well as cumulative effects of the NSDF Project in combination with other reasonably foreseeable developments (if applicable). A key outcome of this section is the predicted changes to emissions of indicator compounds that are passed on to other disciplines for their assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty** (refer to Section 5.2.1.7 Prediction Confidence and Uncertainty). This purpose of this section is to evaluate the available literature, data, and models used for the assessment, and describe the level of certainty that can be placed on predicted residual effects. This section will also identify how the uncertainty has been managed so that the effects are not underestimated.
- **Step 6 – Classify and determine the significance of the predicted residual effects** (refer to Section 5.2.1.8 Residual Effects Classification and Determination of Significance). Residual effects predicted from primary pathways are classified using a common set of criteria: direction, magnitude, geographic extent, duration, reversibility, frequency, and likelihood. A determination of the significance of the predicted residual effects from NSDF Project for the air quality VC is made.
- **Step 7 – Identifying monitoring and follow-up** required to confirm effects predictions and address uncertainty (refer to Section 5.2.1.9 Monitoring and Follow-up).
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** of residual effects on air quality (refer to Section 5.2.1.10 Conclusions).

Information and areas of interest raised by the public, communities of interest, and Indigenous communities or organizations during engagement that influenced the scope of the air quality assessment are summarized in Table 5.2.1-1. Other general areas of interest and questions (if any) raised during the engagement that pertain to the air quality assessment are documented in CNL's Indigenous Engagement Report (CNL 2021) and CNL's Stakeholder's Activity Reports (CNL 2017a,b, 2019a).

Table 5.2.1-1: Summary of Areas of Interest Raised During Engagement Activities that Influenced the Scope of the Air Quality Assessment

Areas of Interest	How the Area of Interest Was Included in the Assessment
Would like information on monitoring air contamination, including dust.	The monitoring program proposed for air quality includes monitoring of fugitive dust emissions and is described in Section 5.2.1.9. Fugitive Dust Monitoring is captured through the implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and air verification monitoring. In addition, the *Dust Management Plan* (AECOM 2018a) to be implemented for the NSDF Project will include information on dust mitigation and monitoring for the NSDF Project.

5.2.1.2 Valued Components

Valued Components (VCs) refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Air quality was selected as a VC as there is a potential for the NSDF Project activities to release air emissions that could affect the air quality (Table 5.2.1-2). Meteorology is also important as it governs the transport, dispersion, and deposition of air emissions from the NSDF Project. An understanding of the meteorological processes is necessary to address and model potential air quality effects of the NSDF Project. Details on meteorology are provided in the Air Quality Assessment Technical Supporting Document (TSD; Golder 2019) Section 2 (Meteorology Assessment).

Table 5.2.1-2: Valued Components for Air Quality Assessment

Valued Component	Rationale for Selection
Air Quality	■ Air quality is selected as a VC as emissions from the NSDF Project activities have the potential to alter the existing air quality regime. ■ Changes in air quality can affect human health, aquatic and terrestrial biodiversity.

VC = valued component

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future generations. The assessment endpoint for air quality is performance against the criteria and thresholds for protection of human health and the environment.

Measurement indicators represent properties of the environment and VCs that, when changed, could result in or contribute to an effect on a VC. Measurement indicators also provide the primary factors for discussing the uncertainty of effects on VCs and, subsequently, are the key variables for study in follow-up and monitoring programs. The assessment of air quality focused on predicting changes in the concentrations of selected non-radiological indicator compounds. The measurement indicator considered in the air quality assessment includes changes to the concentrations of non-radiological indicator compounds listed in Table 5.2.1-3. Deposition rates for non-radiological indicator compounds were also predicted and provided to other disciplines to assess the indirect effects of air quality. In addition, the decomposition of waste can result in emissions due to the breakdown of waste material within the NSDF. Overall, these compounds are generally accepted as indicative in changing air quality, and for which relevant air quality criteria exist. The selected non-radiological indicator compounds fall into the following four categories:

- **particulate matter**: SPM, PM_{10}, and $PM_{2.5}$;
- **combustion gases**: NO_X represented by NO_2, SO_2, CO, and C_3H_4O;

- **decomposition of waste**: H_2S, C_2H_3Cl, and odour; and
- **metals**: Pb and Hg.

Table 5.2.1-3: Assessment Endpoints and Measurement Indicators for the Air Quality Assessment

Valued Component	Assessment Endpoints	Measurement Indicators	Discipline Assessments where Effects on Air Quality are Considered
Air Quality	Performance against criteria and thresholds for protection of human health and the environment	Changes to ambient concentrations of indicator compounds (SPM, PM_{10}, $PM_{2.5}$, NO_2, SO_2, CO, C_3H_4O, H_2S, C_2H_3Cl, Pb, Hg, and odour).	■ Section 5.4.2 Surface Water Quality ■ Section 5.5 Aquatic Environment ■ Section 5.6 Terrestrial Environment ■ Section 5.8 Human Health ■ Section 5.9 Land and Resource Use

SPM = suspended particulate matter; $PM_{2.5}$ = particulate matter less than 2.5 µm (microns) in diameter; PM_{10} = particulate matter less than 10 µm (microns) in diameter; CO = carbon monoxide; NO_2 = nitrogen dioxide; SO_2 = sulphur dioxide; C_3H_4O = acrolein; H_2S; = hydrogen sulfide; C_2H_3Cl = vinyl chloride; Pb = lead; Hg = mercury.

These compounds are associated with various NSDF Project activities, as well as activities at the Chalk River Laboratories (CRL) main campus. Particulate matter in the form of fugitive dust is typically associated with airborne dust from vehicles travelling on unpaved roads/haul routes on site, as well as material loading, stockpiling and unloading activities. Products of combustion (e.g., particulate matter, NO_2, SO_2, CO, and Pb) are associated with the exhaust from on-site vehicles and stationary combustion from the Wastewater Treatment Plant (WWTP) process and comfort heating equipment. In addition, C_3H_4O was included to represent VOCs from combustion. Emissions from the decomposition of waste (e.g., H_2S, C_2H_3Cl, and odour) were not included in *Effluent Verification Monitoring at Chalk River Laboratories in 2018* (CNL 2019b), but are the result of the breakdown of waste material within the NSDF Project; and therefore, included as indicator compounds.

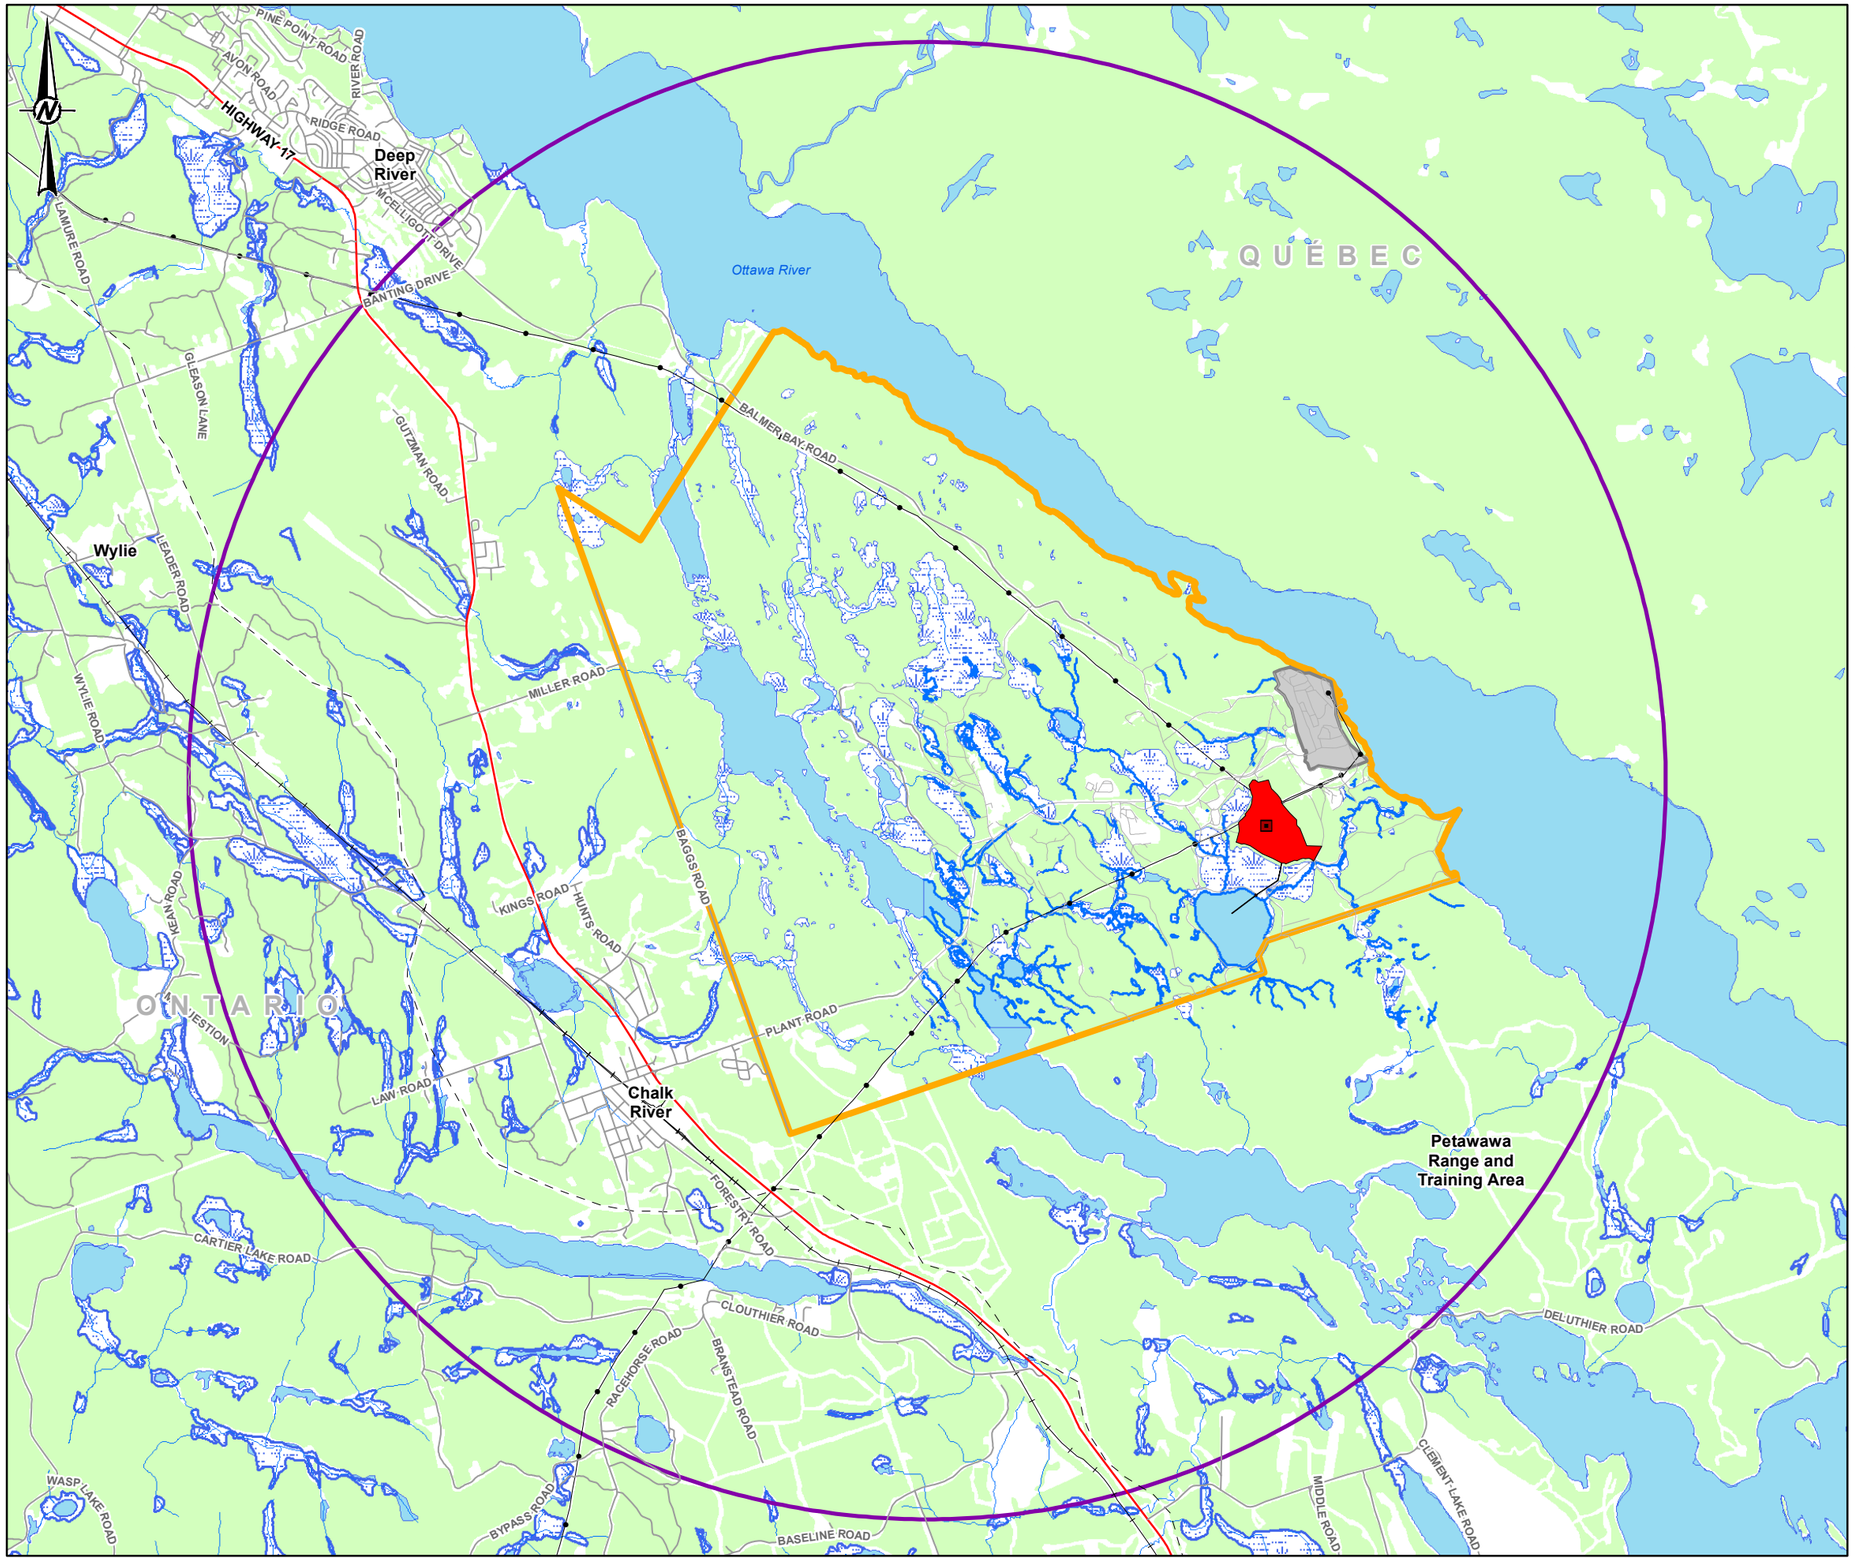
Ozone (O_3) was also included in the air quality assessment as it will be used to calculate the NO_2 in the effects assessment. Ozone is not emitted directly into atmosphere but is associated with the reaction of NO_X and VOCs (MECP 2018).

Other contaminants identified as indicator compounds that occur from the decomposition of the waste in the engineered containment mound (ECM), such as CO and Hg were also included. Odour emissions from the WWTP processes were also included. Metals are associated with number 6 fuel oil consumption at the CRL main campus (CNL 2019b), and have decreased since the conversion to natural gas at the powerhouse as part of the completed facility improvements.

Total VOCs and halocarbon refrigerants identified as emissions from the CRL main campus (CNL 2019b) are not considered indicator compounds for the NSDF Project; and therefore, were not retained for the air quality assessment.

The measurement indicators used for assessing the effects of the NSDF Project on the air quality VC are a combination of indicator compound and averaging period for which federal and provincial air quality objectives and criteria are available. A single measure is used when evaluating effects, namely the maximum predicted concentration resulting from the NSDF Project activities. To evaluate the effect of Project-related changes to air quality on other VCs, the results of the air quality assessment were provided for the disciplines listed in Table 5.2.1-3.

5.2.1.3 Assessment Boundaries



5.2.1.3.1 Spatial Boundaries

The spatial boundaries selected for the air quality assessment are presented on Figure 5.2.1-1 and are described below:

- **Site Study Area (SSA):** the SSA is the NSDF Project footprint (i.e., the NSDF Project site, where NSDF Project activities would be undertaken including proposed facilities, buildings and infrastructure).
- **Local Study Area (LSA):** The LSA is defined to encompass activities and sources of emissions associated with the Project. The LSA includes the SSA and corresponds to the CRL site boundary.
- **Regional Study Area (RSA):** The RSA is defined as the area within which the potential effects of the NSDF Project may interact with the effects of other existing or reasonably foreseeable developments. The RSA is equivalent to a circle surrounding the LSA with an approximate 7.4 km radius (Figure 5.2.1-1).

For the purposes of this assessment, results at the LSA boundary will be presented in the air quality assessment as it represents the highest ground-level concentrations of contaminants expected outside the CRL site.

5.2.1.3.2 Temporal Boundaries

Temporal boundaries (i.e., project phases) establish the timeframe during which NSDF Project effects are assessed. The temporal boundary represents the timeframe during which project activities are actively occurring, and considers the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a project activity or stressor (which is related to the project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the NSDF Project or if the effects were predicted to last so far into the future that the level of uncertainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the NSDF Project:

- **Construction phase**: This phase includes site preparation and all activities associated with the construction of the NSDF Project. This phase includes activities such as installing the necessary supporting and/or ancillary facilities and infrastructure to facilitate NSDF Project operations, inactive commissioning and systems testing, and transportation of construction materials. Construction activities are expected take place from 2022 to 2024.
- **Operations phase**: This phase includes all activities associated with waste placement, water management, WWTP operations, vehicle movements into and from the NSDF Project site, and maintenance activities. Operations activities are expected to last approximately 50 years (i.e., 2025 to 2070).
- **Closure phase:** This phase includes activities necessary to complete the installation of the ECM final cover and implementation of long-term monitoring. Closure activities are expected to last approximately 30 years starting in 2070 and continue through to 2100, after which the NSDF Project will transfer into the post-closure phase.
- **Post-closure phase:** This phase has two discrete periods: institutional control and post-institutional control. The institutional control period includes implementation of controls throughout 2100 to 2400 (i.e., 300 years). During the institutional control period, environmental monitoring will continue to demonstrate compliance with the environmental assessment predictions. The post-institutional control period occurs after year 2400 and continues indefinitely.

The temporal boundaries for the air quality assessment include consideration of the effects of the NSDF Project during the construction and operation phases, as the emissions from these phases will be higher than those during the closure and post-closure phases. Emissions from the construction phase are expected to be representative of those during closure as they will be similar in nature. The emissions from the closure phase are expected to be considerably less than those during the construction and operation phases, as most of the NSDF Project site will have been decommissioned. Effects to air quality would immediately cease following decommissioning of the WWTP and associated water management systems at the end of the closure phase.

5.2.1.3.3 Assessment Cases

The assessment cases considered in the air quality assessment include the Base Case, Application Case and the Reasonably Foreseeable Development Case:

- **Base Case:** This scenario represents existing conditions and characterizes effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural, mining, and residential and recreational development. Current effects from the existing operations and activities on the CRL site are considered part of the Base Case.
- **Application Case:** This scenario represents predictions of the effects of the Base Case combined with the effects that may result from the NSDF Project. The Application Case considers potential effects from the NSDF Project during construction and operations phases.
- **Reasonably Foreseeable Development (RFD) Case**: This scenario represents predictions of the cumulative effects of the Application Case, which includes the Base Case, plus projects that are currently under application review or that have officially entered a regulatory application process, and are therefore considered reasonably foreseeable. Reasonably foreseeable developments in the RSA that are anticipated to overlap with potential effects of the NSDF Project include new/upgrades to research and development facilities, construction and operation of a Small Modular Reactor (SMR), new support infrastructure, on-going decommissioning and environmental remediation activities on the CRL site. As well, there may be overlap of the construction period with limited construction at neighbouring Garrison Petawawa.

5.2.1.4 Description of the Environment

5.2.1.4.1 Climate and Meteorology for the NSDF Project

Climate normals are usually long-term averages of observed climate data used to summarize or describe the average climatic conditions of a particular location. Climate normals from Environment and Climate Change Canada (ECCC) stations located near the NSDF Project are used to describe the long-term record of general meteorological conditions in the region and are used to validate the Ontario Ministry of the Environment, Conservation and Parks (MECP) dispersion meteorological dataset.

The nearest 30-year (1981 to 2010) climate station is located on the CRL site, and is less than 1 km north of the centroid of the SSA. For meteorological parameters not monitored at the Chalk River AECL station, the next closest climate normals station with the required parameters, Ottawa MacDonald-Cartier International Airport (Ottawa), was used for the assessment (ECCC 2016).

The 30-year climate normal from the Chalk River AECL station calculates an average daily temperature of approximately 5.6°C while the daily average temperature in the winter season is approximately -9.3°C and the daily average temperature in the summer season is approximately 19.1°C. Annual precipitation of approximately 859 millimetres equivalent (mm[eq]) is calculated for the region, with the highest precipitation typically occurring in the summer at 252 mm[eq].

A more detailed breakdown of the climate and meteorology for the NSDF Project can be found in Section 2.2 of the Air Quality Assessment TSD (Golder 2019).

5.2.1.4.2 Methods

This section documents the methods, data and assumptions that were used to assess the non-radiological background air quality at the NSDF Project and in the LSA and RSA. The assessment was carried out by:

- identifying the non-radiological indicator compounds expected to be emitted from the NSDF Project;
- identifying and comparing non-radiological air quality guidelines in Ontario and Canada for the indicator compounds;
- identifying existing emission sources located within 25 km of the LSA with shared indicator compounds;
- assessing air quality data sources for use in the background air quality assessment; and
- comparing air quality monitoring data to the applicable air quality guidelines.

These steps are detailed in the following sections.

5.2.1.4.2.1 Applicable Criteria

The relevant air quality criteria used for screening air quality in the region include the Ontario criteria, and federal standards and objectives where provincial guidelines are not available. The MECP has set guidelines related to ambient air concentrations and are summarized in Ontario's Ambient Air Quality Criteria (AAQC) document (MOE 2012). The Ontario AAQCs are characterized as desirable ambient air concentrations and have been set at levels that are protective of human health and the environment. The Ontario AAQCs are not regulatory limits, and therefore, exceedances are permitted. The Ontario AAQCs are used for screening the air quality effects in environmental assessments, in studies using ambient air monitoring data, and as an assessment of general air quality in a community or across the province (MOE 2012).

Where provincial criteria were not available, the National Ambient Air Quality Objectives (NAAQOs) and the Canadian Ambient Air Quality Standards (CAAQSs; formerly National Ambient Air Quality Standards) were used. Similar to the Ontario AAQCs, the NAAQOs are benchmarks that can be used to facilitate air quality management on a regional scale, and provide goals for outdoor air quality that protect public health, the environment, or aesthetic properties of the environment (CCME 1999). The federal government has established the following levels of NAAQOs (Hopper et al. 1994):

- the maximum ***Desirable*** level defines the long-term goal for air quality and provides a basis for an anti-degradation policy for unpolluted parts of the country and for the continuing development of control technology; and
- the maximum ***Acceptable*** level is intended to provide adequate protection against adverse effects on soil, water, vegetation, materials, animals, visibility, personal comfort, and well-being.

The CAAQSs have been developed under the *Canadian Environmental Protection Act, 1999*, and include standards for $PM_{2.5}$, NO_2, SO_2 and ozone that must be achieved by 2020. In 2015 the standard was phased in, with the final standard phase in date in 2020 (Government of Canada 2013). Like the Ontario AAQCs, the CAAQSs are not regulatory limits and are used as national targets for $PM_{2.5}$, NO_2, SO_2 and ozone, excluding Quebec (CCME 2014). These more stringent standards were adopted because, as stated by the CCME (emphasis added):

> *Canadians living in heavily populated and industrialized areas of the country may be exposed to potentially harmful levels of outdoor air pollutants, at concentrations that exceeded established standards. (CCME 2014)*

However, the key aspect of "CAAQS Achievement" (i.e., compliance), as stated by the CCME, is (emphasis added):

> *Achievement of the CAAQS means that the measured air pollutant concentration in an air zone does not exceed the CAAQS numerical value. (CCME 2014)*

These values are reported based on a series of monitoring stations located in airsheds across Canada and in this context, an "air zone" refers to a local or regional sub-region of the established provincial or territorial airsheds. Currently, Southern Ontario and Southern Quebec are treated as a single Airshed (East Central) and Southern Ontario, excluding Hamilton and Sarnia, is designated as a single air zone.

For conservatism in this assessment, the lower of the Ontario AAQCs and the CAAQS, where applicable, were used for comparison to the maximum modelled concentrations. However, comparing the maximum predicted concentrations to the CAAQS standards is not appropriate for the following reasons:

- The NSDF Project boundary does not, nor does the 7.4 km radius circular regional study area (RSA), represent an "air zone", the region over which the CCME states that achievement of the CAAQS is to be evaluated/compared.
- There are not heavily populated or industrialized areas located within the 7.4 km radius circular air quality RSA. Therefore, there is no exposure pathway by which:
  - *Canadians living in heavily populated and industrialized areas of the country may be exposed to potentially harmful levels of outdoor air pollutants, at concentrations that exceeded established standards.* (CCME 2014)

A summary of the applicable Ontario, Quebec and federal objectives and criteria are listed in Table 5.2.1-4.

Table 5.2.1-4: Provincial and Federal Regulatory Air Quality Criteria[1]

Substance	Averaging Period	Ontario Ambient Air Quality Guidelines[a] ($\mu g/m^3$)	Canadian Ambient Air Quality Standards[b] ($\mu g/m^3$)	National Ambient Air Quality Objectives and Canadian Ambient Air Quality Standards[c] ($\mu g/m^3$)		Quebec Atmospheric Quality Standards and Criteria ($\mu g/m^3$)[p]

Note: **Bold** = ambient air criteria retained for use in the assessment.

(1) The lowest values in the table were used in the assessment of significance although the monitoring-based CAAQS numbers are not intended to be used in this manner.

a) Ontario's Ambient Air Quality Criteria (MOE 2012).

b) Canadian Ambient Air Quality Standards (Government of Canada 2013). Final standard phase in date of 2020 used. For SO_2, NO_2 and O_3, the reference is ppb and was converted using a pressure of 1 atmosphere and a temperature of 25ºC.

c) Canadian National Ambient Air Quality Objectives: Process and Status (CCME 1999).

d) SPM in Ontario is defined as <44 µm diameter.

e) Geometric mean.

f) Interim Ambient Air Quality Criteria and is provided as a guide for decision making (MOE 2012).

g) Compliance is based on the 98th percentile of the annual monitored data averaged over three years of measurements.

h) Standard is for nitrogen oxides (NO_X), but is based on the health effects of NO_2.

i) As described by the CCME, 3-year average of the annual 98th percentile of the NO_2 daily maximum 1-hour average concentrations.

j) As described by the CCME, 3-year average of the annual 99th percentile of the SO_2 daily maximum 1-hour average concentrations.

k) Ozone is not emitted directly into the atmosphere but is associated with the reaction of NO_X to calculate NO_2 in the effects assessment.

l) Arithmetic mean.

m) Odour unit per cubic metre (OU/m^3).

n) The Ontario Guideline is based on the 99.5th percentile on a 10-minute averaging period, in OU/m^3.

o) Odour concentration must be 1 odour unit or less 98% of the time and 5 units or less 99.5 % of the time. Predicted concentrations above the 1 odour unit criteria are permitted up to 175 hours per year and predicted concentrations above the 5 odour unit criteria are permitted up to 44 hours per year.

p) MELCC 2018.

— = No guideline available; SPM = suspended particulate matter; $PM_{2.5}$ = particulate matter less than 2.5 µm (microns) in diameter; PM_{10} = particulate matter less than 10 µm (microns) in diameter; CO = carbon monoxide; NO_2 = nitrogen dioxide; SO_2 = sulphur dioxide; H_2S; = hydrogen sulfide; C_2H_3Cl = vinyl chloride; Pb = lead; Hg = mercury; µg/m³ = microgram per cubic metre; C_3H_4O = acrolein; O_3 = Ozone; ppb = parts per billion; OU/m³ = odour unit per cubic metre.

Existing Emissions Sources

There are two industrial facilities, the CRL main campus and the Department of National Defence, that report indicator compounds and pollutant releases, disposals, and transfers for recycling under Part 1A to the National Pollutant Release Inventory (NPRI) within 25 km of the LSA (ECCC 2018a). The only facility within the LSA is the CRL main campus. These emissions contribute to the local air quality and the consideration of effects from the NSDF Project. The reporting facilities and emission totals are summarized in Table 5.2.1-5. In general, these sources are minor contributors of the non-radiological indicator compounds, with the exception of the lead emissions from the Department of National Defence.

CNL baseline emissions of indicator compounds (NOx, SO_2, SPM, PM_{10}, $PM_{2.5}$, Pb and Hg) have decreased appreciably starting in 2017. The reduction of these emissions and greenhouse gas emissions are the direct result of the full switch over to Natural Gas from #6 fuel oil for the CRL Powerhouse, the facility providing most of the heating for buildings on the Chalk River Laboratory Site. The switchover was a CNL initiative to reduce emissions from the CRL site.

Table 5.2.1-5: Air Emission Totals for Industries within 25 km of the Local Study Area

Company Name	Distance to the NSDF Project[a] (km)	Direction from the NSDF Project	Emissions

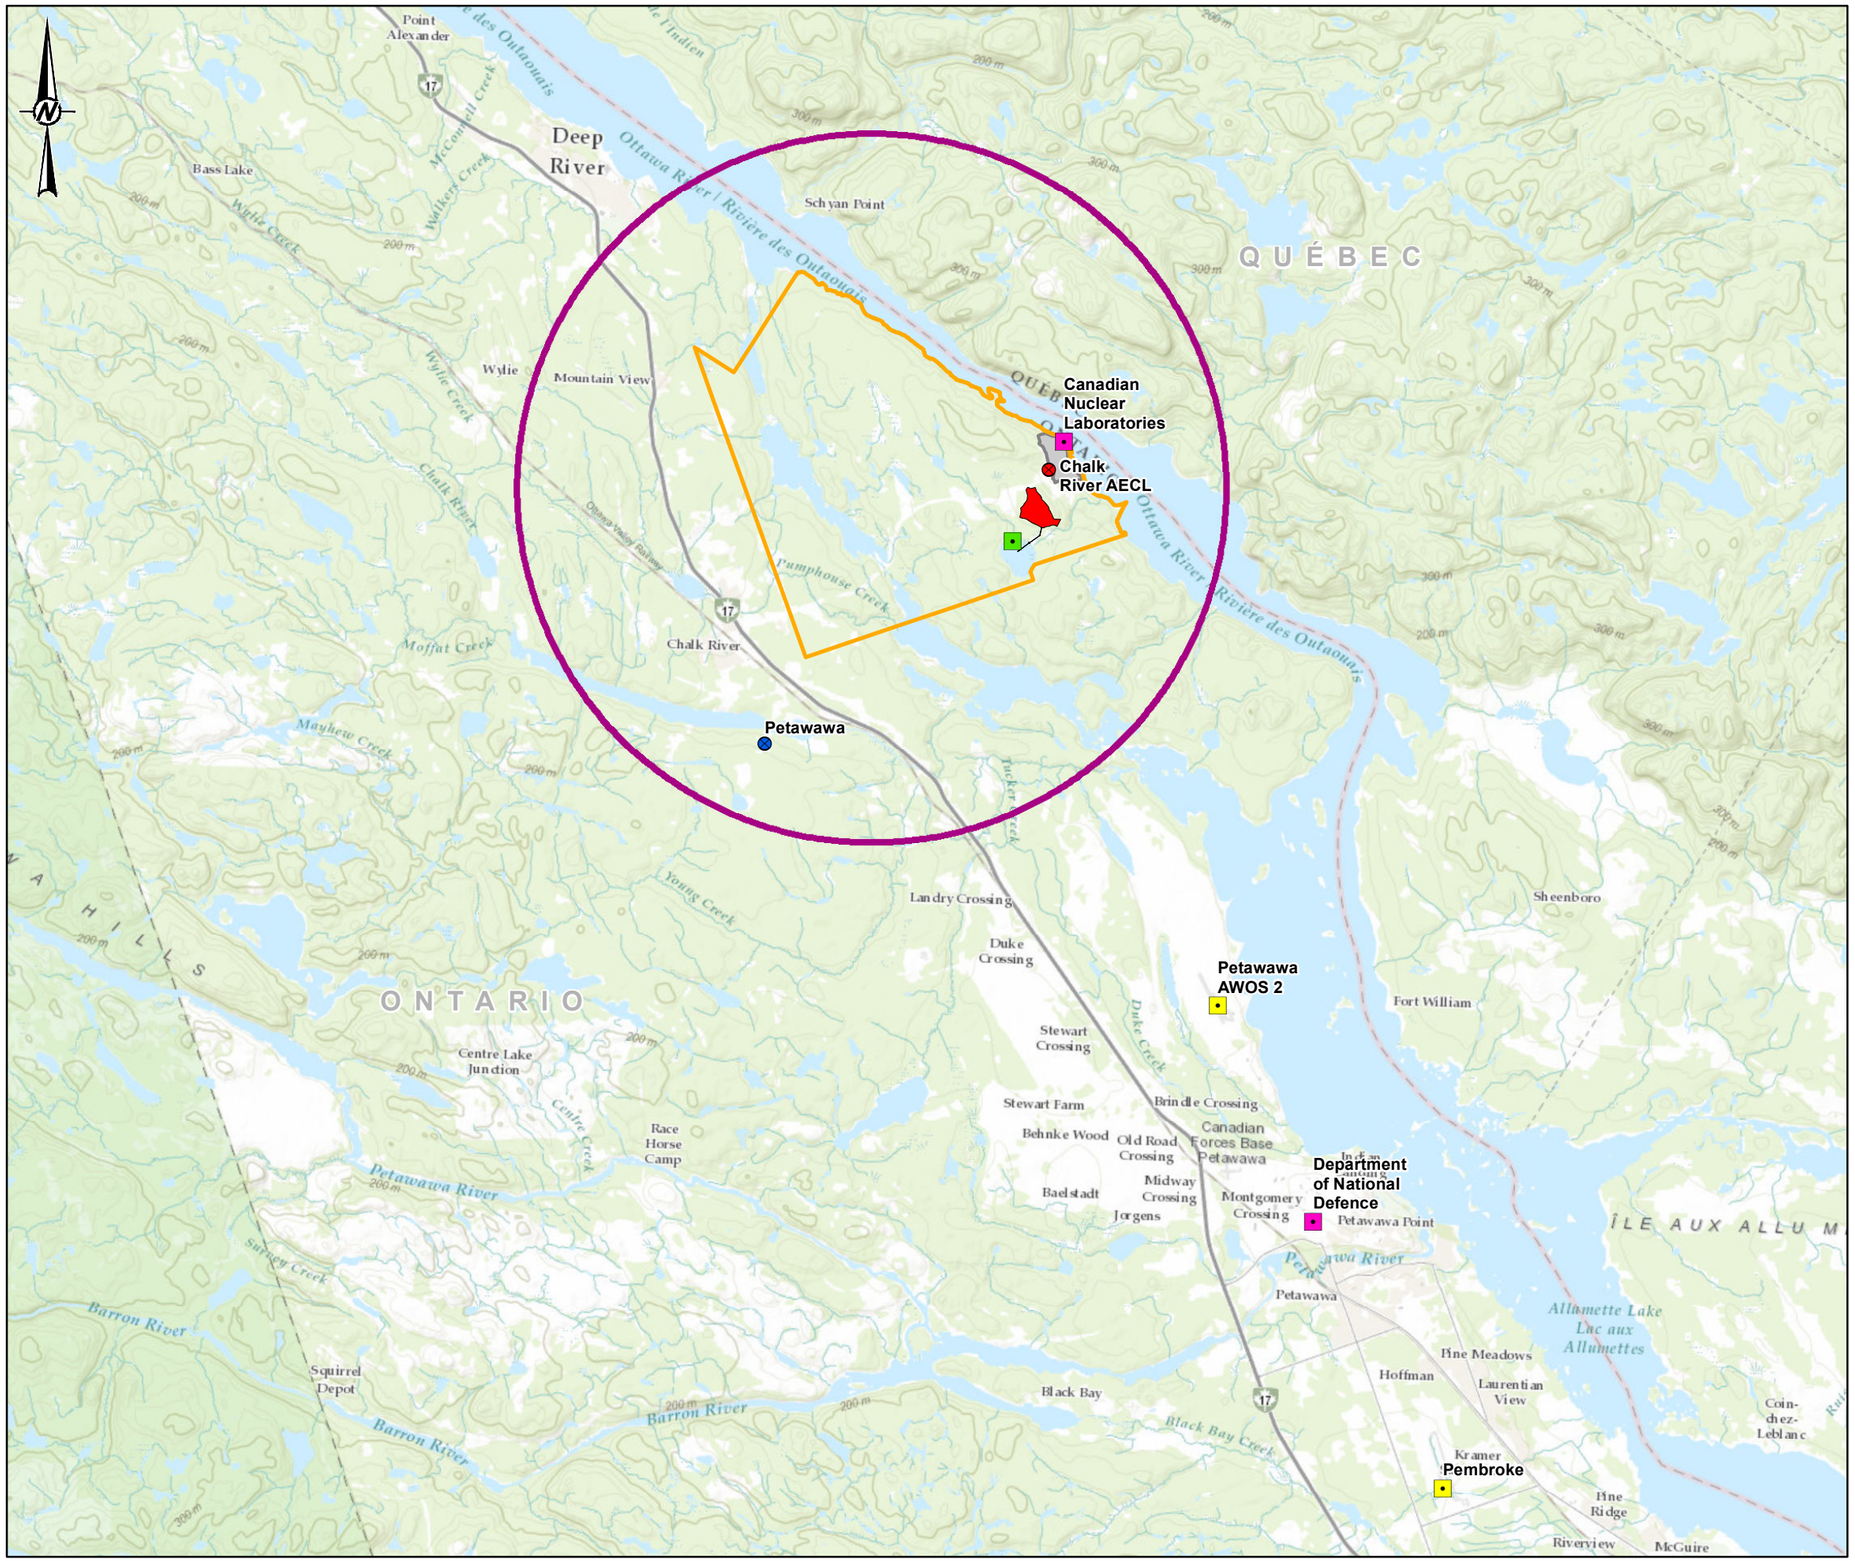
Baseline Air Quality Data

Although air quality data are provided in the report *Effluent Verification Monitoring at Chalk River Laboratories in 2018* (CNL 2019b), the data are based on emission estimates (emission factors), rather than measured data, and represents emissions solely from the CRL main campus. Other industries outside the LSA are not considered in the baseline and, therefore, data from monitored data sources was used and is considered to be more representative of background air quality. Site-specific air quality monitoring was not carried out as part of this assessment.

The background air quality was assessed using observations from the ECCC National Air Pollution Surveillance Network (NAPS) air quality monitoring stations (ECCC 2013) at locations outside the RSA (See Section 3 [Air Quality Baseline] of the Air Quality Assessment TSD [Golder 2019]). The monitoring data considered ranged from 2009 through 2013 which was the latest data available at the time of the baseline assessment in 2015 and is still considered representative of the baseline air quality for the NSDF Project site. Data from the Canadian Air and Precipitation Monitoring Network was received from ECCC for the station located at the CRL site (CAPMCAON1CHA); however due to limited data availability at the time of the assessment (only 2009 to 2011 and only certain indicator compounds) the data were not considered for the air quality assessment. The closest air quality monitoring station otherwise is located in Petawawa, however not all indicator compounds are monitored at the Petawawa station. The next closest air quality monitoring station with additional indicator compounds is the Ottawa Downtown monitoring station. Some indicator compounds (C_3H_4O, Hg, H_2S, C_2H_3Cl, and odour) were not monitored at either monitoring station. The specific stations selected to describe the existing air quality regime are presented in Table 5.2-1-6, and are illustrated on Figure 5.2.1-2.

Table 5.2.1-6: Location of Air Monitoring Station

City	NAPS Station Identification	Location	Latitude and Longitude	Distance to the NSDF Project[(a)] (km)	Location with Respect to the NSDF Project
Petawawa	66201	Outside Regional Study Area	45.996722, -77.441194	7	Southwest, generally downwind
Ottawa Downtown	60104	Outside Regional Study Area	45.43433, -75.676	148	Southeast, generally upwind



a) Distance from the SSA centroid.

NAPS = National Air Pollution Surveillance Network.

The wind direction into the Chalk River area is predominantly from the southeast along the Ottawa River (see Section 2 [Meteorology Assessment]) of the Air Quality Assessment TSD [Golder 2019]). The air quality monitoring station in Ottawa Downtown (NAPS ID 60104) captures this air flow into Chalk River; however, the station is located approximately 150 km from the NSDF Project site. The results can be considered to provide conservative air quality estimates (likely to be greater than the existing conditions in the RSA) given its urban location. The Petawawa station (NAPS ID 66201), located approximately 2 km south of the Village of Chalk River, is generally downwind of the NSDF Project and is considered to be the most representative station of the RSA, due to proximity and similarity in geographic siting (rural location and distance from the Ottawa River). The majority of the stations located outside the 100 km radius only monitor $PM_{2.5}$ and O_3.

There is no monitoring data available for SPM or PM_{10} at the Petawawa station, however, background SPM and PM_{10} concentrations can be estimated from the available $PM_{2.5}$ monitoring results. $PM_{2.5}$ is a subset of PM_{10}, and PM_{10} is a subset of SPM. Therefore, it is reasonable to assume that the ambient concentrations of SPM will be greater than corresponding PM_{10} levels, and PM_{10} concentrations will be greater than the corresponding levels of $PM_{2.5}$. The mean levels of $PM_{2.5}$ in Canadian locations are found to be about 50% of the PM_{10} concentrations and about 25% of the SPM concentrations (Brook et al. 2011). By applying this ratio, it is possible to estimate the background SPM and PM_{10} concentrations for the RSA.

5.2.1.4.3 Results

Table 5.2.1-7 provides a summary of the existing air quality data based on Petawawa station and the Ottawa Downtown stations, for consideration in the Base Case. Due to proximity and similarity in geographic siting (rural location and distance from the Ottawa River), the Petawawa station is considered to be the most representative station of the RSA, and therefore represents the background for indicator compounds monitored at that station. For some of the remaining indicator compounds, monitored data from the Ottawa Downtown have been used in the background although the station is located approximately 150 km from the NSDF Project site. The results from the Ottawa Downtown station can be considered to provide conservative air quality estimates (likely to be greater than the existing conditions in the RSA) given its urban location.

The data presented in Table 5.2.1-7 represent the 90th percentile of the 1-hour, 8-hour, and 24-hour monitored data; a value usually considered to be an appropriate representation of background concentrations from measured data (AESRD 2013). The annual average is used for the annual background concentrations.
The existing concentrations are below the respective provincial and federal criteria for each indicator compound, suggesting that the region has generally good air quality (Table 5.2.1-7).

5.2.1.5 Project Interactions and Mitigation

5.2.1.5.1 Methods

This section describes the process by which interactions between NSDF Project components and activities and air quality were identified and evaluated. Potential effects pathways are identified and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment (i.e., Section 5.2.1.6). As such, the NSDF Project Interactions and Mitigation section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all stages of the NSDF Project. The next step in the analysis was the development of environmental design features and mitigation practices that could be incorporated into the NSDF Project to eliminate and/or reduce effects to air quality. Environmental design features included design elements, environmental best practices, and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the engineering and environmental teams, combined with input from project-specific or regional engagement with other interested parties. The design features and/or mitigation were selected considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effects pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments, and the effectiveness of environmental design features and mitigation:

- **No linkage:** The pathway is removed by environmental design features or mitigation such that the NSDF Project would not be expected to result in a measurable environmental change to concentrations of indicator compounds relative to Base Case values, and therefore would have no residual effects to air quality.
- **Secondary pathway:** The pathway could result in a measurable minor change to concentrations of indicator compounds, but would have a negligible residual effect on air quality relative to Base Case and/or guideline values and is not expected to contribute cumulatively to other NSDF Project effects or to the effects of other previous, existing or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway:** The pathway is likely to result in an environmental change relative to the Base Case and/or guideline values that could contribute to residual effects on air quality.

Environmental design features and mitigation that have been or could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects to air quality were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to air quality through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways were carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the NSDF Project on air quality.

5.2.1.5.2 Results

The potential pathways from sources of air emissions to air quality are dependent on the presence and relative intensity of the activity over the various NSDF Project phases. Each activity or source would have a different level of intensity or use a different amount of equipment depending on the phase in which the activity occurred. Pathways through which all stages of the NSDF Project may interact with and result in changes to concentrations of indicator compounds are provided in Table 5.2.1-8. Operational exposures related to workers were assessed as part of the NSDF *Safety Analysis Report* (CNL 2020) and are summarized in Section 5.8.

Table 5.2.1-8: Pathways Analysis for Air Quality Valued Component

	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment

Construction
■ Site preparation
■ Construction of the ECM
■ Development of surface water management structures
■ Construction of the WWTP and other support facilities
■ On-site road and access development
■ Soil spoils haulage to a soil storage area
	Construction activities use vehicles and equipment that combust fuel and emit indicator compounds. These activities involve material handling, vehicles travelling on unpaved roads, and wind erosion of stockpiles that will result in fugitive dust emissions.	■ Implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and air verification monitoring.
		■ The *Dust Management Plan* (AECOM 2018a) to be implemented for the NSDF Project will provide information on dust mitigation, including:
		  ▪ Use of water spraying or misting techniques (e.g., water trucks) as the primary dust control method.
		  ▪ Use of fixatives (e.g., chemical suppressant) for dust control.
		  ▪ Covering stockpiles and exposed areas prior to high wind or dry conditions where standard dust suppressants may be inadequate in preventing dust generation caused by wind erosion.
		  ▪ Minimizing the size of the exposed working areas containing contaminated materials to the extent practicable using a phased excavation approach.
		  ▪ Revegetating affected areas or adding mulch to completed cells and excavated areas as soon as practicable.
		  ▪ Dampening soil in dry areas prior to commencing truck/machinery activities in the area.
		  ▪ Reducing activities to avoid unnecessary dust generation;
		  ▪ Using wind fencing around work areas.
		  ▪ Postponing work activities likely to cause dust if sustained wind speeds are predicted to exceed 40 km/hr, unless it can be shown that the work site is sufficiently protected that wind will not generate unacceptable amounts of dust.
		■ On-site vehicles and equipment engines will meet Tier 2 emission standards and be maintained in good working order.
		■ Limit idling of vehicles on-site.
			Primary

Table 5.2.1-8: Pathways Analysis for Air Quality Valued Component

	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment

Operations
■ Phased development of ECM disposal cells
■ On-site transportation of waste and placement of waste in the ECM
■ Progressive closure of disposal cells and installation of final cover
■ Operation of the WWTP
	Most activity and material handling occurs during the operations phase, and pathways include:
	■ vehicles and equipment combust fuel and emit indicator compounds.
	■ material handling, vehicles travelling on unpaved roads, and wind erosion of stockpiles emit fugitive dust.
	■ Release of emissions from the disposal cell cover and passive vents.
	■ emissions from the decomposition of waste.
	■ release of emissions from the operation of the WWTP.
		■ Implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and air verification monitoring.
		■ The *Dust Management Plan* (AECOM 2018a) to be implemented for the NSDF Project will provide information on dust mitigation, including:
		  ■ Use of water spraying or misting techniques (e.g., water trucks) as the primary dust control method.
		  ■ Use of fixatives (e.g., chemical suppressant) for dust control
		  ■ Dampening soil in dry areas prior to commencing truck/machinery activities in the area.
		  ■ Reducing activities to avoid unnecessary dust generation;
		  ■ Using wind fencing around work areas.
		  ■ Postponing work activities likely to cause dust if sustained wind speeds are predicted to exceed 40 km/hr, unless it can be shown that the work site is sufficiently protected that wind will not generate unacceptable amounts of dust.
		■ On-site vehicles and equipment engines will meet Tier 2 emission standards and be maintained in good working order.
		■ Limit idling of vehicles on-site.
		■ Processed wastewater will not be heated within the WWTP (raising the temperature increases potential release rates).
		■ There is active ventilation within the WWTP building and all active ventilation exhaust will be filtered through HEPA prior to release.
			Primary

Operations and Post-closure ■ Placement of waste in the ECM	Air emissions from the decomposition of waste.	■ Installation of the interim and final covers will reduce release of emissions from the ECM.	Primary

ECM = engineered containment mound; WWTP = Wastewater Treatment Plant.

5.2.1.5.2.1 No Linkage Pathways

No pathways are identified as having no linkage to air quality as part of this assessment.

5.2.1.5.2.2 Secondary Pathways

No secondary pathways are identified to air quality as part of this assessment.

5.2.1.5.2.3 Primary Pathways

The following primary pathways were identified as having the potential to result in residual effects to air quality, and therefore, have been carried forward to the residual effects analysis.

- Project construction activities use vehicles and equipment that combust fuel and emit indicator compounds. These activities involve material handling, vehicles travelling on unpaved roads, and wind erosion of stockpiles that will result in fugitive dust emissions.
- Most activity and material handling occurs during the operations phase, and pathways include:
  - vehicles and equipment combust fuel and emit indicator compounds;
  - material handling, vehicles travelling on unpaved roads, and wind erosion of stockpiles emit fugitive dust; and
  - the release of emissions from the disposal cell cover and passive vents and the WWTP.
- Air emissions from the decomposition of waste.

5.2.1.6 Residual Effects Analysis

5.2.1.6.1 Methods

Residual effects of the NSDF Project are those effects that remain after implementation of all mitigation. The assessment of effects of the NSDF Project on the air quality involves two steps, namely the calculation of emission rates and use of dispersion modelling to predict the resulting concentrations of indicator compounds.

Emissions Quantification

The method used for calculating and quantifying air emissions resulting from the NSDF Project involved the following steps.

- **Identifying emissions sources:** Emission sources were identified based on the NSDF Project conceptual design and the project information provided in the Project Description (Section 3.0).
- **Calculating emission rates:** Air emission rates were calculated using accepted methods, such as emission factors, and were based on activity data provided in the Project Description (Section 3.0), as well as LandGEM and MOBILE6.2.C modelling results provided in Section 4 (Emissions Estimate) of the Air Quality Assessment TSD (Golder 2019). Emission rates were calculated for the Application Case scenario for both the construction and operations phases.
- **Summarizing overall emissions:** The calculated emissions were summarized by activity type.

The emission estimation methods used in the air quality assessment follow generally accepted practices for conducting environmental assessments and, where appropriate, guidance *Procedure for Preparing an Emission Summary and Dispersion Modelling Report* Version 4.1 (MOECC 2018). Details of the specific emission calculation methods and resulting emissions are provided in Section 4 (Emissions Estimate) of the Air Quality Assessment TSD (Golder 2019).

Dispersion Modelling

Models were used to predict ground-level concentrations of non-radiological indicator compounds. The AERMOD dispersion model (Version 16216r) was used to predict concentrations and deposition rates associated with NSDF Project emissions. The AERMOD dispersion modelling system was developed by the United States Environmental Protection Agency (US EPA) as a replacement to the long-standing Industrial Source Complex model (US EPA 2004), and is the model recommended by the US EPA for regulatory applications in the United States (US EPA 2005). This model has also been adopted in Ontario as the regulatory model recommended for permitting and regulatory applications (MOECC 2018).

The AERMOD modelling system was selected as the dispersion model for the NSDF Project due to its following capabilities:

- has a technical basis that is scientifically sound, and is in keeping with the current understanding of dispersion in the atmosphere;
- applies formulations that are clearly delineated and are subjected to rigorous independent scrutiny;
- makes predictions that are consistent with observations;
- is recognized by federal and provincial regulators as one suitable for use;
- evaluates the various source configurations and indicator compounds associated with the NSDF Project;
- the terrain surrounding the NSDF Project site is relatively simple and can be addressed by the terrain features of the model;
- allows for the use of localised meteorological data;
- incorporates building downwash effects; and
- long-range transport of compounds is not anticipated.

The AERMOD modelling system consists of the AERMOD dispersion model, the AERMET meteorological pre-processor and the AERMAP terrain pre-processor. The following approved dispersion model and pre-processors were used in the assessment:

- AERMOD dispersion model (v. 16216r);
- AERMAP surface pre-processor (v. 11103); and
- Building Profile Input Program building downwash pre-processor (v.42104).

Building heights are required inputs to assess building downwash using the Building Profile Input Program pre-processor. However, for conservatism and because most sources in this assessment would not be subject to building downwash, building downwash has not been included in this assessment. The AERMET meteorological pre-processor was used by the MECP to prepare a 5-year meteorological dataset for the NSDF Project from 2011 to 2015. The meteorological dataset incorporated data from the CNL on-site station. Additional information on the meteorology is presented in Section 2 (Meteorology Assessment) of the Air Quality Assessment TSD (Golder 2019). Details regarding the dispersion modelling, including receptor grids and source input parameters are provided in Section 5 (Dispersion Modelling) of the Air Quality Assessment TSD (Golder 2019).

5.2.1.6.2 Application Case Results

Average and Maximum Emission Rates

In accordance with the CNSC's *REGDOC-2.9.1 Environmental Protection: Environmental Principles, Assessments and Protection Measures* (CNSC 2017), average and maximum emission rates have been provided for the construction and operations phases. Table 5.2.1-9 and Table 5.2.1-10 summarize the average and maximum emission rates in kilograms per day for each activity during construction, respectively. Table 5.2.1-11 and Table 5.2.1-12 summarize the average and maximum emission rates in kilograms per day for each activity during the operations phase, respectively. Maximum emission rates assume the source emits continuously for 24 hrs per day. Average emission rates are scaled from the maximum emission rates based on the source's hours of operation. Sources that emit 24 hrs per day will have identical maximum and average emission rates. Vehicle exhaust and fugitive dust from unpaved roads is the largest contributor to SPM and PM_{10} during both construction and operations. Vehicle exhaust during the construction and operation of the ECM is the largest contributor of $PM_{2.5}$, NOx/NO_2, SO_2, CO, and C_3H_4O. Emissions from the WWTP activities and natural gas combustion for comfort heating include SPM, PM_{10}, $PM_{2.5}$, NOx/NO_2, SO_2, CO, and Pb; however, the only indicator compound that was retained from natural gas combustion emissions is Pb. Indicator compounds from natural gas combustion, other than NOx/NO_2 and Pb, were not retained as they are not required to be assessed per the *Procedure for Preparing an Emission Summary and Dispersion Modelling Report,* Version 4.1 (MOECC 2018). The NOx/NO_2 from combustion was deemed negligible as it contributed to less than 1% of the total emissions and was therefore excluded from the dispersion modelling. Details of the specific emission calculation methods and resulting emissions estimates used for dispersion modelling are provided in Section 4 (Emissions Estimate) of the Air Quality Assessment TSD (Golder 2019).

a) As described in the air quality pathway analysis in Section 5.2.1.5.2

b) Hg and Pb occur as trace elements from the combustion of diesel fuel and are excluded from the diesel combustion sources emissions.

c) Contaminants are presented for completeness however they have not been carried through for the dispersion modelling assessment as they were identified as negligible as identified in Table 5.2.1-13.

d) Hg occurs as trace element from the combustion of natural gas and is excluded from the natural gas combustion sources emissions.

ECM = engineered containment mound; WWTP = Wastewater Treatment Plant; SPM = suspended particulate matter; $PM_{2.5}$ = particulate matter less than 2.5 µm (microns) in diameter; PM_{10} = particulate matter less than 10 µm (microns) in diameter; NO_2 = nitrogen dioxide; SO_2 = sulphur dioxide; CO = carbon monoxide; H_2S = hydrogen sulfide; C_2H_3Cl = vinyl chloride; Pb = lead; Hg = mercury; C_3H_4O = Acrolein; OU/day = Odour Unit per day.

Negligible Emissions from the Project

Not all activities associated with the NSDF Project produce emissions for compounds that are relevant to the overall emissions assessment. All activities that potentially produce emissions are evaluated to identify their relevance; however, only activities that are considered to be relevant are included in the assessment.

The following provides rationale as to why certain activities and/or emissions of certain compounds are excluded from the assessment:

- the emission rates of certain compounds are minor relative to the overall emissions at the NSDF Project;
- the emissions of certain sources are known to not be relevant due to the type of operations in the assessment; and
- the location of the source relative to the rest of the sources on site (i.e., the source is located far away from any potential receptors).

Table 5.2.1-13 lists the activities that are not assessed and the accompanying rationale.

Table 5.2.1-13: Emission Sources and Contaminants not included in the Assessment

Activity/Compound	Rationale for Excluding from the Assessment
Natural gas combustion for WWTP process, Vehicle Decontamination Facility, Administration Office and Operations Support Centre	CO, SO_2, SPM, PM_{10}, and $PM_{2.5}$ emissions from these sources are not required to be assessed (MOECC 2018) and NOx/NO_2 are negligible (<1%) compared to emissions from the mobile combustion sources. Only Pb emissions were included in the dispersion modelling in response to regulator feedback received during the review process.
WWTP and associated equipment (i.e., equalization tanks)	The treatment of wastewater may result in the release of H_2S, mercaptans, chlorine and various other chemicals, to a lesser extent. With the exception of odour, the emissions from the WWTP have been excluded from the assessment as they are expected to have a negligible effect on the overall air quality.
Contact water ponds	Water from precipitation that has not infiltrated into the waste but is treated as suspect of contamination is collected in contact water ponds or equivalent structures on a lined portion of the cell floor. The contact ponds are temporary, and therefore, potential odorous emissions have been excluded from the assessment as they are expected to have a negligible effect on the overall air quality.
Natural gas emergency power generator	The emergency power equipment only operates periodically during monthly routine maintenance testing and for very short duration (20 minutes; rather than continuously). Additionally, the emergency power generator will only be used to supply electricity during power outage when other equipment is not operational; and therefore, is not included in the representative scenario as the modelling is meant to represent normal operations for the NSDF Project.
Diesel pumps, air compressors, and lighting equipment at all NSDF buildings	This equipment is part of miscellaneous equipment and only operates periodically and for short durations. Emissions rates from these sources are minor compared to emissions from the other diesel equipment on-site, and therefore, are not included in the representative scenarios.
Snow removal equipment	Emissions from this equipment occur seasonally and are infrequent (i.e., only during the winter following a snowfall), and therefore, are not included in the representative scenario.
Operational support activities, such as maintenance activities	Emissions from these sources are infrequent, relatively minor, and do not occur at all times compared to the other activities that are occurring regularly and/or continuously. For example, these activities may include minor emissions such as particulates and metals (e.g., welding).

WWTP = Wastewater Treatment Plant; CO = carbon monoxide; SO_2 = sulphur dioxide; SPM = suspended particulate matter; PM_{10}, = particulate matter less than 10 microns in diameter; NOx/NO_2 = nitrogen oxides/nitrogen dioxide; H_2S = hydrogen sulphide; $PM_{2.5}$ = particulate matter less than 2.5 microns in diameter; Pb = lead; < = less than.

Halocarbon emissions are not considered a source of emissions for the NSDF Project. However, if a spill or lead occurs from equipment (e.g., air conditioners) it is reported to the CNL Environmental Protection Program and included in the annual report.

Predicted Modelling Concentrations

Concentrations resulting from the construction and operations phases of the NSDF Project for the air quality indicator compounds were predicted with the aid of the AERMOD dispersion model (Tables 5.2.1-9 to 5.2.1-12). The predicted concentrations at the LSA boundary for the construction and operations phases are presented in Table 5.2.1-14. The maximum predicted incremental concentration represents the incremental effect of the NSDF Project, without taking into consideration existing Base Case concentrations. The predicted concentrations for the Application Case represent the combined concentrations of the Base Case plus the incremental concentrations from the NSDF Project. Predicted concentrations for the Application Case during both construction and operations phases are below applicable air quality guidelines and/or standards, with the exception of NO_2 and the 2020 1-hour CAAQS. The contributing factor to maximum predicted NO_2 concentration being above the 2020 CAAQS is the heavy-duty construction equipment and the conservative assumption that all equipment will run simultaneously and continuously during working hours. In reality, individual equipment will be idling or off for varying parts of the workday that cannot be predicted but will result in lower emissions than currently estimated.

Table 5.2.1-14: Concentrations at the Local Study Area Boundary for the Base Case and Application Case

Indicator	Averaging Period	Air Quality Guideline/ Standard[a] (µg/m³)	Base Case (Existing Conditions)[b] (µg/m³)	Maximum Predicted Incremental Concentration – Construction Phase (µg/m³)	Maximum Predicted Incremental Concentration – Operation Phase (µg/m³)	Application Case - Construction Phase (µg/m³)	Application Case - Operation Phase (µg/m³)

a) Table 5.2.1-4 identifies which guideline or standard was used in the screening of effects to air quality.

b) The 90th percentile predicted existing concentrations; values for SPM and PM_{10} are calculated from the $PM_{2.5}$ as described in Section 5.2.1.

c) "—" indicates there are no predicted concentrations because there are no emissions.

d) Calculated using the Ozone Limiting Method. Refer to Section 5.2 of the Air Quality Assessment TSD (Golder 2019).

e) 99.5th percentile on a 10-minute averaging period, in OU/m^3.

µg/m³ = micrograms per cubic metre; SPM = suspended particulate matter; $PM_{2.5}$ = particulate matter less than 2.5 µm (microns) in diameter; PM_{10} = particulate matter less than 10 µm (microns) in diameter; NO_2 = nitrogen dioxide; SO_2 = sulphur dioxide; CO = carbon monoxide; C_3H_4O = acrolein H_2S; = hydrogen sulfide; C_2H_3Cl = vinyl chloride; Pb = lead; Hg = mercury; µg/m³ = microgram per cubic metre; OU/m^3 = odour unit per cubic metre.

5.2.1.6.3 Reasonably Foreseeable Development Case Results

Reasonably foreseeable developments in the RSA with potential to overlap with the residual effects of the NSDF Project include revitalization activities (i.e., new/upgrades to research and development facilities, new support infrastructure), on-going decommissioning and environmental remediation activities on the CRL site. These revitalization and decommissioning activities involve renovation of some current buildings, construction of new buildings, and removal of more than 100 existing buildings on the CRL site over the 10-year period from 2016 to 2026. A specific new research and development project announced in 2019 is the planned construction and 20-year operation of a SMR at the CRL site. As well, there may be overlap of the construction period with limited construction at neighbouring Garrison Petawawa.

Site revitalization, SMR construction, construction at Garrison Petawawa and on-going decommissioning activities on the CRL site will generate air and dust emissions such as CO, oxides of sulphur (SO_x includes SO_2), oxides of nitrogen (NO_x includes NO_2), particulate matter ($PM_{2.5}$, PM_{10}), and suspended particulate matter (SPM). Air emissions, such as SO_x and NO_x, can result from the use of fossil fuels in generators, vehicles, and machinery. Vehicle exhaust and fugitive dust from unpaved and paved roads is expected to be the largest contributor to particulate matter (SPM, PM_{10}, and $PM_{2.5}$). The waste from the decommissioning of the CRL structures will be placed in the NSDF and the Application Case assessed for the operations phase considers the transport of this waste for disposal in the ECM.

Decommissioning of eight buildings, renovation of three and construction of a new 9,900 m^2 facility for the Royal Dragoons planned within the built-up area at Garrison Petawawa (approximately 10 km south of the SSA) in 2020-2021 are also expected to follow best practice construction techniques. As a result, emissions to air are expected to be short term and limited. Given the distance of these activities from the SSA and limited potential overlap in time of the construction periods, no potential for cumulative effects is identified.

The airborne emissions from new facility construction and decommissioning projects on the CRL site will be assessed as part of the approval process for these projects. Examples of mitigation expected to be implemented by site revitalization, SMR construction and on-going decommissioning activities on the CRL site to limit potential effects to air quality include:

- limiting the construction activities required on-site through the use of modular structures for construction of the SMR (Global First Power 2019);
- staging site revitalization and decommissioning activities over a ten-year period to reduce periods of simultaneous construction at the CRL site;
- implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and verification monitoring;
- implementation of best practice dust management techniques such as water spraying or misting techniques (e.g., water trucks);
- using on-site vehicles and equipment engines that meet Tier 2 emission standards and maintaining them in good working order; and
- limiting idling of vehicles on site.

Site revitalization and decommissioning activities include several small projects staged over a ten-year period where best practices, mitigation and monitoring for management of emissions will to be followed. Accordingly, the incremental additional equipment use and emissions at any one time are expected to be small, distributed across the CRL site and removed from the more intensive activities within the SSA. The conclusions of the NSDF Project assessment in Section 5.2.1.6.2 for the Assessment Case indicate that the predicted concentrations of indicator compounds for air quality are below the relevant guideline/standard during the construction and operations phases, except for 1-hour NO2. These predictions are based on conservative assumptions around number of heavy-duty vehicles and intensity of use, as well as meteorological conditions. When compared with current CRL site operations and NSDF Project activities, it is anticipated that the small incremental effect to indicator compounds from site revitalization and decommissioning activities in progress at any one time would be negligible to air quality outside of the CRL site. Similarly, the scale and modular construction technique for the SMR limits the length of its construction period, as well as associated equipment use. The locations for placement of the SMR under consideration are removed from the SSA within the CRL site. During operation of the SMR, dry cooling towers may be used to dissipate excess heat from steam condensation in operation of the steam turbine generator. No additional activities or new sources for release of indicator compounds are planned (Global First Power 2019). With effective implementation of mitigation measures and monitoring programs, no cumulative residual effect is identified to air quality.

5.2.1.7 Prediction Confidence and Uncertainty

Potential sources of uncertainty in the assessment of air quality include:

- potential modifications associated with the location, physical footprint and activity level of the NSDF Project;
- the accuracy and representativeness of the activity data and emission factors used to estimate emissions;
- the accuracy and representativeness of the waste inventory;
- the accuracy and representativeness of the meteorological data used in the AERMOD model;
- the accuracy of formulations within the AERMOD dispersion modelling system;
- the representativeness of the ambient data used to represent background concentrations; and
- the potential error associated with omitting some emission sources.

Dispersion models employ assumptions that simplify the random processes associated with atmospheric motions and turbulence. While this simplification limits the model's ability to replicate individual events, the strength of the model lies in the ability to predict overall values for a given set of meteorological conditions. The process undertaken by the US EPA ensured that the model predictions can be relied on as reasonable estimate of the likely concentrations. AERMOD is based on known theory and proven to reliably produce repeatable results (Section 5.2.1.6.1). Uncertainties were managed using the following conservative assumptions in the emission estimation and dispersion modelling.

- Waste receipt for the maximum capacity of 1,000,000 m^3 was used in determining emission rates for dispersion modelling. All emission rate calculations were completed for the maximum amount of waste received during the entire life of the NSDF Project.

- The ECM was modelled as an area source that summed emissions from the ECM cap, the passive vents, material handling and vehicle exhaust. Modelling the ECM emissions as an area source assumes that emissions are being released from the entire area, however in reality emissions will only be emitted from discrete areas on the source.
- The modelling assessment includes all operations occurring simultaneously and continuous for each individual source's modelling period.
- The influence of natural mitigation from events such as rainfall, snowfall, residual moisture, or snow cover was not considered in determining fugitive dust emission rates for all sources, except unpaved roads and grading. The modelling will likely yield higher concentrations since contaminants will be deposited from the air by dry or wet depletion and deposition processes.
- The 90th percentile observed concentration was added to maximum predicted concentrations for short-term averaging periods to account for existing background emission sources. The use of 90th percentile background concentrations is conservative in that it assumes that the maximum predicted concentration and the 90th percentile background concentration will occur at the same time, even though background concentrations greater than or equal to the 90th percentile occur only 10% of the time.
- Five years of meteorological data are used as an input to the model to provide that a full range of possible meteorological conditions is evaluated.

The parameters that were required for fugitive dust modelling from unpaved roads include the locations of the roadway segments, base elevations, effective heights of the emissions, and the initial plume size in the lateral and vertical directions. It is recognized that this modelling approach will result in higher predicted concentrations close to the roadways than actual values for the following reasons.

- There has been extensive research on the estimation of the "transportable fraction" of fugitive dust from roadways. Studies completed by the Desert Research Institute in Nevada and in the San Joaquin Valley, California (Watson et al. 1996) showed a large (i.e., greater than 90%) decrease in dust concentration within 100 m of an unpaved road (Watson et al. 1996; Watson et al. 2000). A value of 75% reduction has been suggested beyond 50 m for unpaved roadway emissions. This value would increase at greater distances. This adjustment was not made to the dispersion modelling concentration results.
- When the roads are wet or snow-covered, the emissions will be reduced or eliminated. AERMOD has the capacity to have a variable emission rate that could account for actual meteorological emissions.
- The best management practices will further reduce emissions; specifically, speed limits and watering were assumed to be used on unpaved roads to decrease emissions from roads and a truck-wheel wash station will be used to reduce track out. A conservative control efficiency of 85% was selected to represent the implementation of the best management practices.

It is assumed that the conservative emission rates, when combined with the conservative operating conditions and conservative dispersion modelling assumptions description herein, are not likely to under predict the modelled concentrations at each of the identified receptors.

5.2.1.8 Residual Effects Classification and Determination of Significance

This section classifies the residual effects from changes to measurement indicators for the Application Case and presents a determination of significance for the air quality VC.

5.2.1.8.1 Residual Effects Classification

Effects from adverse residual changes to measurement indicators were classified using a categorical scale and common words to facilitate the determination of significance. The purpose of categorical classification is to provide definitions that permit a clear, thorough and unambiguous classification of residual effects such that reviewers and readers can follow and apply the logic used in the assessment and reach the same classification for a given residual effect.

Magnitude, geographic extent and duration are the principal factors considered to predict significance.
The magnitude of a residual environmental effect is determined by the change in a measurement indicator from a project interaction. Geographic extent refers to the area affected, and duration is defined as the amount of time for a residual effect to be reversed. For air quality, residual effects stop almost immediately when the NSDF Project activity stops. It should be noted that reversibility refers to effects to air quality only; how effects to air quality affect other VCs are assessed in their discipline-specific sections. Other criteria, such as frequency and likelihood are used as modifiers, where applicable. Residual adverse effects were classified using the criteria and definitions outlined in Table 5.2.1-15.

Table 5.2.1-15: Assessment Criteria for Classifying Predicted Residual Adverse Effects to Air Quality

Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Likelihood
Positive: Maximum concentration for an indicator compound represents a decrease from Base Case. **Negative:** Maximum concentration for an indicator compound represents an increase from Base Case. **Neutral:** No change in concentrations of an indicator compound relative to Base Case.	**Negligible:** Maximum concentration for an indicator compound is less than 5% of the corresponding criteria **Low:** Maximum concentration for an indicator compound is less than 50% of the corresponding criteria **Moderate:** Maximum concentration for an indicator compound is between 50% and 100% of the corresponding criteria **High:** Maximum concentration for an indicator compound is above the corresponding criteria	**Local:** Effect is limited to within the LSA **Regional:** Effect extends beyond the LSA, but is contained within the RSA **Beyond Regional:** Effect extends beyond the RSA	**Short-term:** Effects are not evident beyond the construction phase **Medium-term:** Effects are not evident beyond the operations phase **Long-term:** Effects are not evident beyond the closure and post-closure phases **Permanent**: Effects are not reversible	**Infrequent:** Effects are confined to a specific discrete period **Frequent:** Effects occur intermittently, but repeatedly, or continuous over the assessment period	**Reversible:** Change of state in environment is not permanent **Irreversible:** Change of state in the environment is permanent	**Low:** Effect is unlikely to occur **Medium:** Effect is likely to occur **High:** Effect is highly likely to occur

LSA = local study area; RSA = regional study area.

5.2.1.8.2 Determination of Significance

The residual effects classification of primary pathways and the associated predicted changes in measurement indicators provide the foundation for determining the significance of residual effects from the NSDF Project on air quality. Where possible and appropriate, established guidelines, thresholds and screening values were used to support the classification of the predicted amount of change in measurement indicators and associated effects on air quality. For an effect to be deemed significant the effect must be negative in direction, high in magnitude, regional in geographic extent and long-term in duration. As part of the determination of significance, confidence in the assessment identified in Section 5.2.1.7 was considered for the air quality VC. Where uncertainty was high, and the cumulative effect might be either significant or not significant, the assessment conservatively identified the effect as significant and provided additional follow-up actions to reduce uncertainty (Section 5.2.1.9).

The duration, frequency, reversibility and likelihood of effects are the same for all indicator compounds for each of the Application Cases (i.e., construction and operations phases), and only the direction, magnitude and geographic extent varies by indicator compound (Table 5.2.1-16). The magnitude of changes for SPM, PM_{10}, $PM_{2.5}$, NO_2 and SO_2 (annual only) for the Base Case are classified as low before considering effects from the NSDF Project. Emissions of indicator compounds will stop at the end of the construction and operations phase; therefore, the duration of effect is short-term and medium-term, respectively, and they are reversible. Criteria air contaminants will be emitted continuously or near-continuously during the construction and operations phases, and therefore the effect is considered frequent. The likelihood of emissions from the NSDF Project changing indicator compound concentrations for the Application Case during construction and operations is medium (Table 5.2.1-16).

Construction Phase

For the Application Case construction phase, the direction is neutral for some indicator compounds as there are no emissions of these compound during this phase of the NSDF Project (i.e., H_2S, C_2H_3Cl, and odour).
The magnitude of changes to indicator compound emissions are predicted to be negligible to moderate, as the predicted concentrations are below the relevant guideline/standard with the exception of 1-hour NO_2 when compared to the CAAQS. However, comparison to the CAAQS is not appropriate and the maximum predicted 1-hour NO_2 concentrations above the CAAQS standard is not significant because the NSDF Project boundary does not, nor does the 7.4 km radius circular regional study area (RSA), represent an “air zone”, the region over which the CCME states that achievement of the CAAQS is to be evaluated/compared (Section 5.2.1.4.2).

The predicted 1-hr CAAQS for NO_2 can be calculated within the RSA using the model output, however, such a comparison is inherently biased by model input assumptions and is not suitable for comparison to a monitoring based values such as the CAAQS that use a 3-year averaging period. The NO_2 emissions inventory for the NSDF Project are designed to be conservative and represent a ‘worst-case’ scenario. NSDF Project emissions assume all heavy-duty construction equipment combustion sources operate at their peak intensity/load/capacity for each hour for 1-hr simulations. In reality, individual equipment will be idling or off for varying parts of the workday, which cannot be predicted but will result in lower emissions than currently estimated. The likelihood that all equipment operates simultaneously for an hour or more along with unfavourable weather conditions to produce the maximum concentrations modelled is very low. A less conservative but more appropriate comparison to the Ontario AAQS of 400 $\mu g/m^3$ for 1-hr NO_2 would result in a Low magnitude.

The predicted effects at the highest magnitude modelled are beyond regional for all indicator compounds except for SPM and PM_{10}. The moderate magnitude results of SPM and PM_{10} do not extend beyond the RSA and are therefore classified as regional. For an effect to be deemed significant the effect must be negative in direction, high in magnitude, regional in geographic extent and long-term in duration. No indicator compounds meet all of these requirements; therefore, the overall residual adverse effect of the Application Case during construction on air quality is determined to be not significant.

Operations Phase

For the Application Case operations phase, the direction is negative for all indicator compounds as concentrations of emissions are predicted to increase during this phase of the NSDF Project. However, the magnitude of changes to indicator compound emissions are predicted to be negligible to moderate as the predicted concentrations are below the relevant guideline/standard with the exception of 1-hour NO_2 when compared to the CAAQS. However, on the same grounds described in the construction phase, comparison to the CAAQS is not appropriate and the maximum predicted 1-hour NO_2 concentrations above the CAAQS standard is not significant. A less conservative but more appropriate comparison to the Ontario AAQS of 400 $\mu g/m^3$ for 1-hr NO_2 would result in a Low magnitude.

The predicted effects at the highest magnitude modelled are beyond regional for all indicator compounds except for NO_2. The high magnitude result for NO_2 when compared to the CAAQS does not extend beyond the RSA and is therefore classified as Regional. For an effect to be deemed significant the effect must be negative in direction, high in magnitude, regional in geographic extent and long-term in duration and zero indicator compounds meet all of these requirements, therefore, the overall residual adverse effect of the Application Case during operations on air quality is determined to be not significant.

Table 5.2.1-16: Classification of Predicted Residual Adverse Effects on Air Quality for the Application Case

Indicator Compound	Direction	Magnitude[a]	Geographic Extent	Duration	Frequency	Reversibility	Likelihood
Application Case – Construction Phase							
SPM	Negative	Moderate (24hr)	Regional	Short-term	Frequent	Reversible	Medium
PM_{10}	Negative	Moderate (24hr)	Regional	Short-term	Frequent	Reversible	Medium
$PM_{2.5}$	Negative	Low (All)	Beyond Regional	Short-term	Frequent	Reversible	Medium
NO_2	Negative	High (1hr)	Beyond Regional	Short-term	Frequent	Reversible	Medium
SO_2	Negative	Low (Annual)	Beyond Regional	Short-term	Frequent	Reversible	Medium
CO	Negative	Negligible (All)	Beyond Regional	Short-term	Frequent	Reversible	Medium
C_3H_4O	Negative	Negligible (All)	Beyond Regional	Short-term	Frequent	Reversible	Medium
Hg	Negative	Negligible (All)	Beyond Regional	Short-term	Frequent	Reversible	Medium
Pb	Negative	Negligible (All)	Beyond Regional	Short-term	Frequent	Reversible	Medium
H_2S	Neutral	n/a	n/a	n/a	n/a	n/a	n/a
C_2H_3Cl	Neutral	n/a	n/a	n/a	n/a	n/a	n/a
Odour	Neutral	n/a	n/a	n/a	n/a	n/a	n/a
Application Case – Operations Phase							
SPM	Negative	Low (All)	Beyond Regional	Medium-term	Frequent	Reversible	Medium
PM_{10}	Negative	Low (All)	Beyond Regional	Medium-term	Frequent	Reversible	Medium
$PM_{2.5}$	Negative	Low (All)	Beyond Regional	Medium-term	Frequent	Reversible	Medium
NO_2	Negative	High (1hr)	Regional	Medium-term	Frequent	Reversible	Medium
SO_2	Negative	Low (Annual)	Beyond Regional	Medium-term	Frequent	Reversible	Medium
CO	Negative	Negligible (All)	Beyond Regional	Medium-term	Frequent	Reversible	Medium
C_3H_4O	Negative	Negligible (All)	Beyond Regional	Medium-term	Frequent	Reversible	Medium
Hg	Negative	Negligible (All)	Beyond Regional	Medium-term	Frequent	Reversible	Medium
Pb	Negative	Negligible (All)	Beyond Regional	Medium-term	Frequent	Reversible	Medium
H_2S	Negative	Negligible (All)	Beyond Regional	Medium-term	Frequent	Reversible	Medium

Table 5.2.1-16: Classification of Predicted Residual Adverse Effects on Air Quality for the Application Case

Indicator Compound	Direction	Magnitude[a]	Geographic Extent	Duration	Frequency	Reversibility	Likelihood
C_2H_3Cl	Negative	Negligible (All)	Beyond Regional	Medium-term	Frequent	Reversible	Medium
Odour	Negative	Negligible (All)	Beyond Regional	Medium-term	Frequent	Reversible	Medium

a) Averaging period with the highest magnitude in brackets ( )

n/a = neutral effects are not classified; SPM = suspended particulate matter; $PM_{2.5}$ = particulate matter less than 2.5 µm (microns) in diameter; PM_{10} = particulate matter less than 10 µm (microns) in diameter; CO = carbon monoxide; NO_2 = nitrogen dioxide; SO_2 = sulphur dioxide; C_3H_4O = acrolein; H_2S; = hydrogen sulfide; C_2H_3Cl = vinyl chloride; Pb = lead; Hg = mercury.

5.2.1.9 Monitoring and Follow-up

Implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and air verification monitoring, will continue for the NSDF Project as it outlines the key management practices to limit effects to air quality. The CRL Radioactive Effluent Verification Monitoring Program includes airborne effluents verification monitoring that comprises 56 monitoring points and will also continue for the NSDF Project. In addition, air quality monitoring activities for the NSDF Project will be implemented (Table 5.2.1-17) and the purpose it to:

- verify effects predictions, and compare actual with predicted effects;
- confirm effectiveness of mitigation, and in doing so evaluate if alternate mitigation is required;
- provide information for use in adaptive management to address potential unforeseen effects; and
- demonstrate compliance with regulatory requirements.

Table 5.2.1-17: Environmental Monitoring and Follow up Programs for Air Quality

Valued Component	Project Phase and Potential Effect	Monitoring Program Objective	Conceptual Monitoring Program	Suggested Duration	Implementing Program
Air Quality	Construction activities will result in fugitive dust emissions.	■ Verify that mitigation is being implemented effectively. ■ Verify predictions in the assessment are reasonable and conservative. ■ Verify predictions are within air quality criteria (SPM monitoring).	■ Application of aggregate to unpaved roads – a record will be kept of the date of each application of aggregate to unpaved roads. ■ Road misting and fixative application – a record will be maintained of dust suppression applications. ■ Site inspection – during periods of high dust susceptibility, regular inspections will be carried out to monitor the efficacy of dust mitigation and any potential concerns with regards to fugitive dust and, if required, implementation of mitigation will be recommended. Environmental conditions will be recorded. ■ Particulate monitoring –SPM using a high volume sampler.	Through the construction phase.	*Dust Management Plan* (AECOM 2018a) to be implemented for the NSDF Project.
Air Quality	Operations activities will result in fugitive dust emissions.	■ Verify that the mitigation is being incorporated as planned, and are effective. ■ Verify predictions in the assessment are reasonable and conservative. ■ Verify predictions are within air quality criteria.	■ Application of aggregate to unpaved roads – a record will be kept of the date of each application of aggregate to unpaved roads. ■ Road misting and fixative application – a record will be maintained of dust suppression applications. ■ Site inspection – during periods of high dust susceptibility, regular inspections will be carried out to monitor the efficacy of dust mitigation and any potential concerns with regards to fugitive dust, and if required implementation of mitigation will be recommended. Environmental conditions will be recorded. ■ Particulate monitoring – SPM using a high volume sampler.	Based on observations and monitoring data during first year of operation, the frequency of monitoring will be determined	Captured through the implementation of the *Dust Management Plan* (AECOM 2018a) and CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and air verification monitoring.

SPM = suspended particulate matter.

5.2.1.10 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community, or the public (The Agency 2018). Air quality was selected as a VC as emissions from the NSDF Project activities have the potential to alter the existing air quality regime. The assessment endpoints for the air quality assessment are comparison against criteria and thresholds for protection of human health and the environment.
The measurement indicators for air quality include changes in ambient concentrations of indicator compounds and dustfall deposition rates in comparison to the provincial or federal ambient air quality criteria.

Residual effects from activities that occur during the construction and operations phases have been identified as the primary linkage to potentially affect ambient air quality. During the construction and operations phases, NSDF Project activities will result in emissions associated with the operation of vehicles and equipment, as well as emissions from the decomposition of waste in the ECM. A summary of the predicted residual adverse effects for air quality, including associated mitigation, are provide in Table 5.2.1-18. Examples of mitigation practices implemented to limit predicted residual effects to air quality include:

- implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring, air verification monitoring and environmental monitoring;
- implementation of the *Dust Management Plan* (AECOM 2018a) for the NSDF Project;
- use of water spraying or misting techniques (e.g., water trucks) as the primary dust control method;
- vehicles that have come into contact with contamination will need to pass through the vehicle decontamination facility; and
- compliance of on-site vehicles and equipment engines with Tier 2 emission standards and their maintenance in good working order.

The predicted residual effects on air quality are estimated to increase because of the NSDF Project. Vehicle exhaust and fugitive dust from unpaved roads is the largest contributor to SPM and PM_{10} during both the construction and operations phases. Vehicle exhaust during the construction of the ECM is the largest contributor of $PM_{2.5}$, SO_2, NO_x/NO_2, CO and C_3H_4O. Predicted concentrations for the Application Case during both construction and operations phases are below applicable air quality guidelines and/or standards, except for NO_2 that will not meet the 2020 1-hour CAAQS. However, as described in Section 5.2.1.4.2.1, in reviewing the criteria used for the assessment of magnitude, a less conservative but still applicable comparison for 1-hour NO_2 concentrations to the Ontario AAQS would result in a low magnitude at less than 50% of the criteria.

For an effect to be deemed significant the effect must be negative in direction, high in magnitude, regional in geographic extent and long-term in duration. None of the indicator compounds meet all of these requirements and consequently, the residual effects from the NSDF Project on air quality was predicted to be not significant. CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018) outlines the key management practices that limit air quality emissions effects, as well as the current monitoring requirements.

Table 5.2.1-18: Summary of Predicted Residual Adverse Effects for Air Quality Valued Components

Valued Components	Assessment Endpoint	Residual Adverse Effects	Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation	Significance
Air Quality	Performance against criteria and thresholds for protection of human health and the environment	■ Construction and operation activities use vehicles and equipment that combust fuel and emit indicator compounds. These activities involve material handling, vehicles travelling on unpaved roads, and wind erosion of stockpiles that will result in fugitive dust emissions. ■ Decomposition of waste during the operations and post-closure phases will emit indicator compounds.	Construction, Operations and Post-Closure	**Construction** ■ Site preparation ■ Construction of the ECM ■ Development of surface water management structures ■ Construction of the WWTP and other support facilities ■ On-site road and access development **Operations** ■ Phased development of disposal cells ■ On-site transportation of waste and placement of waste in the ECM ■ Progressive closure of disposal cells and installation of final cover ■ Operation of the WWTP **Operations and Post-Closure** ■ Decomposition of waste from the ECM	■ Implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring, air verification monitoring and environmental monitoring. ■ The *Dust Management Plan* (AECOM 2018a) to be implemented for the NSDF Project will provide information on dust mitigation, including: ▪ Use of water spraying or misting techniques (e.g., water trucks) as the primary dust control method. ▪ Use of fixatives (e.g., chemical suppressant) for dust control. ▪ Covering stockpiles and exposed areas prior to high wind or dry conditions where standard dust suppressants may be inadequate in preventing dust generation caused by wind erosion. ▪ Minimizing the size of the exposed working areas containing contaminated materials to the extent practicable using a phased excavation approach. ▪ Revegetating affected areas or adding mulch to completed cells and excavated areas as soon as practicable. ▪ Dampening soil in dry areas prior to commencing truck/machinery activities in the area. ▪ Reducing activities to avoid unnecessary dust generation; ▪ Using wind fencing around work areas. ▪ Postponing work activities likely to cause dust if sustained wind speeds are predicted to exceed 40 km/hr, unless it can be shown that the work site is sufficiently protected that wind will not generate unacceptable amounts of dust. ■ On-site vehicles and equipment engines will meet Tier 2 emission standards and be maintained in good working order. ■ Limit idling of vehicles on-site. ■ Processed wastewater will not be heated within the WWTP (raising the temperature increases potential release rates). ■ There is active ventilation within the WWTP building and all active ventilation exhaust will be filtered through HEPA prior to release. ■ Installation of the interim and final covers will reduce release of emissions from the ECM.	Not Significant

ECM = engineered containment mound; WWTP = Wastewater Treatment Plant.

5.2.2 Greenhouse Gases

5.2.2.1 Scope of the Assessment

Greenhouse gases have the potential to affect future climate as they contribute to the greenhouse effect by absorbing infrared radiation in the atmosphere, increasing temperature and changing weather patterns. The GHG assessment follows the overall approach and methods described in Section 5.1 Environmental Assessment Approach. The assessment is completed in the following eight primary steps:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries, and assessment cases** for the GHG assessment (refer to Sections 5.2.2.2 Valued Components and Section 5.2.2.3 Assessment Boundaries). The VCs, assessment endpoints, and measurement indicators used to assess project-related changes to GHG; the spatial and temporal boundaries at which the assessment occurred; and the assessment cases considered.
- **Step 2 – Describe the existing conditions** (refer to Section 5.2.2.4 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation).
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 5.2.2.5 Project Interactions and Mitigation). Project components and/or activities with the potential to affect GHG are identified and mitigation developed to limit or avoid effects is presented. A pathways analysis is then used to focus further assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects to GHG after incorporating mitigation are carried forward to Steps 4 for further analysis and residual effects characterization.
- **Step 4 - Present the methods and results of the residual effects analysis** (refer to Section 5.2.2.6 Residual Effects Analysis). This section outlines the methods used to predict and characterize residual effects to GHG from primary effects pathways. The analysis results are also presented including the characterization of incremental effects from the NSDF Project, as well as cumulative effects of the NSDF Project in combination with other reasonably foreseeable developments (if applicable).
- **Step 5 – Describe the level of certainty and management of uncertainty** (refer to Section 5.2.2.7 Prediction Confidence and Uncertainty). This purpose of this section is to evaluate the available literature, data, and models used for the assessment, and describe the level of certainty that can be placed on predicted residual effects. This section will also identify how the uncertainty has been managed so that the effects are not underestimated.
- **Step 6 – Classify and determine the significance of the predicted residual effects** (refer to Section 5.2.2.8 Residual Effects Classification and Determination of Significance). Residual effects predicted from primary pathways are classified using a common set of criteria: direction, magnitude, geographic extent, duration, reversibility, frequency, and likelihood. A determination of the significance of the predicted residual effects from NSDF Project for the GHG VC is made.

- **Step 7 - Identify monitoring and follow-up** required to confirm effects predictions and address uncertainty (refer to Section 5.2.2.9 Monitoring and Follow-up).
- **Step 8 - Present a consolidated summary of conclusions and outcomes of the assessment** of residual effects on air quality (refer to Section 5.2.2.10 Conclusions).

Information and areas of interest raised by the public, communities of interest, regulators, and Indigenous communities or organizations during engagement that influenced the scope of the GHG assessment are summarized in Table 5.2.2-1. Other general areas of interest and questions (if any) raised during the engagement that pertain to the GHG assessment are documented in CNL's Indigenous Engagement Report (CNL 2021) and CNL's Stakeholder's Activity Reports (CNL 2017a,b, 2019a).

Table 5.2.2-1: Summary of Areas of Interest Raised During Engagement Activities that Influenced the Scope of the Greenhouse Gases Assessment

Area of Interest	How the Area of Interest Was Included in the Assessment
Will the Near Surface Disposal Facility produce methane gas?	The release of methane gas from the engineered containment mound is evaluated in the greenhouse gas assessment. Mitigation to limit the release of methane gas are discussed in Section 5.2.2.5 and predictions of methane gas release from the engineered containment mound are found in Section 5.2.2.6.2. The monitoring program to be implemented to verify that the measures for controlling landfill gas generated from wasted deposited in the engineered containment mound during operations and following final closure are adequate is described in Section 5.2.2.9.
Would like information on monitoring air contamination, including greenhouse gases.	The monitoring program proposed for greenhouse gas emissions is described in Section 5.2.2.9. Greenhouse gas monitoring is also captured through the implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and verification monitoring.

5.2.2.2 Valued Components

Valued Components (VCs) refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Greenhouse gases was selected as a VC as there is a potential for the NSDF Project activities to release GHG emissions that could contribute incrementally to climate change (Table 5.2.2-2). The mechanism by which the NSDF Project has the potential to contribute to global climate change is by the addition of GHG emissions. Greenhouse gases refer to a group of gases that build up in the atmosphere and have the potential to contribute incrementally to climate change.

Table 5.2.2-2: Valued Components for the Greenhouse Gases Assessment

Valued Component	Rationale for Selection
Greenhouse Gases	This VC, assessed through incremental changes in emissions of a group of gases, considers the potential of the NSDF Project to contribute to climate change.

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future generations. The assessment endpoint for GHG is comparison to provincial and national totals (Table 5.2.2-3). Measurement indicators represent properties of the environment and VCs that, when changed, could result in, or contribute to, an effect on an assessment endpoint. Measurement indicators also provide the primary factors for discussing the uncertainty of effects on VCs and, subsequently, are the key variables for study in follow-up and monitoring programs. The measurement indicators considered in the GHG assessment include changes in concentrations of the following indicator compounds:

- CO_2;
- CH_4; and
- N_2O.

There are no NSDF Project activities that are expected to emit sulphur hexafluoride (SF_6), perfluorocarbons (PFCs) or hydrofluorocarbons (HFCs); therefore, these compounds are not included in the GHG assessment. Greenhouse gas emissions are expressed as tonnes of carbon dioxide equivalent (CO_2e), calculated by multiplying the annual emissions of each indicator compound by its 100-year global warming potential (GWP). A single measure is used when evaluating effects, namely the maximum annual GHG emissions resulting from the NSDF Project activities in tonnes of carbon dioxide equivalent. The assessment endpoints and measurement indicators used in the GHG assessment are listed in Table 5.2.2-3.

Table 5.2.2-3: Assessment Endpoints and Measurement Indicators for the Greenhouse Gas Assessment

Valued Component	Assessment Endpoints	Measurement Indicators
Greenhouse gases	Comparison of GHG emissions to provincial and national totals	Changes in greenhouse gas emissions (CO_2, CH_4 and N_2O) compared to provincial and national GHG totals

CO_2 = carbon dioxide; CH_4 = methane; N_2O = nitrous oxide; GHG = greenhouse gas.

5.2.2.3 Assessment Boundaries

5.2.2.3.1 Spatial Boundaries

The spatial boundaries for the GHG assessment are considered to be beyond regional as the predicted residual adverse effect of GHG emissions is considered global in nature.

5.2.2.3.2 Temporal Boundaries

Temporal boundaries (i.e., project phases) establish the timeframe during which NSDF Project effects are assessed. Four phases were identified for the NSDF Project including the construction phase, operations phase, closure phase, and post-closure phase (refer to Section 5.2.1.1 for more details on each phase). For the purposes of the GHG assessment, only the construction and operation phases have been considered. The GHG emissions from operations include the first year after closure, which represents the year where emissions from the decomposition of the waste within the ECM are expected to be at their highest as demonstrated in *Radon and Other Landfill Gas Modelling and Evaluation* (AECOM 2018b). Therefore, GHG emissions during operations phase are expected to be greater than the GHG emissions from the closure phase and the emissions from the post-closure phase are expected to be considerably less than the operations phase.

5.2.2.3.3 Assessment Cases

The assessment cases considered in the GHG assessment include the Base Case and the Application Case:

- **Base Case –** This scenario represents existing conditions and characterizes effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances in the area, such as forestry, transportation, agricultural, mining, and residential and recreational development. For example, current effects from the existing operations and activities on the CRL site are considered part of the Base Case.
- **Application Case –** This scenario represents the effects of the Base Case combined with the predicted effects that from the NSDF Project. The Application Case was divided into the construction phase and the operations phase, and therefore, the emissions and associated effects during the construction and operations phases of the NSDF Project represent the bounding cases. Only direct GHG emissions within the LSA have been considered in this assessment (i.e., emissions outside of the Local Study Area, for example from off-site transportation of construction materials, are not included in the assessment). Direct emissions include emissions that are owned or controlled by CNL, such as fuel use and GHG emitted from the decomposition of the waste within the ECM. Indirect GHG emissions, such as electricity, are emissions that are a consequence of the CNL activities, but occur at sources owned or controlled by another entity; and therefore, are excluded from the assessment.
- **Reasonably Foreseeable Development (RFD) Case** – Reasonably foreseeable developments in the RSA that are anticipated to overlap with the potential effects of the NSDF Project include new/upgrades to research and development facilities, construction and operation of an SMR, new support infrastructure, on-going decommissioning and environmental remediation activities on the CRL site. The waste from the decommissioning of the CRL structures will be placed in the NSDF Project and the Application Case for the operations phase considers the transport of this waste for disposal in the ECM. As well, there may be overlap of the construction period with limited construction at neighbouring Garrison Petawawa. These RFD Case projects will involve smaller amounts of similar equipment used during the construction phase of the NSDF Project, and are expected to implement similar mitigation to limit release the same GHG emissions (vehicle and equipment exhaust).

5.2.2.4 Description of the Environment

5.2.2.4.1 Methods

Applicable Criteria

The relevant GHG emissions criteria include the provincial and federal emission levels. These emission levels are calculated using the assessment frameworks summarized below, followed by the baseline GHG emissions levels considered for the Base Case.

Federal Guidance on Reporting Greenhouse Gas Emissions

The *Technical Guidance on Reporting Greenhouse Gas Emissions* (ECCC 2019a) provides direction in determining if facilities are required to submit a GHG report to ECCC under the Greenhouse Gas Reporting Program (GHGRP), an overview of the reporting process, as well as technical information related to GHG emissions estimations, including identifying GHG emission sources subject to reporting (ECCC 2018b). The GHGRP falls under the *Canadian Environmental Protection Act, 1999*. The GHGRP Guideline references GHG estimation methodologies from the United Nations Framework Convention on Climate Change (UNFCCC) and was developed by the Intergovernmental Panel on Climate Change. The GHGRP Guideline states that "no specific estimation methods are prescribed" and that facilities should choose estimation methods that are most appropriate for their particular industry, but are consistent with the guidelines adopted by the UNFCCC for preparing GHG inventories. The reporting threshold for the GHGRP is 10,000 tonnes of carbon dioxide equivalent (CO_2e).

Provincial Guideline for Quantification, Reporting and Verification of Greenhouse Gas Emissions

The documenting and reporting of GHG emissions in Ontario are governed by *Ontario Regulation (O. Reg.) 390/18 Greenhouse Gas Emissions: Quantification, Reporting and Verification.* The *Guideline for Quantification, Reporting and Verification of Greenhouse Gas Emissions* (MEPC 2018) (i.e., O. Reg. 390/18 Guideline) provides the emission estimation methods that are required to be used under this reporting regulation. The emissions generated at the NSDF Project are defined by the O. Reg. 390/18 Guideline GHG emission estimation method ON.20 (General Stationary Combustion) for natural gas and diesel combustion and ON.280 (Mobile Equipment Operation) for the mobile equipment. The emissions generated from the ECM final cover are not covered under O. Reg. 390/18. The reporting threshold for O. Reg. 390/18 is 10,000 tonnes of CO_2e.

Baseline GHG Emissions Data

Existing GHG emissions are not measured; however, they are routinely estimated. For the purposes of this GHG assessment, federal and provincial reported GHG data, as well as CNL data, is used to describe the GHG emissions. The following sources of information were used to characterize the existing GHG emissions:

- ECCC National Inventory Report 1990-2017: Greenhouse Gas Sources and Sinks in Canada (ECCC 2019b);
- ECCC Greenhouse Gas Reporting Program (GHGRP) – Facility Greenhouse Gas (GHG) Data (ECCC 2018b); and
- Annual Compliance Monitoring Report *Effluent Verification Monitoring at Chalk River Laboratories in 2018* (CNL 2019b).

5.2.2.4.2 Base Case Results

The latest available federal and provincial reported GHG data were used to describe the background GHG emissions. The latest available federal and provincial data are from the 2017 reporting year (ECCC 2019b). There are no large GHG emitters within 100 km of the NSDF Project, with the exception of the CRL main campus and the Department of National Defense, located in Petawawa, that reported 31,655 tonnes of CO_2e in 2017. (ECCC 2019b). The latest data provided by CNL, indicated that the CNL main campus contributed 30,608 tonnes of CO_2e in 2018 (CNL 2019b). Total federal, provincial, and CRL main campus GHG emissions are provided in Table 5.2.2-4.

Table 5.2.2-4: Baseline Greenhouse Gas Emissions

Source	GHG Emissions (tonnes CO_2e)
Canada-wide 2017 Greenhouse Gas Emissions Total[(a)]	716,000,000
Ontario-wide 2017 Greenhouse Gas Emissions Total[(a)]	159,000,000
CRL Main Campus 2018 Greenhouse Gas Emissions[(b)]	30,608
Department of National Defense 2017 Greenhouse Gas Emissions[(a)]	31,655

a) ECCC 2019b

b) CNL 2019b

CO_2e = carbon dioxide equivalent.

5.2.2.5 Project Interactions and Mitigation

5.2.2.5.1 Methods

This section describes the process by which interactions between NSDF Project components and activities and GHG were identified and evaluated. Potential effects pathways are identified and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment (i.e., Section 5.2.2.6). As such the ‘Project Interactions and Mitigations’ section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all stages of the NSDF Project. The next step in the analysis was the development of environmental design features and mitigation practices that could be incorporated into the NSDF Project to eliminate and/or reduce changes to GHG emissions. Environmental design features included design elements, environmental best practices, and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the engineering and environmental teams, combined with input from project-specific or regional engagement with other interested parties. The design features and/or mitigation were considered for their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effects pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments, and the effectiveness of environmental design features and mitigation:

- **No linkage:** This pathway is removed by environmental design features or mitigation such that the NSDF Project would not be expected to result in a measurable environmental change to concentrations of indicator compounds relative to Base Case values, and therefore would have no residual effects to GHG.
- **Secondary pathway:** The pathway could result in a measurable minor change to concentrations of indicator compounds, but would have a negligible residual effect on GHG relative to Base Case and/or guideline values and is not expected to contribute cumulatively to other NSDF Project effects or to the effects of other previous, existing or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway:** The pathway is likely to result in an environmental change to concentrations of indicator compounds relative to the Base Case and/or guideline values that could contribute to residual effects to GHG.

Environmental design features and mitigation that have been or could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects to GHG were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to GHG through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways were carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the NSDF Project on GHG (see Section 5.2.2.6).

5.2.2.5.2 Results

Pathways through which all stages of the NSDF Project may interact with and result in changes to GHG emissions are provided in Table 5.2.2-5. The GHG emissions were estimated using information provided in the NSDF *Landfill Gas Management Plan* (AECOM 2018c) and by taking into consideration the mitigation that were considered to be integral to the design and implementation of the NSDF Project activities. These mitigation, which are considered to be typical and consistent with best practices, are presented in Table 5.2.2-5.

Table 5.2.2-5: Pathways Analysis for Greenhouse Gas Emissions Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Construction ■ Site preparation ■ Construction of the ECM ■ Development of surface water management structures ■ Construction of the WWTP and other support facilities ■ On-site road and access development ■ Soil spoils haulage to 'a soil storage area'	■ Construction activities use vehicles that combust fuel and emit GHGs. These vehicles travel on roads on CRL site and are used for material handling. ■ Additionally, there are GHG emissions associated with land clearing for the NSDF Project. One-time emissions will be presented over the life-time of the NSDF Project.	■ Implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and verification monitoring. ■ On-site vehicles and equipment engines will be maintained in good working order. ■ Limit idling of vehicles on site.	Primary

Operations
■ Phased development of disposal cells
■ On-site transportation of waste and placement of waste in the ECM
■ Progressive closure of disposal cells and installation of final cover
■ Operation of the WWTP
	■ Most activity and material handling occurs during the operations phase.
	  ▪ Vehicles and equipment combust fuel and emit GHGs. These activities involve material handling with vehicles travelling on roads.
	  ▪ The disposal cell emits GHG emissions from the decomposition of waste.
	  ▪ The WWTP will be fuelled by Natural Gas.
	  ▪ Additionally, there is a loss of carbon sink as a result of the cleared land for the NSDF Project.
		■ Implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and verification monitoring.
		■ On-site vehicles and equipment engines will be maintained in good working order.
		■ Limit idling of vehicles on-site.
			Primary

Operations and Post-closure ■ Placement of waste in the ECM	■ GHG emissions from the decomposition of waste.	■ Installation of the interim and final covers will reduce release of emissions from the ECM.	Primary

ECM = engineered containment mound; GHG = greenhouse gas; WWTP = Wastewater Treatment Plant.

5.2.2.5.2.1 No Linkage Pathways

No pathways are identified as having no linkage to climate change as part of this assessment.

5.2.2.5.2.2 Secondary Pathways

No secondary pathways are identified to climate change as part of this assessment.

5.2.2.5.2.3 Primary Pathways

The following primary pathways were identified as having the potential to result in residual effects to climate change, and therefore, have been carried forward to the residual effects analysis.

- Construction activities use vehicles and equipment that combust fuel and emit GHGs. These activities involve material handling and vehicles travelling on roads.
- Additionally, there are GHG emissions associated with land clearing for the NSDF Project. One-time emissions will be presented over the lifetime of the NSDF Project.
- Most activity and material handling occurs during this stage. Vehicles and equipment combust fuel and emit GHGs. These activities involve material handling with vehicles travelling on roads. The disposal cell emits GHG emissions from the decomposition of waste. The WWTP will be fuelled by natural gas. Additionally, there is a loss of carbon sink as a result of the cleared land for the NSDF Project.
- GHG emissions from the decomposition of waste.

5.2.2.6 Residual Effects Analysis

5.2.2.6.1 Methods

Residual effects of a project are those effects that remain after implementation of all mitigation measures. The assessment of effects of the NSDF Project on the GHG involves two steps, namely the calculation of emission rates and use of dispersion modelling to predict the resulting concentrations of GHG emissions. These steps are described below.

Identification of emission sources was completed by defining an inventory boundary, which frames the GHG emission sources that are included in the assessment for the NSDF Project. The inventory boundary is based on the GHGRP; and therefore, stationary fuel combustion emissions, on-site mobile emissions, and emissions from waste have been included in this GHG assessment of effects. Additionally, there is a loss of carbon sink as a result of the cleared land for the NSDF Project. Table 5.2.2-6 outlines the GHG inventory boundaries of the provincial and federal programs and presents the source categories included in the GHG assessment.

Table 5.2.2-6: Sources Categories included in the Greenhouse Gas Assessment

Source Category	O. Reg.390/18	GHGRP	GHG Assessment
On-site stationary fuel combustion sources	Yes	Yes	Yes
On-site stationary fuel combustion for generator	No[a]	Yes	Yes
On-site mobile fuel combustion sources	Yes[b]	Yes	Yes
Final cover (emissions from waste)	No	Yes	Yes
Land clearing	No	No	Yes
WWTP and associated equipment (i.e., equalization tanks)	No	Yes	Yes

a) On-site generators are used for emergency purposes and are less than 10 megawatts, therefore are exempt from GHG reporting under O. Reg.390/18.

b) Reporting mobile fuel combustion sources is currently optional under O. Reg.390/18.

ECM = engineered containment mound; GHG = greenhouse gases; GHGRP = Greenhouse Gas Reporting Guideline.

The emission estimation methods follow guidance in *Guideline for Quantification, Reporting and Verification of Greenhouse Gas Emissions* (MECP 2018), as set out under O. Reg. 390/18 under the Ontario *Environmental Protection Act*, as well as the ISO 14064-1 standard entitled *Specification with Guidance at the Organizational Level for Quantification and Reporting of Greenhouse Gas Emissions and Removals* (ISO 2006). Additional alternative methods, such as LandGEM (US EPA 2005) were also used in the assessment to estimate emissions from the decomposition of waste within the landfill and Intergovernmental Panel on Climate Change guidelines were used to calculate greenhouse gas emissions from land clearing. Details of the specific GHG emission source identification, calculation methods, and sample calculations are provided in Section 4 (Emissions Estimate) of the Air Quality Assessment TSD (Golder 2019).

5.2.2.6.2 Application Case Results

Emission Rates

Table 5.2.2-7 and Table 5.2.2-8 summarizes the annual emission rates in tonnes per year for each activity at the NSDF Project for the construction and operations phases, respectively. The GWP used to calculate GHG emission in CO_2e correspond to the Ontario O. Reg. 390/18 GWPs. Details of the specific emission calculation methods, GWPs, and resulting emissions are provided in Section 4 (Emissions Estimate) of the Air Quality Assessment TSD (Golder 2019).

Table 5.2.2-7: Summary of Annual Greenhouse Gas Emissions during the Construction Phase

Project Activity	Source	Source Description	Annual GHG Emissions (tonnes/yr)			Annual Total (tonnes/ yr)[a]
			CO_2	CH_4	N_2O	CO_2e
Construction of the ECM, development of surface water management structures, construction of the WWTP and other support facilities, and on-site road and access development	Mobile Fuel Combustion (road and non-road vehicles)	Vehicle exhaust	26,986	1.3	4.1	28,271
Site Preparation	Land Clearing	One-time loss of carbon stored in biomass	160	—	—	160
		Loss of carbon sink potential	337	—	—	337

a) Calculated using provincial global warming potentials

"–"Not included in this assessment in the construction phase; CO_2 = carbon dioxide; CH_4 = methane; N_2O = nitrous oxide; CO_2e = carbon dioxide equivalent; GHG = greenhouse gas; ECM = engineered containment mound; WWTP = Wastewater Treatment Plant.

Table 5.2.2-8: Summary of Annual Greenhouse Gas Emissions during the Operation Phase

Project Activity	Source	Source Description	Annual GHG Emissions (tonnes/yr)			Annual Total (tonnes/ yr)[a]
			CO2	CH4	N2O	CO2e
ECM (decomposition of waste)	Engineered Containment Mound	Final cover (decomposition of waste emissions)	228	83	—	1,964
Operation of the WWTP	Stationary Fuel Combustion	Natural Gas comfort heating	1,071	0.02	0.02	1,078
Phased development of disposal cells, on-site transportation of waste and placement of the waste in the ECM, progressive closure of disposal cells and installation of final cover	Mobile Combustion (road & non-road vehicles)	Vehicle exhaust	5,589	0.3	0.8	5,855
Operations	Cleared Land	Loss of carbon sink potential	337	—	—	337

a) Calculated using provincial global warming potentials

"—" not included in the assessment; = CO_2 = carbon dioxide; CH_4 = methane; N_2O = nitrous oxide; CO_2e = carbon dioxide equivalent; GHG = greenhouse gas; ECM = engineered containment mound; WWTP = Wastewater Treatment Plant.

Negligible Emissions from the NSDF Project

There are many activities associated with the NSDF Project that produce GHG emissions; however, not all activities produce emissions for any or all compounds that are relevant to the overall emissions assessment. All activities that potentially produce emissions were evaluated to assess their relevance; however, only activities that were considered to be relevant were included in the assessment. The following lists rationale as to why certain activities and/or emissions of certain compounds are excluded from the assessment:

- the emission rates of certain compounds are minor relative to the overall emissions at the NSDF Project; and
- the emissions of certain sources are known to not be relevant due to the type of operations in the assessment.

Table 5.2.2-9 lists the activities that were not assessed and the accompanying rationale.

Table 5.2.2-9: GHG Emission Sources and Contaminants Not Included in the Assessment

Activity/Compound	Rationale for Excluding from the Assessment
WWTP and associated equipment (i.e., equalization tanks)	The process of treatment of wastewater may result in a minor release of greenhouse gases. These emissions have been excluded from the assessment as they are negligible in comparison to the other GHG emissions from the NSDF Project. At approximately, 29 tonnes CO_2e per year, GHG emissions from the WWTP process are less than 1% of the total GHG emissions and therefore have not been carried through the assessment.
Natural gas emergency power generator	The emergency natural gas generator only operates periodically during monthly routine maintenance testing and for very short duration (20 minutes) (rather than continuously). Additionally, the emergency power generator will only be used to supply electricity during power outage when other equipment is not operation, and therefore, is not included in the representative scenario. These emissions have been excluded from the assessment as they are expected to be negligible in comparison to the other GHG emissions from the NSDF Project relative to other present sources.
Diesel pumps, air compressors, and lighting equipment at all NSDF buildings	This equipment is part of miscellaneous equipment and only operates periodically and for short durations. Emissions rates from these sources are minor compared to emissions from the other diesel equipment on-site, and therefore, are not included in the representative scenarios.
Snow removal equipment	Emissions from this equipment occur seasonally and are infrequent (i.e., only during the winter following a snowfall), and therefore, are not included in the representative scenario. These emissions have been excluded from the assessment as they are expected to be negligible in comparison to the other GHG emissions from the NSDF Project relative to other present sources.
Upstream GHG emissions	A March 19, 2016 Notice in the Canada Gazette presented ECCC's proposed methodology for estimating the upstream GHG emissions associated with projects undergoing federal environmental assessments. Upstream GHG emissions are those resulting from all industrial activities from the point of resource extraction to the NSDF Project. The specific processes will vary by resource but generally include extraction, processing, handling, and transportation. The NSDF Project is not planned to enable new soil or clay extraction or cement production facilities. Rather, the NSDF Project will be a customer for existing soil or clay supply and cement facilities and is unlikely to impact the Provincial supply and demand for these materials. While grouting will occur during waste placement, it is expected to be minor as it will primarily be used to reduce void space in packages and is not anticipated to require a mobile cement facility. Therefore, these emissions have been excluded from the assessment as they are expected to be negligible in comparison to the other GHG emissions from the NSDF Project.

GHG = greenhouse gas; WWTP = Wastewater Treatment Plant; CO_2e = carbon dioxide equivalent.

GHG Results

Table 5.2.2-10 summarizes the annual overall emissions in tonnes of CO_2e for the NSDF Project construction and operations phase, respectively. It also summarizes the NSDF Project combined with the 30,608 tonnes of CO_2e the CRL main campus emitted in 2018 to show a projected annual total for the entire CRL site for both the construction and operations phases. Construction phase GHG emissions are approximately 6% less than the 2018 CRL main campus emissions while operations phase GHG emissions are approximately 70% less. Greenhouse gas emissions by source is presented in Tables 5.2.2-7 and 5.2.2-8. Since both construction and operations phase GHG emissions represent less than 0.02% of the provincial total and less than 0.005% of the Canada-wide total, a comparison to the global GHG emissions total was not completed as GHG emissions from the NSDF Project represent a negligible fraction of global GHG emissions.

Table 5.2.2-10: Comparison of Greenhouse Gas Emissions from the NSDF Project to Ontario and Canadian Emission Totals

Source	Construction GHG Emissions (CO_2e tonnes/yr)	Operation GHG Emissions (CO_2e tonnes/yr)
NSDF Project		
GHG Emissions	28,768	9,233
Comparison to Canada-wide Total	0.0040%	0.0013%
Comparison to Ontario Total	0.018%	0.0058%
NSDF Project + CRL main campus		
GHG Emissions[(a)]	59,376	39,841
Comparison to Canada-wide Total	0.0083%	0.0056%
Comparison to Ontario Total	0.037%	0.025%
Canada-wide GHG Emissions (2017)	**716,000,000**	
Ontario-wide GHG Emissions (2017)	**159,000,000**	

a) CRL main campus GHG Emissions for 2018 were 30,608 tonnes CO_2e (CNL 2019b)

GHG = greenhouse gases; NSDF = Near Surface Disposal Facility; CO_2e = carbon dioxide equivalent.

5.2.2.6.3 Reasonably Foreseeable Development Case Results

Consistent with the consideration of the RFD Case for air quality, revitalization activities (i.e., new/upgrades to research and development facilities, new support infrastructure), on-going decommissioning and environmental remediation activities on the CRL site, as well as construction and operations of a SMR at the CRL site will generate GHG emissions that may overlap with residual effects of the NSDF Project. As NSDF Project contributions within the LSA represent a negligible change to GHG emissions to provincial and national totals, contribution by the limited construction at neighbouring Garrison Petawawa would be anticipated to be similarly negligible and the areas of effect would not be anticipated to overlap.

The airborne emissions from new facility construction and decommissioning projects on the CRL site will be assessed as part of the approval process for these projects. Examples of mitigation to limit effects from GHG emissions applicable to all projects on the CRL site include:

- implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and verification monitoring;
- on-site vehicles and equipment engines will meet Tier 2 emission standards and be maintained in good working order; and
- limiting idling of vehicles on-site.

Revitalization and decommissioning activities at the CRL site are planned to be staggered over the ten- year period (2016 to 2026), and the required activities to be completed at any one time are anticipated to be less than that required for the larger scale construction of the NSDF Project. Similarly, the equipment requirements for construction and operations of the SMR are expected to be less than that assessed for the NSDF Project. Consistent with the conclusions in Section 5.2.2.6.2 for the Application Case, GHG emissions as a result of RFD Case projects are anticipated to result in a negligible change relative to provincial and national totals. With effective implementation of mitigation measures and monitoring programs, no cumulative residual effect is identified to GHGs.

5.2.2.7 Prediction Confidence and Uncertainty

For the assessment of GHGs, the main sources of error are the accuracy of the activity data and hours of operation used to estimate emissions to the NSDF and the omission of some emission sources. These uncertainties were managed using conservative assumptions in the emission estimation, including:

- maximum handling and operating capacities were used in determining emission rates;
- all equipment on-site was assumed to operate concurrently; and
- with respect to the GHG emissions and production levels used to calculate emission intensity factors, the information was derived either from the federal and provincial GHG reporting websites or from recent environmental assessments.

Sources not included in the assessment contribute less than 1% each to the total GHG emissions and the Ontario regulation dictates that materiality threshold is set to 5%. Therefore, the emissions from these sources do not constitute a material error and are within the conservatism assumed in the assessment.

5.2.2.8 Residual Effects Classification and Determination of Significance

This section classifies the residual effects from changes to measurement indicators for the Application Case and presents a determination of significance for the GHG VC. The results from the GHG assessment were compared to the relevant residual effects assessment criteria to evaluate the significance of the residual adverse effects.

5.2.2.8.1 Residual Effects Classification

Effects from adverse residual changes to measurement indicators were classified using a categorical scale and common words to facilitate the determination of significance. The purpose of categorical classification is to provide definitions that permit a clear, thorough and unambiguous classification of residual effects such that reviewers and readers can follow and apply the logic used in the assessment and reach the same classification for a given residual effect.

Magnitude, geographic extent and duration are the principal factors considered to predict significance.
The magnitude of a residual environmental effect is determined by the change in a measurement indicator from a project interaction. Geographic extent refers to the area affected and duration is defined as the amount of time for a residual effect to be reversed. For GHG, residual effects are not evident beyond the closure and post closure phases. Other criteria, such as frequency and likelihood are used as modifiers, where applicable.
Residual adverse effects were classified using the criteria and definitions outlined in Table 5.2.2-11.

Table 5.2.2-11: Assessment Criteria for Classifying Predicted Residual Adverse Effects to Greenhouse Gases

Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Likelihood
Positive: Predicted GHG emissions represents a decrease from Base Case. **Negative:** Predicted GHG emissions represents an increase from Base Case. **Neutral:** No change predicted GHG emissions relative to Base Case.	**Negligible:** <0.1% of the provincial emission levels, or by <0.01% of the federal emission level **Low:** >0.1% but <1% of the provincial emission levels, or by <0.01% of the federal emission levels **Moderate:** >1% compared to provincial totals, or by >0.1% compared to national totals. **High:** >5% compared to provincial totals, or by >1% compared to national totals	Beyond Regional: Effects extends beyond the RSA	**Short-term:** Effects are not evident beyond the construction phase **Medium-term:** Effects are not evident beyond the operations phase **Long-term:** Effects are not evident beyond the closure and post-closure phases **Permanent**: Effects are not reversible	**Infrequent:** Effects are confined to a specific discrete period **Frequent:** Effects occur intermittently, but repeatedly, or continuous over the assessment period	**Reversible:** Change of state in environment is not permanent **Irreversible:** Change of state in the environment is permanent	**Low:** Effect is unlikely to occur **Medium:** Effect is likely to occur **High:** Effect is highly likely to occur

GHG = greenhouse gas; < = less than; > = greater than

5.2.2.8.2 Determination of Significance

The residual effects classification of primary pathways and the associated predicted changes in measurement indicators provide the foundation for determining the significance of residual effects from the NSDF Project on GHG. Where possible and appropriate, established guidelines, thresholds and screening values were used to support the classification of the predicted amount of change in measurement indicators and associated effects on GHG. For an effect to be deemed significant the effect must be negative in direction, high in magnitude, beyond regional in geographic extent and long-term in duration. As part of the determination of significance, confidence in the assessment identified in Section 5.2.2.7 was considered for the GHG VC. Where uncertainty was high and the cumulative effect might be either significant or not significant, the assessment conservatively identified the effect as significant and provided additional follow-up actions to reduce uncertainty (Section 5.2.2.9).

The predicted residual adverse effect of GHG emissions is considered global in nature, and therefore the geographic extent was rated as beyond regional. Predicted effects of GHG emissions from the NSDF Project are anticipated to be reversible within the temporal boundary of the assessment and would occur continuously during operations (Table 5.2.2-12). The magnitude of the effects is rated negligible, as the change in GHG emissions due to the NSDF Project are estimated to be less than a 0.02% increase in total provincial GHG emissions and less than a 0.005% increase in total national GHG emissions. Consequently, the overall residual adverse effect of the Application Case during the construction and operations phases on GHG are determined to be not significant. Only the construction and operation phases have been considered as the emissions from these phases will be higher than those during the closure and post-closure phases.

Table 5.2.2-12: Classification of Predicted Residual Adverse Effects on Greenhouse Gases for the Application Case

Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Likelihood
Application Case – Construction Phase						
Negative	Negligible	Beyond regional	Short-term	Frequent	Reversible	High
Application Case – Operations Phase						
Negative	Negligible	Beyond regional	Medium-term	Frequent	Reversible	High

5.2.2.9 Monitoring and Follow-up

Implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and air verification monitoring, will continue for the NSDF Project as it outlines the key management practices to limit effects to air quality. The CRL Radiological Air Effluent Verification Monitoring Program comprises 56 monitoring points and will also continue for the NSDF Project. In addition, GHG emissions monitoring activities for the NSDF Project will be implemented (Table 5.2.2-13) and the purpose is to:

- verify effects predictions, and compare actual with predicted effects;
- confirm effectiveness of mitigation, and in doing so evaluate if alternate mitigation is required;
- provide information for use in adaptive management to address potential unforeseen effects; and
- demonstrate compliance with regulatory requirements.

Table 5.2.2-13: Monitoring and Follow up Programs for Greenhouse Gas Emissions

Valued Component	Project Phase and Potential Effect	Monitoring Program Objective	Conceptual Monitoring Program	Suggested Duration	Implementing Program
Greenhouse gases	GHG emissions from the decomposition of waste during operations and closure.	■ Verify that the measures for controlling landfill gas generated from wasted deposited in the ECM during operations and following final closure are adequate ■ Verify that methane emission rates used in the assessment are reasonable and conservative. ■ Verify that there is no combustion hazard from methane gas generation	■ Monitoring for methane will be performed using handheld portable combustible gas meter detectors. ■ A passive landfill gas venting system will be constructed contemporaneously with installation of the ECM final cover system which will provide measured concentrations and emission rates. ■ The landfill gas monitoring probes will also be installed around the perimeter of the ECM to detect evidence of potential landfill gas migration away from the ECM.	Periodic monitoring during operations and for a specific period of time during closure phase (during which the frequency may be progressively reduced and possibly ultimately eliminated if no evidence of landfill gas migration from the ECM is detected)	*Landfill Gas Management Plan* (AECOM 2018c) to be implemented for the NSDF Project.
	Construction and operations activities will result in increased GHG emissions.	Verify that GHG emission rates used in the assessment are reasonable, but conservative. Monitoring results will be used for GHG reporting requirements.	Fuel Usage – a record will be kept of the fuel usage related to the NSDF Project.	Annual estimations and GHG reporting as required	Captured through the implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and verification monitoring.

GHG = greenhouse gas; ECM = engineered containment mound;

5.2.2.10 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Greenhouse gases was selected as a VC as there is a potential for the NSDF Project activities to release GHG emissions that could contribute incrementally to climate change. The assessment endpoint for the GHG assessment is comparison to provincial and national totals. The measurement indicator for GHG include changes in emissions of CO_2e to provincial and national GHG totals.

Residual effects from activities that occur during the construction and operations phase have been identified as the primary linkage to potentially affect GHG emissions. During the construction and operations phases, NSDF Project activities will result in GHG emissions associated with the land clearing, operation of vehicles and equipment, as well as emissions from the decomposition of waste in the ECM. A summary of the predicted residual adverse effects for GHGs, including associated mitigation, are provide in Table 5.2.2-14. Examples of mitigation practices implemented to limit predicted residual effects to GHGs include:

- Implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and verification monitoring;
- on-site vehicles and equipment engines will be maintained in good working order; and
- limit idling of vehicles and equipment on-site.

The predicted residual effects to GHG emissions were estimated to increase because of the NSDF Project. Emissions of GHGs from the CRL site are estimated to increase approximately 94% during the construction phase and approximately 30% during the operations phase. However, the change is estimated to be less than a 0.02% increase in total provincial GHG emissions and less than a 0.005% increase in total national GHG emissions. Consequently, the residual effects from the NSDF Project on GHGs was determined to be not significant. CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018) outlines the key management practices that limit GHG emissions effects, as well as the current monitoring requirements.

Table 5.2.2-14: Summary of Predicted Residual Adverse Effects for Greenhouse Gas Emissions Valued Component

Valued Component	Assessment Endpoint	Residual Adverse Effects	Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation	Significance
Greenhouse gases	Comparison to provincial and national totals	GHG emissions from the decomposition of waste.	Operations and Post-closure	■ Placement of waste in the ECM ■ Progressive closure of disposal cells and installation of final cover	Installation of the interim and final covers will reduce release of emissions from the ECM.	Not Significant
Greenhouse gases	Comparison to provincial and national totals	Construction and Operations activities will result in increased greenhouse gas emissions.	Construction and Operations	**Construction** ■ Site preparation ■ Construction of the ECM ■ Development of surface water management structures ■ Construction of the WWTP and other support facilities ■ On-site road and access development **Operations** ■ Phased development of disposal cells ■ On-site transportation of waste and placement of waste in the ECM ■ Progressive closure of disposal cells and installation of final cover ■ Operation of the WWTP	■ Implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and verification monitoring. ■ On-site vehicles and equipment engines will be maintained in good working order. ■ Limit idling of vehicles on-site.	Not Significant

ECM = engineered containment mound; WWTP = Wastewater Treatment Plant

5.3 Geological and Hydrogeological Environment

Section 5.3 of the Environmental Impact Statement for the Canadian Nuclear Laboratories (CNL) Near Surface Disposal Facility (NSDF) Project seeks to understand and characterize potential residual effects of the NSDF Project and other past, present and reasonably foreseeable developments on the physical aspects of the environment. Section 5.3.1 focuses on geology and Section 5.3.2 focuses on hydrogeology (groundwater).

5.3.1 Geology

5.3.1.1 Scope of the Assessment

This section focuses on geology, which includes bedrock, soils and geomorphology (i.e., the study of physical features on the earth and their relation to underlying geological structures). The geology assessment follows the overall environmental assessment approach and methods described in Section 5.1. The assessment was completed following the key steps listed below:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** for the geology assessment (refer to Section 5.3.1.2 Valued Components and Section 5.3.1.3 Assessment Boundaries). The VCs and measurement indicators used to assess Project-related changes to geology are described, along with the spatial and temporal boundaries at which the assessment occurred and the assessment cases considered.
- **Step 2 – Describe the existing conditions** (refer to Section 5.3.1.4 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation). The existing conditions provide a reference to which the effects of the NSDF Project can be compared.
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 5.3.1.5 Project Interactions and Mitigation). Project components and/or activities with the potential to affect geology are identified, and mitigation developed to limit or avoid effects is presented. A pathways analysis is then used to focus further assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways were not identified for geology; therefore, no residual effects are carried forward for further analysis and characterization.
- **Step 4 - Present the methods and results of the residual effects analysis**. This step was not required as no primary pathways were identified in the geology assessment.
- **Step 5 - Describe the level of certainty and management of uncertainty.** This step was not required as no primary pathways were identified in the geology assessment.
- **Step 6 - Classify and determine the significance of the predicted residual effects**. This step was not required as the geology VC is an intermediate component which does not include an assessment endpoint to determine significance.
- **Step 7 – Identify monitoring and follow-up** required to confirm effects predictions and address uncertainty (refer to Section 5.3.1.6 Monitoring and Follow-up).

- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** of residual effects on geology (refer to Section 5.3.1.7 Conclusions).

This section also describes how the input from engagement influenced the scope of the geology assessment. To date, no areas of interest have been raised by the public, communities of interest, and Indigenous Peoples during engagement activities specific to geology.

5.3.1.2 Valued Components

VCs refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community, or the public (The Agency 2018). Geology, which includes bedrock, soils and geomorphology, is recognized as an important component of the environment that may be affected by the NSDF Project, and changes to geology could, in turn, lead to effects on other VCs selected for assessment. For example, changes to the characteristics of geology, such as soil quality and quantity, have an influence on the local and regional diversity, contributing to the abundance and distribution of plants and animals on the landscape. Subsequently, changes to these characteristics by NSDF Project activities could affect terrestrial and aquatic ecosystem structure and function (Table 5.3.1-1). In addition, soil quality can potentially affect soil organisms. Consequently, soil quality is considered as a measurement indicator for geology. The effects of changes to soil quality on the aquatic and terrestrial environments are discussed in Sections 5.5 and 5.6, respectively, and effects on soil invertebrates are discussed in Section 5.7.

Acknowledging that changes to geology are important aspects of the natural and human environment, geology is referred to as an intermediate component (i.e., it does not have an assessment endpoint). Changes to intermediate component VCs must be understood to facilitate assessment of project interactions. The geology assessment, therefore, is analyzed for incremental and cumulative (if applicable) changes in the relevant measurement indicators associated with geology (Table 5.3.1-2). The assessment of geology focused on predicting changes in the concentrations of selected non-radiological substances; radiological parameters are considered in Section 5.7 Ambient Radioactivity and Ecological Health. The changes are characterized in terms of magnitude, duration and geographic extent, but are not classified using rankings for effects criteria. The geology assessment also does not include the assessment of the significance of these changes; rather, results of the analysis of changes in measurement indicators for geology are provided to other disciplines for inclusion in their assessment (Table 5.3.1-2).

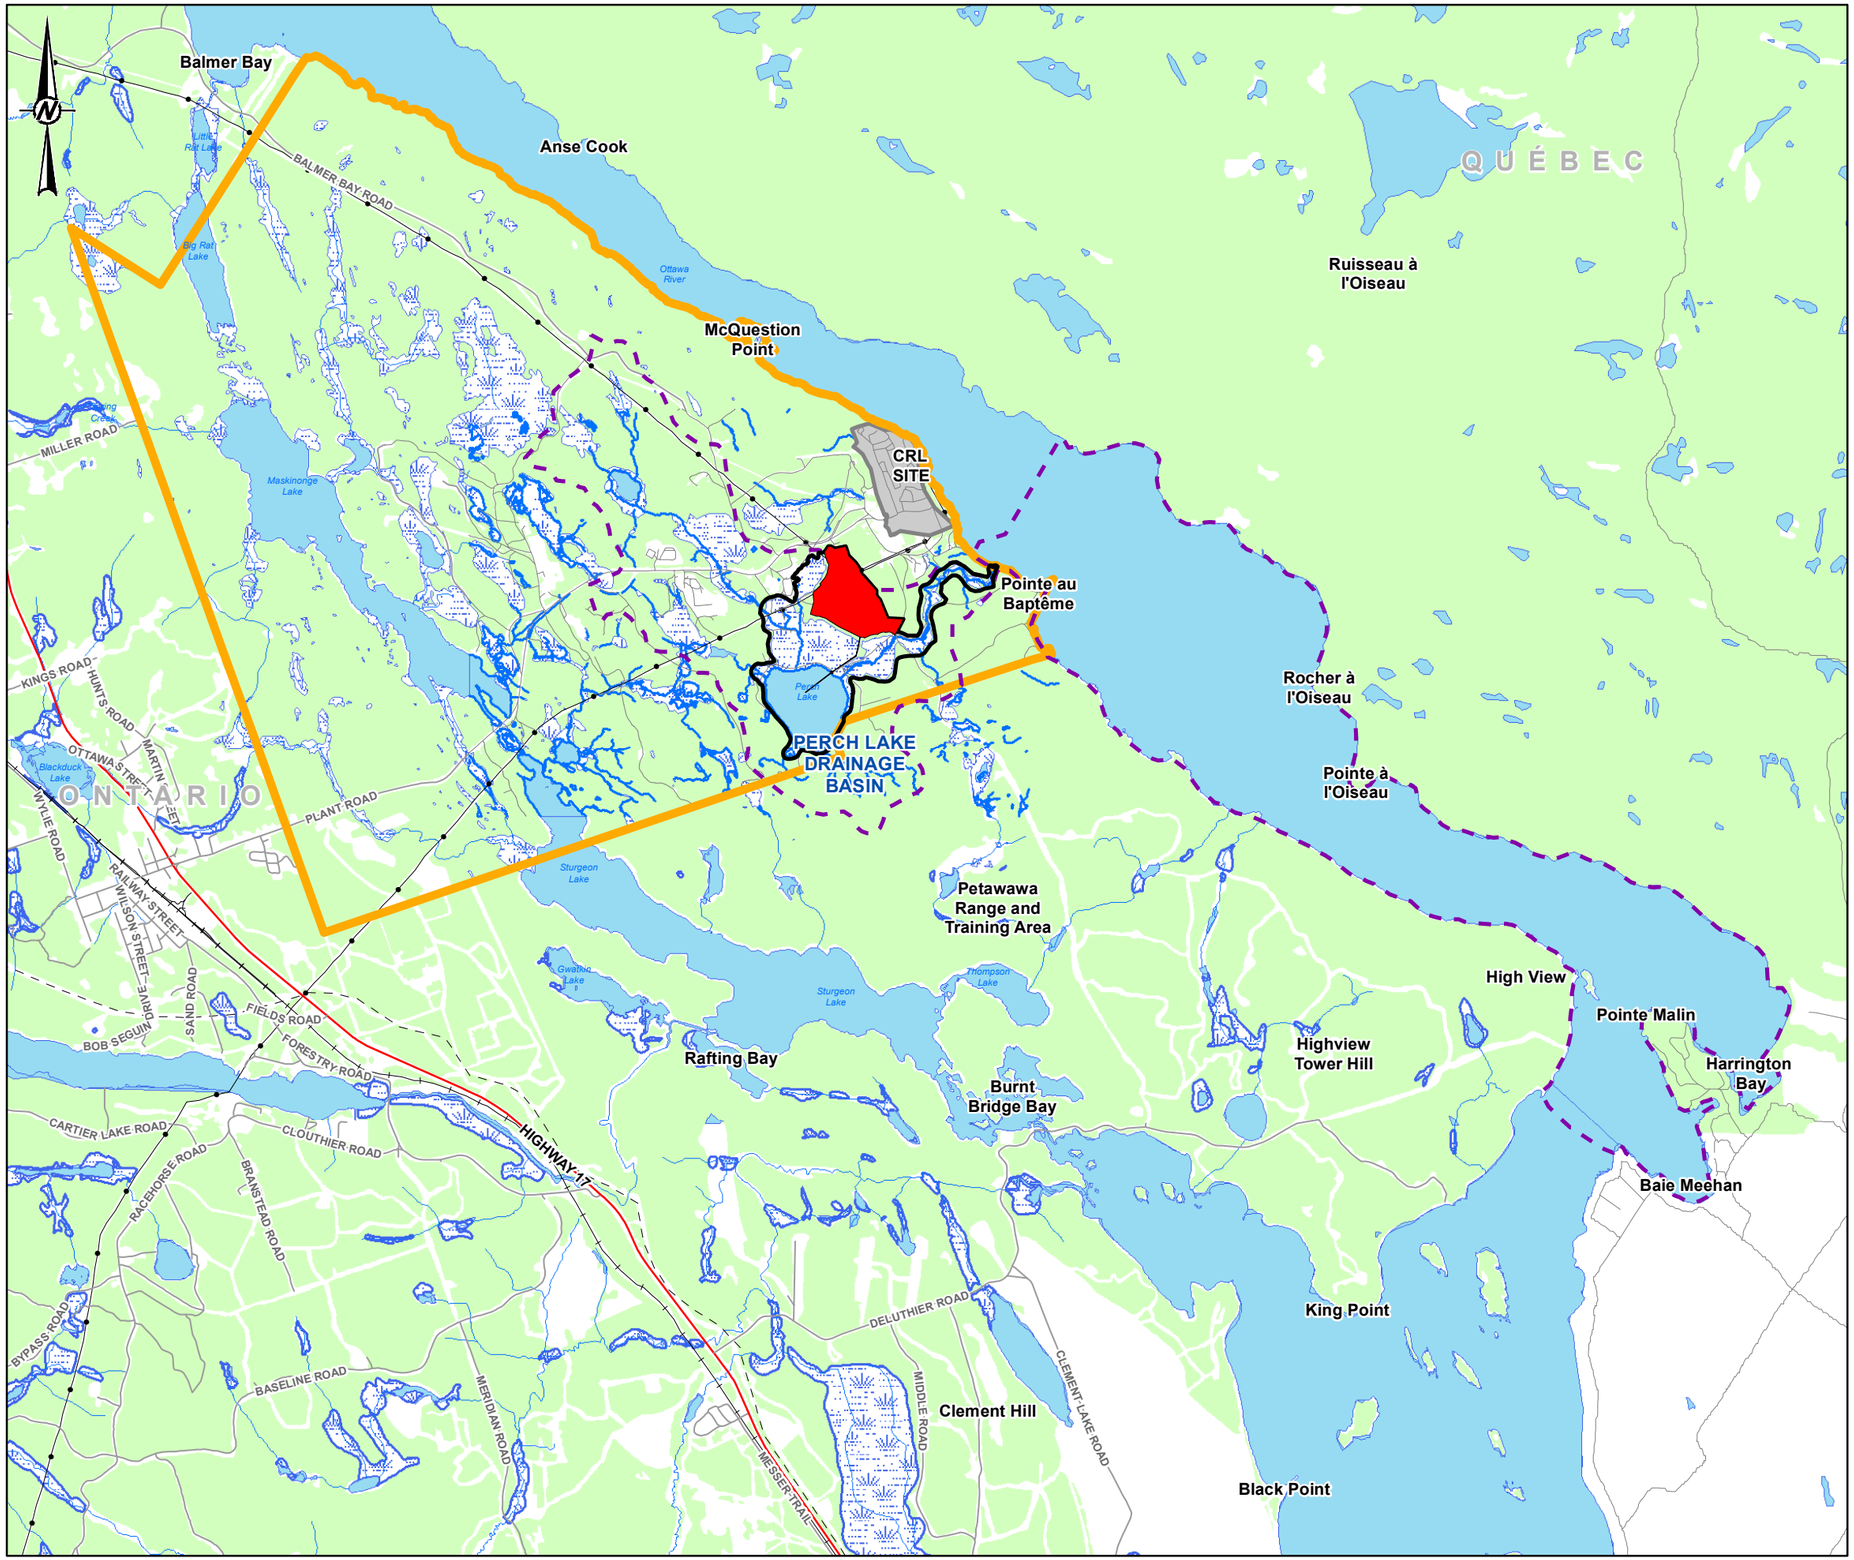
Table 5.3.1-1: Valued Components for Geology Assessment

Valued Component	Rationale for Selection
Geology	Characteristics of geology, such as soil quality and quantity, bedrock and geomorphology, are important components that interact with other VCs (e.g., hydrogeology, hydrology and surface water quality) and if changed by NSDF Project activities, these characteristics could affect terrestrial and aquatic biodiversity.

VC = valued component

Table 5.3.1-2: Measurement Indicators for the Geology Assessment

Valued Component	Measurement Indicators	Discipline Assessments where Effects on Geology are Considered
Geology	■ Bedrock ■ Soil quality, quantity and distribution ■ Geomorphology	■ Section 5.3.2 Hydrogeology ■ Section 5.4.2 Surface Water Quality ■ Section 5.5 Aquatic Environment ■ Section 5.6 Terrestrial Environment ■ Section 5.9 Land and Resource Use



5.3.1.3 Assessment Boundaries

5.3.1.3.1 Spatial Boundaries

The spatial boundaries selected for the geology assessment were chosen because they permit description of existing conditions in sufficient detail to enable potential project-VC interactions and effects to be identified, understood and assessed, including understanding and assessing the contribution of the NSDF Project to cumulative effects. The spatial boundaries selected for the geology assessment are the same as those identified for hydrogeology and are presented on Figure 5.3.1-1 and described below:

- **Site Study Area (SSA):** The SSA is the NSDF Project footprint (i.e., where NSDF Project activities would be undertaken, including the NSDF Project's proposed facilities, buildings and infrastructure).
- **Local Study Area (LSA):** The LSA is selected in consideration of the NSDF Project footprint and the spatial extent of potential direct effects of the NSDF Project on the VCs. The LSA includes the SSA and is bounded by Perch Lake and Perch Creek and adjacent wetlands to be consistent with the LSA of the aquatic disciplines (e.g., hydrology, surface water quality).
- **Regional Study Area (RSA):** The RSA is defined as the area within which the potential effects of the NSDF Project may interact with the effects of other existing or reasonably foreseeable developments. The RSA for geology is determined by the spatial extent of the Perch Creek and Perch Lake Watershed, and includes the Perch Lake and Perch Creek basins, as well as a portion of the Ottawa River (i.e., roughly 8 km downstream in the Ottawa River to Harrington Bay), to be consistent with the aquatic disciplines.

5.3.1.3.2 Temporal Boundaries

Temporal boundaries (i.e., project phases) establish the timeframe during which NSDF Project effects are assessed. The temporal boundary represents the timeframe during which project activities are actively occurring, and considers the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a project activity or stressor (which is related to the project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the NSDF Project or if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., a residual effect that lasts for thousands of years). The following phases were identified for the NSDF Project:

- **Construction phase**: This phase includes site preparation and all activities associated with the construction of the NSDF Project. This phase includes activities such as installing the necessary supporting and/or ancillary facilities and infrastructure to facilitate NSDF Project operations, inactive commissioning and systems testing, and transportation of construction materials. Construction activities are expected to take place from 2022 to 2024.
- **Operations phase**: This phase includes all activities associated with waste placement, water management, Wastewater Treatment Plant (WWTP) operations, vehicle movements into and from the SSA, and maintenance activities. Operations activities are expected to last approximately 50 years (i.e., 2025 to 2070).
- **Closure phase:** This phase includes activities necessary to complete the installation of the final cover and implementation of long-term monitoring. Closure activities are expected to start in 2070 and continue through to 2100, after which the NSDF Project will transfer into the post-closure phase.
- **Post-closure phase:** This phase has two discrete periods: institutional control and post-institutional control. The institutional control period includes implementation of controls throughout 2100 to 2400 (i.e., 300 years). During institutional control, environmental monitoring will continue to demonstrate compliance with the environmental assessment predictions. Post-institutional control occurs after year 2400 and continues indefinitely.

The temporal boundaries for the geology assessment consider all NSDF Project phases, from the construction phase through to the post-closure phase.

5.3.1.3.3 Assessment Cases

The assessment cases considered in the geology assessment are the Base Case and Application Case (the Reasonably Foreseeable Developments Case has not been considered for the reasons outlined below):

- **Base Case:** This scenario represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural, mining, and residential and recreational development. Current effects from the existing Chalk River Laboratories (CRL) facilities and operations are considered part of the Base Case.
- **Application Case:** This scenario represents predictions of the effects of the Base Case combined with the effects that may result from the NSDF Project. The Application Case considers potential effects from the NSDF Project from the construction phase through the post-closure phase.

- **Reasonably Foreseeable Developments (RFD) Case:** This scenario represents predictions of the cumulative effects of the Application Case, which includes the Base Case, plus projects that are currently under application review or that have officially entered a regulatory application process, and are therefore considered reasonably foreseeable. An RFD Case is not presented as part of this assessment because RFDs will either have no spatial overlap with NSDF Project effects or are likely to positively affect the geology. New support infrastructure, research and development facilities and the proposed small modular reactor (SMR) are planned within areas of the CRL site outside of the NSDF Project site and generally within existing disturbed areas. As such, potential effects from these activities are not expected to spatially overlap with potential effects to geology from the NSDF Project. The end-state plan for the CRL site will be to return lands disturbed by site activities to a condition that is physically stable and safe in keeping with the land use and landscape of the day. Therefore, decommissioning and environmental remediation activities are anticipated to positively affect measurement indicators for geology including soil quality and distribution, and geomorphology.

5.3.1.4 Description of the Environment

5.3.1.4.1 Methods

CNL completed previous studies in support of proposed geological waste management facilities (GWMFs) within the RSA in which data on the geological environment were compiled and used to develop a descriptive geosphere model of the site. These studies are documented in CNL's *Geologic Waste Management Facility Descriptive Geosphere Site Model Report: Phase 1* (CNL 2016a) and *Geologic Waste Management Facility Integrated Geosynthesis Report: Phase 1* (CNL 2016d). Data presented in these reports forms the basis of the current geological and hydrostratigraphic interpretations within the RSA, including characterization of the bedrock geology (lithology, mineralogy and structural geology), geomechanics, seismicity, overburden geology (soil characteristics and geotechnical properties), hydrogeology (hydraulic response testing of the overburden and shallow bedrock), and provides context on the anticipated evolution of the geological conditions at the CRL site over the assessment timeframe (10,000 years).

The geology of the SSA was characterized through a multidisciplinary site characterization consisting of intrusive and non-intrusive investigation completed under several phases, as summarized in the following reports:

- *Subsurface Geotechnical Survey of the Proposed Near Surface Disposal Facility at Chalk River Laboratories, Chalk River, Ontario* (Golder 2016)
- *Multidisciplinary Subsurface Investigation, Phase 1* (AMEC 2017a)
- *Multidisciplinary Subsurface Investigation, Phase 2* (AMEC 2017b)
- *Multidisciplinary Subsurface Investigation, Phase 3* (AMEC 2017c)
- *Multidisciplinary Subsurface Investigation, Phase 4* (AMEC 2018a)
- *Hydraulic Conductivity (Slug Test) Results for PH17-001 to PH17-010, Canadian Nuclear Laboratories, Chalk River, ON* (Wood 2018)
- *Wood Geotechnical Investigation (Ring Road for Effluent to Perch Lake)* (Wood 2019)
- *Proposed Initial (Baseline) Operational Control Monitoring for the Near Surface Disposal Facility (NSDF) Site* (CNL 2018a)

The multidisciplinary site characterization included the following intrusive components: 25 test pits to a maximum depth to 4 metres below ground surface (mbgs); 70 boreholes, drilled to a maximum depth of 30.3 mbgs; and 50 groundwater monitoring wells used to measure groundwater elevation and sample for groundwater quality. Eleven of the monitoring wells are located outside of the ECM footprint and were developed for operational control monitoring. Non-intrusive investigations included two rounds of ground penetrating radar surveys (Golder 2016; AMEC 2017c).

In consideration of the relatively shallow extents of the Near Surface Disposal Facility (NSDF) and its predicted impacts, site characterization focused on shallow depths to approximately 30 mbgs at the NSDF Project site. At this depth, the characteristics of overburden, upper bedrock and shallow groundwater have the most significant impact on the development of the design and numerical models of the Engineered Containment Mound (ECM).

Field and laboratory tests were conducted for the NSDF to characterize “intact rock” and “rock mass” properties relevant to develop the design and numerical models. “Intact rock” represents ‘small’ samples of unfractured rock tested in a laboratory setting, while the term “rock mass” represents large volume of rock tested in situ and takes into account the bulk properties of the rock mass, including discontinuities and fractures features. The scope of rock characterization for NSDF included:

- Determination of elastic modulus and rock strength;
- Petrographic analysis to determine the quantitative distribution of constituent minerals, and characteristics and physical features of the bulk rock and fractures;
- X-ray diffraction (XRD) analyses;
- Rock Quality Designation (RQD);
- Downhole seismic survey;
- Geophysics survey, including photographic and acoustic televiewer;
- Field testing of hydraulic conductivity or permeability; and
- Installation and development of wells to monitor groundwater level and quality (e.g., chemical characteristics).

Considering the focus of the GWMF was different (i.e., deeper, e.g., 500 to 1,200 mbgs) from the NSDF, the results (e.g., CNL 2016a, d) were considered as supplementary information for the NSDF Project.

The information contained in the reports cited above was supplemented for the SSA and LSA by stratigraphic boundary points (i.e., elevations of contact between geological surfaces), overburden (i.e., the soil or unconsolidated material that overlies the bedrock surface) thickness data and light detection and ranging (LiDAR) topographic data provided by CNL to develop isopach maps (i.e., a map illustrating the thickness variations for a geological unit) for the SSA. The stratigraphic boundary points were screened to remove duplicate points, and elevations were corrected using LiDAR data, where necessary. The data were then contoured using Golden Software’s Surfer package to generate isopach maps of the thickness of each stratigraphic unit. Where surfaces were found to spatially overlap, they were corrected by shifting the underlying layers downward, with ground surface topography and total overburden thickness maintained. These isopach maps are described in greater detail in Section 5.3.1.4.2.

Data collected within the SSA and LSA were also supplemented by baseline geology data collected from the review of selected geological literature (Catto et al. 1982, Chapman and Putman 1984, Raven Beck 1994, King and Killey 1994, CNL 2016a) along with geological mapping produced by the Ontario Geological Survey.

A desktop study was completed to identify the soils baseline conditions in the LSA. Information for the characterization of soils baseline conditions obtained from *The Canadian System of Soil Classification* (SCWG 1998), *The Ecosystems of Ontario, Part 1: Ecozones and Ecoregions* (Crins et al. 2009) and the *Soil Survey of Renfrew County* (Gillespie et al. 1964). Soil mapping involved the correlation of vegetation mapping to soil substrate units (i.e., the type of soil that underlies the vegetation (e.g., organic, disturbed, or coarse textured)). The primary soil characteristics used to group soil substrates into map units included parent material (i.e., the underlying geological material (e.g., bedrock) from which soils form) and terrain (slope and surface expression). Map units (soil polygons) were created after considering relationships between map resources, vegetation mapping and Google Earth satellite imagery.

5.3.1.4.2 Results

5.3.1.4.2.1 Regional Geological Conditions

Bedrock

The CRL site is located within the Central Gneiss belt of the Grenville Structural Province of the Canadian Shield. Structurally, the CRL site is located within the Ottawa-Bonnechere Graben, a rift valley which trends from northwest to southeast from Lake Nipissing to the St. Lawrence River, occupying a 60 km-wide by 700 km-long area. The Ottawa River occupies the eastern bounding fault of the rift valley, with the CRL site located on the western edge of the river. Secondary faulting (also oriented northwest to southeast) has a considerable effect on surface drainage and bedrock topography (CNL 2016a,b) in the vicinity of the SSA. Historical glaciations have generated a knobby bedrock surface (CNL 2016a,b), which outcrops in several locations in the region.

Bedrock in the area consists of highly altered gneissic rock (coarse grained metamorphic rock) and felsic igneous rock of late Precambrian-early Paleozoic age. Bedrock at the CRL site has been grouped into three main assemblages as shown on Figure 5.3.1-3. The bedrock within the Perch Lake basin and the SSA has been mapped as quartz monzonitic, monzonitic and monzodioritic gneisses of Assemblage B. Assemblage C (mainly composed of granitic, granodioritic and leucodioritic gneisses) has been mapped at the bedrock surface under the eastern portion of the SSA.

Two east-west trending post-orogenic Neoproterozoic diabase dykes are mapped at CRL site: the northern dyke mapped approximately 400 m north of the SSA, and the southern dyke identified in the LSA in close proximity to the western boundary of the SSA. These dykes are part of the Grenville dyke swarm that extends from the Georgian Bay-Lake Timiskaming region to at least north of Montreal. The dykes are proven at the CRL site by borehole intersections from CR-, FS- and CRG-series boreholes, strong magnetic geophysical signature and dispersed outcrop exposures and in floats/boulders (mainly near Maskinonge Lake). The northern and southern dykes dip steeply north (~70°), range in true width between about 15 and 40 m and appear to be relatively continuous across the property. They have lower permeabilities (*c.* 10^{-21} m^2 and 10^{-18} m^2 in borehole intersections in boreholes CRG-3 and CRG-6, respectively) as compared to the host rock mass and thus have potential to act as relatively impermeable flow barriers (aquitards). The decreased permeability is attributed to the ubiquitous distribution of fracture fillings in most fractures. This earlier observation is confirmed by tests done for the GWMF project and its predecessors. Transitions between these relatively low permeability rock types are not expected to be significant to this assessment.

Lineament studies for the CRL site and surrounding area were completed as a part of previous studies (Canadian Nuclear Fuel Waste Management Program [CNFWMP] from 1977 to 1983, Raven Beck 1994, and the Geological Waste Management Facility [GWMF] Project in 2015). The lineament studies performed by the CNFWMP (1977-1983) focused on the area around Maskinonge Lake, and due to its distance from NSDF SSA therefore not relevant for the NSDF. Based on analysis of air photo and linear geophysical anomalies, the lineament study by Raven Beck (1994) provided the basis for major fracture and fault zones interpretation, though this survey did not cover the NSDF SSA. Fracture and fault zones were categorized based on their level of confidence i.e., zones were ranked as “confirmed or very high probability”, “high probability”, “moderate probability” and “possible”). The “confirmed or very high probability” and “high probability” were adapted by the GWMF project and further site investigation was done to develop the conceptual 3D geological model for CRL site and surrounding area.

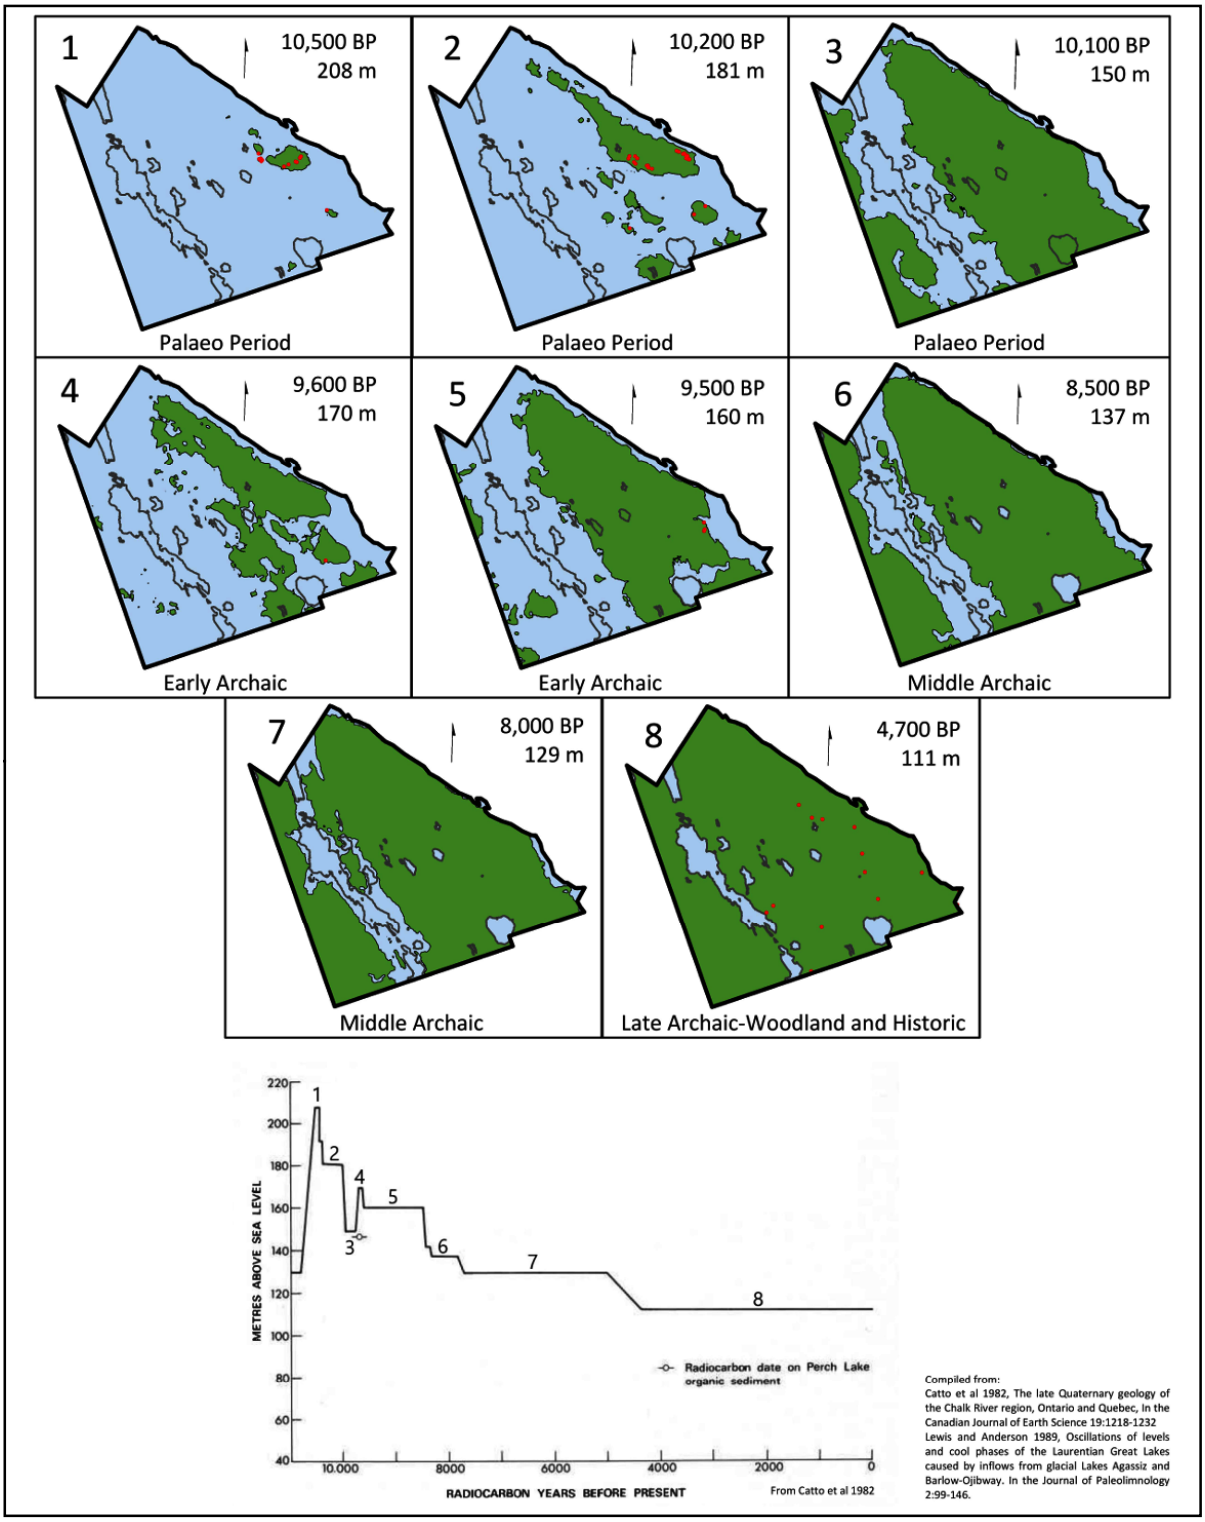
In conclusion, the lineament analyses performed by the GWMF project and its predecessors provides an indication for the general orientation and location of potential fracture zones as well as the confidence level associated to these geological features. However, they do not include detailed information regarding spatial location, attitude and characteristics to be applied for the NSDF footprint. Consequently, an alternative approach was adopted to take into account the fracture features for the NDSF as discussed below.

One feature identified in the previous work (i.e., Feature #17, a possible fracture zone) is located in the southern section of the NSDF SSA and on the edge of the southwestern boundary of the ECM. The degree of confidence corresponding to this feature was categorized as a “high-probability” fracture zone by the Siting Task Force (STF; Natural Resources Canada 1994), but later it was re-categorized as “possible” by the GWMF (CNL 2016d). The Feature # 17 was assigned an ESE-WNW (105/285°azimuth) trend, a length of 1,100 m and width of 10 m. A clearly defined structural control parallel to this feature was observed in the LiDAR image and in air photos. A dip direction of 70° towards the NE is assumed based on the field mapping data. This feature has potential to exhibit permeability values several orders of magnitude greater than bulk rock mass and is considered potential groundwater flow pathway. However, considering that the interpreted orientation is perpendicular to the direction of groundwater flow, this feature is considered to have limited potential as a preferential groundwater flowpath. The implications of potential fracture zones are further assessed through numerical groundwater flow modelling (as detailed in Section 5.3.2 of the EIS and Golder 2019b, 2020).

While there may be potential to accelerate groundwater transport through fracture zone, it is important to recognize that bedrock fractures have been indirectly incorporated in the model through the use of field measurements of bulk rock properties as input to the groundwater flow model. Additional scenarios have been developed that take into account the hypothetical existence of bedrock fracture zones within the NSDF SSA (Golder 2020). The results show that the presence of the geological features have negligible effect on the groundwater travel times between the ECM and downgradient receptors (i.e., Perch Creek) for post closure scenarios where the liner and/or cover of the ECM were compromised. This is reflective of the fact that the primary groundwater flow pathway is situated in the overburden.

Overburden

The regional topography of the CRL site is shown on Figure 5.3.1-4 and regional surficial geology of the CRL site is shown on Figure 5.3.1-5 (from King and Killey 1994). A widespread but thin deposit of glacial till overlies the bedrock in most areas where overburden is present (Catto et al. 1982). The more recent post-glacial sediments (above the till) formed following the last glacial retreat, which began approximately 11,000 years before present in the area east of Mattawa (Barry 1975). The Ancestral Ottawa River inundated the CRL property until about 10,500 BP, in the Late Palaeo-Indian cultural period, when the highest elevations above 195 m and 180 masl emerged successively as islands in the Ancestral Ottawa River. The Geological Survey of Canada (Catto et al.



1982; Lewis and Andersen 1989) postulate an Early Holocene water plane that fell in sequentially lower episodes until modern continental drainage patterns developed in the mid-Holocene about 4,700 BP (see Figure 5.3.1-2). River terraces formed as the Ancestral Ottawa River retreated, and the Ottawa River down-cut and eroded the local surficial deposits. This occurred between approximately 9,900 and 7,000 years before present (Barry 1975). The early post-glacial Ottawa River covered most of the CRL site and deposited fluvial sands and silts throughout the region. These fluvial deposits filled the depressions in the bedrock and glacial till surfaces. A brief period of Aeolian reworking (i.e., shaped by wind) of the fluvial sands into dune and sheet deposits occurred as the Ottawa River dropped to its current level and location.

Recent sediment accumulation has been in the form of organic deposits in the low-lying and wetland areas of the region. The thickness of the unconsolidated sediments is variable as a result of the variable bedrock topography and the historical location of the Ottawa River. In general, the sediments are thickest towards the centre of the rift valley and thinnest to the west and east towards the bounding faults. Within the Perch Lake Basin, which came into existence during the early erosional phases of the Ottawa River (approximately 9,900 years before present), the sedimentation rate has been estimated to be 16.5 years per centimetre (Barry 1975). As shown on Figure 5.3.1-5, surficial geology within the low-lying areas of the Perch Lake Basin is predominately composed of recent organic soils. Sand and glacial till are present at surface near topographic highs, such as the SSA.

5.3.1.4.2.2 Future Evolution of Geological Environment

Previous studies completed by CNL in support of proposed geological waste management facilities at the CRL site include discussion on the long-term future evolution of geological conditions (CNL 2016a). Although the focus of these studies is on factors that influence the deep geological setting (as compared to the shallow geological setting of the NSDF) over timeframes on the order of 100,000 years (as compared to the shorter NSDF assessment timeframe of 10,000 years), the presented information is relevant to the current assessment. The natural processes identified as having potential to influence the geological conditions at the CRL site include glaciation (glacial erosion and deposition of surficial material, glacial loading, permafrost formation, changes in sea level, changes in topography, isostatic adjustment, post-glacial effects such as flooding); tectonism (fault rupture or reactivation); and volcanism. A summary of the findings for each of these factors is provided as follows:

- Long-term future climate predictions indicate that the next major glaciation will occur at least 60,000 years after the present time. Therefore, the effects of glacial erosion permafrost and associated changes to the groundwater flow system are expected to be minimal over the NSDF assessment timeframe (10,000 years).
- The potential for fault reactivation in the vicinity of the NSDF Project exists, but the effects are expected to be minimal on the existing fault system. Evidence from bedrock fractures that have been subjected to historical tectonic stresses and glacial loading and unloading indicates that the rock is inherently stable. No evidence of post-glacial structural disruption has been found. A detailed seismic analysis of the site was completed as a part of the design package (AECOM 2019), which discusses the potential for future seismic events in greater detail.
- Volcanic activity and orogenic (i.e., upward displacement of the earth’s crust) events are not considered to be factors that could potentially influence the geological setting over the assessment timeframe.

In consideration of the above findings, the primary factors influencing the future geological evolution in the vicinity of the CRL site over the 10,000-year assessment timeframe are erosion and deposition of the overburden and weathering of the shallow bedrock. The future climate will be the primary natural control on these factors. *Climate Change Assessment for the Near Surface Disposal Facility Project* (Golder 2019a) provides an assessment of long-term future climate for the CRL site, and concludes that the climate will be warmer (by up to 8°C) and wetter (by up to 20%) in the early portion (the first 1,000 years) of the assessment timeframe. Because of the uncertainty associated with estimating future climate in the long-term, the predictions are limited to this early portion of the assessment timeframe.

Given the uncertainty associated with future climate predictions, one approach to evaluating future geological changes to the CRL site is to qualitatively extrapolate future conditions based on historical geological evolution. This assumes processes that have in the past (and at present) influenced the geological conditions will continue to do so in the future. The recent geological evolution has been primarily controlled through glacial activity; the last major deposition of sediment in Perch Lake basin occurred during the draining of Glacial Lake Agassiz via the early post-glacial Ottawa River, which ceased approximately 9,800 years before present (Teller 1988). Since that time the geological setting in the Perch Lake Basin has been stable, as indicated by the development of organic deposits in Perch Lake (Boyko-Diakonow and Terasmae 1975). Because glacial activity has been the primary factor influencing the near-surface geological evolution at the site, and glacial activity is not expected to occur within the assessment timeframe (CNL 2016a), it is inferred that the geological conditions will be relatively stable over the assessment timeframe.

5.3.1.4.2.3 Seismicity

Major seismic events (i.e., earthquakes) are related to movements at tectonic plate boundaries. The CRL property is located in the Ottawa-Bonnechere Graben geologic feature and adjacent to the Western Quebec Seismic Zone. This region of the country has continued to experience minor to moderate seismic activity, and several earthquakes have been documented within this zone. These include the following:

- Timiskaming, Quebec, earthquake of 1935 (6.2 on the Richter Scale and epicentre over 100 km away);
- Cornwall, Ontario, earthquake of 1944 (5.6 on the Richter Scale and epicentre over 200 km away); and
- Val-des-Bois, Quebec, earthquake of 2010 (5.0 on the Richter Scale and epicentre over 137 km away).

Most recently, an earthquake with a magnitude of 3.7 on the Richter Scale occurred on October 15, 2015, approximately 40 km from the SSA, and an earthquake with a magnitude of 3.5 occurred on May 14, 2016, approximately 10 km from the SSA, 6 km north of Petawawa, Ontario.

A site-specific *Probabilistic Seismic Hazard Analysis* (AECOM 2018a) was completed for the SSA to determine design ground motions for the NSDF. The analysis included a review of potential seismic sources in the surrounding region and it utilized the latest generation seismic hazard model for southeastern Canada developed by the Geological Survey of Canada, in agreement with the method used in the latest *National Building Code of Canada* (NRCC 2015). As noted above, the SSA is located within a region (within 500 km) that has historically experienced low- to moderate-magnitude historical seismicity. However, few recent (i.e., Quaternary) faults have been mapped within this region. This is in agreement with the findings of a recent paleoseismicity investigation completed at the CRL site (CNL 2015a). This investigation involved excavation of trenches through the overburden and a review of the trench faces for evidence of soil displacement related to seismic activity. Although displacement of the overburden was found in some locations, none of the displacements were attributed to seismic activity.

There are seismic monitoring stations located at CRL site which are operated by Natural Resources Canada (NRCan), as well as three microseismic monitoring stations operated by CNL (CNL 2015d). These monitoring stations have the capability to monitor lower magnitude of seismic events. The primary objective of the microseismic monitoring system (MMS) has been to provide an analysis of the natural seismic activity of the area associated with tectonic faulting and to detect any specific active geological structures. The current seismic array consists of three surface seismic stations monitoring an area of approximately 7 km x 7 km to the west of the CRL facilities.

5.3.1.4.2.4 Local and Site Study Area Geological Conditions

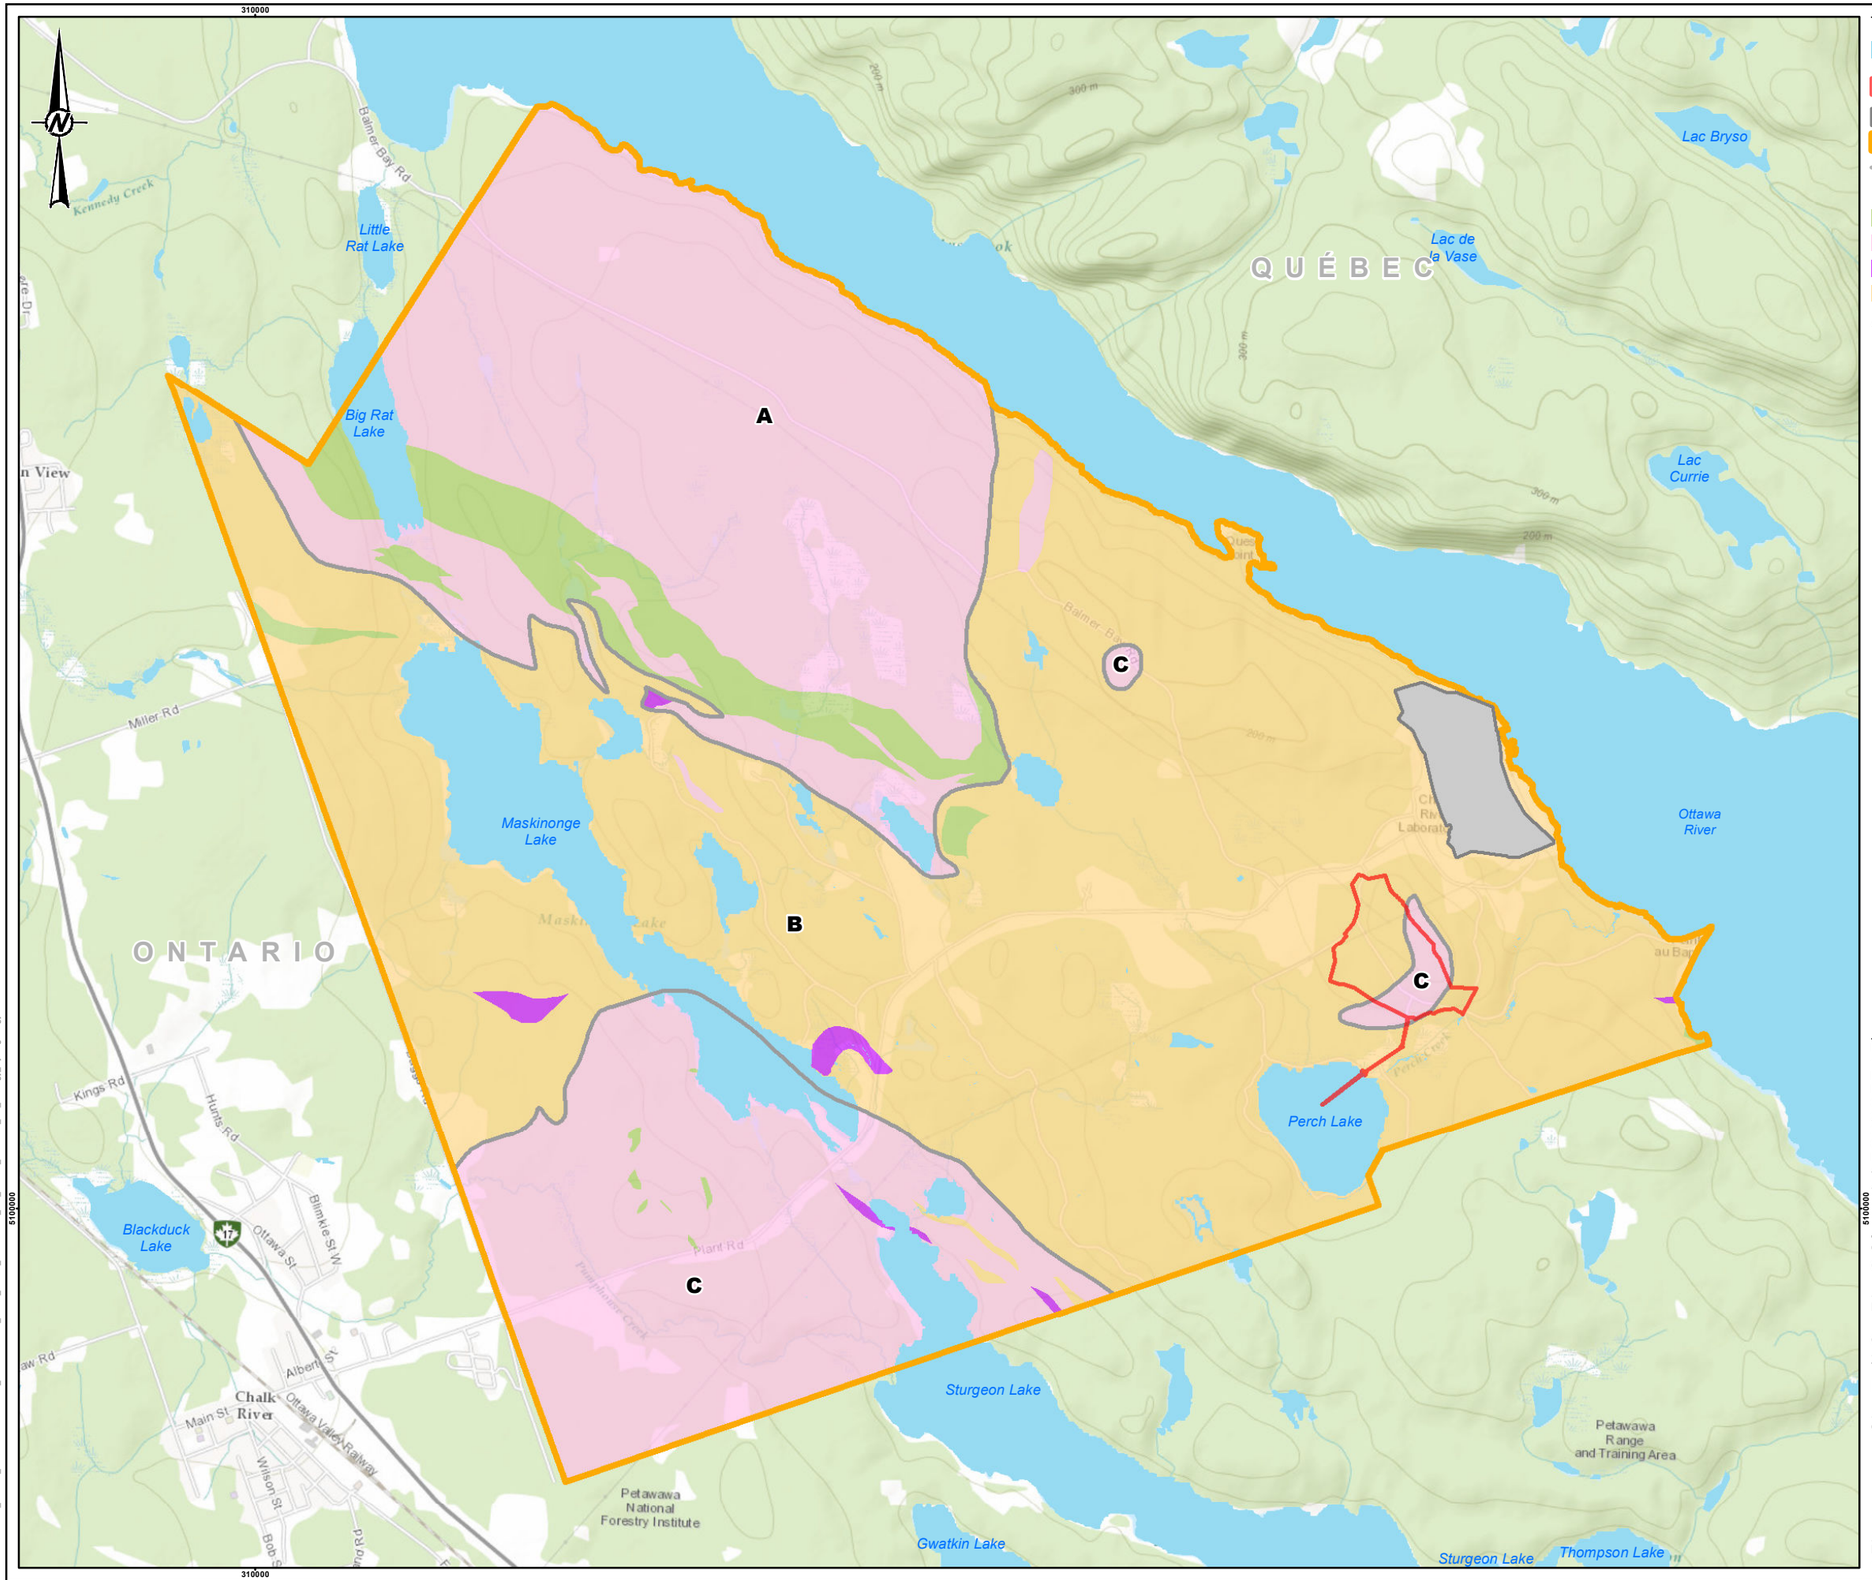
The local geological conditions in the subsections below describe the lower portion of the Perch Lake Basin and the SSA on the basis of previous investigations of the waste management areas and recent investigations within the SSA.

Topography

Ground surface elevations range from a low of approximately 156 metres above sea level (masl) within the low-lying and relatively flat terrain bordering the north side of Perch Lake to a high of 197 masl along the crest of the ridge to the east of East Mattawa Road that separates the Perch Lake and Ottawa River drainage basins. Topography and local drainage features are shown on Figure 5.3.1-6. The SSA is located in the central portion of the lower Perch Lake Basin. Topographic evidence suggests that a former branch of the Ottawa River followed a chain of lakes, the largest of which is Maskinonge Lake, that bisect the western part of the CRL site boundary.

Bedrock Topography and Geology

A bedrock topography map was generated for the SSA using stratigraphic data (Figure 5.3.1-7). The bedrock topography is dominated by the ridge that delineates the eastern boundary of the Perch Lake Basin and the depression or valley that runs from the northwest corner of Waste Management Area A, to the southeast towards Perch Creek. The bedrock ridge reaches an elevation of approximately 192 masl and dips to the northwest and southeast, to an elevation of 165 masl at Plant Road and 155 masl at Perch Creek. The bedrock valley is composed of a western portion that slopes irregularly from north to south and a southern portion that slopes irregularly from east to west. These two portions meet just north of where the Main Stream discharges to Perch Lake. Bedrock in that area is at an elevation of 120 masl. The northwestern portion of the SSA is underlain by a spur from the bedrock valley, at an elevation of 151 masl. The ridge that delineates the western boundary of the Perch Lake Basin is shown reaching an elevation of 175 masl at the limit of the map on Figure 5.3.1-7.



Bedrock within the Perch Lake Basin and surroundings is primarily composed of quartz monzonitic, monzonitic and monzodioritic gneisses with some occurrence of granitic-granodioritic and leucodioritic gneisses (CNL 2016a). As previously mentioned in Section 5.3.1.4.2.1 the east-west trending post-orogenic Neoproterozoic southern diabase dyke was identified in the LSA in close proximity to the western boundary of the SSA.

Two main fracture or faulting zones are present at the CRL site: the Mattawa Fault, which lies below the Ottawa River and consists of the northeast boundary of the property, and the Maskinonge Lake lineament in the southwest area of the property. As noted in Section 5.3.1.4.2.1, a possible fracture zone trending westnorthwest-eastsoutheast through the upper portion of Perch Lake Basin (Raven Beck 1994, CNL 2016a). This feature (Feature # 17), categorized as “possible” in the 3D sub-regional scale geological model, is a suspected structural feature. The absence of direct evidence prevents correlating this lineament with a proven discontinuity in the rock mass. The NSDF site specific borehole data provided by AMEC (2017a,b) do not show the presence of any major fracture zone. Further, the interpreted orientation of Feature #17 is perpendicular to the direction

of groundwater flow, and is limited in spatial extent within the SSA, thus limiting its potential as a preferential groundwater flow pathway.

Investigations by AMEC (2017a,b) included the advancement of 32 boreholes to depths of up to 13.2 m below bedrock surface. Borehole logs included in AMEC (2017a,b) indicate that the upper several metres of bedrock generally consist of a pink gneiss, with the exception of boreholes W7, W8, BH2-1, BH2-6 and GH1-4, in which diorite was logged. This transition in rock types in the eastern portion of the SSA appears to be consistent with the mapping shown on Figure 5.3.1-3, with the exception of the presence of gabbro in borehole BH2-1 in the northwest corner of the SSA.

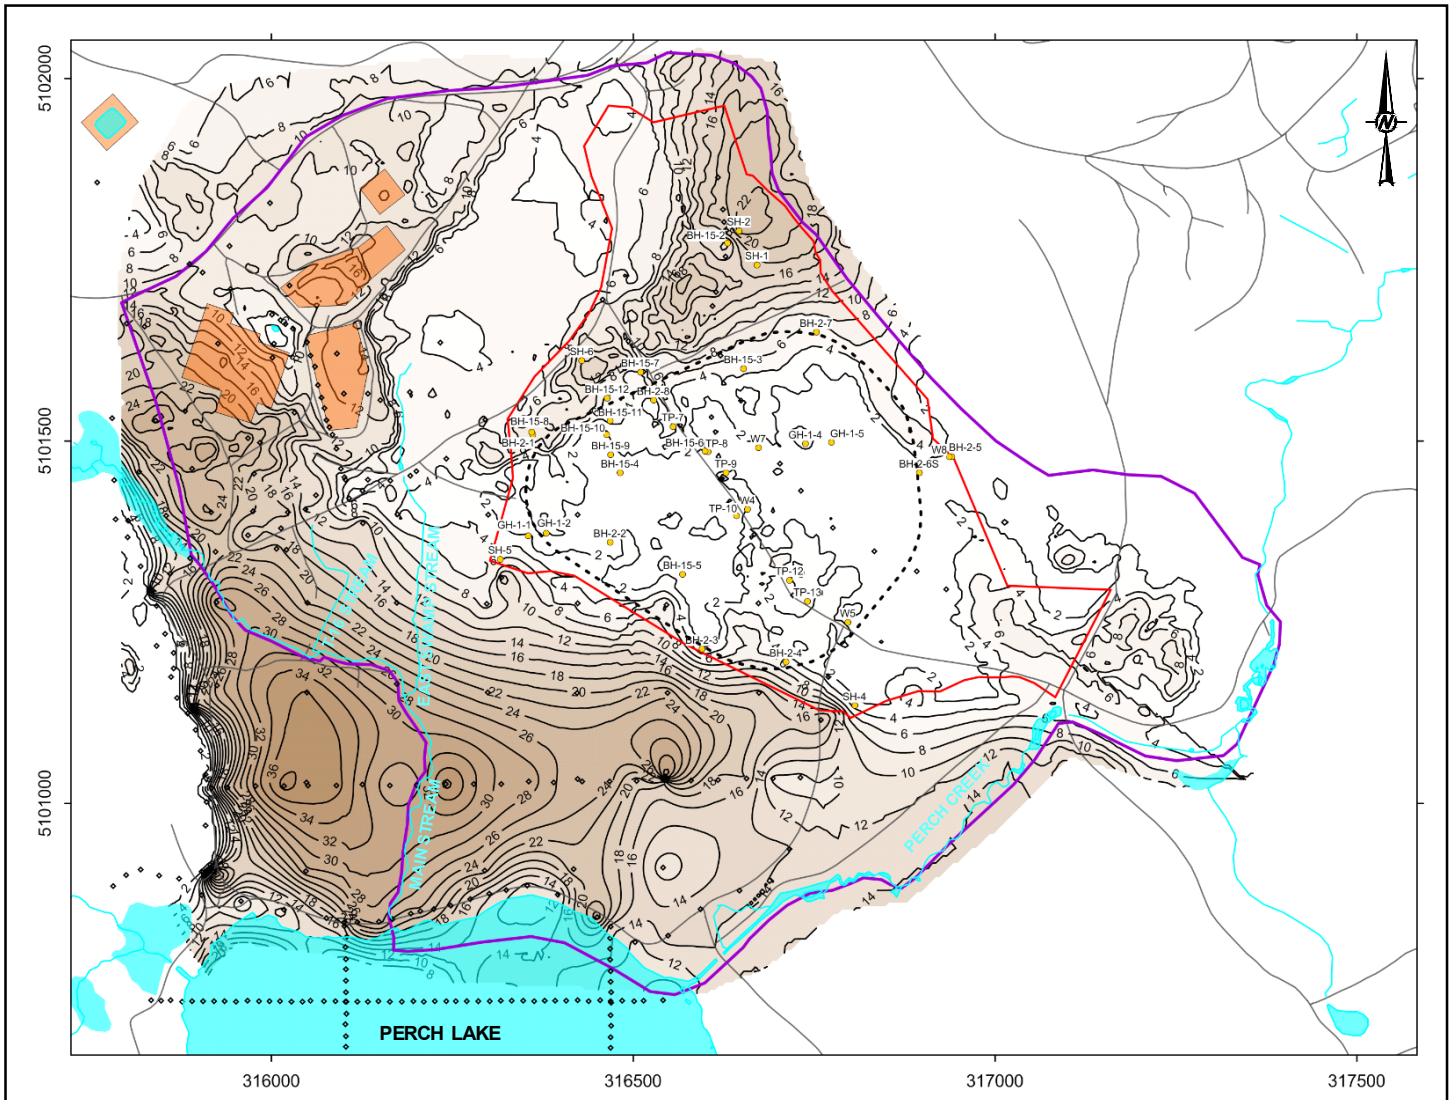
Overburden Geology

The overburden geology at the SSA consists primarily of fine sands, underlain locally by glacial till. The sands are interpreted to be the result of Aeolian reworking of precursor fluvial sands and silts laid down in the late Pleistocene/early Holocene period by an early phase of the Ottawa River. Unconsolidated glacial and post-glacial deposits in the Perch Lake Basin (which includes the LSA and SSA) have been subdivided into six main units:



- glacial till;
- basal sand and gravel;
- clayey silt;
- middle sand;
- interstratified silt and sand; and
- upper sand.

More recent organic deposits are also present in the Perch Lake Basin, but are not considered substantial hydrostratigraphic units (i.e., geological formations with similar hydrological characteristics regarding groundwater flow). The total thickness of the unconsolidated deposits is shown by an isopach map on Figure 5.3.1-8. The thickness of the unconsolidated sediments is generally lowest on the eastern bedrock ridge (in the vicinity of the SSA). The thickness of these sediments increases to the west and is highest in the bedrock valley, reaching more than 36 m in the bedrock low. Within the area of the SSA, unconsolidated deposits are locally thicker in the area to the north and east, reaching more than 26 m thick at the northern terminus of the bedrock ridge (Figure 5.3.1-8). Elsewhere on the CRL site, overburden thickness ranges from 0 m (i.e., no overburden) to more than 25 m, being thickest in topographic lows (Raven Beck 1994). The sedimentary geology in the Perch Lake Basin is illustrated in cross-section on Figure 5.3.1-9. Logging of the overburden at the 2016 and 2017 boreholes was not sufficient to delineate the geological units listed above. Therefore, interpolation of the overburden surfaces in the area of the ECM was based on the assumption that the thickness of the Glacial Till was at least 1 m, with the remaining overburden thickness comprised of upper sand.

Glacial Till

The thickness of the glacial till unit within the SSA is shown by an isopach on Figure 5.3.1-10. Glacial till covers a large portion of the bedrock surface and is thickest in the areas of the bedrock lows. Glacial till thins to the east towards the bedrock ridge. Where present, glacial till is generally less than 12 m thick but reaches thicknesses of up to 15 m within the bedrock valley and 24 m in the area to the north of the eastern bedrock ridge. Glacial till is locally thicker along a line that extends from the northern edge of the eastern bedrock ridge to the south of the East Swamp, ending approximately 250 m northeast of where the East Stream meets the Main Stream. In this area, the glacial till ranges from 3 to 8 m in thickness. Within the southern portion of the SSA (where bedrock is close to ground surface) the till is generally less than 1 m thick.

Glacial till within the Perch Lake Basin consists of poorly sorted boulders, cobbles and gravel in a silty sand to sandy silt matrix (Golder 2016), with no visible stratification (CNL 2016b). Grain size analyses indicate a low silt content (less than 10%) and a negligible clay content (CNL 2016b).

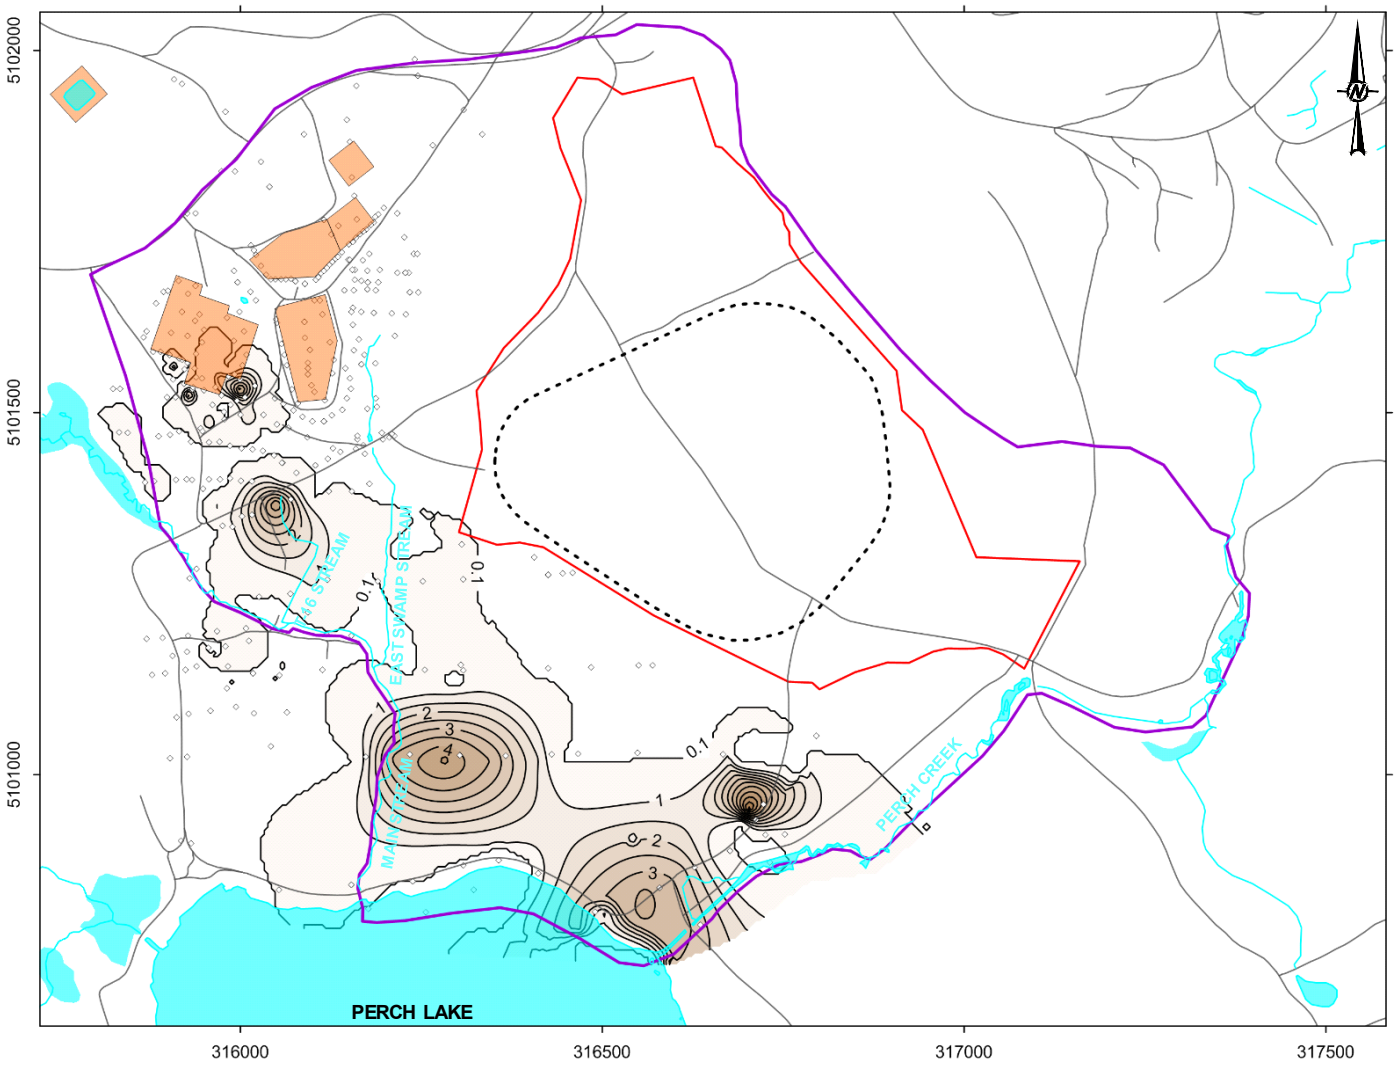
Basal Sand and Gravel

A basal sand and gravel unit overlies the glacial till in a limited area of the western portion of the Perch Lake Basin. The areal extent and thickness of this unit is shown by an isopach map on Figure 5.3.1-11. This unit ranges from 3.5 to 5.5 m in thickness within the bedrock valley to the north of Perch Lake and Perch Creek. The unit has also been found to underlie Waste Management Area A and the South Swamp, in thicknesses ranging from 1 to 4 m. This unit is not present in the SSA.

Clayey Silt



The thickness and areal extent of the clayey silt unit is shown as an isopach map on Figure 5.3.1-12. The clayey silt is generally present in the southwest portion of the Perch Lake Basin, where there are depressions in the surfaces of the till and the bedrock. Where present, the clayey silt is generally less than 2 m thick, but is more than 5 m thick in the bedrock depression approximately 200 m north of Perch Lake. North of the SSA, the clayey silt unit ranges in thickness from 0.5 to 1.5 m, being thickest to the east along East Mattawa Road. Clayey silt in the Perch Lake Basin is fluvial in origin and consists of laminations of coarser and finer fractions. The clay content of this unit, as determined through grain size analysis, is less than 20% by weight (CNL 2016b).

Middle Sand

The extent and thickness of the middle sand unit is shown by an isopach map on Figure 5.3.1-13. As with the other sedimentary units, the middle sand is thickest in the areas of the bedrock depressions. This unit generally fills the bedrock valley and ranges in thickness from 2 m to 9 m in this area. Middle sand is also present in the southern portion of Reactor Pit 2 (up to 4 m in thickness) and on the northern and southern flanks of the eastern bedrock ridge that delineates the Perch Lake Basin (up to 3 m in thickness in the south and 2 m thickness in the north). The middle sand has been classified as moderately well sorted fine sand through the results of grain size analyses.

Interstratified Silt and Sand

The extent and thickness of the interstratified sand and silt unit is shown by an isopach map on Figure 5.3.1-14. Where present, this unit is generally less than 0.4 m thick but can reach thicknesses of up to 2 m locally (i.e., near the point of discharge from Perch Lake to Perch Creek and to the south and west of Waste Management Area A). This unit has been encountered in the northern portion of the SSA at thicknesses of less than 0.4 m. The interstratified silt and sand consist of alternating layers of fine to very fine sand and sandy silts. Individual layers are on the order of several centimetres (CNL 2016b).

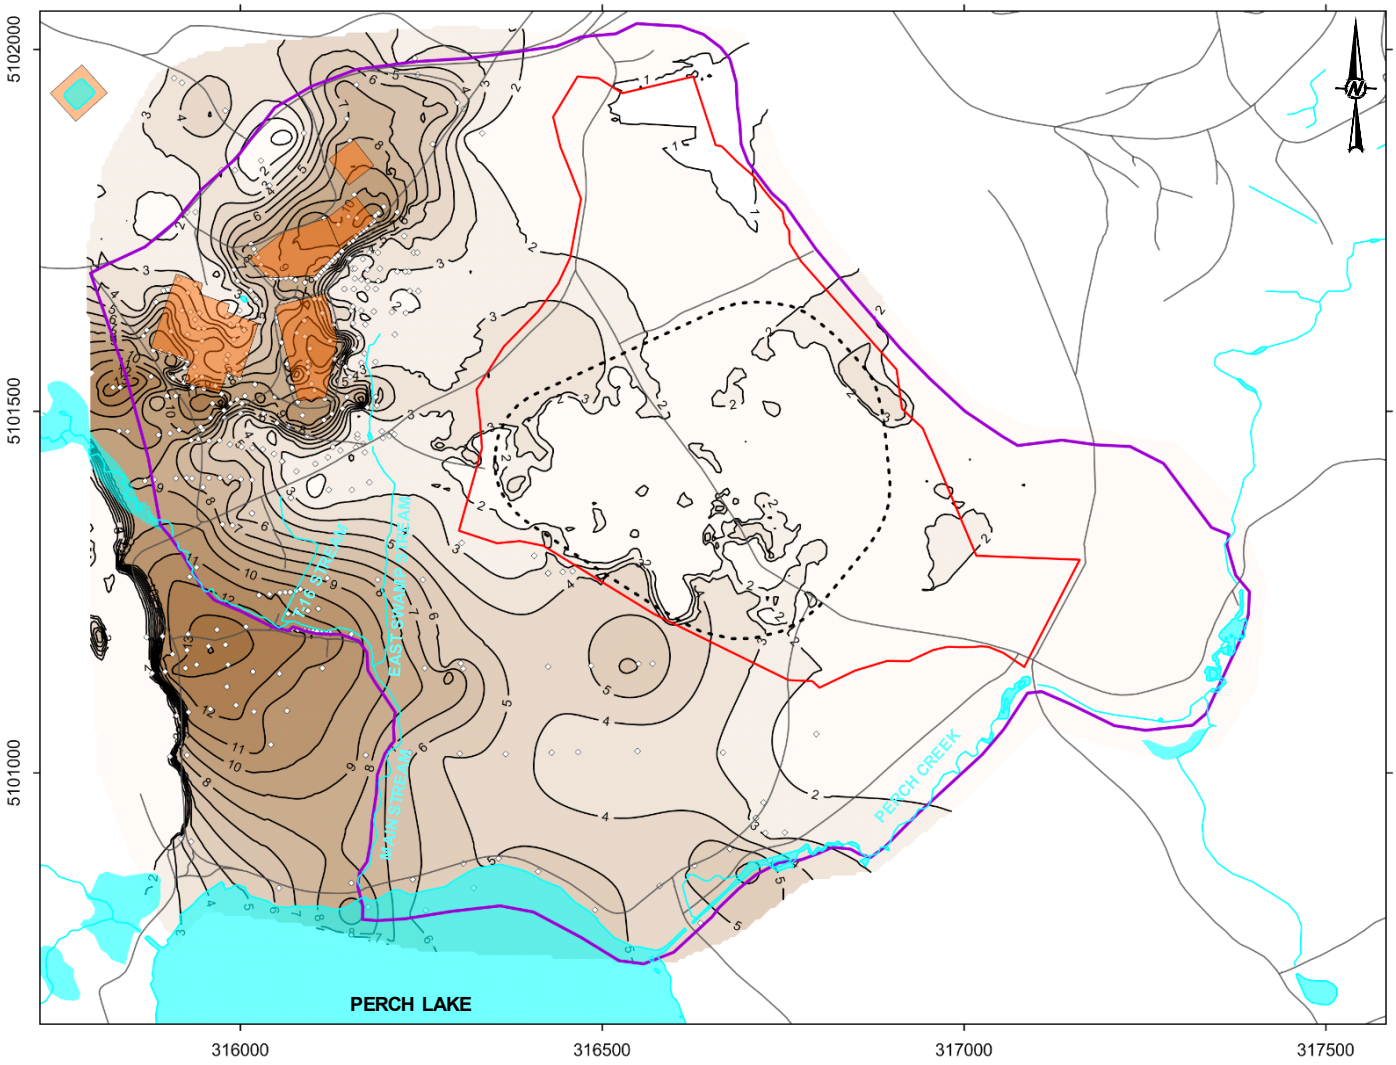
Upper Sand

The upper sand unit is the uppermost sand unit in the Perch Lake Basin. The base of the upper sand unit is defined by either the top of the interstratified silt and sand unit, or by an inferred contact with the middle sand. The thickness of the upper sand unit is shown as an isopach map on Figure 5.3.1-15. The unit is thickest where the bedrock valley abuts the bedrock ridge that delineates the western boundary of the Perch Lake Basin. In this area, the unit can be up to 13 m thick. The upper sand unit is also locally thicker through an area extending from Plant Road, south through Reactor Pit 1 and Reactor Pit 2, then extending west through the southern portion of Waste Management Area A. In this area, the unit reaches thicknesses of up to 10 m. The upper sand unit is present in the SSA at a relatively uniform thickness of approximately 1 m. There is a localized area to the immediate southwest of the SSA where the upper sand thickness increases to approximately 5 m. In comparison to the middle sand, the upper sand is slightly coarser and better sorted (CNL 2016b).

Surficial Soils

The LSA is located in the Brent Ecodistrict in the Georgian Bay Ecoregion of the Ontario Shield Ecozone. Ecodistricts are subdivisions of the region that are based on patterns of relief, geology, geomorphology and substrate parent material (Crins et. al. 2009). A layer of leaf litter and organic silt (topsoil), 50 to 230 mm thick was encountered at the ground surface (Golder 2016). This material was generally a mixture of organic and mineral soil components. No purely organic soils were encountered during the 2016 geotechnical investigations (Golder 2016).



Soil substrates generally consist of well-drained sandy soils in the LSA. The coarse-grained parent materials have been derived from acidic gneissic and granitic rocks of the Precambrian shield and, as such, have aided in the development of Humo-ferric podzolic soils and to a lesser extent Melanic Brunisols (Gillespie et al. 1964). Organic peats and gleysols are found in poorly drained sites and depressions (Crins et al. 2009). The dominant soil substrates in the LSA are a thin layer of organic/gleysolic soils overlying well-drained sandy soils (Table 5.3.1-3 and Figure 5.3.1-16).

Table 5.3.1-3: Dominant Soil Orders in the Local Study Area

Dominant Soil Substrate	Area (ha)	Proportion (%)
Coarse Grained	54	31
Organic/Gleysolic	61	34
Water	41	23
Previously Disturbed	21	12
Total	**177**	**100**

This page left intentionally blank

Drainage ranges from well-drained, coarse-textured soils to poorly and very poorly drained organic soils in lower slope positions. Coarse-textured soils, with higher initial total porosity, are relatively resistant to compaction compared to finer textured soils found in other geographies (Carr et al. 1991); these soils are, however, prone to wind erosion. Sandy textured soils typically do not have a well-developed soil structure. The lack of soil structure is due to limited soil aggregation or adhesion of the soil particles and, therefore, does not form larger and more stable soil aggregates. Aggregated soil particles are less likely to be moved by wind. Soil erosion risk is a concern for disturbed soils because the sparse vegetation cover exposes soil materials to the elements (e.g., wind and water).

The NSDF Project site is an area of largely undeveloped land within the CRL site. Soil samples have been collected at 36 locations within the SSA and analyzed for radioactivity and metals. The soil analysis results concluded that the SSA does not contain radionuclide concentrations above local background levels (CNL 2017a). The analytical results for metals in surface soils at the SSA are below the provincial background values (Table 1, Residential / Parkland / Institutional / Commercial / Community Land Use [MECP 2019]) and are comparable to CRL site wide background values for soils (CNL 2018b).

Radiological contamination in the East Swamp wetland may be relevant to the NSDF Project, as this area is immediately west of the SSA. The East Swamp wetland has existing contamination associated with a shallow subsurface plume from the Chemical Pit, and a second plume from Reactor Pit 2. The surface contamination distribution in the East Swamp has been characterized with radiation field surveys, surface surveys and vegetation contamination surveys performed in 2002, 2007 and 2012. In 2002 and 2012, these surveys included wetland soil and vegetation sampling to determine the radionuclide concentrations in these media. These results are discussed in Section 5.7.4.7 Radioactivity in Soils.

5.3.1.5 Project Interactions and Mitigation

5.3.1.5.1 Methods

This section describes the process by which interactions between NSDF Project components and activities and geology were identified and evaluated. Potential effects pathways are identified, and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment, as required. As such, the “Project Interactions and Mitigation” section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all phases of the NSDF Project. The next step in the analysis was the development of environmental design features and mitigation that could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects to geology. Environmental design features included NSDF Project design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the Project’s engineering and environmental teams, combined with input from Project-specific or regional engagement with other interested parties. The environmental design features and/or mitigation were selected

considering their effectiveness for implementation and maintenance and their appropriateness within the context of the identified effects pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation:

- **No linkage:** The pathway is removed by environmental design features or mitigation such that the NSDF Project would not be expected to result in a measurable environmental change relative to Base Case values and therefore would have no residual effects on geology.
- **Secondary pathway:** The pathway could result in a measurable minor environmental change, but would have a negligible residual effect on geology relative to Base Case and/or guideline values and is not expected to contribute cumulatively to other Project effects or to the effects of other previous, existing or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway:** The pathway is likely to result in an environmental change relative to the Base Case and/or guideline values that could contribute to residual effects on geology.

Environmental design features and mitigation that have been or could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to geology through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways were carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the NSDF Project.

5.3.1.5.2 Results

Pathways through which all stages of the NSDF Project may interact with and result in changes to measurement indicators for geology are provided in Table 5.3.1-4.

Table 5.3.1-4: Pathways Analysis for Geology Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation	Pathway Assessment
■ Project activities during the construction phase: ▪ Site preparation ▪ Construction of the ECM ▪ Blasting (as required) ▪ Development of surface water management structures ▪ Construction of the WWTP and other support facilities ▪ On-site road and access development	■ Construction activities can alter soil quantity, quality and distribution. ■ Construction activities can alter geomorphology. ■ Construction activities (i.e., blasting) can locally alter physical properties of the bedrock	■ The SSA has been designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. ■ Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site (i.e., CNL's procedure for *Management of Land, Habitat and Wildlife* [CNL 2018c]) will be used during construction around disturbed areas, where appropriate. ■ Blasting activities will follow industry standard Best Management Practices and applicable federal regulations. Physical changes to the bedrock resulting from blasting (e.g., blast-induced fracturing) will be limited to the local area within the ECM footprint.	Secondary
	■ Blasting residuals and metals may be released during construction of the ECM, and surface water drainage features through the SSA may cause changes to soil quality.	■ Blasting activities will follow industry standard Best Management Practices and applicable federal regulations. ■ Additional guidance for the NSDF Project blasting limits will be obtained from *OPSS 120 – General Specification for the Use of Explosives* (OPSS 2014).	Secondary
	■ Storage and use of blasted rock in ECM berm construction may result in metal leaching and acid rock drainage	■ Blasting and use of excavated rock and ECM construction activities will follow industry standard Best Management Practices and applicable federal regulations. ■ ECM liner will extend to the berm crest thereby limiting infiltration through these materials. ■ Additional guidance for the NSDF Project blasting limits will be obtained from *OPSS 120 – General Specification for the Use of Explosives* (OPSS 2014).	Secondary

Table 5.3.1-4: Pathways Analysis for Geology Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation	Pathway Assessment

■ Project activities during the construction phase (as described above) and
  ▪ Haulage of construction materials
■ Project activities during the operations phase:
  ▪ On-site transportation of waste and placement in the ECM
  ▪ Progressive closure of disposal cells and installation of final cover
  ▪ Surface water management
  ▪ Domestic waste (solid and liquid) management; and,
  ▪ Routine operational management and monitoring activities.
	■ General activities that require the use of vehicles and equipment that combust fuel and emit criteria air contaminants. These activities involve material handling, vehicles travelling on paved and unpaved roads, and wind erosion of stockpiles that will result in fugitive dust emissions. Air and dust emissions and subsequent deposition may cause a change in soil quality.	■ Implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018d), which includes operational control monitoring, verification monitoring and environmental monitoring.
		■ The *Dust Management Plan* (AECOM 2018b) to be implemented for the NSDF Project includes measures for dust mitigation, such as:
		  ▪ restricting or suspending activities if unacceptable amounts of dust are generated due to winds or other site conditions;
		  ▪ use of water spraying or misting techniques (e.g., water trucks) as the primary dust control method;
		  ▪ use of fixatives (e.g., chemical suppressant) for dust control and for use as daily ECM cover;
		  ▪ suspension of excavating, loading, hauling and disposal operations when wind speeds exceed the specified criterion; and
		  ▪ requirement that vehicles that have come into contact with contamination pass through the vehicle decontamination facility.
		■ On-site vehicles and equipment engines will meet Tier 2 emission standards and be maintained in good working order.
		■ Idling of vehicles on-site will be limited.
			Secondary

Table 5.3.1-4: Pathways Analysis for Geology Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation	Pathway Assessment
■ General Project activities during the construction and operations phases (as described above)	■ Surface water runoff from the CRL site can alter soil quantity, quality and distribution	■ Procedures for surface water management are being developed and implemented for the NSDF Project (CNL 2018e). ■ Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site (i.e., CNL's *Management of Land, Habitat and Wildlife* procedure [CNL 2018c] and NSDF *Environmental Protection Plan* [CNL 2018e]) will be used around disturbed areas, where appropriate. ■ The target surface water quality objective is provided in the *Stormwater Management Planning and Design Manual* (MOE 2003). ■ Surface water from all external areas will be conveyed by ditches, swales and culverts to surface water management ponds (SWMPs) to address water quality and water quantity criteria established for the wetland receiving waters and, ultimately, Perch Creek. ■ The SWMPs are designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during operations, closure and post-closure. ■ The current SWMP footprints reflect the overall storage required to control post-closure flows to predevelopment levels for the 2-year through to 100-year rainfall events at the site. This volume also contains the storage required for sediment control during construction and water quality control during operations.	No Linkage

Table 5.3.1-4: Pathways Analysis for Geology Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation	Pathway Assessment

■ Project activities during the operations and closure phases:
  ▪ Surface water management
  ▪ Operation of the WWTP
	■ Leakage of leachate from the ECM during operations and closure may cause changes to groundwater quality, which can affect soil quality	■ Design of the ECM includes base contours that have been developed using a herringbone pattern with ridges and valleys to promote leachate transport to the leachate collection system for removal.
		■ The base liner design includes both primary and secondary liner systems that are designed to have redundancy in case of premature failure and are a combination of natural and synthetic barrier systems. These include a compacted clay liner (CCL), two geosynthetic clay liners (GCL) and a high density polyethylene (HDPE) geomembrane.
		■ Clay materials were selected for the CCL and GCL components of the liner system as these materials are anticipated to maintain their function as hydraulic barriers throughout and beyond the design life of the disposal facility (i.e., 550 years).
		■ The HDPE geomembrane for the liner was selected as it is compatible with the leachate generated by the waste and achieves a long service life.
		■ The base liner system includes an underlying compacted clay liner to supplement the primary and secondary liner systems.
		■ The leachate collection and monitoring system design provides access points for monitoring, inspections, maintenance, repairs and replacements.
		■ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water and groundwater quality.
			No Linkage

Table 5.3.1-4: Pathways Analysis for Geology Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation	Pathway Assessment

■ Project activities during the closure and post-closure phases:
  ▪ Maintenance of fencing around perimeter of ECM
  ▪ Installation of final cover, restoration and grading of SSA
  ▪ On-going long-term performance monitoring, transfer of NSDF Project into Institutional Control
	■ The installation of the final cover of the ECM and decommissioning and site grading of SSA can cause increased erosion and alter soil quality, quantity and distribution.	■ The final cover is designed to promote positive drainage from the SSA and reduce erosion or abrasion of the final cover.
		■ Performance monitoring will be completed throughout the post-closure phase for the NSDF Project to confirm that the final cover is functioning as intended.
			Secondary

ECM = engineered containment mound; WWTP = Wastewater Treatment lant; OPSS = Ontario Provincial Standard Specification; CNL = Canadian Nuclear Laboratories; CRL = Chalk River Laboratories; SWMP = surface water management pond; HDPE = high density polyethylene; SSA = site study area; MECP = Ministry of Environment, Conservation and Parks.

5.3.1.5.2.1 No Linkage Pathways

The following pathways were assessed as having no measurable environmental change and, hence, no linkage to residual effects on geology VCs.

- **Surface water runoff from the CRL site can alter soil quantity, quality and distribution.**

The surface water management ponds (SWMPs) are designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during operations, closure and post-closure. The current SWMP footprints reflect the overall storage required to control post-closure flows to predevelopment levels for the 2-year through 100-year rainfall events at the site. This volume also contains the storage required for sediment control during construction and water quality control during operations. The target surface water quality objective of 60% TSS removal that provides basic water quality treatment for discharge to the receiving wetland is provided in *Stormwater Management Planning and Design Manual* (MOE 2003). SWMP #1 will meet 80% TSS removal which will provide enhanced water quality treatment. SWMP #2 will provide 76% TSS removal and SWMP #3 will provide 60% TSS removal during operations, which will be sufficient because the receiving waterbody is a wetland and not a watercourse. The wetland functions as a sediment trap that will provide additional treatment prior to stormwater reaching any watercourses in wetlands.

During the construction phase, erosion and sediment control measures will be in place to mitigate the effects of soil erosion and sediment transport (CNL 2018e). The measures include the use of erosion control blankets, as needed, to control erosion on steep slopes, check dams in ditches and swales, and the three proposed SWMPs that will be constructed to serve as interim sediment control facilities during the construction phase and then as stormwater management facilities during the operations, closure and post-closure phase. Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site (i.e., CNL's *Management of Land, Habitat and Wildlife* procedure [CNL 2018c]) will be used around disturbed areas, where appropriate. An Environmental Management Plan will be developed as part of construction planning for the site to provide detailed erosion and sediment control measures and the SWMP construction schedule. The plan will include administrative protocols such as training, contractor document submissions and staffing required for effective surface water management throughout all phases of the NSDF Project.

Site operations include surface water management for the ECM and all external areas. Surface water from all external areas will be conveyed by ditches, swales and culverts to SWMPs that will address water quality and water quantity criteria established for the wetland receiving waters and, ultimately, Perch Creek. Contact water, which is exposed to waste within the ECM, will drain from the active cells of the ECM and be conveyed to the WWTP. Non-contact water drainage from completed cells and yet-to-be-completed cells will be directed either by gravity to the external surface water management system or to temporary holding ponds within the ECM, and then pumped to the three SWMPs.

Facility inspections will be completed twice annually and after major storm events to confirm that inlets and outlets are clear of debris and to confirm that there are no major erosion issues at the inlet or outlet. As well, the integrity of berms and outlet structures will be confirmed by visual inspections (e.g., to identify any animal burrowing activity or active soil erosion). Inspections will also include an annual sediment level monitoring component within each pond to identify sediment accumulation rates that may require clean-out requirements. If necessary, pond sediment will be extracted by excavation equipment and will be disposed of based on sediment sampling, testing and classification according to MECP standards, or stockpiled, dewatered and reused on site for the

daily ECM cover operations. Sediment removal will follow procedures identified in the *Stormwater Management Planning and Design Manual* (MOE 2003).

Roadway, sidewalk and parking lot winter maintenance activities that may release road salt to the environment include snow plowing/shoveling and de-icing practices, salt and sand storage and snow stockpiling, removal and disposal. The current winter maintenance practices outlined in the *CRL Salt Management Plan* (AECL 2013) provide for effective management of salt use and will be applied to the NSDF Project, as necessary. As stated in the plan, the application of road salt on the CRL site will be limited as salt residual within contact water and/or leachate may compromise the treatment effectiveness of the WWTP systems. Instead, alternative products in winter road management, such as a sand-stone mixtures, are currently being considered.

Overall, the implementation of the above-mentioned mitigation will reduce the potential for changes to soil quality, quantity and distribution. As such, this pathway was determined to have no linkage to effects on geology.

- **Leakage of leachate from the ECM during the operations and closure phases may cause changes to groundwater quality, which can affect soil quality.**

Design of the ECM includes base contours that have been developed using a herringbone pattern with ridges and valleys to promote leachate transport to the leachate collection system for removal. The base liner design includes both primary and secondary liner systems that are designed to provide redundancy in case of premature failure and are a combination of natural and synthetic barrier systems. The primary liner includes a leachate collection system with the secondary liner housing a leak detection system. The primary and secondary liner systems each include a high density polyethylene (HDPE) geomembrane that is compatible with the leachate generated by the waste and is expected to perform as an effective hydraulic and diffusion barrier over the 550-year design life (see Section 3.4.1.4). The base liner system includes an underlying compacted clay liner to supplement the primary and secondary liner systems. The leachate collection system design provides access points for inspections, maintenance, repairs and replacements.

The primary liner system will contain the leachate collection system, and will convey leachate to a single collection point for removal from the mound, for transfer to the WWTP for treatment. The primary liner system serves as the primary source of protection for the natural environment below the mound from leachate migration. The secondary liner system will contain the leak detection system, which will be used to detect leaks in the unlikely event that the primary liner system fails. Leachate collected by the leachate collection system will be pumped to the on-site WWTP for treatment.

Perimeter berms consist of three main geotechnical elements, or layers, each contributing to the soundness and integrity of the berm itself and the whole ECM. A slope stability analysis was completed to provide the information needed to support the design of the base slopes, sidewalls and side slopes of the ECM. The slope stability analysis addresses the range of anticipated loading conditions, under both short-term and long-term scenarios, to confirm that the slope designs will satisfy minimum factor-of-safety requirements for stability. Size and shape of the berms and each of the elements and layers were determined using a seismic design basis, including the National Building Code of Canada (NBCC).

Overall, implementation of the above-mentioned mitigation will reduce the potential for changes to groundwater water quality from the SSA and thereby soil quality. As such, this pathway was determined to have no linkage to effects on geology.

5.3.1.5.2.2 Secondary Pathways

The following pathways were assessed as potentially having a measurable minor environmental change but resulting in a negligible residual effect on geology relative to the Base Case.

- **Construction activities can alter soil quantity, quality and distribution.**
- **Construction activities can alter geomorphology.**
- **The installation of the final cover of the ECM and closure and site grading of the SSA can cause increased erosion and alter soil quality, quantity and distribution.**

Changes to surface flows, water levels and water quality from NSDF Project construction and closure are expected to be limited using environmental design features and mitigation. The NSDF Project site was designed to be as small as possible to limit disturbance to the natural environment to the extent feasible and will avoid stream and wetland habitats. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. Excavation for the ECM, drainage ditches and the SWMPs will be completed once the SSA has been cleared and topsoil removed.

During the construction phase, erosion and sediment control measures will be in place to mitigate the effects of soil erosion and sediment transport. The measures include the use of erosion control blankets, as needed, to control erosion on steep slopes, check dams in ditches and swales, and the three SWMPs that will be constructed to serve as interim sediment control facilities during construction, and then as stormwater management facilities during the operations, closure and post-closure phases. Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site (i.e., CNL's *Management of Land, Habitat and Wildlife* procedure [CNL 2018c]) will be used around disturbed areas, where appropriate. Closure activities include the installation of a final cover over the ECM to limit ponding and water infiltration into the waste. Modification to the drainage ditches and conveyance channels will be made to promote positive drainage from the site and limit erosion or abrasion of the final cover. Runoff control for the final cover is designed to limit ponding and infiltration of water into the ECM, erosion of the final cover and waste material, and destabilization of the structure. The ECM design approach is to control the direction and velocity of the runoff to prevent erosion and abrasion of the final cover. Any surface water infiltrating the final cover will be collected by the leachate collection system and sent to the WWTP. The three SWMPs will remain to promote infiltration and settlement of suspended solids and restrict discharge rates to the nearby wetland. Decommissioning of the WWTP and all associated surface water management structures will be completed after the leachate quantity and quality no longer requires treatment. In the event that the WWTP is required beyond its design life, the unit would be refurbished to enable continued treatment of leachate or other treatment options investigated.

Environmental monitoring will be completed as required during the institutional control period for the NSDF Project to confirm that the final cover is functioning as intended. Overall, changes to soil quantity and quality from the NSDF CRL site, and changes to geomorphology from the closure activities was determined to have no residual effect on geology.

- **Construction activities (i.e., blasting) can locally alter physical properties of the bedrock.**

Blasting activities related to excavation of bedrock for construction of the ECM will result in localized physical changes to the bedrock (e.g., blast-induced fracturing), which will be limited to the local area within the ECM footprint. These have been considered as a part of the overall hydrogeological assessment (see Section 5.3.2).

- **Blasting residuals and metals may be released during construction of the ECM and surface water drainage features through the SSA may cause changes to soil quality.**

Use of explosives during the construction phase of the NSDF Project could cause changes in soil quality. Explosives have the potential to release nitrogen residual substances (e.g., ammonium nitrate/fuel oil). Blasting activities and the removal of waste rock could increase dust deposition and could increase trace metal (e.g., aluminum, cadmium, chromium, copper, iron, mercury and silver) concentrations and nitrogen residual substances.

The Blasting Plan will provide mitigation to limit the potential for effects on soil quality from fugitive dust generation through excavation and material transport. Additional guidance will be obtained from *OPSS 120 – General Specification for the Use of Explosives* (OPSS 2014). The anticipated quantities of blasted rock are approximately 170,000 m^3. An allowance will also be made for additional trench blasting that may be required to facilitate utility runs. It is anticipated that the majority of blasted rock will be recycled for use within the construction of the ECM. Rock that cannot be recycled for reuse will either be stored at the CRL site or cleared for off-site use. Any runoff in contact with blasting residues at the SSA will be managed where appropriate (e.g., SWMPs) during the construction phase to avoid adverse environmental effects off site. Consequently, change to soil quality from the use of explosives was determined to have a negligible residual effect on geology.

- **Storage and use of blasted rock may result in metal leaching and acid rock drainage**

Due to the stable nature of the bedrock constituent minerals it is anticipated that the potential generation of metal leaching, acid rock drainage and any potential adverse effects on water quality are negligible.

Bedrock in the vicinity of the NSDF is primarily comprised of quartzofeldspathic and dioritic gneiss. Mineralogically, the rocks are comprised of quartz, potassium and plagioclase feldspars, hornblende, clinopyroxene, biotite and garnet as major minerals (CNL 2016d). These minerals are generally considered to have low potential for acid rock drainage and leachability (Jambor et al. 2003, Jambor et al. 2002).

Iron sulphide minerals (e.g., pyrite, pyrrhotite), which would indicate potential for acid rock drainage, have been identified through previous studies as alteration minerals formed through low-temperature fracture infilling in deep bedrock boreholes at the CRL site. One occurrence of pyrite was noted in the logs of boreholes at the NSDF site (PH17-008) at a depth of approximately 14m, which is approximately 2 m deeper than the excavation horizon (CNL 2016d).

Given the relatively low occurrence of the sulphide minerals and the relative stability of the constituent minerals of the rock the potential for metal leaching and acid rock drainage is anticipated to be low.

The excavated rock is intended to be used as construction material for the berm around the perimeter of the ECM, situated above the water table. The interior portion of the berm (from the berm crest inwards) will be covered with a base liner and cover system that will limit infiltration through the material.

A Blasting Plan will be developed by the Construction Contractor after that contract has been awarded since it is required to be prepared by qualified individuals. The Blasting Plan will follow ‘DFO Guidelines for the Use of

Explosives In or Near Canadian Fisheries Waters' (Wright and Hopky 1998) and Ontario Provincial Standard Specification (OPSS) in the document *OPSS 120 – General Specification for Use of Explosives* (OPS 2014), as well as standard best management practices to minimizing the transport of blasting residuals into downstream waterbodies. Although the Blasting Plan is not available at this phase of the NSDF Project, CNL has specified requirements in technical specifications to the Construction Contractor.

Therefore, based on the discussion above, this pathway was determined to have negligible residual effects on geology.

- **General activities that require the use of vehicles and equipment that combust fuel and emit criteria air contaminants (CACs). These activities involve material handling, vehicles travelling on paved and unpaved roads, and wind erosion of stockpiles that will result in fugitive dust emissions. Air and dust emissions and subsequent deposition may cause a change in soil quality.**

The construction and operations phases of the NSDF Project will generate air and dust emissions such as carbon monoxide, oxides of sulphur (includes sulphur dioxide), oxides of nitrogen (includes nitrogen dioxide), particulate matter less than 2.5 microns in diameter ($PM_{2.5}$) and suspended particulate matter (SPM). Air emissions such as oxides of sulphur and oxides of nitrogen can result from the use of fossil fuels in generators, vehicles and machinery. Vehicle exhaust and fugitive dust from unpaved and paved roads is the largest contributor to particulate matter (SPM, PM_{10} and $PM_{2.5}$) during both the construction and operations phases (Section 5.2.1.6.2).

Implementation of mitigation measures are anticipated to limit predicted residual effects from NSDF Project emissions to air quality (and subsequently to aquatic biodiversity VCs) include: meeting Tier 2 emission standards for on-site vehicles and equipment engines, use of vehicles that are maintained in good working order and idling of vehicles on site will be limited consistent with CNL's Environmental Protection Program. Dust control will be conducted to support waste placement operations in accordance with the *Dust Management Plan* (AECOM 2018b) during loading, transportation, placement and compaction operations. Work areas that have the potential for generating dust will require implementation of dust suppression techniques. The primary dust control method will include water spraying or misting techniques (e.g., water trucks). Water application is controlled to avoid generation of free liquids. Fixatives (e.g., chemical suppressant) may also be used for dust control and for use as daily ECM cover. The use of fixatives is reviewed prior to application for potential effects on leachate and surface water runoff generated by the ECM.

Predicted concentrations for the Application Case during both construction and operations phases are below applicable air quality guidelines and/or standards with the exception of nitrogen dioxide, that will not meet the 2020 1-hour CAAQS (Section 5.2.1.6.2, Table 5.2.1-14). The contributing factor to the high magnitude nitrogen dioxide emissions is the heavy-duty construction equipment and the conservative assumption that all equipment will run simultaneously and continuously during working hours. In reality, individual equipment will be idling or off for varying parts of the workday that cannot be predicted but will result in lower emissions than currently estimated. The likelihood that all equipment operates simultaneously for an hour or more along with unfavourable weather conditions to produce the maximum concentrations modelled is very low. With the implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018d) and through the implementation of the *Dust Management Plan* (AECOM 2018b) for the NSDF Project, air and dust emissions and subsequent deposition are expected to result in minor and local changes to soil quality relative to Base Case conditions. Therefore, this pathway was determined to have negligible residual effects on geology.

5.3.1.5.2.3 Primary Pathways

No primary pathways were identified as having potential for residual effects on geology.

5.3.1.6 Monitoring and Follow-up

Monitoring and follow-up programs are not specifically identified for geology; rather, operational monitoring will be implemented to verify effects predictions for geology. For example, continued seismic and microseismic monitoring on the CRL site, and visual inspections of the SSA and surface water management systems will be completed to confirm erosion control measures are effective (AECOM 2018c).

5.3.1.7 Conclusions

VCs refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Geology, which includes bedrock, soils and geomorphology, is recognized as an important component of the environment that may be affected by the NSDF Project and changes to geology could, in turn, lead to effects on other VCs selected for assessment. Acknowledging that changes to geology are important aspects of the natural and human environment, geology is referred to as an intermediate component. Results of the analysis of changes in measurement indicators for geology are provided to other disciplines for inclusion in their assessment (Table 5.3.1-2).

Potential effects on geology are related to changes in soil quantity and quality and geomorphology as a result of construction of the NSDF Project, and changes to soil quality from blasting activities and air emissions. Mitigation and environmental design features implemented for the NSDF Project are well understood and include existing practices at the CRL site. For example, a Blasting Plan and the NSDF *Dust Management Plan* (AECOM 2018b) includes mitigation measures to limit the potential for effects on soil quality from fugitive dust generation through excavation and material transport. Consequently, residual effects on geology are predicted to be negligible as a result of the NSDF Project.

5.3.2 Hydrogeology

5.3.2.1 Scope of the Assessment

This section focuses on hydrogeology and follows the overall environmental assessment approach and methods described in Section 5.1. The assessment was completed following the key steps listed below:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** for the hydrogeology assessment (refer to Sections 5.3.2.2 Valued Components and 5.3.2.3 Assessment Boundaries). The VCs and measurement indicators used to assess Project-related changes to hydrogeology are described, along with the spatial and temporal boundaries at which the assessment occurred and the assessment cases considered.
- **Step 2 – Describe the existing conditions** (refer to Section 5.3.2.4 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation). The existing conditions provide a reference to which the effects of the NSDF Project can be compared.
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 5.3.2.5 Project Interactions and Mitigation). Project components and/or activities with the potential to affect hydrogeology are identified and mitigation developed to limit or avoid effects is presented. A pathways analysis is then used to focus further assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects to hydrogeology after incorporating mitigation are carried forward to Steps 4 for further analysis and residual effects characterization.
- **Step 4 – Present the methods and results of the residual effects analysis** (refer to Section 5.3.2.6 Residual Effects Analysis). This section outlines the methods used to predict and characterize residual effects to hydrogeology from primary effects pathways. The analysis results are also presented including the characterization of: (i) residual incremental effects of the NSDF Project and the effects of the NSDF Project in combination with previous and existing developments on hydrogeology (Application Case); and (ii) residual effects of the NSDF Project in combination with previous and existing developments, as well as other reasonably foreseeable developments (Reasonably Foreseeable Developments [RFD] Case). A key outcome of this section is the predicted effects to hydrogeology that are passed on to other VCs for inclusion in their assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty** (refer to Section 5.3.2.7 Prediction Confidence and Uncertainty). Evaluate the available literature, data and models used for the assessment, and describe the level of certainty that can be placed on predicted residual effects. This section will also identify how the uncertainty has been managed so that the effects are not underestimated.
- **Step 6 – Classify and determine the significance of the predicted residual effects**. This step was not required as no primary pathways were identified in the hydrogeology assessment.

- **Step 7 – Identifying monitoring and follow-up** required to confirm effects predictions and address uncertainty (refer to Section 5.3.2.8 Monitoring and Follow-up).
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** of residual effects on hydrogeology (refer to Section 5.3.2.9 Conclusions).

This section also describes how the input from engagement influenced the scope of the hydrogeology assessment. Information and areas of interest raised by the public, communities of interest, and Indigenous Peoples during engagement are summarized in Table 5.3.2-1. Other general areas of interest and questions raised during the engagement that pertain to the hydrogeology assessment (if any) are documented in CNL's Indigenous Engagement Report (CNL 2021) and CNL's Stakeholder's Activity Reports (CNL 2017b,c, 2019a).

Table 5.3.2-1: Summary of Areas of Interest Raised During Engagement Activities that Influenced the Scope of the Hydrogeology Assessment

Area of Interest	How the Area of Interest Was Included in the Assessment
Potential for changes in groundwater quality to affect uses downstream of the ECM	Potential changes in groundwater quality from the NSDF Project were evaluated in the hydrogeology assessment and included potential changes from construction activities (e.g., erosion and blasting activities), changes from treated effluent discharge from the WWTP and leakage from the ECM during the post-closure phase following decommissioning of the WWTP.
Treatment of leachate and contaminated water	Leachate and contaminated water from the ECM will be collected and pumped to the WWTP for treatment prior to discharge.
Potential leakage of leachate from the ECM	Potential leakage of leachate from the ECM during operations will be mitigated through the design and implementation of a composite base liner system, a leachate detection system and a leak collection system. Potential leakage from the ECM during the operations and post-closure phases is considered in the hydrogeology assessment.
Long-term monitoring of groundwater	A conceptual long-term monitoring program for the NSDF Project as it relates to groundwater has been developed and is described in the hydrogeology assessment. A detailed groundwater monitoring program will be provided in the follow-up monitoring plan.

ECM = engineered containment mound; WWTP = Wastewater Treatment Plant.

5.3.2.2 Valued Components

Valued Components (VCs) refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Hydrogeology is recognized as an important component of the environment that may be affected by the NSDF Project and changes to hydrogeology could, in turn, lead to effects on other VCs selected for assessment. For example, changes to the characteristics of groundwater quality may have a large influence on surface water quality. Subsequently, changes to these characteristics by NSDF Project activities could affect the terrestrial and aquatic ecosystems structure and function, and human health including future use (e.g., human intrusion; Table 5.3.2-2).

Acknowledging that changes to groundwater quantity and quality are important aspects of the natural and human environment, hydrogeology is referred to as an intermediate component (i.e., it does not have an assessment endpoint). Changes to intermediate component VCs must be understood to facilitate assessment of project interactions. The hydrogeology assessment, therefore, is analyzed for incremental and cumulative (if applicable) changes in the relevant measurement indicators associated with hydrogeology (Table 5.3.2-3). The assessment of hydrogeology focused on predicting changes in the groundwater flow patterns, groundwater table elevations and concentrations of selected non-radiological substances. Radiological parameters are mainly considered in

Section 5.7 Ambient Radioactivity; however, some discussion of radiological parameters is provided in this section (i.e., Section 5.3.2). The changes are characterized in terms of magnitude, duration and geographic extent, but are not classified using rankings for effects criteria. The hydrogeology assessment does not include the assessment of the significance of these changes; rather, results of the analysis of changes in measurement indicators for hydrogeology are provided to other disciplines for inclusion in their assessment (Table 5.3.2-3).

Table 5.3.2-2: Valued Components for the Hydrogeology Assessment

Valued Component	Rationale for Selection
Groundwater quantity and quality	Characteristics of hydrogeology, such as groundwater quantity and quality are important components that interact with other VCs (e.g., hydrology and surface water quality) and if changed by NSDF Project activities, these characteristics could affect terrestrial and aquatic biodiversity, and human health including future use (e.g., human intrusion).

VC = valued component

Table 5.3.2-3: Assessment Endpoints and Measurement Indicators for the Hydrogeology Assessment

Valued Component	Measurement Indicators	Discipline Assessments where Effects on Hydrogeology are Considered
Groundwater quantity	■ Groundwater flow patterns and discharge rates ■ Groundwater table elevations	■ Section 5.4 Surface Water Environment ■ Section 5.5 Aquatic Environment ■ Section 5.6 Terrestrial Environment ■ Section 5.7 Ambient Radioactivity and Ecological Health ■ Section 5.8 Human Health
Groundwater quality	■ Groundwater quality with a focus on changes to the groundwater discharged to Perch Creek and Perch Lake Watershed	

5.3.2.3 Assessment Boundaries

5.3.2.3.1 Spatial Boundaries

The spatial boundaries selected for the hydrogeology assessment are the same as those defined for geology (see Section 5.3.1.3.1 and Figure 5.3.1-1).

5.3.2.3.2 Temporal Boundaries

Temporal boundaries (i.e., project phases) establish the timeframe during which NSDF Project effects are assessed. The phases identified for the NSDF Project are described in Section 5.3.1.3.2. The temporal boundary of the hydrogeology assessment considers all phases of the NSDF Project.

5.3.2.3.3 Assessment Cases

The assessment cases defined for the hydrogeology assessment are the same as those defined for geology (see Section 5.3.1.3.3). Similar to the geology assessment, the hydrogeology assessment includes the Base Case and Application Case.

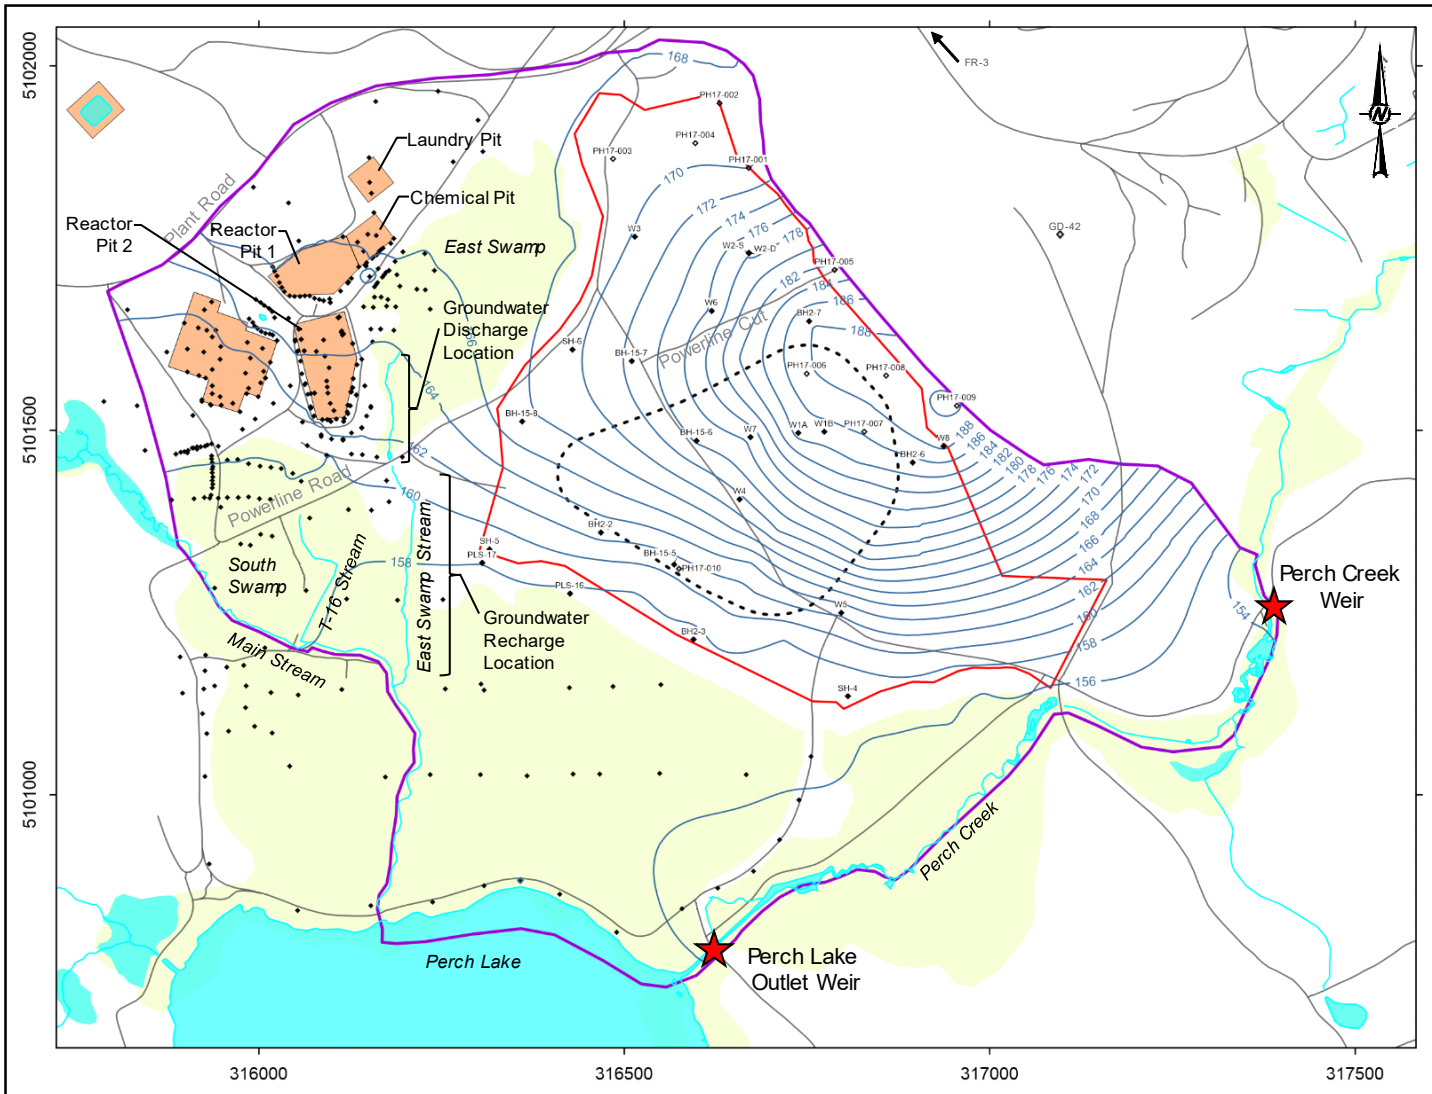
An RFD Case is not presented as part of this assessment because RFDs will either have no spatial overlap or are likely to positively affect hydrogeology. New support infrastructure, research and development facilities and the proposed small modular reactor (SMR) are planned within areas of the CRL site outside of the SSA and generally within existing disturbed areas. Best practices, such as storm water management systems and waste management programs, are expected to be implemented to minimize any potential effects to hydrogeology during construction or operation of these facilities, including groundwater flow or quality. No process water intakes from or discharges to surface or groundwater are identified in the description of the planned SMR (Global First Power 2019). As such, potential effects from the construction and operation of the SMR or revitalization activities are not

expected to spatially overlap with potential effects to hydrogeology from the NSDF Project. The end-state plan for the CRL site will be to return lands disturbed by site activities to a condition that is physically stable and safe in keeping with the land use and landscape of the day. Therefore, decommissioning and environmental remediation activities are anticipated to positively affect measurement indicators for hydrogeology such as groundwater quality.

There are no potable water wells anticipated to be installed within the Regional Study Area (RSA) during the time up to the end of the post-closure phase. However, a Human Intrusion Scenario assuming a borehole is drilled into the ECM during the post-closure phase has been evaluated in Section 5.8 Human Health.

5.3.2.4 Description of the Environment

5.3.2.4.1 Methods



Base Case hydrogeological data were collected from the review of the following reports:

- *Subsurface Geotechnical Survey of the Proposed Near Surface Disposal Facility at Chalk River Laboratories* (Golder 2016);
- *Multidisciplinary Subsurface Investigation, Phase 1*, (AMEC 2017a);
- *Multidisciplinary Subsurface Investigation, Phase 2* (AMEC 2017b);
- *Multidisciplinary Subsurface Investigation, Phase 4* (AMEC 2018a);
- *Hydraulic Conductivity (Slug Test) Results for PH17-001 to PH17-010, Canadian Nuclear Laboratories, Chalk River* (Wood 2018)
- *Wood Geotechnical Investigation (Ring Road for Effluent to Perch Lake* (Wood 2019)
- *Radiological Contamination in the South Swamp, 1997 to 2011* (CNL 2015b);
- *Radiological Contamination in the East Swamp, 2002 to 2012* (CNL 2015c);
- *Subsurface Radionuclide Migration from the Chemical Pit* (AECL 2014);
- *Chalk River Laboratories Groundwater Monitoring Program Annual Report for 2017* (CNL 2019b);
- *Contaminant Migration from Reactor Pit 2* (CNL 2016b);
- *Baseline Groundwater Quality in the Vicinity of the Proposed NSDF Project site* (CNL 2017d); and
- *Hydrographs – October 2016 to June 2018* (AMEC 2018b).

The Groundwater Monitoring Program (GWMP) at the CRL site includes annual and semi-annual water level measurements, and sampling and analysis from 180 monitoring wells or boreholes at 32 sites. These wells or boreholes are referred to by borehole ID, which typically includes a study location (e.g., PLS = Perch Lake Series) and borehole number. All locations referred to in the text are indicated on Figure 5.3.2-1A. Many of the GWMP monitoring locations are at the perimeters of various operating areas, and the objective of the program is to monitor the behavior and condition of the facilities. The data from this monitoring program is reported annually (CNL 2019b). These data provide operational feedback on the conditions and behaviour of facilities, including the performance of existing remedial measures (e.g., infiltration barriers). The GWMP includes wells that are upgradient of the monitored areas, in order to provide reference values. Where groundwater contamination is present downgradient of these facilities, this routine monitoring is augmented by periodic detailed evaluations of subsurface contaminants. Contaminant migration (i.e., plume) reports such as AECL (2014) and CNL (2016a) are updated on 5- and 10-year cycles based on data collected as part of the annual program and supplementary investigations.

Hydrogeological investigations to support the NSDF Project by Golder (2016) and AMEC (2017a,b, 2018a) have included in-situ permeability/hydraulic conductivity testing, groundwater sampling and groundwater elevation measurements at the wells noted in Section 5.3.1.4.1.

A water table elevation map throughout the lower Perch Lake Basin, which includes the SSA, is shown on Figure 5.3.2-1A for average water table conditions. For monitoring wells within the SSA, groundwater levels observed in January 2017 were used to infer the water table elevation. For monitoring wells outside of the SSA the average of historical groundwater elevation (from 1982 to 2017) at each monitoring well was calculated and used to infer a water table elevation.

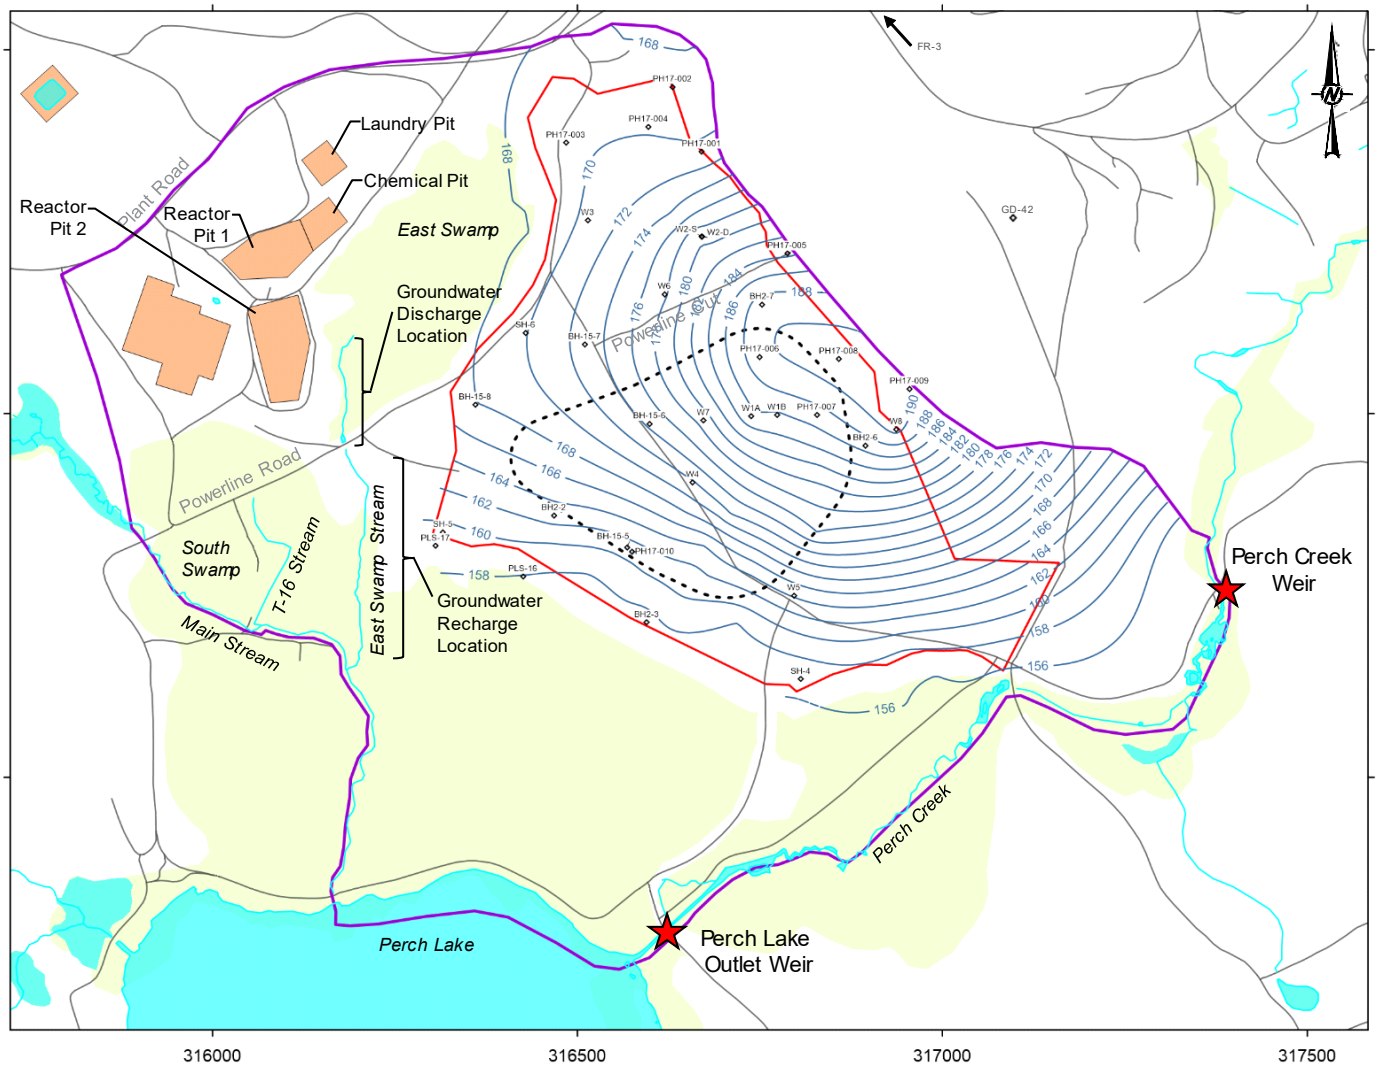
5.3.2.4.2 Results

5.3.2.4.2.1 Groundwater Flow



The average water table elevation within the SSA, and throughout the lower Perch Lake Basin (the domain of the groundwater model) is shown on Figure 5.3.2-1A. Elevation contours were generated based on historical information and from data collections between October 2016 and June 2018 at the SSA (AMEC 2017b, 2018a). The seasonal high water table elevation within the SSA is shown on Figure 5.3.2-1B. The high water table elevation contours were generated based on the maximum groundwater elevation from the transducer records collected by AMEC between October 2016 and June 2018. On average, the maximum value from the transducer record was 1.2 m above the average values and approximately 3 m above the minimum value. The high water table position occurred in April or May at most locations. Elsewhere within the Perch Lake Basin the water table elevation is expected to vary seasonally by 1 to 2 m (depending on location), with the high water table position occurring in April and May (CNL 2016b). The length of transducer records varies at individual wells, depending on the date of installation. For the most recent installations the transducer records span a period of approximately 6 months. Figure 5.3.2-1C provides a “snapshot” of the seasonal high water table elevation from April 26, 2018 when the most recent seasonal high elevation was measured for most wells. A comparison of Figures 5.3.2-1B and 5.3.2-1C shows that the groundwater elevations and flow directions are similar for the absolute maximum and snapshot readings (April 26, 2018). Hydrographs of the transducer data are included in Appendix 5.3-1.

Within the lower Perch Lake Basin, groundwater flow within the overburden is influenced by local topography (and bedrock topography) and is interpreted to be primarily horizontal (CNL 2016b). In the overburden deposits, groundwater flow occurs mainly within the basal sand and gravel, middle sand and upper sand units, where present (CNL 2016b). As the silty clay and interstratified silt and sand units that separate these aquifers are not continuous throughout the valley, groundwater elevations, groundwater flow directions and horizontal hydraulic gradients are not differentiated between units. The available data includes monitoring wells located at the peak of the bedrock ridge to the northeast (e.g., W8, PH17-005, PH17-008, PH17-009, BH2-6). Data from these locations indicate the presence of a northeast to southwest groundwater divide corresponding to the topographic high along the ridge. Hydrogeological mapping of the CRL site completed by Raven Beck (1994) also infers the presence of a groundwater divide along this ridge.

The water table depth within the SSA was calculated based on average groundwater elevation data collected by transducer between October 2016 and June 2018 (AMEC 2018a). Average groundwater depths ranged from 0.06 metres below ground surface (mbgs; at monitoring well SH-4) to 15.95 mbgs (at monitoring well PH17-001). The seasonal high water table elevations range from 0.26 meters above ground surface (at W-4) to 15.43 mbgs (at PH17-001). The average water table depth across the SSA was 4.81 mbgs under average conditions and 3.61 mbgs under seasonal high water table conditions. Depth to the water table is generally greatest near the top of the bedrock ridge, and decreases to the south, west and north, towards the low-lying wetland areas. Cross-sections through the ECM (AECOM 2017) were used to compare the interpreted water table surface (based on January 2017 and May 2017 water level measurements) against ground surface and bedrock topography (see Figures 5.3.2-2A through 5.3.2-2C). Figure 5.3.2-2D provides a simulated water table for post-closure. The water table elevation generally follows topography. The water table elevation was higher in May 2017 compared to January 2017 in the upper portions of the ECM (to the east of East Mattawa Road), with increases of up to 6 m occurring in bedrock monitoring wells located in areas of high elevation (e.g., W-8, W-7). Increases in groundwater elevation at these monitoring wells occurred during thaw and precipitation events in the spring. Variability in groundwater elevations in monitoring wells located near the low-lying areas (i.e., in close proximity to East Swamp and Perch Lake Swamp) was generally within 1 m to 2 m. It should be noted that installation of the ECM will limit local recharge to the water table, resulting in a lowering of the water

table elevation beneath the facility. The reduction in water table elevation was assessed as a part of numerical modelling (Golder 2019b). Additionally, the bedrock beneath the ECM will undergo blasting as a part of ECM construction activities, which is anticipated to result in localized increases to hydraulic conductivity of the bedrock (Golder 2019b).

Within the SSA, groundwater flow to the northwest of the ECM footprint is generally to the northwest towards the East Swamp (see Figure 5.3.2-1A). In this area hydraulic gradients are low, and minor variations in groundwater elevations can result in a component of groundwater flow towards the northeast for the northernmost portion of the NSDF study area. Based on the transducer records from the PH-series monitoring wells, these reversals in groundwater flow direction are sustained for a period of less than a month. Groundwater flow within the ECM footprint is generally to the southwest and south towards the Perch Lake Swamp and Perch Creek. In the operations areas adjacent to the SSA, groundwater flow from Waste Management Area A and Reactor Pit 2 is generally to the south and southwest towards the South Swamp, while groundwater flow from the Chemical Pit is generally to the southeast towards the East Swamp. Within the southern portion of the Perch Lake Basin, groundwater flow is generally towards Perch Lake and Perch Creek.

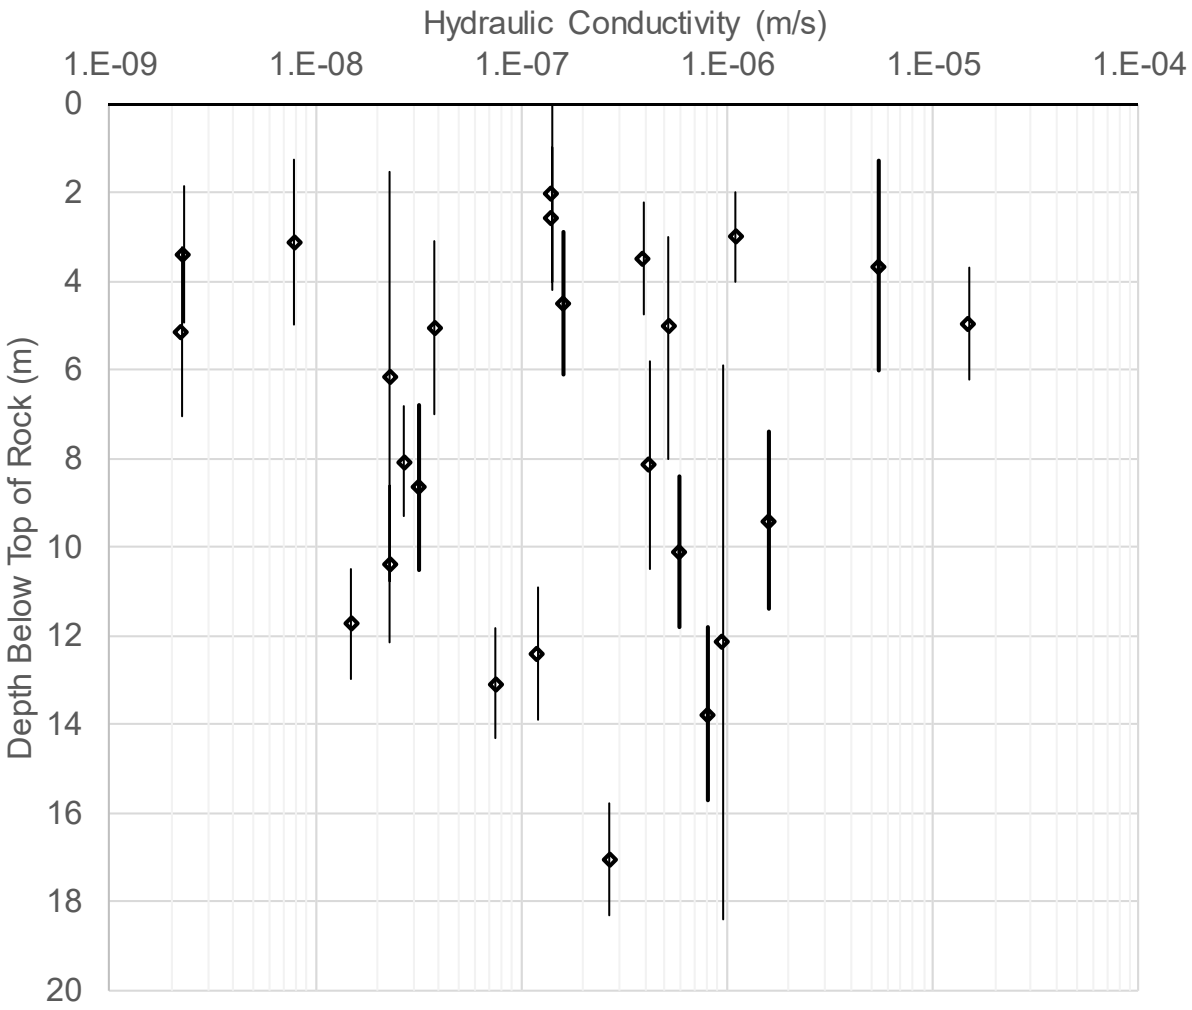
Hydraulic Gradients

Horizontal hydraulic gradients within the SSA were calculated based on average groundwater levels collected by AMEC between October 2016 and June 2018 (AMEC 2018a,b) and the groundwater elevation mapping shown on Figure 5.3.2-1A. The horizontal hydraulic gradient within the overburden in the northern portion the SSA was approximately 0.04 metres per metre (m/m) to the northwest (between monitoring wells W2-S and PH17-003). In the southern portion of the SSA the horizontal hydraulic gradient is approximately 0.05 m/m to the southwest in the overburden between monitoring wells BH-15-8 and SH-5 and approximately 0.07 m/m to the southwest in the bedrock between monitoring wells W4 and BH2-3.

Under high water table conditions (as shown on Figure 5.3.2-1B) the horizontal hydraulic gradient within the overburden in the northern portion of the SSA is increased to approximately 0.05 m/m to the northwest (between W2-S and PH17-003). In the southern portion of the SSA the horizontal hydraulic gradient to the southwest in the overburden (between BH15-8 and SH-5) is 0.05 m/m (unchanged from average conditions), while the horizontal hydraulic gradient to the southwest in the bedrock (between W4 and BH2-3) is increased to 0.09 m/m.



Vertical hydraulic gradients between the overburden and the bedrock were calculated for monitoring well pairs W2-S/D and BH2-2S/D based on groundwater elevation data collected in between December 2017 and June 2018 (AMEC 2017b, 2018a). At W2-S/D downward vertical gradients of 0.13 m/m and 0.16 m/m under average and high water table conditions respectively, from the overburden to the bedrock was calculated, indicating recharging conditions at the topographic high. At BH2-2S/D a downward gradient of 0.03 m/m was calculated under average water table conditions. A very slight upward gradient of 0.006 m/m was calculated at this location under high water table conditions. From June 2017 to December 2017, vertical gradients at BH2-S/D were predominately downwards, while vertical gradients at this location were predominately upwards between December 2017 and June 2018.

Average horizontal hydraulic gradients measured in low-lying portions of the Perch Lake Basin range from 0.006 to 0.03 m/m in the area between Reactor Pit 2 and the South Swamp (CNL 2016b). The average horizontal hydraulic gradient is slightly higher, 0.05 m/m, between the South Swamp and Perch Lake Swamp. In the aquifers underlying the Perch Lake swamp, the average horizontal hydraulic gradients decrease in a southerly direction, from 0.009 m/m) to 0.002 m/m. Average horizontal hydraulic gradients were found to increase slightly (to 0.006 m/m) towards the zone of groundwater discharge at Perch Creek. In general, the horizontal hydraulic gradients observed in the low-lying areas of the Basin are lower than those observed at the SSA.

Hydraulic Conductivity

Interpretation of hydraulic response testing of the till completed at the SSA by AMEC and Golder has been summarized in AMEC (2017a,b). Till hydraulic conductivity was found to range from 0.00000057 to 0.000016 m/s with a geometric mean of 0.0000016 m/s based on the results of hydraulic response tests completed at 14 locations. Two additional tests were completed at the bedrock overburden interface, resulting in a slightly higher range of hydraulic conductivity (from 0.0000072 to 0.000031 m/s).

A total of 41 hydraulic response tests were completed in the bedrock at 24 borehole locations within the SSA. Of these tests, 26 were suitable for analysis and interpretation and the remainder were not analyzable due to slow recovery or instrument malfunction. Hydraulic conductivity was found to range from 0.0000000023 to 0.000015 m/s with a geometric mean of 0.00000014 m/s. As shown on Figure 5.3.2-3, no significant trend in hydraulic conductivity with depth is observed through the tested interval; however, at depths greater than 6 mbgs the hydraulic conductivity did not exceed 0.000002 m/s. Overburden porosity was found to range from 0.25 to 0.5 in sand and silty sand intervals, and from 0.25 to 0.3 in sand and gravel intervals (porosity of the bedrock core samples was not reported) (AMEC 2017b).

S:\Clients\Canadian_Nuclear_Laboratories\NSDF\99_PROJ\1547525_NSDF_EIS\40_PROD\0000_EIS_Section_5\Section_5.3_Geology_Hydrogeology\1547525-0109-CH-0021.mxd

A significant amount of additional hydraulic property information is available based on studies throughout the CRL site in units similar to those encountered at the SSA. This information is summarized as follows:

- A total of approximately 66 historical measurements of hydraulic conductivity have been made the upper 50 m of bedrock throughout the CRL site (including within the Perch Lake Basin). The geometric mean hydraulic conductivity from these tests was 0.000000052 m/s, with a range of 0.00000000002 m/s to 0.0008 m/s (CNL 2016b). The fracture porosity of the bedrock is estimated to range from 0.0002 to 0.005 (CNL 2016b,c). A total of 42 single well response tests have been completed in the glacial till and the resulting mean hydraulic conductivity is 0.0000015 m/s with a one log standard deviation of 0.0000004 m/s to 0.0000058 m/s. The results of permeameter tests (to measure permeability) indicate that vertical hydraulic conductivity may be almost five times lower than these values. However, as only five permeameter tests have been completed and no visible layering is present in the till, this unit is not considered anisotropic (CNL 2016b). Porosity of the glacial till unit ranged from 0.19 to 0.33 (CNL 2016b).
- Testing of the basal sand and gravel has been limited due to the limited extent of the unit (see Section 5.3.1.4.2.4). Sand within this unit is characterized as a moderately to poorly sorted medium sand (CNL 2016b). The mean vertical hydraulic conductivity of the basal sand and gravel is 0.00011 m/s based on the results of two permeameter tests. The porosity of this unit has not been measured, but is assumed to be 0.38 (CNL 2016b).
- The laminated nature of the clayey silts in the Perch Lake Basin results in a degree of hydraulic conductivity anisotropy as expected. The vertical mean hydraulic conductivity of this unit, based on the results of 12 permeameter tests, is 0.0000000055 m/s, with a one log standard deviation ranging from 0.00000000046 m/s to 0.000000065 m/s. The horizontal hydraulic conductivity of this unit has been inferred from the results of six single well response tests. The mean horizontal hydraulic conductivity is 0.00000013 m/s, with a one log standard deviation ranging from 0.000000037 m/s to 0.00000043m/s. The average porosity of the clayey silt unit is 0.48 (CNL 2016b).
- The vertical mean hydraulic conductivity of the middle sand unit, based on the results of 53 permeameter tests, is 0.0000087 m/s, with a one log standard deviation ranging from 0.0000036 m/s to 0.000021 m/s. The horizontal hydraulic conductivity of this unit is 0.000078 m/s, based on the geometric mean of the results of 13 borehole dilution tests (CNL 2016b). The porosity of this unit is 0.38 (CNL 2016b).
- The vertical mean hydraulic conductivity of the interstratified silt and sand unit, based on the results of 14 permeameter tests, is 0.000000036 m/s, with a one log standard deviation ranging from 0.00000000176 m/s to 0.00000075 m/s. Due to the limited thickness of this unit, only one single well response test was completed and the mean horizontal hydraulic conductivity of 0.000018 m/s is estimated from the results of grain size analyses (CNL 2016b). The one log standard deviation of horizontal hydraulic conductivity based on the grain size analyses ranges from 0.0000055 to 0.000086 m/s. The measured porosity of this unit is 0.39 (CNL 2016b).
- The vertical mean hydraulic conductivity of the upper sand unit, based on the results of 103 permeameter tests, is 0.000014 m/s, with a one log standard deviation ranging from 0.0000053 m/s to 0.000038 m/s. The horizontal hydraulic conductivity of this unit is 0.000048 m/s, based on the geometric mean of the results of 38 borehole dilution tests (CNL 2016b). The porosity of this unit is 0.38 (CNL 2016b).

The hydraulic conductivity of the bedrock at the SSA is at the higher end of the range observed throughout the CRL site. Testing at the SSA was limited to the upper 20 m of the bedrock unit, while the range observed throughout the CRL site includes tests up to 50 m below the top of the bedrock unit. These results indicate a likely decrease in hydraulic conductivity with depth in bedrock. Overburden hydraulic conductivity at the SSA is consistent with the range in glacial till and sand units observed elsewhere on the CRL site.

Groundwater Recharge and Discharge

The bedrock ridges and topographic highs at the eastern and western boundaries of the Perch Lake Basin act as groundwater (and surface water) divides. A groundwater divide is also present to the north, along Plant Road (CNL 2016b). The shallow groundwater flow system is expected to be recharged through precipitation at these topographic highs. Groundwater discharge generally occurs at the surface water features within the low-lying portions of the Perch Lake Basin. Groundwater springs are observed in the East Swamp Stream to the north of Powerline Road and in Perch Creek, downstream of the Perch Lake Outlet. Groundwater discharge to the East Swamp Stream to the north of Powerline Road was observed to range from 25 to 770 (m^3/day) during low-flow periods (Golder 2019b). Groundwater discharge to Perch Creek during low-flow periods is estimated to be approximately 790 m^3/day based on the difference in average flow measurements between the Perch Lake Outlet and the Perch Creek weir (shown on Figure 5.3.2-1A). It is noted that the East Swamp Stream south of Powerline Road and the T-16 Stream act as sources of groundwater recharge to the upper sand unit; however, no quantitative estimates are available for these areas.

Within the SSA, groundwater to the north of the powerline cut likely discharges to surface water within the East Swamp, while groundwater to the south of the powerline cut likely discharges to the surface water within Perch Lake Swamp (or to Perch Creek for the southern portion of the SSA). No areas of groundwater discharge (i.e., seeps or springs) were noted within the observable portions of the SSA by AMEC (2017b).

Surface water within the East Swamp receives groundwater discharge from the Chemical Pit (AECL 2014) and to a lesser degree from Reactor Pit 2 (CNL 2015c). Groundwater flow from the Chemical Pit to the East Swamp follows a relatively short groundwater flow-path, with a travel time of approximately four months (CNL 2015c). Surface water within the South Swamp receives groundwater discharge from Waste Management Area A and Reactor Pit 2.

5.3.2.4.2.2 Groundwater Quality

Long-term Groundwater Quality Data

Bedrock groundwater quality throughout the CRL site was previously characterized through the sampling of a series of deep bedrock boreholes (as documented in AECL 2011 and King-Sharpe et al. 2016). It was found that variations in bedrock groundwater quality with depth are generally consistent throughout the CRL site. Shallow groundwater, to depths of up to 100 m, is dominated by sodium and bicarbonate, with pH values generally between 7 and 8. Deeper groundwater (between depths of 100 and 900 m) is consistently alkaline with a pH value of about 9. Concentrations of sodium and chloride were found to increase with depth; however, concentrations of these parameters are relatively low (total dissolved solids concentrations generally below 200 mg/L) in comparison to deep groundwater in other parts of the Canadian Shield (King-Sharpe et al. 2016). A profile of chloride concentrations in borehole CR9 indicated three distinct zones: a shallow zone (in the upper 300 m) with chloride concentrations ranging from 10 to 60 mg/L, a middle zone (from 300 to 500 m) with chloride concentrations ranging from 150 to 200 mg/L and a deep zone (from 500 to 700 m) with chloride concentrations ranging from 1,000 to 1,600 mg/L indicating slightly saline conditions (AECL 2011). It was concluded that these

relatively dilute waters are likely related to recharge of meteoric waters at the end of the last glaciation (King-Sharpe et al. 2016).

As discussed in Section 5.3.2.4.1, the GWMP at the CRL site includes annual and semi-annual water level measurements, sampling and analysis from 180 monitoring wells or boreholes at 32 sites. The proposed SSA is in a portion of the Perch Lake/Perch Creek basin that has not previously been used for the storage of waste or other materials. As a result, there is no longer-term groundwater quality data that specifically applies to the SSA; however, monitoring wells included in the GWMP are present to the east and west of the SSA.

Monitoring wells FR-3 and GD-42 are located to the east of the SSA and to the east of the bedrock-controlled ridge where the rock surface slopes towards the Ottawa River. The screened interval of well FR-3 straddles the contact between the till and the silty very fine sand, and the screen of well GD-42 is located in the fluvial silty sand. These monitoring locations are in a hydrogeological setting that is not entirely analogous to that of the SSA, but they do represent the closest conditions for which longer-term data are available. It should also be noted that well FR-3 is downgradient of the Foundation Road Landfill, making it not entirely a background monitoring location, but the data from it do not show any inorganic water quality anomalies. Well GD-42 is upgradient of a historic non-radiological waste landfill and the current non-radiological landfill (CNL 2017d).

The overall water quality at FR-3 and GD-42 is classified as diluted calcium/sodium bicarbonate, with sulphate and chloride as the other dominant anions. There is little to no reduced nitrogen in these groundwaters, and iron and manganese concentrations are also low, all showing the oxidizing character of the groundwater. Average concentrations of trace metals are all below the Ontario background groundwater quality criteria (MECP 2019). No temporal trends are evident in the data from FR-3, which consists of twice-yearly samples spanning the period from 2005 to the present. The annual samples from GD-42 extend only from 2011, although an earlier background well (GD-22, adjacent to the current non-radiological landfill) was monitored annually from 1996 to 2013 and provided data similar to GD-42, and no temporal trends are noted (CNL 2017d). Water quality from these two monitoring wells is summarized in Table 5.3.2-4; only the parameters monitored at these locations are included.

Table 5.3.2-4: Background Inorganic Water Quality Data for GWMP Wells East of the Ridge of the Site Study Area

a) Table 1: Full Depth Background Site Conditions (MECP 2019).

Std Dev = standard deviation; µS/cm = microSiemens per centimetre; µg/L = micrograms per litre; — = no value

Groundwater samples collected by the GWMP at locations FR-3 and GD-42 are also analysed for a variety of volatile organic compounds (CNL 2017d). None of these compounds have been detected in groundwaters from FR-3 or GD-42.

Radiological data from the groundwater samples collected from FR-3 and GD-42 are summarized in Tables 5.3.2-5 and 5.3.2-6, respectively. The consistent presence of tritium in samples from FR-3 and GD-42 reflects the presence of elevated concentrations of tritium in local precipitation from routine emissions through the National Research Universal reactor stack and from roof vents on facilities in the CRL main campus. Over the 12-year record for FR-3, the tritium concentration has averaged 140 becquerels per litre (Bq/L), while over the shorter record at GD-42, the average tritium concentration has been 270 Bq/L. Gross alpha activity has always been below detection limits (averaging 0.17 Bq/L) at both of these monitoring locations. Gross beta activity has always been below detection (averaging 0.36 Bq/L) in samples from GD-42; a few of the early samples from FR-3 yielded detectable quantities of beta activity (to a maximum of 1.35 Bq/L), but since 2007 gross beta activity has either been below the detection limit or less than 1 counting standard deviation above it (CNL 2017d).

Bq/L = becquerels per litre.

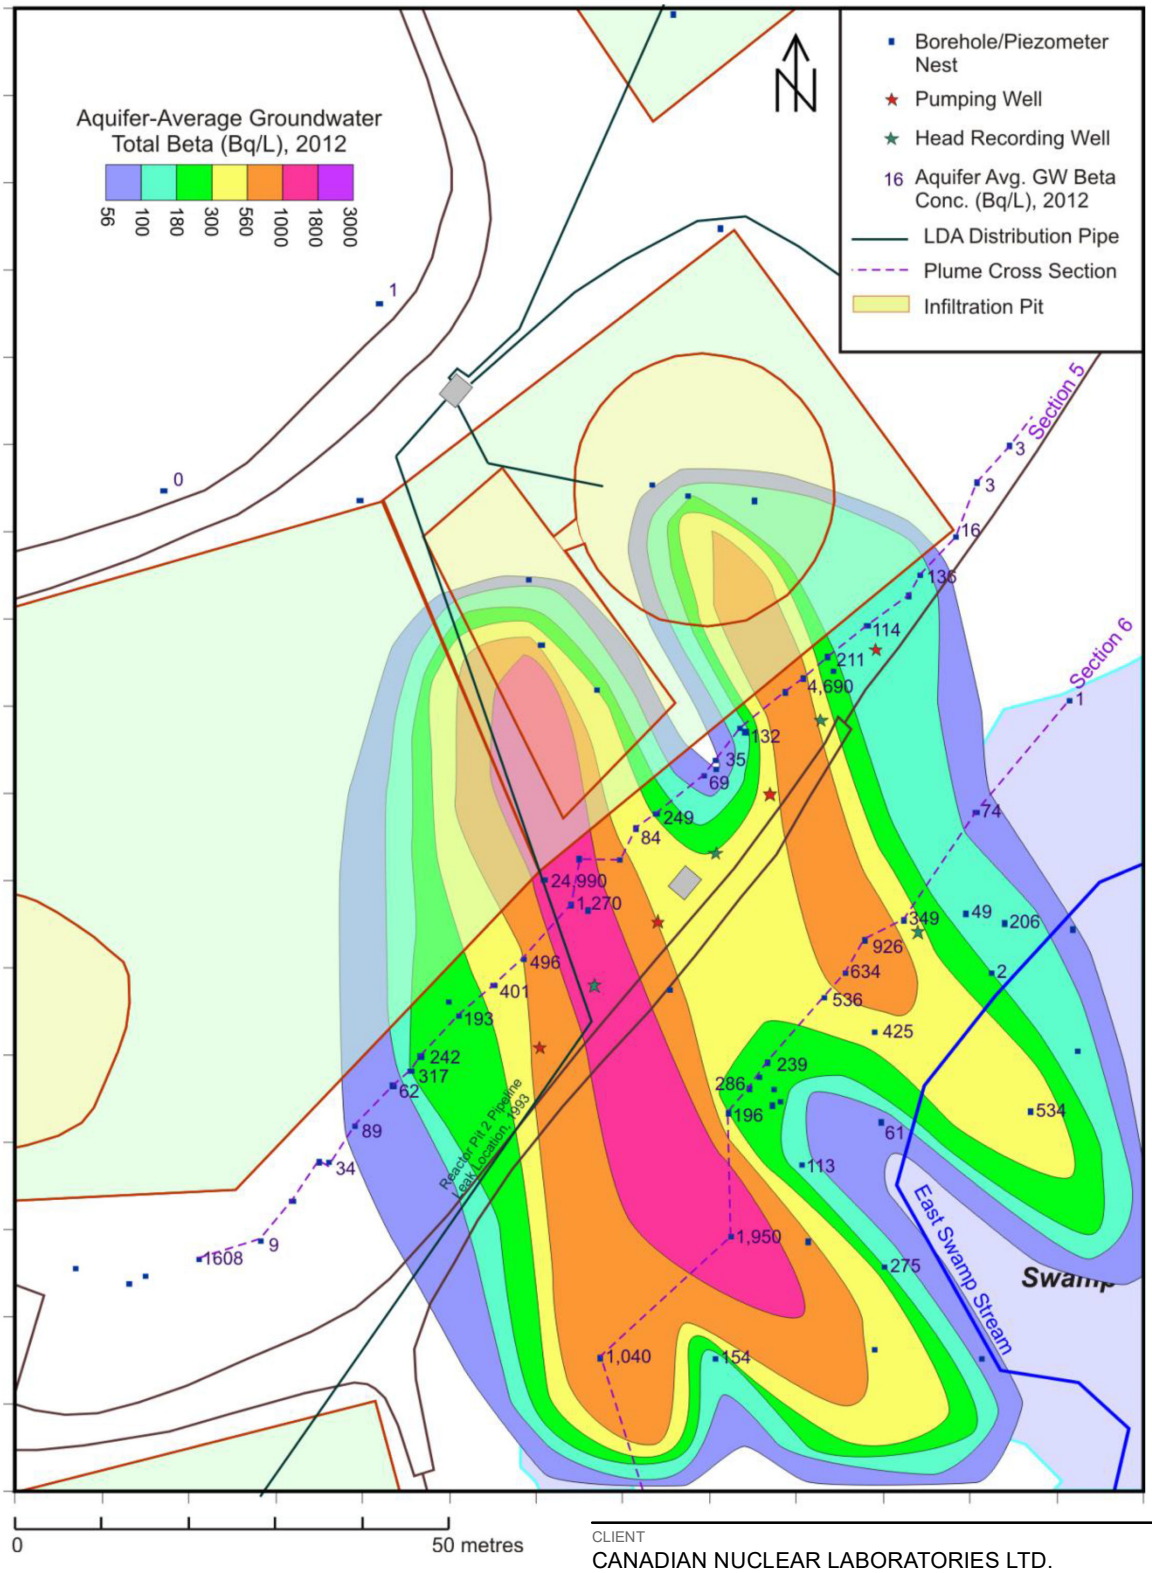
Long-term groundwater quality to the west of the SSA has been characterized through both the GWMP and a series of detailed evaluations of subsurface contaminant distributions for facilities such as the Chemical Pit, Waste Management Area A and Reactor Pit 2. It should be noted that groundwater treatment systems are in place at Waste Management Area A (passive treatment) and Chemical Pit (pump-and-treat) to facilitate the removal of strontium-90.

Downgradient of the Chemical Pit, elevated concentrations of mercury (generally less than 2 micrograms per litre [µg/L]), lead (generally less than 10 µg/L) and uranium (between 10 and 20 µg/L) have been observed in groundwater (AECL 2014). No elevated concentrations of mercury or other heavy metals have been detected downgradient of Waste Management Area A or Reactor Pit 2. Elevated chloride concentrations attributed to road salt effects have been observed in groundwater downgradient of Waste Management Area A and Reactor Pit 2. Downgradient of these facilities chloride concentrations are on the order of 500 to 1,000 mg/L (CNL 2016b). Based on results of routine monitoring conducted since 1997 for the GWMP (CNL 2018f), as well as detailed plume monitoring downgradient of the Liquid Dispersal Areas (LDAs) including Chemical Pit (AECL 2014), Reactor Pit 2, Reactor Pit 1 and Laundry Pit, it can be concluded that these facilities do not make a considerable contribution to inorganic parameter concentrations in the groundwater (CNL 2018f).

Volatile organic compounds have been detected downgradient of Waste Management Area A at concentrations generally below 10 µg/L; however, the most prevalent volatile organic compound 1,1,2,2-Tetrachloroethane has been detected at concentrations as high as 50 µg/L. With the exception of chloroform (and only for a brief period), no volatile organic compounds or extractable organic compounds were detected in groundwater downgradient of Reactor Pit 2 between 1997 and 2012 (CNL 2016b). No polycyclic aromatic hydrocarbons (PAHs), dioxins, or furans were present in the groundwater plumes from Waste Management Area A or Reactor Pit 2 (CNL 2018g). PCBs were detected at downgradient of the Chemical Pit at concentrations up to 0.7 µg/L (AECL 2014). Trace detections of dioxins and furans were also noted downgradient of the Chemical Pit in 2014 (CNL 2016c).

Downgradient of the SSA, the highest concentrations and widest variety of radioactive constituents in groundwater on the CRL site are located downgradient of the Chemical Pit in East Swamp (CNL 2018f). Total beta activity associated with strontium-90 in groundwater between the Chemical Pit and the East Swamp is on the order of 10,000 to 70,000 Bq/L. Total beta activity in the groundwater plume downgradient of the Chemical Pit (as reported in 2012) is shown on Figure 5.3.2-4. The Chemical Pit plume consists of two partially distinct plumes extending from the two chemical pits. Extension of the plumes to the northwest, northeast and southwest (upgradient and cross-gradient of the current groundwater flow direction) is likely the result of a period of groundwater mounding during the early period of operation of the pits (AECL 2014). The groundwater plume shown on Figure 5.3.2-4 is similar to the plume measure in 2002; however, total beta concentrations in the shallow groundwater in the East Swamp were two to six times higher in 2012 in comparison to 2002 (AECL 2014). Gross alpha, caesium-137 and cobalt-60 in groundwater downgradient of the chemical pit are also elevated (AECL 2014).



Downgradient of Waste Management Area A, total beta activity in groundwater was generally between 3,000 and 10,000 Bq/L with a peak of 30,000 Bq/L (CNL 2018g). Downgradient of Reactor Pit 2, total beta activity in groundwater was generally between 2,000 and 15,000 Bq/L with a peak of 22,100 Bq/L based on data from 2001, 2006, and 2011 (CNL 2016b). Total beta activity in the groundwater plume downgradient of Reactor Pit 2 (as reported in 2011) is shown on Figure 5.3.2-5. The groundwater plume downgradient of Reactor Pit 2 consists of two lobes. One lobe extends towards the south-southeast, terminating in the East Swamp Stream near Powerline Road. The second lobe extends to the south-southwest towards Perch Lake. As the groundwater plume mapping completed in 2011 was based on data from an expanded network of piezometers in comparison to mapping completed in 2001 and 2006, differences in plume extent and geometry in 2011 may be related to the increased monitoring density. Total beta activities downgradient of Reactor Pit 2 are consistently highest along the eastern perimeter; however, concentrations in this area have shown a consistently decreasing trend based on plume mapping completed in 2001, 2006 and 2011 (CNL 2016b). Ecological risk associated with radioactivity in the East Swamp is assessed every five years. Further details are provided in Section 5.7.

Investigations of contamination in East Swamp have included measurements of radioactivity in pore water (indicative of groundwater discharging to the surface water (CNL 2015c). The East Swamp has existing contamination due to groundwater plumes from the Chemical Pit and Reactor Pit 2. Since it is immediately west of the SSA, this contamination is relevant to the Base Case radioactivity characterization for the SSA. Surveying conducted in 2012 included collection and analysis of pore water at seven locations. All gross alpha concentrations in these pore water samples were less than detection limits (less than 8 Bq/L). Total beta ranged from 180 Bq/L to a maximum of 4,900 Bq/L. Strontium-90 concentrations ranged from 120 Bq/L to a maximum of 2,960 Bq/L. Ambient radiological contaminant concentrations upgradient of the waste management areas are summarized in Section 5.7.4.6.

Eight surveys of tritium concentration in groundwater have been completed within the lower Perch Lake since 1962 (1962, 1969, 1982, 1986, 1992, 2001, 2006, and 2011), with a focus on the areas downgradient of the Chemical Pit and Reactor Pit 2 (CNL, 2016b). Data collected in the surveys was used to calculate inventories of tritium within the sand aquifers, and to estimate groundwater travel times between the source areas and downgradient receptors.

Early conclusions of the tritium surveys were that tritium (and hence groundwater) transit time in the Upper Sand Aquifer between Reactor Pit 2 and Perch Lake was 5.7 years. It was also found that groundwater from Reactor Pit 2 that discharges to East Swamp Stream and then recharged to the Upper Aquifer downstream of the East Swamp Stream weir would have a 4-year transit time from RP 2 to Perch Lake. The projected groundwater transit time between Reactor Pit 2 and Perch Lake in the Middle Sand Aquifer was seven years.

The estimated total tritium mass inventory in the Lower Perch Lake Basin aquifers in 2011 (96 tera becquerels [TBq] to 112 TBq) has decreased (through decay and loss to Perch Lake) from the peak value (412 to 515 TBq), which was estimated following the 1992 survey.

Groundwater Quality Data Specific to the Site Study Area

To date, 21 wells in and adjacent to the proposed SSA have been sampled for inorganic water quality parameters and for a number of radiological parameters. The sampling locations are shown on Figure 5.3.2-1A. Nine locations were sampled in 2016 October and the results are provided in AMEC (2017a). An additional 12 samples were collected in December 2016 from a series of newly installed (Phase 2) wells (shown on Figure 5.3.2-6) and the data for those samples are presented in (AMEC 2017b). Although the wells were purged repeatedly to remove drilling water prior to sampling, at some locations drilling water may still have been present. This interpretation is based on the presence of chloroform (indicative of residual drilling water) in a number of the October 2016 samples (CNL 2017d). As such, additional sampling of all 21 wells was completed in August and September 2017 (CNL 2018f). Analysis of the 2017 sample data indicates that the effects of drilling water remain in some of the monitoring wells (particularly those that have low capacity to produce water), though in general the groundwater quality is consistent with expectations of background conditions. As discussed in CNL's *Baseline Groundwater Chemistry Evaluation of the Proposed NSDF Site (*CNL 2018f), the results of the 2017 sampling (neglecting the potential influence of drilling water) indicates the following:

- Groundwater collected from wells screened in rock had pH levels of between 5.9 and 8.0, and in groundwaters from well screened in overburden (or straddling the overburden/bedrock contact) pH levels were between 5.4 and 7.2.
- Total dissolved solids concentrations ranged from 43 to 370 mg/L. Bedrock groundwater was either dominated by sodium and bicarbonate or by calcium-magnesium bicarbonate with sulphate at concentrations between 4 and 22 mg/L as the next most abundant anion. The one exception was water from bedrock well W-7, which contained 115 mg/L of sulphate and 15 mg/L of chloride.
- Overburden groundwater chemistry is characterized as dilute calcium-magnesium bicarbonate-sulphate, although most of the wells located downgradient (west) of the East Mattawa Road also feature low levels of road salt contamination. Nitrate concentrations are generally less than 1 mg/L, with one sample containing 1.5 mg/L, and one trace detection of nitrite. Phosphate and total phosphorus were not detected in any of the samples.
- Groundwater from well SH-4 contained 6.8 mg/L of iron, indicating moderately reducing conditions in the groundwater at that location. This well is located at the margin of the Perch Lake Swamp and the top of the well screen is at the base of the surficial organic-rich sand; this may account for the relatively high iron concentration. Otherwise, iron concentrations range from 4 to 990 µg/L, indicating moderately to highly oxidizing conditions in the local flow system.
- Most trace elements are present at concentrations below the background concentration limits expected in Ontario regulation 153.4 [5]. The exceptions to this are cobalt (well W-5), copper (wells W-5 and W-2S), nickel (wells W-5 and W-2S), and zinc (wells W-7, W-8, W-2S, W-3, and W-4). Elevated copper and nickel concentrations are highly correlated with each other and moderately correlated with elevated nickel. This, coupled with the general decreases in their concentrations between 2016 and 2017, argue for a drilling-related source of these metals. The cause of the zinc anomalies remains unexplained.
- The radiological analyses of the 2017 September samples did not encounter elevated concentrations of tritium, alpha or beta emitting radionuclides, or gamma emitters

5.3.2.5 Project Interactions and Mitigation

5.3.2.5.1 Methods

This section describes the process by which interactions between NSDF Project activities and groundwater quantity and quality were identified and evaluated. Potential effects pathways are identified and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment. As such, this section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all phases of the NSDF Project. The next step in the analysis was the development of environmental design features and mitigation practices that could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects to hydrogeology. Environmental design features included NSDF Project design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the Project's engineering and environmental teams, combined with input from Project-specific or regional engagement with other interested parties. The design features and/or mitigation activities were selected considering their effectiveness for implementation and maintenance and their appropriateness within the context of the identified effects pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation:

- **No linkage:** The pathway is removed by environmental design features or mitigation such that the NSDF Project would not be expected to result in a measurable environmental change relative to Base Case values and therefore would have no residual effects on hydrogeology.
- **Secondary pathway:** The pathway could result in a measurable minor environmental change, but would have a negligible residual effect on hydrogeology relative to Base Case and/or guideline values and is not expected to contribute cumulatively to other Project effects or to the effects of other previous, existing or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway:** The pathway is likely to result in an environmental change relative to the Base Case and/or guideline values that could contribute to residual effects on hydrogeology.

Environmental design features and mitigation that have been or could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to hydrogeology through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways were carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the NSDF Project.

5.3.2.5.2 Results

Pathways through which all stages of the NSDF Project may interact with and result in changes to measurement indicators for hydrogeology is provided in Table 5.3.2-7.

Table 5.3.2-7: Pathways Analysis for the Hydrogeology Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation	Pathway Assessment
■ Project activities during the construction phase: ▪ Site preparation ▪ Construction of the ECM (including blasting of bedrock during ECM construction) ▪ Development of surface water management structures ▪ Construction of the WWTP and other support facilities ▪ On-site road and access development	■ The construction of the NSDF Project will physically alter groundwater levels and flows	■ The NSDF Project footprint has been designed to limit disturbance to the natural environment. ■ Discharge of treated effluent primarily to the exfiltration gallery area will help to reduce water loss from the hydrogeological system. ■ Discharge of treated effluent to Perch Lake via transfer line will help reduce high water table conditions in the area of the exfiltration gallery.	Primary

Table 5.3.2-7: Pathways Analysis for the Hydrogeology Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation	Pathway Assessment
■ Project activities during the construction phase (as listed above) ■ Project activities during the operations phase: ▪ Phased development of disposal cells in the ECM ▪ On-site transportation of waste and placement in the ECM ▪ Progressive closure of disposal cells and installation of final cover ▪ Operation of the WWTP ▪ Existing presence of fencing around perimeter of ECM ▪ Surface water management ▪ Domestic waste (solid and liquid) management; and, ▪ Routine operational management and monitoring activities.	■ Surface water runoff from the NSDF site can contain contaminants, which can cause changes to groundwater quality	■ Procedures for surface water management will be developed and implemented for the NSDF Project. ■ The target surface water quality objective is provided in the *Stormwater Management Planning and Design Manual* (MOE 2003). ■ Surface water from all external areas will be conveyed by ditches, swales and culverts to SWMPs that will address water quality and water quantity criteria established for the wetland receiving waters and, ultimately, Perch Creek. ■ The SWMPs are designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during the operations, closure and post-closure phases. ■ The current SWMP design reflect the overall storage required to control post-closure flows to predevelopment levels for the 2-year through to 100-year rainfall events at the site. This volume also contains the storage required for sediment control during the construction phase and water quality control during the operations phase. ■ Where drainage crosses roadways, culverts are sized to convey the 25-year design event without road overtopping ■ For each SWMP, the water level will be sampled to estimate the inflow and outflow of each pond. ■ The outlet water quality will be sampled periodically to confirm that surface water discharges meet applicable environmental criteria.	No Linkage

Table 5.3.2-7: Pathways Analysis for the Hydrogeology Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation	Pathway Assessment
■ Project activities during the operations phase	■ Leakage of leachate from the ECM may affect groundwater quality during operations	■ Design of the ECM includes base grading configured in a herringbone pattern with ridges and valleys to promote leachate transport to the leachate collection system for removal. ■ The base liner design includes primary and secondary liner systems designed to have redundancy in case of premature degradation and are a combination of natural and synthetic barrier systems. These include a compacted clay liner (CCL), two geosynthetic clay liners (GCL) and an HDPE geomembrane. ■ Clay materials were selected for the CCL and GCL components of the liner system as these materials are anticipated to maintain their function as hydraulic barriers throughout and beyond the design life of the disposal facility (i.e., 550 years). ■ The HDPE geomembrane design for the liner will be compatible with the leachate generated by the waste and provide a long service life. ■ The base liner system will include an underlying compacted clay liner to supplement the primary and secondary liner system. ■ The leachate collection system design will provide accessible access points for inspections, maintenance, repairs, and replacements. ■ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water and groundwater quality. ■ Appropriate responses to leachate leakage and contamination will be implemented as described in the Operations and Maintenance Plan and Contingency Plan.	No linkage

■ Project activities during the operations and closure phases:
  ▪ Surface water management
  ▪ Operation of the WWTP
  ▪ Discharge of treated effluent from the WWTP
	■ Discharge of treated effluent from the WWTP to the ground (via an exfiltration gallery) can cause changes to groundwater quality.	■ The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses the best available technology that is economically achievable, and capable of meeting regulatory requirements.
		■ Effluent discharge targets for wastewater discharges are protective of the environment and human health.
		  ▪ Discharge targets for non-radiological contaminants are sourced from federal and provincial guidelines for protection of aquatic biota.
		  ▪ Discharge targets for radionuclides are the Canadian Drinking Water Guidelines with the exception of tritium for which a site-specific target is developed (Section 3.4.2.5.1).
		■ Treated effluent will be sampled and confirmed that it meets the effluent discharge targets before release to the environment.
		■ When applied, the proposed exfiltration gallery will promote the exfiltration of treated water into the local groundwater regime where further retention of radioactivity by the geosphere is anticipated.
		■ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water and groundwater quality.
		■ Appropriate procedures will be in place to effectively identify spill occurrences in the event treated effluent is released to areas other than directly to the exfiltration gallery and initiate appropriate emergency responses
			Secondary

	■ Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) can cause changes to groundwater levels and flows through evapotranspiration.		Primary

Table 5.3.2-7: Pathways Analysis for the Hydrogeology Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation	Pathway Assessment
■ Project activities during the closure and post-closure phases: ▪ Installation of final cover, restoration and grading of SSA ▪ On-going long-term performance monitoring, transfer of NSDF Project into Institutional Control ▪ Liner and final cover degradation as a result of normal evolution	■ Leakage of leachate from the ECM during the post-closure phase (i.e., after Year 2400) from liner and final cover degradation as a result of normal evolution can cause changes to groundwater quality.	■ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound and minimize leachate generation. ■ The final cover system design incorporates a series of shallow, trapezoidal, riprap-lined drainage channels that are designed to convey water at low velocity. ■ The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the final cover and underlying waste materials, destabilization of the ECM structure and damage to access roads. ■ The ECM final grading and drainage plan also includes collection ditches along the top of the ECM berm road to collect side slope drainage. ■ The design life for the ECM is 550 years to meet the required time period to allow for radioactive decay of the waste placed in the facility (i.e., until it has decayed to levels that do not present a risk to the public and environment). ■ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to groundwater quality.	Primary

ECM = engineered containment mound; WWTP = Wastewater Treatment Plant; HDPE = high density polyethylene; SWMPs = surface water management ponds; SSA = Site Study Area; LLW = low-level waste.

5.3.2.5.2.1 No Linkage Pathways

The following pathways were assessed as having no measurable environmental change and hence, no linkage to residual effects on hydrogeology VCs.

- **Surface water runoff from the CRL site can contain contaminants, which can cause changes to groundwater quality.**

A variety of mitigation strategies will be implemented during all NSDF Project phases to reduce the potential for changes to soil, water and vegetation quality from surface water runoff from the SSA. These include surface water management, erosion and sediment control measures, surface water management ponds, maintenance and inspection activities, and monitoring.

Site operations include surface water management for the ECM and all external areas. Surface water from all external areas will be conveyed by ditches, swales and culverts to surface water management ponds that will address water quality and water quantity criteria established for the wetland receiving waters and, ultimately, Perch Creek. Contact water, which is exposed to waste within the ECM, will drain from the active cells of the ECM and be conveyed to the WWTP. Non-contact water drainage from completed cells and yet-to-be completed cells will be directed either by gravity to the external surface water management system or to temporary holding ponds within the ECM, then pumped to the three surface water management ponds.

During the construction phase, erosion and sediment control measures will be in place to mitigate the effects of soil erosion and sediment transport. The measures include use of erosion control blankets, as needed, to control erosion on steep slopes. Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site (i.e., CNL's Management of Land and Habitat Procedure [CNL 2018c]) will be used around disturbed areas within the SSA, where appropriate. Furthermore, an Environmental Management Plan has been developed as part of the design plan for the site outlining the erosion and sediment control measures and surface water management pond construction schedule discussed. It additionally outlines administrative protocols such as training, contractor document submissions and staffing required for effective surface water management throughout all phases of the NSDF Project.

The surface water management ponds are designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during operations, closure and post-closure. The current surface water management pond footprints reflect the overall storage required to control post-closure flows to predevelopment levels for the 2-year through to 100-year rainfall events at the site. This volume also contains the storage required for sediment control during construction and water quality control during operations. The target surface water quality objective of 60% TSS removal that provides basic water quality treatment for discharge to the receiving wetland is provided in the *Stormwater Management Planning and Design Manual* (MOE 2003). SWMP #1 will meet 80% TSS removal which will provide enhanced water quality treatment. SWMP #2 will provide 76% TSS removal and SWMP #3 will provide 60% TSS removal during operations, which will be sufficient because the receiving waterbody is a wetland and not a watercourse. The wetland functions as a sediment trap that will provide additional treatment prior to surface water reaching any watercourses in wetlands.

Roadway, sidewalk and parking lot winter maintenance activities that may release road salt to the environment, include snow plowing/shoveling and de-icing practices, salt and sand storage and snow stockpiling, and removal and disposal. The winter maintenance practices outlined in the current CRL Salt Management Plan provide for effective management of salt use and will be applied to the NSDF Project as necessary. As per the plan, the application of road salt on the NSDF site will be to be limited as salt residual within contact water and/or leachate may compromise the treatment effectiveness of the WWTP systems. Instead, alternative products in winter road management, such as a sand-stone mixtures, are currently being considered.

Facility inspections will be completed on a defined schedule to confirm that inlets and outlets are clear of debris and to confirm that there are no major erosion issues at the inlet or outlet. As well, the integrity of berms and outlet structures will be confirmed by visual inspections that would identify soil erosion. Inspections will identify sediment clean-out requirements. Sediments will be extracted by excavation equipment and will be disposed of based on sediment sampling, testing and classification according to MECP standards or stockpiled, dewatered and reused on-site for daily ECM cover operations. The sediment removal assessment follows procedures identified in the *Stormwater Management Planning and Design Manual* (MOE 2003).

The implementation of proposed mitigation at the SSA will reduce the potential for changes to soil, water and vegetation quality from runoff from the NSDF Project. This pathway was determined to have no linkage to effects to groundwater quality.

- **Leakage of leachate from the ECM may affect groundwater quality during operations and closure phases.**

Design of the ECM includes base contours that have been developed using a herringbone pattern with ridges and valleys to promote leachate transport to the leachate collection system for removal. The base liner design includes both primary and secondary liner systems that are designed to have redundancy in case of premature degradation and are a combination of natural and synthetic barrier systems. The primary liner will include a leachate collection system with the secondary liner housing a leak detection system. The composite base liner will contain perforated high density polyethylene (HDPE) collection and monitoring pipes. The HDPE geomembrane was selected as it is compatible with the leachate generated by the waste and is expected to perform as an effective hydraulic and diffusion barrier over the 550-year design life (see Section 3.4.1.4). The base liner system will include an underlying compacted clay liner to supplement the primary and secondary liner system. The leachate collection and monitoring system design will provide accessible access points for monitoring, inspections, maintenance, repairs and replacements.

The primary liner system will contain the leachate collection system and will convey leachate to a single collection point for removal from the ECM, for transfer to the WWTP for treatment. The primary liner system serves as the primary source of protection for the natural environment below the ECM from leachate migration, and will maintain a maximum depth of leachate on the geomembrane liner of less than or equal to 300 mm. The secondary liner system will contain the leak detection system, which will be used to detect leaks in the unlikely event that the primary liner system fails. The secondary liner will also protect the natural environment from leachate migration if the primary liner system fails. Leachate collected by the leachate collection system will be pumped to the on-site WWTP for treatment.

Perimeter berms consist of three main geotechnical elements or layers, each contributing to the soundness and integrity of the berm itself and the whole ECM. A slope stability analysis was completed to provide the information needed to support the design of the base slopes, sidewalls and side slopes of the ECM. The slope stability analysis addresses the range of anticipated loading conditions, under both short-term and long-term scenarios, to confirm that the slope designs will satisfy minimum factor-of-safety requirements for stability. Size and shape of the berms and each of the elements and layers were determined using a seismic design basis.

The implementation of the above mitigation will limit the potential for changes to groundwater quality from the SSA. As such, this pathway is determined to have no linkage to effects on hydrogeology.

5.3.2.5.2.2 Secondary Pathways

The following pathways were assessed as potentially having a measurable minor environmental change, but negligible residual effect on the hydrogeology VCs relative to the Base Case.

- **Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) can cause changes to groundwater quality.**

The WWTP for the NSDF Project will be a new, stand-alone facility with a new discharge point. The WWTP will treat leachate generated in the ECM during the operation phase. The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses best available technology that is economically achievable, and capable of meeting regulatory requirements. In the event that the WWTP is required beyond its design life, the unit would be refurbished to enable continued treatment of leachate, or other treatment options would be investigated.

The chemical and radionuclide concentrations in leachate are calculated using a partitioning model that assumes that the ratio of the contaminant concentration in the solid phase to the contaminant concentration in the leachate is constant. These factors conservatively estimate the leachate characteristics. The radionuclide concentrations in wastewater are a combination of the leachate concentrations and the leachate volume, combined with the contact water and decontamination volumes. The contact water is assumed to have very low radionuclide concentrations because of the effects of daily ECM cover and water management practices within the disposal cell. Similarly, decontamination water is assumed to have very low radionuclide concentrations as radionuclide loading from decontamination activities would be very low. These values present a reasonable and conservative estimate of concentrations in wastewater such that the WWTP design is capable of treating wastewater to meet effluent discharge targets.

Treated effluent from the WWTP will be released to an exfiltration gallery to promote the exfiltration of treated water into the local groundwater regime. Treated effluent will be sampled and confirmed that it meets the effluent discharge targets before release to the environment. Overall, with the implementation of the above mitigation, the discharge of treated effluent is expected to have negligible residual effects on groundwater quality.

5.3.2.5.2.3 Primary Pathways

Primary pathways identified for hydrogeology and that are evaluated in the residual effects analysis (Section 5.3.2.6) include:

- **the construction of the NSDF Project will physically alter groundwater levels and flows;**
- **discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) can cause changes to groundwater levels and flows; and**
- **leakage of leachate from the ECM during the post-closure phase (i.e., after Year 2400) from liner and final cover degradation as a result of normal evolution can cause changes to groundwater quality.**

5.3.2.6 Residual Effects Analysis

5.3.2.6.1 Groundwater Flow

5.3.2.6.1.1 Methods

Residual effects from the Application Case are evaluated based on the results of hydrogeological modelling (Golder 2019b). The hydrogeological modelling was completed to estimate the groundwater flow pathways from the ECM, and the rates of groundwater flow from the SSA to downstream receptors. This was accomplished by constructing a groundwater flow model based on the conceptual model and calibrating it to the existing conditions. Calibration involved an iterative process where steady-state model runs were completed with adjustments to the model input parameters (within acceptable ranges) until model results provided an acceptable match to observed conditions (groundwater elevations, groundwater flow directions, baseflow estimates and advective flowpaths from the Reactor Pit 2 source area). After an acceptable model calibration was achieved, the calibrated model was then modified to represent the SSA under operations and post-closure conditions and steady-state simulations were completed to evaluate the changes in groundwater flow patterns and water table elevations from the SSA.

MODFLOW-2005 (Harbaugh 2005) was used to complete the simulations. Visual MODFLOW® (Version 4.6.0.156) was used as the numeric flow engine for the simulations and the MODFLOW-NWT solver was used to solve the groundwater flow equations (Niswonger et al. 2011). MODPATH (Pollock 1989), a companion code to MODFLOW, was used to complete the particle tracking analyses necessary to illustrate the flowpaths from the WWTP and ECM. Details of the conceptual model development, modelling approach, model extent and discretization, boundary conditions, hydrostratigraphy and parameterization and model calibration are reported in Golder (2019b).

Two operations phase scenarios were evaluated with the model as follows:

- **Operations Scenario A –** Average water table conditions with approximately 11,000 m^3/yr collected within the footprint of one open cell with half of this volume applied in the model as surficial recharge at the exfiltration gallery over a four-month period.
- **Operations Scenario B –** High water table conditions with all treated effluent routed to Perch Lake (i.e., no discharge at the exfiltration gallery). It should be noted that WWTP discharge is anticipated to occur under high water table conditions when the capacity of the exfiltration gallery is limited.

For the operations scenarios, zero infiltration was applied over the footprint of the open and closed cells (precipitation is being collected via the liner) (Golder 2019b). For Operations Scenario A, water collected within the footprint of the open cell is sent to the WWTP and in part discharged in the model as surficial recharge at the exfiltration gallery. Based on groundwater flow modelling sensitivity analysis results, the exfiltration gallery capacity is estimated to be approximately 50% of the wastewater volume of 11,000 m^3/yr. Runoff is collected from the closed cells and an equivalent volume is applied as recharge in the model to the SWMPs outfall areas.

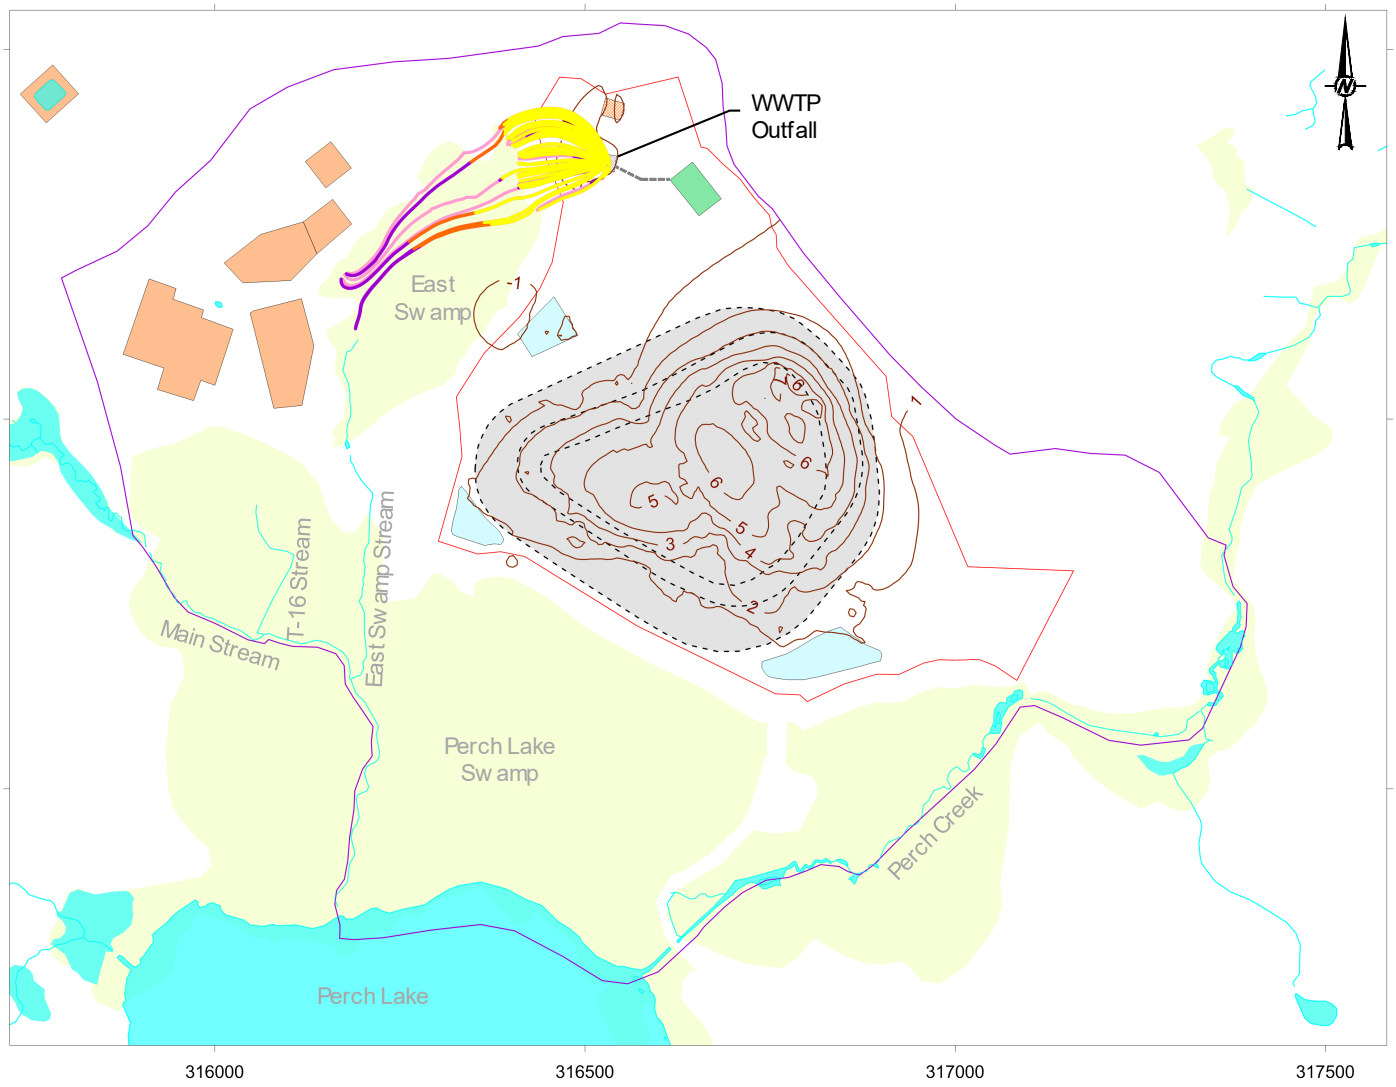
Three scenarios were evaluated using the model under post-closure conditions as summarized below:

- **Post-closure – Final Cover Intact:** A final cover is in place above the waste in the ECM, extending to the crest of the berm surrounding the facility. In this area, zero recharge is applied in the groundwater flow model. Runoff that occurs from precipitation falling on the final cover is directed to the SWMPs. It is assumed that during the post-closure phase the pond liners will no longer be effective and the runoff collecting in the ponds will infiltrate through the bottom of the pond. This scenario was evaluated with and without consideration of evapotranspiration (Golder 2019b).
- **Post-closure – Final Cover Compromised:** The final cover is assumed to be compromised resulting in infiltration through the mound into the waste materials. The base liner is assumed to remain intact resulting in a “bathtub” effect with spillover along the low point of the base liner, located in the southern portion of the ECM. For this scenario, the surface runoff from the ECM was assumed to have a negligible effect on local groundwater conditions, and no additional water was applied beyond the natural surficial recharge.
- **Post-closure – Final Cover and Liner Compromised:** Both the final cover and liner are assumed to be compromised resulting in infiltration through the waste materials and into the underlying geological materials.

5.3.2.6.1.2 Application Case Results

The main findings of the operations and post-closure phase base case simulations are discussed in Golder (2019) and summarized below:

Operations Phase



- For the operations scenario where the WWTP is operational (Scenario A), groundwater particles released from the exfiltration gallery area travel towards the west, ultimately discharging at the East Swamp. The majority of the particles discharge to the East Swamp immediately downgradient from the exfiltration gallery, whereas the remaining particles follow a deeper flowpath and discharge at the East Swamp Stream after approximately 3 years (Figure 5.3.2-7). During the operations phase, the additional infiltration applied at the exfiltration gallery results in a localized increase in water table elevation of up to 1 m compared to the current conditions.
- For Operations Scenarios A and B (i.e., scenarios where the SWMPs are lined) there was localized drawdown in the simulated water table in the vicinity of the SWMPs. The maximum drawdown for all scenarios was approximately 1 m and was limited to the area of SWMP #1. The extent of the drawdown beneath the lined ponds is limited by infiltration applied at the pond spillover location (i.e., immediately downgradient of the pond locations). (Figure 4.3 and Figure 4.4 in Golder 2019b).
- Post-closure

- For the Post-closure Scenario with an intact final cover (i.e., the scenario where runoff is directed to the SWMPs, and the pond liners are compromised), there were localized rises in the simulated water table in the vicinity of the SWMPs. The maximum rise was approximately 2 m in the vicinity of the SWMP #1 (Figure 4.5 in Golder 2019b). The extent of the rise in the water table was limited to the area located between the SWMP#1 and the boundary of East Swamp, extending approximately 50 m northwest of the SWMP #1 (as defined by the -1 m drawdown contour). The simulated change in groundwater elevation in the area of the ponds remained below ground surface (under high water table conditions). As such, the infiltration of runoff applied in the pond areas is anticipated to have a limited impact on the surface water regime.
- For the Post-closure Scenario where the final cover was assumed to be compromised the groundwater particles follow a flowpath towards the south-southeast, with the majority of particles discharging to Perch Creek (a small portion of the particles released from the westernmost and easternmost spillover area locations discharged at surface to the Perch Lake Swamp). Groundwater travel times between the spillover and Perch Creek for the majority of particles ranged from approximately 5 years to 15 years with the majority of particles arriving between approximately 7 years to 10 years (Figure 5.3.2-8). Based on the position of the water table, the groundwater particles began at the spillover location travelling through the till unit, then transitioned to the upper sand units before reaching their ultimate discharge location. An example of a conservative (i.e., early arriving) groundwater particle is illustrated on Figure 5.3.2-8 (in Golder 2019b; see the path with points marked from A through D). At this location, the groundwater particle reaches Perch Creek in approximately 6 years, and has a groundwater velocity ranging from 0.15 m/day to 0.26 m/day depending on its position in the groundwater flowpath.
- Between the ECM and Perch Creek a similar groundwater particle flowpath to that described above was simulated for the Post-Closure Scenario where the final cover and liner were assumed to be compromised. Some particles that originated from the northwestern perimeter of the ECM travelled through a longer flowpath to the west before ultimately discharging to Perch Lake. The conservative example illustrated on Figure 5.3.2-9 is based on a flowpath from the southern end of the ECM to Perch Creek, where groundwater velocities ranged from 0.12 to 0.25 m/day (depending on the position along the flowpath). Total travel times between the ECM and Perch Creek ranged from approximately 6.5 to 12 years.
- For the Post-Closure scenario with a compromised final cover and liner, the simulated groundwater pathway flow rates from the ECM location to Perch Creek were approximately 141 m^3/day. Of this, approximately 92 m^3/day originates from the ECM leachate (i.e., the spillover) and 49 m^3/day originates from upgradient sources (Figure 5.3.2-10).
- For the Post-Closure Scenario with a compromised cover and liner, the simulated groundwater pathway flow rates from the ECM location to Perch Creek were approximately 137 m^3/day (as measured from the groundwater discharge location in Perch Creek). Of this, approximately 92 m^3/day originates from the ECM leachate and 45 m^3/day originates from upgradient sources (see Figure 5.3.2-9).
- As shown on Figure 5.3.2-10, for both the operations and post-closure phases, minor localized changes to the directions of groundwater flow occur in the vicinity of the SSA as a result of captured and/or redirected water, while the overall groundwater flowpaths are the same as under current conditions (i.e., the calibrated model).

- The final cover is designed to minimize water infiltration by directing percolating or surface water away from the disposed waste. Therefore, the quantities of leachate generated within the ECM will decline over time and it is expected that leachate generation rates will eventually trend toward zero through time as the time length of the post-closure phase increases.

General

- Collection of water (infiltration and/or runoff) over the ECM footprint resulted in a lowering of the water table for all operations and post closure scenarios, though this was generally limited to the local footprint of the ECM and the area to the northeast of the ECM (i.e., towards the groundwater flow divide). The maximum simulated reduction in groundwater elevation occurred over the central and eastern portions of the ECM, to a maximum of approximately 7 m for average water table conditions and 9 m for high water table conditions. The magnitude and distribution of water table lowering was approximately equal among the high water table condition scenarios (Operations Scenario B, and the Post-closure scenarios). For the Post-Closure Scenario where the cover and liner were assumed to be compromised the recharge applied over the ECM footprint (300 mm/yr) was less than the recharge applied over the same area in the “high water table” calibrated model; this resulted in a lowering of the water table of up to approximately 8 m in the northern portion of the ECM compared to high water table conditions (see Figure 4.7 in Golder 2019b).
- The simulated water table remains beneath the threshold value of 1.5 m below the primary liner elevation for all scenarios. In general, the minimum separation distance between the liner and the simulated water table occurred in the southern portion of the ECM. It should be noted that separation between the water table and liner is important for the construction phase (for compaction of the clay liner) and that no impact on ECM performance would be expected in the event that the water table reaches the ECM during operations or in the post closure phase.
- The findings from the sensitivity simulations are discussed in Golder 2019b. In general, the overall groundwater flowpaths from the ECM to Perch Creek estimated using the sensitivity simulations are similar to the results of the calibrated model (i.e., current conditions at the site).

5.3.2.6.2 Groundwater Quality

5.3.2.6.2.1 Methods

As discussed in Section 5.3.2.5.2, during the operations phase and the beginning of the post-closure phase when the WWTP is active, leachate from the ECM will be collected and treated prior to discharge (i.e., secondary pathway). Therefore, the assessment of groundwater quality is focused on predicting changes in the groundwater contaminant concentrations from the leakage of leachate from the ECM during the post-closure phase, after the WWTP has been decommissioned. The assessment of residual effects on groundwater quality for the post-closure phase is documented in the *Post-Closure Safety Assessment Report for the NSDF Project* (PostSA; Arcadis and Quintessa 2020b) and summarized herein.

Operations Phase

During the operations phase the potential impact on groundwater is from discharge of treated wastewater to ground via the exfiltration gallery. Groundwater flow from the exfiltration gallery is through the East Swamp with groundwater discharging to East Swamp Stream. The treated effluent discharge will meet federal and provincial guidelines for protection of aquatic biota for non-radiological constituents and will meet drinking water guidelines for radiological constituents (CNL 2019c). One exception is tritium, for which the discharge target is 360,000 Bq/L. The discharge target, although exceeding the drinking water guideline for tritium of 7,000 Bq/L is well below the no-effects concentration for biota of 17,400,000 Bq/L for the CRL site (CNL 2019d).

Impacts on groundwater quality from discharge of the treated effluent to ground via the exfiltration gallery will be negligible. Effluent will be monitored to verify that discharge targets are met. The potential impacts of groundwater discharge on surface water quality (i.e., East Swamp Stream) are assessed in the surface water quality assessment (see Section 5.4.2). Surface water quality modelling confirms that environmental concentrations of contaminants are below No-effect concentrations for radiological dose to biota. For non-radiological contaminants, concentrations are maintained below the CCME's guidance levels for the protection of aquatic biota or are below levels that would result in potential adverse effects on aquatic life. Therefore, no exposure from non-radiological constituents to non-human biota is calculated.

Post-closure Phase

Groundwater quality effects were represented for the post-institutional control period, when the final cover, leachate collection and water treatment systems are no longer maintained. Prior to this period the ECM final cover and base liner will be maintained, leachate will be collected and treated, and no uncontrolled or untreated release to groundwater is expected.

Conceptually, during post-institutional control it is expected that rain may infiltrate through the final cover into the waste, resulting in leachate generation. As leachate accumulates within the ECM during this period it was assumed that leachate will enter the groundwater flowpath through either a breach in the base liner or an overtopping in the southeast portion of the ECM (Arcadis and Quintessa 2020b). With sufficient deterioration of the base liner, leachate will begin to drain from the waste at a rate faster than it can be generated and the waste will begin to dry.

For leachate released from the ECM through a breach in the base liner it was assumed that contaminants would be transported to Perch Creek via the groundwater flow system, where it would discharge and eventually flow to the Ottawa River. These scenarios are referred to as natural evolution scenarios in the PostSA (Arcadis and Quintessa 2020b).

The groundwater transport model is described in the PostSA (Arcadis and Quintessa 2020b). Groundwater transport modelling considers advective transport (i.e., the movement of contaminants in groundwater at the mean groundwater velocity) and decay. The transport modelling does not credit reduction in concentrations along the groundwater flowpath from dispersion.

5.3.2.6.2.2 Application Case Results

Operations Phase

Impacts on groundwater from discharge of treated WWTP effluent will be negligible as the treated effluent will meet effluent discharge targets that are protective of the environment and human health. The discharge targets for non-radiological contaminants are sourced from federal and provincial guidelines for protection of aquatic biota. The discharge targets for radionuclides are the Canadian Drinking Water Guidelines with the exception of tritium for which a site-specific target is developed (Section 3.4.2.5.1). Potential impacts of groundwater discharging to surface water is assessed in the surface water quality assessment (See Section 5.4.2).

Post Closure Phase

The effects on the groundwater quality during the post-closure phase is assessed with respect to the potential effect on ecological receptors in the *Ecological Risk Assessment for the NSDF Project* (EcoRA; Arcadis 2020a). The natural evolution scenarios addressed are:

- failure of the cover resulting in water overtopping the berm and moving via groundwater from the ECM to Perch Creek; and
- failure of the base liner resulting in leaching to groundwater and leachate transported via groundwater to Perch Creek.

Groundwater transport predictions are made over a 10,000-year time frame. Maximum predicted concentrations are used to assess impacts on ecological receptors.

Radionuclides

Maximum concentrations in groundwater along the flowpath from the ECM to Perch Creek are assessed and compared against no-effect concentrations for the radionuclides for ecological receptors in the EcoRA (Arcadis 2020a). Biota exposure to groundwater only occurs once groundwater has migrated into surface water. This is captured through the use of surface water data, which implicitly includes the contribution from groundwater. Despite the above, groundwater quality can also be assessed (for perspective only) using a hypothetical invertebrate (earthworm) in contact with groundwater.

Predicted radionuclide concentrations are below no-effect concentrations for all radionuclides. No residual effects are expected. Section 5.7 and Section 5.8 provide further discussion on the assessment of doses to ecological receptors and human health associated with contaminant migration from the ECM via groundwater.

Non-Radionuclides

Effects on groundwater quality for non-radiological constituents were assessed with respect to their potential effect on ecological receptors. The hypothetical receptor considered is an earthworm exposed to groundwater.

A preliminary screening was conducted to identify constituents for potential concern (COPCs) for inclusion in the assessment and is documented in the EcoRA (Arcadis 2020a). Four COPCs were identified, aluminum, copper, lead and uranium. The EcoRA eliminated aluminum and uranium from the assessment on the basis of factors

such as negligible concentrations relative to background and limited mobility. Only copper and lead screened into the assessment. For both copper and lead, predicted concentrations in groundwater were below benchmark values and no residual effects are predicted.

For the COPCs that screened in (i.e., copper and lead), the exposure assessment concluded no residual effects on ecological receptors (see Section 5.7).

5.3.2.7 Prediction Confidence and Uncertainty

Hydrogeological modelling was completed to estimate the groundwater flow pathways from the ECM and the rates of groundwater flow from the SSA to downstream receptors. To achieve this objective, a deterministic approach was used where a 3D numerical (MODFLOW) groundwater model was constructed and calibrated to represent the “best estimate” of groundwater flow conditions based on the conceptual model described above. The model was calibrated through an iterative process where steady-state model runs were completed with adjustments to the model input parameters (within acceptable ranges) until model results provided an acceptable match to observed conditions (groundwater elevations, groundwater flow directions, baseflow estimates, and advective flowpaths from the Reactor Pit 2 source area). Additional simulations were completed in order to address the uncertainty associated with the “best estimate” configuration and to examine the sensitivity of model results to some of the key controlling parameters of the hydrogeological system and assumptions made in the development of the conceptual model. A total of ten sensitivity scenarios were evaluated, which addressed potential variation in the hydraulic conductivity of the bedrock and sand units, the recharge distribution, the position of the model boundaries, and various aspects of the ECM design (e.g., the liner, blast zone, cover evapotranspiration and exfiltration gallery flow). Complete details of the model calibration and sensitivity analysis are included in Golder (2019b).

Contaminants released to groundwater are transported uniquely based on their chemical form and specific hydrogeological characteristics. A key parameter influencing the mobility of contaminants in groundwater is the water-soil distribution coefficient. The PostSA (Arcadis and Quintessa 2020b) includes a sensitivity analysis case that tests the uncertainty of the distribution coefficient on groundwater transport predictions.

To address the uncertainty associated with bedrock structures additional simulations investigated the presence of a hypothetical or undetected bedrock fracture zone in below the ECM in direct hydraulic connection with Perch Creek (as detailed in Golder, 2020a and 2020b). For the case where a hypothetical bedrock fracture zone was considered to exist under current conditions the resulting groundwater travel times between the ECM and Perch Creek were similar with the hypothetical bedrock fracture zone included as compared to the base post closure scenarios (i.e. typically 7 to 10 years for the majority of groundwater with an overall range of 5 to 15 years). Simulations completed to represent a future “activation” of a hypothetical bedrock fracture zone resulted in an earlier arrival time for a portion of the plume (i.e., an arrival time of approximately 2 to 15 years as opposed to 5 to 15 years for the base post closure scenario).

5.3.2.8 Monitoring and Follow-up

A groundwater monitoring network will be developed including installation of groundwater monitoring wells to monitor hydraulic and chemical conditions in preferential flow zones in both vertical and horizontal orientations, with an emphasis on locations downgradient from the ECM. The GWMP developed for the NSDF Project will be integrated into the overall CNL Groundwater Monitoring Program, and will be compliant with Canadian Standards Association (CSA) N288.7-15 5, *Groundwater Protection Programs at Class I Nuclear Facilities and Uranium Mines and Mills* (CSA Group 2015). The Standard indicates the need for both upgradient (background) and

downgradient monitoring well locations. The CSA N288.7-15 Standard also includes a process step where contaminants of potential concern are evaluated for sampling.

The GWMP will begin prior to operations. Base Case groundwater data will be collected and used to confirm groundwater conditions. Groundwater monitoring will continue through operations, closure and post-closure. The number of parameters and locations may change based on annual review of monitoring data. Initial sampling frequency will likely be twice per year (Spring and Fall) consistent with the existing site GWMP (Table 5.3.2-8).

Table 5.3.2-8: Monitoring and Follow up Programs for Hydrogeology

Valued Component	Project Phase and Potential Effect	Monitoring Program Objective	Conceptual Monitoring Program	Suggested Duration	Implementing Program
Hydrogeology	The NSDF Project may affect groundwater quality during operations, closure and post-closure (institutional control)	■ Verify environmental assessment predictions on groundwater from the ECM and WWTP operation ■ Verify the effectiveness of mitigation	■ Groundwater elevation measurements to determine groundwater flow direction and gradients ■ Sampling to confirm groundwater quality to detect potential releases of constituents from the ECM containment area ■ Initial sampling frequency will likely be twice per year (Spring and Fall)	■ Groundwater monitoring will continue through operations, closure and post-closure (institutional control). ■ The number of parameters, locations and frequency may change based on annual review of monitoring data	■ NSDF Project groundwater monitoring will be integrated into the overall CNL Groundwater Monitoring Program, and will be compliant with CSA N288.7-15

ECM = engineered containment mound; WWTP = Wastewater Treatment Plant.

5.3.2.9 Conclusions

Valued Components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Hydrogeology is recognized as an important component of the environment that may be affected by the NSDF Project and changes to hydrogeology could, in turn, lead to effects on other VCs selected for assessment. Acknowledging that changes to groundwater quantity and quality are considered to be important aspects of the natural and human environment, hydrogeology is referred to as an intermediate component. The hydrogeology assessment does not include the assessment of the significance of these changes; rather, results of the analysis of changes in measurement indicators for hydrogeology are provided to other disciplines for inclusion in their assessment (Table 5.3.2-3).

The residual effects on hydrogeology are related to the alteration of groundwater levels and flows due to the construction of the NSDF Project and potential changes to groundwater quantity and quality due to leakage from the ECM following post-closure activities (Table 5.3.2-9). Residual effects to groundwater from leakage of leachate from the ECM during operations are not anticipated due to the implementation of environmental design features, mitigation and operational monitoring plans. Environmental design features and mitigation implemented to reduce residual effects on groundwater quantity and quality include:

- discharge of treated effluent to the exfiltration gallery area will help to reduce water loss from the hydrogeological system;
- procedures for surface water management will be developed and implemented;
- the composite base liner design will include both primary and secondary liner systems, including a compacted clay liner, two geosynthetic clay liners which are anticipated to maintain their function as hydraulic barriers throughout and beyond the design life of the disposal facility (i.e., 550 years);
- the primary liner will include a leachate collection system with the secondary liner housing a leak detection system;
- the HDPE geomembrane was selected as it is compatible with the leachate generated by the waste and will achieve a long service life; and
- sampling of the treated effluent discharge will be completed in accordance with CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018d).

A conceptual groundwater model was developed that identified the key hydrostratigraphic units controlling groundwater flow, the hydraulic properties of these units, and the directions and rates of groundwater flow. The general findings from this assessment indicated that groundwater flow primarily occurs through the sandy overburden units (the Upper Sand, Middle Sand and Basal Sand/Till), whereas the bedrock is considered to be of low transmissivity. Groundwater flow patterns generally follow topography, with recharge occurring in the upland areas and with the ultimate discharge location at Perch Lake or Perch Creek. Groundwater recharge and discharge occurs locally in streams within the lower Perch Lake Basin.

Hydrogeological modelling was completed to estimate the groundwater flow pathways from the ECM and the rates of groundwater flow from the SSA to downstream receptors. This was accomplished by constructing a groundwater flow model based on the conceptual model and calibrating it to the existing conditions. In general, minor localized changes to the directions of groundwater flow are predicted to occur in the vicinity of the SSA as a result of captured and/or redirected water, while the overall groundwater flowpaths are the same as under current conditions. However, with final cover placement, quantities of leachate generated within the ECM will decline and it is expected that leachate generation rates will eventually trend toward zero throughout post-closure. The flux of radionuclides from the ECM to groundwater through the post-closure phase was calculated. The discharge of this groundwater to surface water in Perch Creek was included in an evaluation of doses to receptors.

Early waste management practices included burying LLW in sand trenches with no engineered barriers thus impacting the surrounding soils as well as the groundwater within the Perch Lake Basin. Although appropriate risk management actions have taken place (i.e., interception and treatment of strontium-90 groundwater plumes), large scale remediation of the contamination sources may be necessary to ensure appropriate long-term management of this legacy waste. The NSDF Project design is based on containment and isolation of the LLW inventory from the environment including engineered barriers such as the base liner system which mitigates impacts to the surrounding groundwater. Therefore, decommissioning and environmental remediation activities, which will generate waste for disposal in the ECM, are anticipated to positively affect measurement indicators for hydrogeology such as groundwater quality outside the SSA.

A groundwater monitoring network will be developed including installation of groundwater monitoring wells to monitor hydraulic and chemical conditions in preferential flow zones in both vertical and horizontal orientations along the critical flow pathways, with an emphasis on locations downgradient of the ECM. The main emphasis of the GWMP is to monitor locations that are downgradient from the ECM. The GWMP developed for the NSDF Project will be integrated into the overall CNL GWMP, and will be compliant with CSA N288.7-15. Groundwater monitoring will continue through operations, closure and post-closure.

Table 5.3.2-9: Summary of Predicted Residual Adverse Effects for Hydrogeology Valued Components

Valued Components	Residual Adverse Effects	Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation
Groundwater quantity	The construction of the NSDF Project will physically alter groundwater levels and flows.	Construction through to post-closure	■ NSDF Project activities during the construction phase: ▪ Site preparation ▪ Construction of the ECM ▪ Development of surface water management structures ▪ Construction of the WWTP and other support facilities ▪ On-site road and access development.	■ The NSDF Project has been designed to limit disturbance to the natural environment. ■ Discharge of treated effluent primarily to the exfiltration gallery area will help to reduce water loss from the hydrogeological system. ■ Discharge of treated effluent to Perch Lake via pipeline will help reduce high water table conditions in the area of the exfiltration gallery.

Table 5.3.2-9: Summary of Predicted Residual Adverse Effects for Hydrogeology Valued Components

Valued Components	Residual Adverse Effects	Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation

Groundwater quality	Adverse changes to groundwater quality from the discharge of treated effluent from the WWTP to the exfiltration gallery.	Operations	■ Discharge of treated effluent to the exfiltration gallery.	■ The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses the best available technology that is economically achievable, and capable of meeting regulatory requirements.
				■ Effluent discharge targets for wastewater discharges are protective of the environment and human health.
				  ■ Discharge targets for non-radiological contaminants are sourced from federal and provincial guidelines for protection of aquatic biota.
				  ■ Discharge targets for radionuclides are the Canadian Drinking Water Guidelines with the exception of tritium for which a site-specific target is developed (Section 3.4.2.5.1).
				■ Treated effluent will be sampled and confirmed that it meets the effluent discharge targets before release to the environment.
				■ When applied, the proposed exfiltration gallery will promote the exfiltration of treated water into the local groundwater regime where further retention of radioactivity by the geosphere is anticipated.
				■ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water and groundwater quality.
				■ Appropriate procedures will be in place to effectively identify spill occurrences in the event treated effluent is released to areas other than directly to the exfiltration gallery and initiate appropriate emergency responses.

Table 5.3.2-9: Summary of Predicted Residual Adverse Effects for Hydrogeology Valued Components

Valued Components	Residual Adverse Effects	Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation
Groundwater quantity and quality	Leakage of leachate from the ECM during the post-closure phase (i.e., after Year 2400) from liner and final cover degradation as a result of normal evolution can cause changes to groundwater quality.	Closure and Post-closure	■ Installation of final cover, restoration and grading of Site Study Area (SSA). ■ On-going long-term performance monitoring, transfer of NSDF Project into Institutional Control. ■ Liner and final cover degradation as a result of normal evolution.	■ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound and minimize leachate generation. ■ The final cover system design incorporates a series of shallow, trapezoidal, riprap-lined drainage channels that are designed to convey water at low velocity. ■ The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the final cover and underlying waste materials, destabilization of the ECM structure and damage to access roads. ■ The ECM final grading and drainage plan also includes collection ditches along the top of the ECM berm road to collect side slope drainage. ■ The design life for the ECM is 550 years to meet the required time period to allow for radioactive decay of the waste placed in the facility (i.e., until it has decayed to levels that do not present a risk to the public and environment). ■ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to groundwater quality.

ECM = engineered containment mound; LLW = low-level waste

This page intentionally left blank

5.4 Surface Water Environment

This section of the Environmental Impact Statement for the Canadian Nuclear Laboratories (CNL) Near Surface Disposal Facility (NSDF) Project seeks to understand and characterize potential residual effects of the NSDF Project and other previous, existing, and reasonably foreseeable developments on the physical aspects of the environment. Section 5.4.1 focuses on hydrology and Section 5.4.2 focuses on surface water quality.

5.4.1 Hydrology

5.4.1.1 Scope of the Assessment

This section focuses on hydrology, which includes surface water quantity, flow and direction. It considers those surface water features in the vicinity of the NSDF Project including wetlands, streams, creeks, lakes and rivers. The hydrology assessment follows the overall environmental assessment approach and methods described in Section 5.1. The assessment was completed following the key steps listed below:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** for the hydrology assessment (refer to Sections 5.4.1.2 Valued Components and Section 5.4.1.3 Assessment Boundaries). The VCs and measurement indicators used to assess Project-related changes to hydrology, are described, along with the spatial and temporal boundaries at which the assessment occurred and the assessment cases considered.
- **Step 2 – Describe the existing conditions** (refer to Section 5.4.1.4 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation). The existing conditions provide a reference to which the effects of the NSDF Project can be compared.
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 5.4.1.5 Project Interactions and Mitigation). The NSDF Project components and/or activities with the potential to affect hydrology are identified and mitigation developed to limit or avoid effects is presented. A pathways analysis is then used to focus further assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects to hydrology after incorporating mitigation are carried forward to Step 4 for further analysis and residual effects characterization.
- **Step 4 – Present the methods and results of the residual effects analysis** (refer to Section 5.4.1.6 Residual Effects Analysis). This section outlines the methods used to predict and characterize residual effects to hydrology from primary effect pathways. The analysis results are also presented including the characterization of incremental effects from the NSDF Project, as well as cumulative effects of the NSDF Project in combination with other reasonably foreseeable developments (if applicable). A key outcome of this section is the predicted changes to surface water quantity that are passed on to other disciplines for their assessment.

- **Step 5 – Describe the level of certainty and management of uncertainty** (refer to Section 5.4.1.7 Prediction Confidence and Uncertainty). Evaluate the available literature, data and models used for the assessment, and describe the level of certainty that can be placed on predicted residual effects. This section will also identify how the uncertainty has been managed so that the effects are not underestimated.
- **Step 6 - Classify and determine the significance of the predicted residual effects**. This step was not required as the hydrology VC is an intermediate component which does not include an assessment endpoint to determine significance.
- **Step 7 – Identify monitoring and follow-up** required to confirm effects predictions and address uncertainty (refer to Section 5.4.1.8 Monitoring and Follow-up).
- **Step 8 – Present a consolidated summary of conclusions** and outcomes of the assessment of residual effects on hydrology (refer to Section 5.4.1.9 Conclusions).

Section 5.4.1 also describes how the input from engagement influenced the scope of the hydrology assessment. Information and areas of interest raised by the public, communities of interest, and Indigenous Peoples during engagement that influenced the scope of the hydrology assessment are summarized in Table 5.4.1-1. Other general areas of interest and questions raised during the engagement that pertain to the surface water environment assessment (if any) are documented in CNL's Indigenous Engagement Report (CNL 2021) and CNL's Stakeholder's Activity Reports (CNL 2017a,b, 2019a).

Table 5.4.1-1: Summary of Areas of Interest Raised During Engagement Activities that Influenced the Scope of the Hydrology Assessment

Areas of Interest	How the Area of Interest was Included in the Assessment
Potential for contamination in the Ottawa River from the NSDF Project.	The spatial boundaries of the assessment were selected to include consideration of potential effects to the Ottawa River. Surface water quality modelling was completed to estimate contaminant concentrations within the Perch Creek basin, which flows directly into the Ottawa River. Meeting effluent discharge targets within the Perch Creek and Perch Lake is protective of the Ottawa River. The Regional Study Area was expanded to include a reach of the Ottawa River extending 8 km downstream of CRL in response to comments received from Indigenous communities and organizations, and the public.

5.4.1.2 Valued Components

Valued Components (VCs) refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Hydrology, which includes surface water quantity, flow and direction, is recognized as an important component of the environment that may be affected by the NSDF Project, and changes to hydrology could, in turn, lead to effects on other VCs selected for assessment. For example, changes to the characteristics of hydrology, such as water quantity, have a large influence on the local and regional diversity, contributing to the spatial and temporal distribution of aquatic and terrestrial ecosystems. Subsequently, changes to these characteristics by NSDF Project activities could affect fish and wildlife, and land and resource use (Table 5.4.1-2).

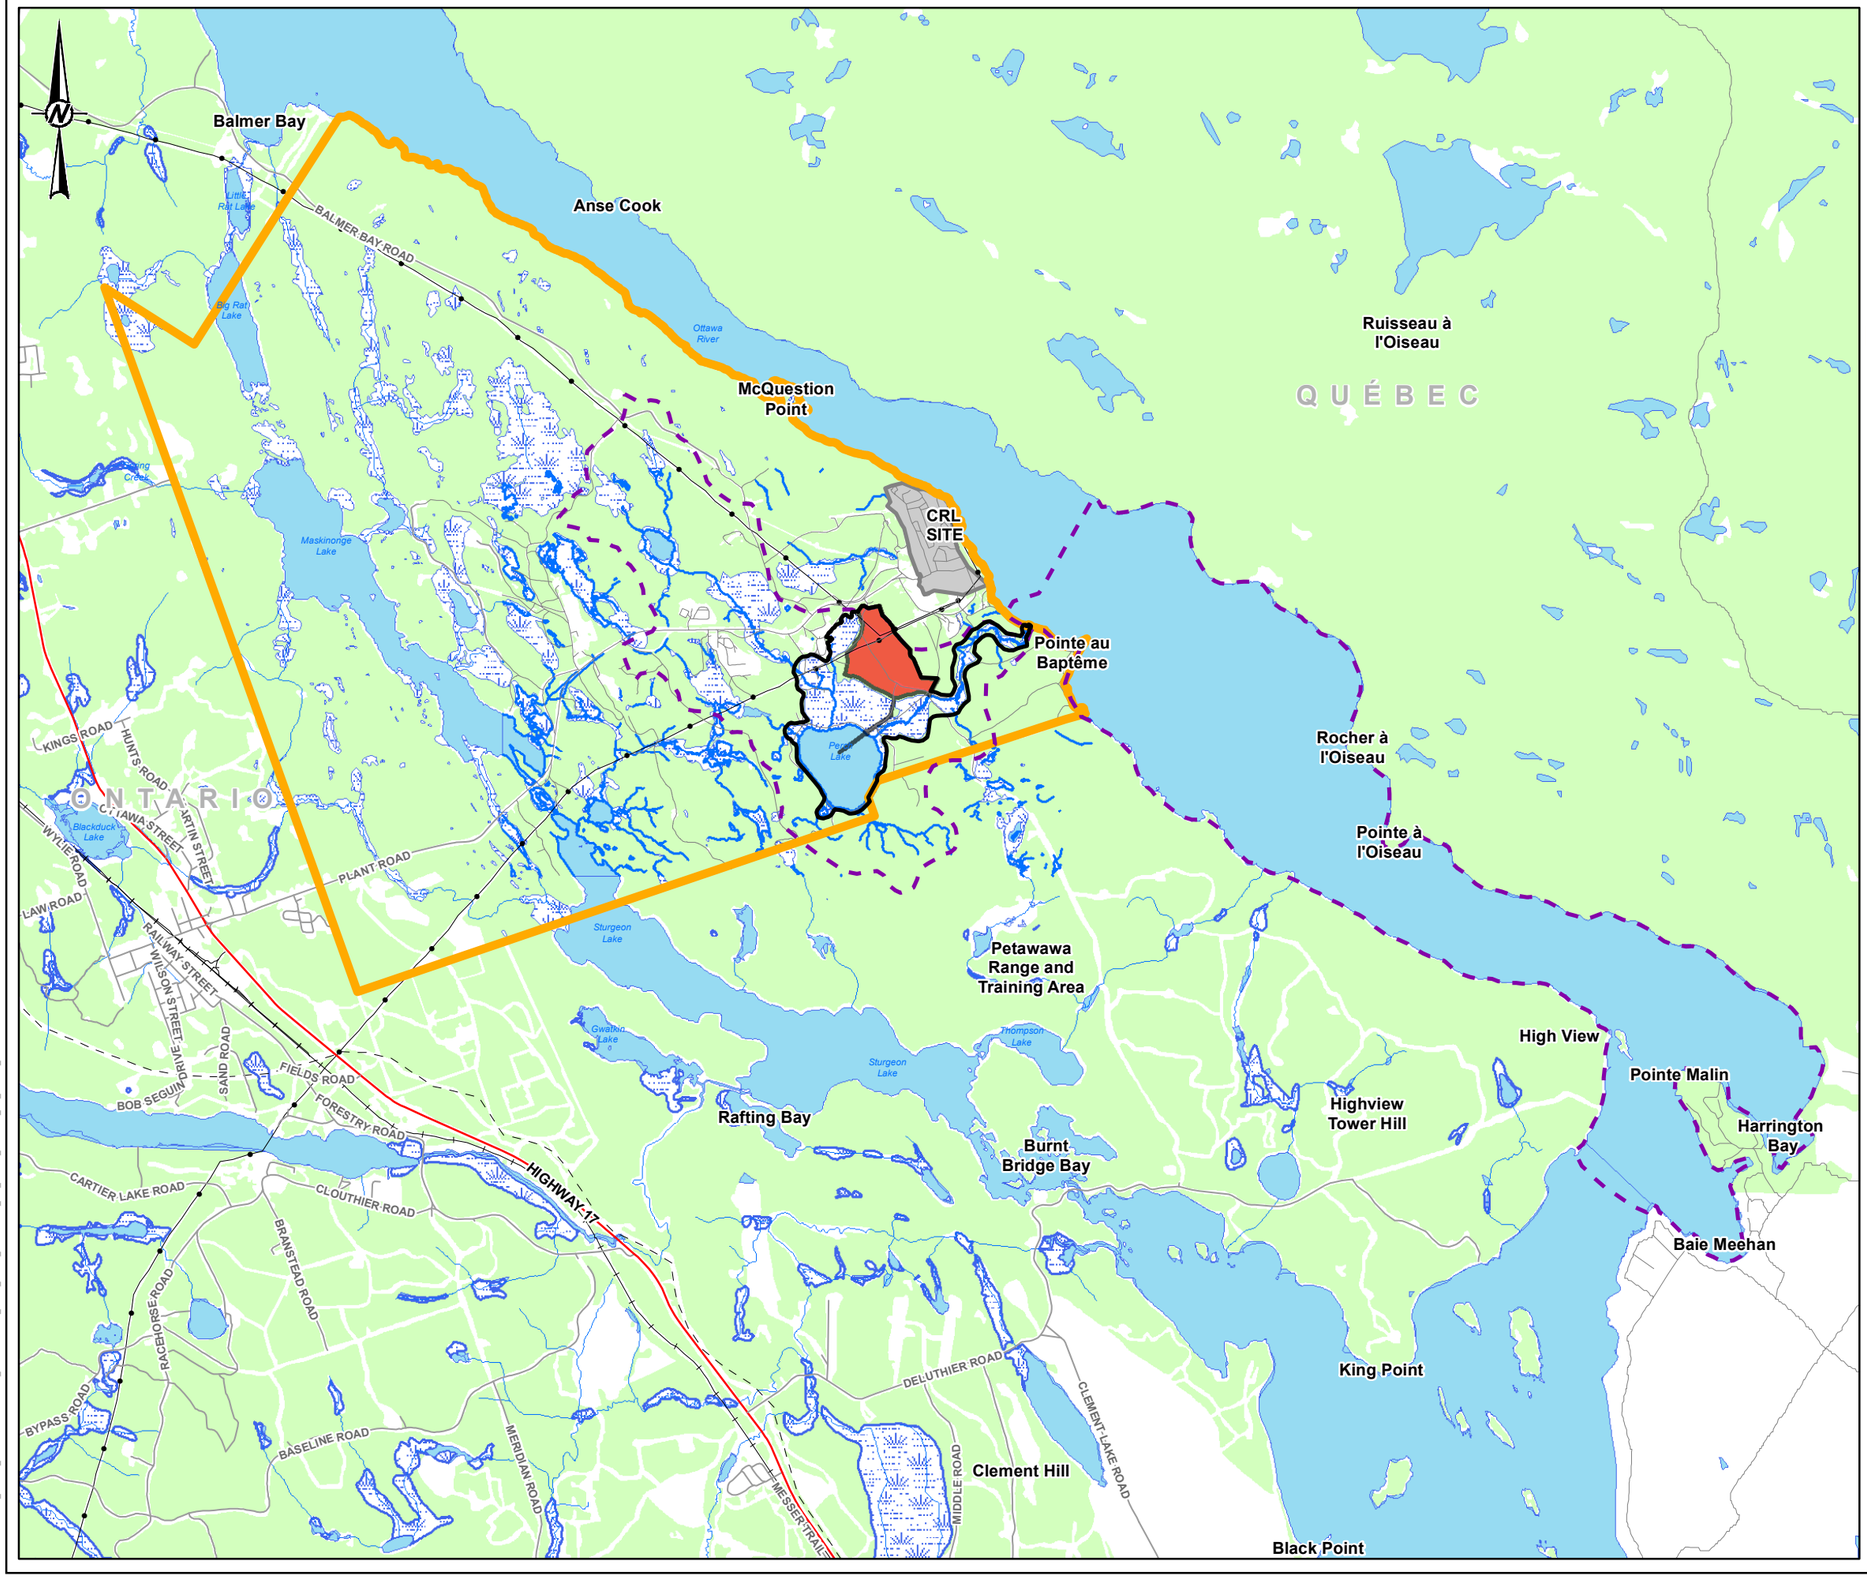
Table 5.4.1-2: Valued Components for Hydrology Assessment

Valued Component	Rationale for Selection
Hydrology	■ The NSDF Project may affect existing availability of the spatial and temporal distribution of water quantity for aquatic and terrestrial biodiversity, which can in turn affect land and resource use. ■ Societal values concerning changes in water quantity are an important consideration in understanding potential effects of the NSDF Project.

Acknowledging that changes to hydrology are considered to be important aspects of the natural and human environment, hydrology is referred to as an intermediate component (i.e., it does not have an assessment endpoint). Changes to intermediate component VCs must be understood to facilitate assessment of project interactions. The hydrology assessment, therefore, is analyzed for incremental and cumulative (if applicable) changes in the relevant measurement indicators associated with hydrology (Table 5.4.1-3). The changes are characterized in terms of magnitude, duration and geographic extent, but are not classified using rankings for effects criteria. The hydrology assessment also does not include the assessment of the significance of these changes; rather, results of the analysis of changes in measurement indicators for hydrology are provided to other disciplines for inclusion in their assessment (Table 5.4.1-3).

Table 5.4.1-3: Measurement Indicators for the Hydrology Assessment

Valued Component	Measurement Indicators	Discipline Assessments where Effects on Hydrology are Considered
Hydrology	■ Peak flow rates, time to peak flow and total runoff volumes ■ Stream channel parameters (e.g., channel depths, widths) and shoreline integrity	■ Section 5.4.2 Surface Water Quality ■ Section 5.5 Aquatic Environment ■ Section 5.6 Terrestrial Environment ■ Section 5.9 Land and Resource Use



5.4.1.3 Assessment Boundaries

5.4.1.3.1 Spatial Boundaries

The spatial boundaries selected for the hydrology assessment were chosen because they permit description of existing conditions in sufficient detail to enable potential Project-VC interactions and effects to be identified, understood and assessed, including understanding and assessing the contribution of the NSDF Project to cumulative effects. The spatial boundaries selected for the hydrology are consistent with the surface water quality and aquatic biodiversity assessment are presented on Figure 5.4.1-1 and are described below:

- **Site Study Area (SSA):** The SSA is the NSDF Project footprint (i.e., where NSDF Project activities would be undertaken, including the NSDF Project's proposed facilities, buildings and infrastructure).
- **Local Study Area (LSA):** The LSA is selected in consideration of the NSDF Project footprint and the spatial extent of potential direct effects of the NSDF Project on the VCs. The LSA includes the SSA and is bounded by Perch Lake and Perch Creek, and adjacent wetlands and swamps.
- **Regional Study Area (RSA):** The RSA is defined as the area within which the potential effects of the NSDF Project may interact with the effects of other existing or reasonably foreseeable developments. The RSA for hydrology is determined by the spatial extent of the Perch Creek and Perch Lake Watershed. A portion of the Ottawa River (i.e., roughly 8 km downstream in the Ottawa River to Harrington Bay) is also included in the RSA.

5.4.1.3.2 Temporal Boundaries

- Temporal boundaries (i.e., project phases) establish the timeframe during which NSDF Project effects are assessed. The temporal boundary represents the timeframe during which project activities are actively occurring, and considers the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a project activity or stressor (which is related to the project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the NSDF Project or if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., a residual effect that lasts for thousands of years). The following phases were identified for the NSDF Project:
- **Construction Phase**: This phase includes site preparation and all activities associated with the construction of the NSDF Project. This phase includes activities such as installing the necessary supporting and/or ancillary facilities and infrastructure to facilitate NSDF Project operations, inactive commissioning and systems testing, and transportation of construction materials. Construction activities are expected take place from 2022 to 2024.
- **Operations Phase**: This phase includes all activities associated with waste placement, water management, WWTP operations, vehicle movements into and from the SSA and maintenance activities. Operations activities are expected to last approximately 50 years (i.e., 2025 to 2070).
- **Closure Phase:** This phase includes activities necessary to complete the installation of the final cover and implementation of long-term monitoring. Closure activities are expected to start in 2070 and continue through to 2100, after which the NSDF Project will transfer into the post-closure phase.
- **Post-closure Phase:** This phase has two discrete periods: institutional control and post-institutional control. The institutional control period includes implementation of controls throughout 2100 to 2400 (i.e., 300 years). During institutional control, environmental monitoring will continue to demonstrate compliance with the environmental assessment predictions. Post-institutional control occurs after year 2400 and continues indefinitely.

The temporal boundaries for the hydrology assessment include consideration of effects of the NSDF Project during the construction, operations and post-closure phases as it is during these phases that the NSDF footprint will have the largest change on the existing surface drainage and peak flows.

5.4.1.3.3 Assessment Cases

The assessment cases considered in the hydrology assessment are the Base Case and Application Case (the Reasonably Foreseeable Developments Case has not been considered for the reasons outlined below):

- **Base Case –** This scenario represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural, mining, and residential and recreational development. Current effects from the existing Chalk River Laboratories (CRL) facilities and operations, for example, are considered part of the Base Case.
- **Application Case –** This scenario represents predictions of the effects of the Base Case combined with the effects that may result from the NSDF Project. The Application Case considers potential effects from the NSDF Project during construction through to the closure and post-closure phases.

- **Reasonably Foreseeable Development (RFD) Case –** This scenario represents predictions of the cumulative effects of the Application Case, which includes the Base Case, plus projects that are currently under application review or that have officially entered a regulatory application process, and are therefore considered reasonably foreseeable (see Section 8.0 Summary of Cumulative Effects for descriptions of RFDs). Because RFDs will either have no spatial overlap or are likely to positively affect hydrology, an RFD Case is not presented as part of this assessment. RFDs expected in the CRL site (i.e., the RSA) include new and upgrades to research and development facilities, construction and operation of a Small Modular Reactor (SMR), new support infrastructure, and on-going decommissioning and environmental remediation activities. New support infrastructure and research and development facilities will generally be located within existing disturbed areas on the CRL site (i.e., minimal disturbance to largely undeveloped areas). Through application of effective erosion and sediment control practices, and surface water management systems, potential effects from revitalization activities and through development of the SMR are not expected to spatially overlap with potential effects to surface water quantity from the NSDF Project. No process water intakes from or discharges to surface or groundwater are identified in the description of the planned SMR (Global First Power 2019). The end state plan for the CRL site is to return lands disturbed by site activities to a condition that is physically stable and safe in keeping with the land use and landscape of the day. Therefore, decommissioning and environmental remediation activities are anticipated to positively affect hydrology.

5.4.1.4 Description of the Environment

5.4.1.4.1 Methods

Existing hydrological conditions (e.g., flow, direction, quantity, velocity) within and surrounding the CRL site, including the Ottawa River, were obtained from published hydrology reports and available baseline data. Regional and local hydrology described in the 2010 *Environmental Impact Statement for Atomic Energy of Canada Limited for the National Research Universal Reactor Long-Term Management Project* (SENES 2010) is summarized in the following sections. The hydrological baseline conditions for Perch Lake and Perch Creek are also presented. Rainfall data were sourced from the Ministry of Transportation. All hydrology modelling results and design information presented in this section can be found in the NSDF *Surface Water Management Plan* (AECOM 2019).

5.4.1.4.2 Results

5.4.1.4.2.1 Drainage Conditions

The drainage basin slopes from a highpoint ridge (elevation 195 metres above sea level [masl]) along the eastern limit of the CRL site, westerly towards Perch Lake and the wetlands located on the western boundary (elevation 160 masl). CNL completed previous studies in support of proposed geological waste management facilities at the CRL site in which data on the geological environment were compiled and used to develop a descriptive geosphere model of the site. These studies are documented in CNL's *Geologic Waste Management Facility Descriptive Geosphere Site Model Report Phase 1* (CNL 2016a) and *Geologic Waste Management Facility Integrated Geosynthesis Report Phase 1* (CNL 2016b). These studies describe the surface soils as primarily fine sands underlain by glacial tills (Golder 2016). Currently, much of the area is heavily treed and undisturbed, indicating good infiltration capacity. Overburden depth to bedrock ranges from less than 1 m up to 24 m in thickness (Golder 2019a). Groundwater table depth varied significantly throughout the site and varies seasonally. The average groundwater depths ranged from 0.06 m in the vicinity of the wetlands to 15.95 m in the northern section of the SSA which corresponds to the thickest overburden (Golder 2019a). A depiction of the drainage basin is presented on Figure 5.4.1-2. Surface water flow is generally dispersed as shallow sheet flow, with the only channel flow occurring within the wetlands at the southern and western boundaries of the basin.

5.4.1.4.2.2 Ottawa River

The CRL site is located entirely within the Ottawa River watershed, which has several sub-watersheds (i.e., drainage basins). Chalk River and the Petawawa River are the two major tributaries near the CRL site. Approximately 12% of the CRL site drains directly into the Ottawa River (Figure 5.4.1-2). The confluence of the Petawawa River and the Ottawa River is approximately 20 km downstream of the CRL site.

Daily flow measurements of the Ottawa River taken at the Des-Joachims hydroelectric dam (approximately 32 km upstream of the NSDF site) were obtained from the Ottawa River Regulation Planning Board for the time period of June 1950 to December 2016 (Table 5.4.1-4). To account for seasonal variations, to exclude data outliers and to ensure an appropriate level of conservatism, the 5th percentile and 95th percentile data values were used for the minimum and maximum values respectively. The resulting flow rates are 336 m^3/s (minimum flow rate) and 1,560 m^3/s (maximum flow rate). The mean flow rate was calculated to be 807 m^3/s. The flow past the Des-Joachims hydroelectric dam is regulated according to the demands of the generating station.

The water level in the Ottawa River along the CRL site boundary is controlled by a set of rapids at Cotnam Island (located approximately 40 km downstream of the CRL site boundary), and by adjustments to the discharge rate at the Des-Joachims hydroelectric dam. The Ottawa River water levels at the CRL site boundary have also been measured daily since 1950. The highest recorded river level at the CRL site boundary (as of April 2007) is 113.6 masl, which was recorded in April 1979 (AECL 2008). The lowest level is 110.6 masl recorded in August 1971 (as of June 2002).

Table 5.4.1-4: Summary of Ottawa River Flows at the Des-Joachims Hydroelectric Dam and Water Level Data at Pembroke (1950-2016)

Flow Data	Flow Rate (m^3/s)	Water Level Data	Water Level (masl)	Date of Occurrence for Water Level
Average Flow Rate	807	Average Water Level	111.5	not applicable
Maximum Monthly (95^{th} Percentile)	1,560	Maximum Monthly	113.1	May 1960
Minimum Monthly (5^{th} Percentile)	336	Minimum Monthly	110.8	August 2005

masl = metres above sea level.

Ottawa River water level data were also sourced from the Pembroke Station, which is approximately 36 km downstream of the CRL site. Water level data has been collected daily between 1950 and 2019 and is presented as an average over a monthly period in Appendix 5.4-1 (Ottawa River Elevations Recorded at Pembroke Station between 1950 and 2019). Review of the data shows that lowest water levels are typically recorded in September, while highest water levels are usually observed in May. The lowest monthly water level recorded was 110.8 masl in August 2005, while the highest monthly water level recorded was 113.1 masl in May 1960. The average water elevation recorded at this station is 111.5 masl.

5.4.1.4.2.3 Perch Creek and Perch Lake Watershed

The NSDF Project is located entirely within the Perch Creek and Perch Lake Watershed (Figure 5.4.1-2), at the southern edge of the Canadian Shield in the Ottawa River Valley (Robertson and Barry 1985). Ground surface elevations range from a low of approximately 156 masl within the low-lying and relatively flat terrain bordering the north side of Perch Lake, to a high of 197 masl along the crest of the ridge to the east of East Mattawa Road that separates the Perch Lake and Ottawa River drainage basins (Golder 2016). The watershed includes Waste Management Areas A and B as well as the Liquid Dispersal Areas which encompasses the Reactor Pits, the Laundry Pit and the Chemical Pit. From Perch Lake, surface water (Perch Creek) flows in a north-easterly direction through Perch Creek to its confluence with the Ottawa River. The Perch Creek basin drains approximately 18% of CRL site area and drains to the Ottawa River through Perch Lake and Perch Creek (CNL 2016c).

The Perch Creek and Perch Lake Watershed is defined by seven-basins, six of which drain into Perch Lake (Robertson and Barry 1985) (Figure 5.4.1-2). Basins 1 to 5 drain into the lake through surface streams with discernible channels (Sub-basins 1 to 5) while the sixth basin (Sub-basin B) lacks a discernible stream channel for drainage into Perch Lake. The seventh basin (Border) drains through Perch Creek below the lake outlet and into the Ottawa River. Sub-basin elevation and areas are provided in Table 5.4.1-5.

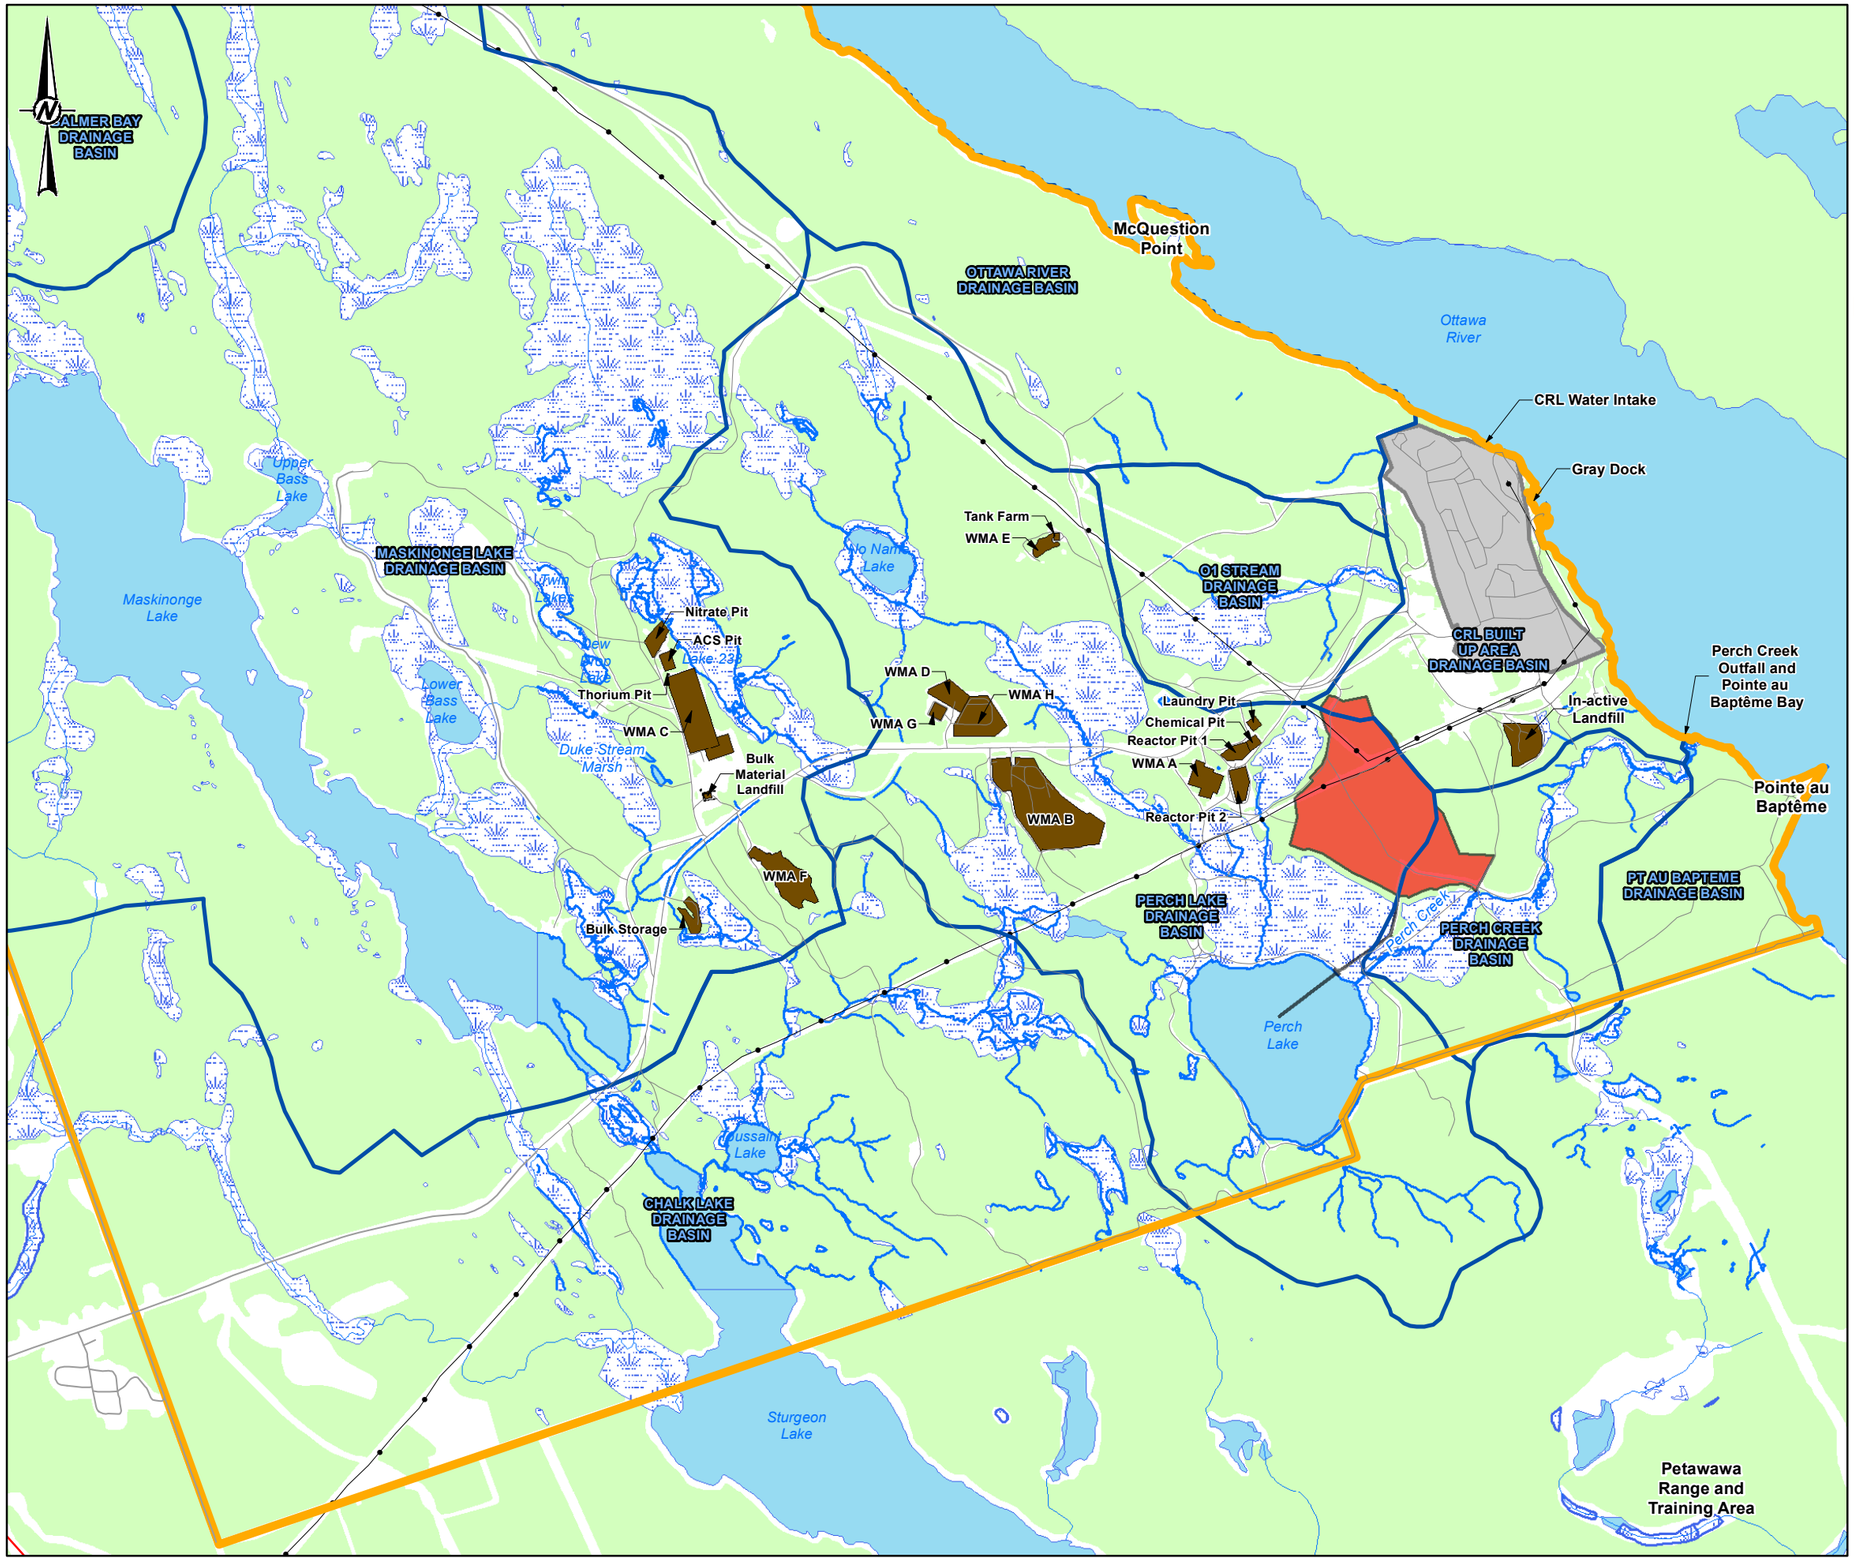

Table 5.4.1-5: Perch Creek Sub-Basin Weir Elevations and Areas

Basin	Elevation[(a)] (masl)	Area (km^2)	Area (ha)
Sub-basin 1	156.27	0.93	93
Sub-basin 2	156.37	3.6	360
Sub-basin 3	156.43	0.81	81
Sub-basin 4	156.28	0.24	24
Sub-basin 5	157.52	0.11	11
Sub-basin B	ND	0.093	9.3
Border	ND	0.056	5.6
Perch Lake	155.95	0.46	46
Perch Creek	ND	1.02	102
Totals			
To lake		5.84	584
To lake outlet		6.30	630
To basin outlet		7.3	730

This page left intentionally blank

Physical characteristics of Perch Lake such as wetted area, maximum depth and average depth were measured by Robertson and Barry (1985) and via a series of studies carried out between 1965 and 1974 (Barry 1975). More recently, Perch Lake was surveyed from June 18 to 22, 2018 in the creation of an updated bathymetry map. The bathymetry map relied upon data points measured from a combination of a single-beam sonar unit and a GPS unit. Depth profiles were measured along the latitudinal width and longitudinal length of Perch Lake. The survey also included depth measurements along the shallow perimeter of Perch Lake using a meter stick (where the sonar was unable to take accurate measurements due to vegetation interference). Based on recent field data and aerial imagery, Perch Lake is characterized by an approximate wetted area of 46 ha, maximum depth of 4 m, and an estimated drainage area of 730 ha and an average depth of 2 m. The results of the June 2018 bathymetric survey suggest negligible change in lake volume in comparison to the measured data from Robertson and Barry (1985) based on the water depth.

In late summer and fall, the water level usually drops by as much as 0.25 m. Most of Perch Lake is open water except for littoral zones along the shore, including a region of floating, emergent and submerged vegetation, which amounts to about 30% of the lake's surface (Yankovich et al. 2000). The outer fringe of this zone is known as Perch Lake Marsh. This open marsh may be considered as part of the lake, with which it is physically continuous. To the north, there are extensive wetlands, notably Perch Lake Swamp, South Swamp, East Swamp and West Swamp. The lake is confined in part by sand outcrops along the northern and southern shores, and by bedrock along the western shores.

The hydrology of Perch Lake was studied extensively from 1969 to 1988 (e.g., Robertson and Barry 1985; Yankovich et al. 2000) through the collection of measurements in a system of dikes and ditches that enabled all surface flows in and out of the lake to be accurately measured. Five of the tributaries to Perch Lake and the outlet stream (Perch Creek) include V-notch weirs. The lake outlet and two of the inlet streams (inlet 2 and 5) are each equipped with a modified V-notch weir. Streams for inlets 1, 3 and 4 are each equipped with 90° V-notch weirs. Most of the weir installations were completed in 1969. The weir at inlet 5 was installed in 1972.

Mean annual flow at the outlet of Perch Lake is 0.057 m^3/s, based on the 11-year average water budget (1969 to 1980) for the hydrologic year (September 1 to August 31; Table 5.4.1-6). Flow results from measurements taken at the weir locations are summarized in Table 5.4.1-6.

Table 5.4.1-6: Perch Lake Hydrology for Inlet Streams (Sub-Basin 1-5) and the Outlet Stream Based on Annual Average Water Budget (1969-1980)

	Mean Annual Flow (m^3/yr)	Mean Annual Flow (m^3/s)	Depth Equivalent (m)	Standard Deviation	Coefficient of Variation
Inlet 1	2.15×10^5	0.007	0.23	0.57	0.27

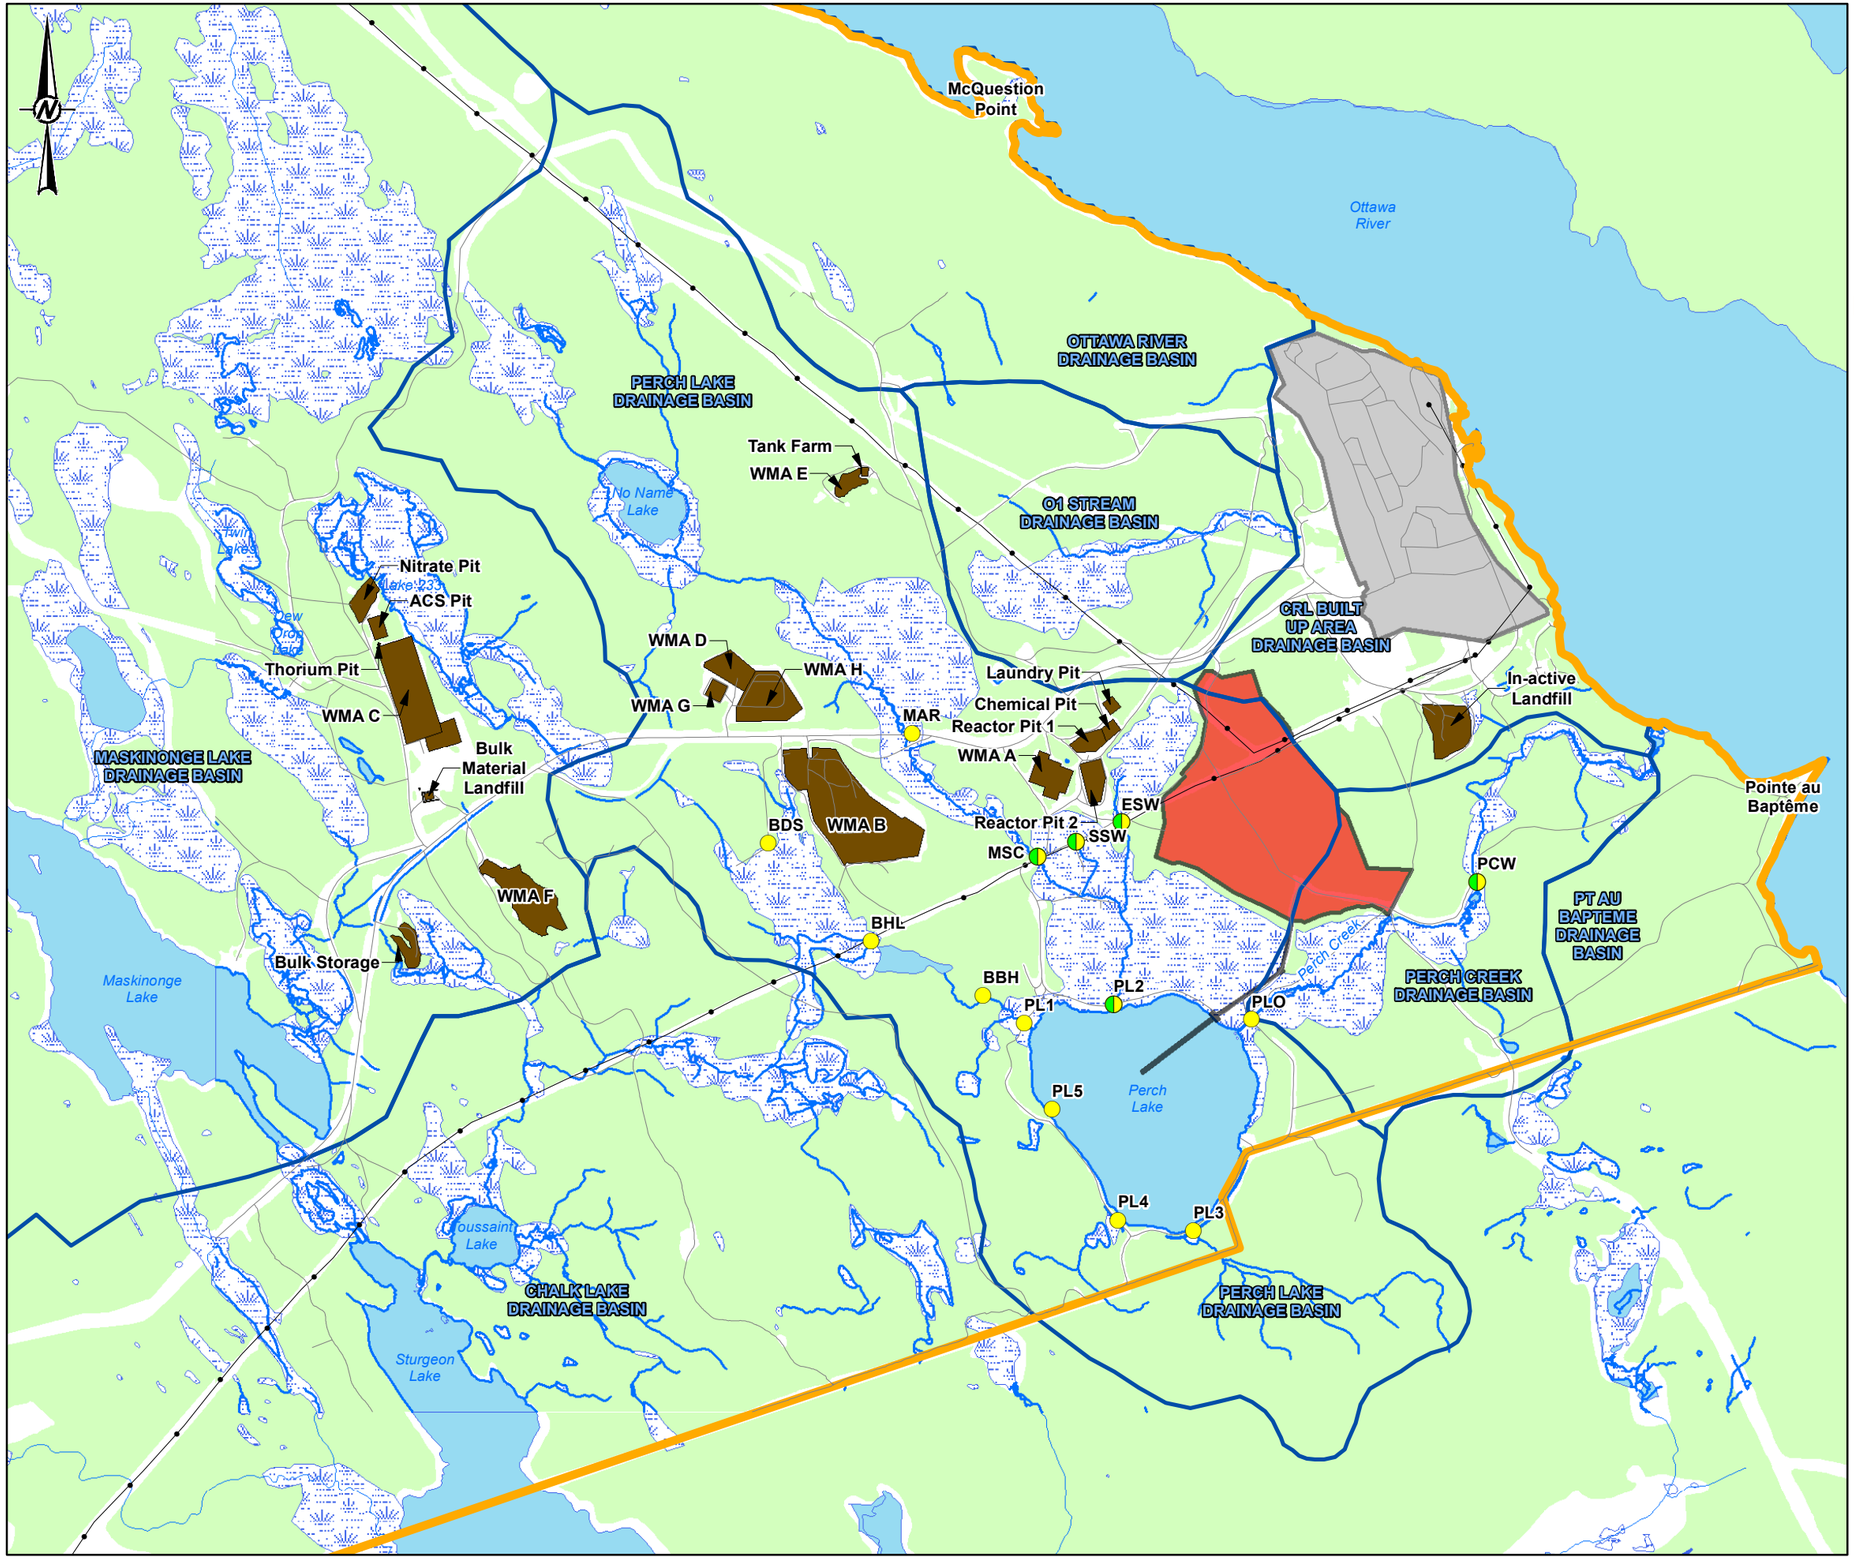
Source: Robertson and Barry 1985.

In 1988, the wooden weir box at the Perch Lake outlet began to fail, and flow measurements at Perch Lake outlet were discontinued (CNL 2016c). Over the measurement period, the annual average flow out of Perch Lake was 1,700,000 m^3. In the mid-1980s a concrete dam fitted with a compound V-notch weir was constructed on Perch Creek approximately 950 downstream of Perch Lake Outlet, and routine streamflow measurements have been collected at the Perch Creek weir since 1992. Between 1992 and 2015 the annual average flow through the Perch Creek weir has been 2,040,000 m^3 (CNL 2016c). The annual average total outflow from Perch Creek to the Ottawa River (i.e., Perch lake outflow and water added along Perch Creek) is 2,210,000 m^3.



Perch Creek is the dominant surface water feature that drains the Perch Creek Basin directly into the Ottawa River. Perch Creek ranges from about 5 to 10 m in width and generally has a depth of less than 1 m. Figure 5.4.1-3 shows the location of the creek marked by the Perch Creek weir northeast of Perch Lake at the extent of the wetlands, approximately 700 m downstream of Perch Lake (Photo 5.4.1-1).

Photo 5.4.1-1: Upstream View of the Perch Creek Weir, August 2012

Below the Perch Creek weir, the creek enters a mixed deciduous woodlot and overhead cover increases substantially (Sowden and Power 1981). The stream gradient also increases sharply, exceeding a 10% slope in sections. A series of small waterfalls (or cascades) occur just downstream of the weir which then lead to a riffle-pool sequence, followed by slow-flowing water in the lower reach of the creek. The substrate in the middle reach is rock, gravel and coarse sand; the substrate in the lower section of the creek is dominated by silt and sand. The overall slope of Perch Creek is approximately 3%.

Flow rates from the Perch Creek weir were measured by CNL from 2009 to 2015 (CNL 2016c), as summarized in Table 5.4.1-7 and on Figure 5.4.1-4. The highest flows typically occur in conjunction with spring melt (i.e., freshet) events in April, while lower flows are encountered during the summer season, particularly in August. The overall annual mean flow from years 2009 to 2015 was estimated to be approximately 0.063 m^3/s.

5.4.1.4.2.4 Site Study Area

Development of the SSA involves the construction of three surface water management ponds (SWMP #1, SWMP #2, SWMP #3). SWMP #1 is proposed for the northern section of the site, will receive runoff from the buildings and parking lots, and will discharge to the East Swamp. SWMP #2 is proposed for the southern section of the site, where it will receive runoff from the post-closure engineered containment mound (ECM) and the nearby lay down/stockpile areas. SWMP #3 is proposed in the western section of the site and will also receive runoff from the post–closure ECM. Both SWMP #2 and SWMP #3 will discharge to the Perch Lake Swamp wetland complex. The current SWMP footprints reflect the overall storage required to control closure flows to pre-development levels for the 2-year through to 100-year rainfall events at the site. This volume also contains the storage required for sediment control during construction and water quality control (more than 80% total suspended solids [TSS] removal for SWMP #1, 76% TSS removal for SWMP #2 and 60% TSS removal for SWMP #3) during operations. The current footprints typically assume a maximum 100-year operating water level at a 3 m depth with 1 m of freeboard that includes allowance for climate change effects and rain on snowmelt.

The surface water runoff within the SSA under existing (Base Case) conditions was modelled using Visual Otthymo 4.0 software for the 2-year through to 100-year rainfall events and the regional storm event for the area was also modelled along with the probable maximum precipitation. Visual Otthymo is a hydrologic management model that is capable of simulating runoff from single storm events. It is well suited to hydrologic studies of watersheds and sub-watersheds and is a useful tool in creating master drainage plans, site stormwater designs and surface water management design. Rainfall intensity data inputted into the model was sourced from the Town of Arnprior as the storm data were more recent than that available from Environment and Climate Change Canada for the area. Modelling simulations included consideration of 6-hour, 12-hour and 24-hour Soil Conservation Service Type II storm distributions but since the 12-hour distribution generated the highest peak flows it was used in the conveyance and pond designs.

Under pre-development conditions four distinct catchment areas are seen: The north catchment is a 5.8 ha area to the north of the site which has overland flow to the East Swamp. The south catchment area is 4.8 ha and has overland flow towards Perch Creek. The west catchment is approximately 22.2 ha and drains south westerly to the Perch Lake Swamp. The east catchment is approximately 0.7 ha and drains overland off-site to the east (Figure 5.4.1-5). Discharge model outputs for these catchments for the 1:2 year, 1:5 year and 1:100 year 12-hour events are summarized in Tables 5.4.1-8 through 5.4.1-11 below (AECOM 2019).

Table 5.4.1-8: Hydrologic Model Results for Base Conditions in North Catchment

Model Output	Storm Event		
	1:2 Year	1:5 Year	1:100 Year
Peak Runoff Flow Rate (m^3/s)	0.18 m^3	0.34 m^3	0.94 m^3
Time to Peak (hours)	6.25	6.25	6.00
Total Area Runoff (m^3)	422 m^3	806 m^3	2,239 m^3

5.4.1.5 Project Interactions and Mitigation

5.4.1.5.1 Methods

This section describes the process by which interactions between NSDF Project components and activities and hydrology were identified and evaluated. Potential effects pathways are identified, and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the NSDF Project and the environment by evaluating the different effect pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment. As such, this section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all phases of the NSDF Project. The next step in the analysis was the development of environmental design features and mitigation that could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects to hydrology. Environmental design features included project design elements, environmental best practices, and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the NSDF Project's engineering and environmental teams, combined with project-specific input from engagement with other interested parties. The design features and/or mitigation were selected considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effect pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments, and the effectiveness of environmental design features and mitigation:

- **No linkage:** The pathway is removed by environmental design features or mitigation such that the NSDF Project would not be expected to result in a measurable environmental change relative to Base Case values and therefore would have no residual effects to hydrology.
- **Secondary pathway:** The pathway could result in a measurable minor environmental change, but would have a negligible residual effect on hydrology relative to Base Case and/or guideline values and is not expected to contribute cumulatively to other NSDF Project effects or to the effects of other previous, existing or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway:** The pathway is likely to result in an environmental change relative to the Base Case and/or guideline values that could contribute to residual effects to hydrology.

Environmental design features and mitigation that have been or could be incorporated into the NSDF Project to eliminate or reduce adverse effects were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to hydrology through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways were carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the NSDF Project.

5.4.1.5.2 Results

Pathways through which all phases of the NSDF Project may interact with and result in changes to measurement indicators for hydrology are provided in Table 5.4.1-13.

Table 5.4.1-13: Pathways Analysis for the Hydrology Valued Component

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
General project activities during the operations phase	Discharge of treated domestic wastewater/sanitary sewage may cause a change in water levels, flows and channel and bank stability at downstream locations.	■ The grey water/sanity sewage will be managed through a gravity sewer network connected to the two sewage disposal systems as described in Section 3.4.4.4. These systems are completely separate from the ECM leachate and other contact water sewer conveyance for the on-site WWTP. ■ Sewage discharges to the sewage disposal system will conform with CNL's *Acceptability Criteria for Routine and Non-Routine Discharge of Liquids on the CRL Site* (CNL 2015b).	No Linkage
Project activities during the operations and closure phases: ■ Surface water management ■ Operation of the WWTP ■ Discharge of treated effluent from the WWTP	Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) and the discharge of non-contact water to adjacent wetlands may cause changes to water levels, flows and channel and bank stability in downstream waterbodies and water levels in the adjacent wetlands.	■ Discharge of treated effluent to the exfiltration gallery area will help to reduce water loss from the hydrogeological system. ■ Design consideration was given during the selection of the discharge location of treated effluent for environmental effects of scour on the receiving waterbodies. As such, the preferred design (i.e., discharge to the exfiltration gallery and Perch Lake diffuser) was chosen as the favourable alternative as they resulted in negligible scour potential. ■ Outlet flows from all three SWMPs will be dispersed by level spreaders that will provide an even flow distribution to the wetlands with an appropriately wide dispersal pattern. ■ The WWTP system's outlet utilizes a headwall which discharges to a level spreader for the purposes of preventing erosion and sedimentation at the outlet for the exfiltration gallery. ■ The outlet locations of the SWMPs are limited by the site boundary (greater than 5 m separation required) so that there is no discharge from the spreader directly to the wetland. ■ Annual inspection and maintenance activities will identify any erosion problems. ■ Inspections will be undertaken and maintenance activities completed, as required, after major storm events and after the annual spring melt to confirm there are no major erosion issues.	Secondary
Project activities during the construction phase: ■ Site Preparation ■ Construction of the ECM ■ Blasting (as required) ■ Development of surface water management structures ■ Construction of the WWTP and other support facilities ■ On-site road and access development ■ Construction of transfer line and Perch Lake diffuser ■ Domestic waste (solid and liquid) management ■ Soil spoils haulage to a soil storage area	The construction of the NSDF Project will physically alter drainage patterns in the Perch Creek and Perch Lake Watershed and may change downstream discharge, water levels, channel and bank stability, and water levels in adjacent wetlands.	■ The NSDF Project footprint has been designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. ■ A 30 m buffer will be established along identified wetlands near the SSA; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion. ■ Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site will be used during construction around disturbed areas, where appropriate. ■ During the construction phase, erosion and sediment control measures in place to mitigate the effects of sediment transport include the use of erosion control blankets, as needed, to control erosion on steep slopes, check dams in ditches and swale. ■ Surface water from all external areas will be conveyed by ditches, swales and culverts to SWMPs to address water quality and water quantity criteria established for the wetland receiving waters and, ultimately, Perch Creek. ■ Where drainage crosses roadways, culverts are sized to convey the 25-year design event without road overtopping. ■ The SWMPs are designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during operations, closure and post-closure. ■ Annual maintenance activities will identify any erosion problems. ■ Inspections will be undertaken and maintenance activities completed, as required, after major storm events and after the annual spring melt to confirm there are no major erosion issues.	Primary
	Changes to the hydrology within the Perch Creek and Perch Lake Watershed as a result of the intake of water from the Ottawa River for construction activities.		Secondary
Project activities during the operations, closure and post-closure phases: ■ Installation of final cover, restoration and grading of the site ■ Continued operation of surface water management structures	The installation of the ECM will physically alter drainage patterns, and may change downstream discharge, water levels in adjacent wetlands and channel and bank stability.	■ The final cover and site grading are designed to promote positive drainage from the Site Study Area and reduce erosion or abrasion of the final cover. ■ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound and minimize leachate generation. ■ The final cover system design incorporates a series of shallow, trapezoidal and lined drainage channels that are designed to convey water at low velocity. ■ The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the final cover and underlying waste materials, destabilization of the ECM structure and damage to access roads. ■ The ECM final grading and drainage plan includes collection ditches along the top of the ECM berm road to collect side slope drainage. ■ The SWMPs are designed to address erosion and sediment control concerns by providing water quality/quantity controls during operations, closure and post-closure. ■ Environmental monitoring will be completed as required during the institutional control period for the NSDF Project to confirm that the final cover is functioning as intended.	Primary

ECM = engineered containment mound; WWTP = Wastewater Treatment Plant.

This page intentionally left blank

5.4.1.5.2.1 No Linkage Pathways

The following pathway was assessed as having no measurable environmental change relative to Base Case values and therefore would have no effects to hydrology.

- **Discharge of treated domestic wastewater may cause a change in water levels, flows and channel and bank stability at downstream locations.**

The NSDF Project's sanitary conveyance system is designed to convey the peak sewage flows generated by up to 65 full-time employees (although this will be adjusted based on operational demand) who will work at the NSDF Project. The NSDF sanitary sewage will be managed through a gravity sewer network connected to a sewage disposal system. This system is completely separate from the ECM leachate and other contact water sewer conveyance for the on-site Wastewater Treatment Plant (WWTP).

There are two site sewage disposal systems proposed to service the NSDF Project, including:

- one larger system adjacent to East Mattawa Road servicing the WWTP, Vehicle Decontamination Facility, Operations Support Center, Administrative Office and North Kiosk; and
- one smaller system for the South Kiosk.

Each of these two systems will contain a pump station septic tank and piped leach field. The NSDF gravity sewers have been sized to convey the peak sewage flow rate of 13 L/s. The sanitary system uses a network of gravity sewers to convey sewage from the Vehicle Decontamination Facility, the Operations Support Center, the Administration Building, the North Kiosk and the WWTP to a sanitary pumping station located near the staff operations center. The sanitary pumping station transfers the collected sewage using a force main that discharges to a second gravity sewer network located near the perimeter road on the east side of the SSA. The second gravity sewer terminates at the South Kiosk. Both north and south sewage disposal systems use a leach field through which sewage effluents are disposed into the soil.

Sewage discharges to the sewage disposal systems will conform to CNL requirements for discharge to septic systems provided in CNL's Environmental Protection Program procedure *Acceptability Criteria for Routine and Non-Routine Discharge of Liquids on the CRL Site* (CNL 2015b). As such, discharge of treated domestic wastewater for the NSDF Project to downstream locations is considered to have no linkage to effects on hydrology.

5.4.1.5.2.2 Secondary Pathways

The following pathways were assessed as potentially having a measurable minor environmental change, but negligible effect on the hydrology relative to Base Case.

- **Changes to the hydrology within the Perch Creek and Perch Lake Watershed as a result of the intake of water from the Ottawa River for construction activities.**

The NSDF Project construction phase will be carried out from 2022 to 2024. During the construction phase, CNL anticipates an average daily usage of approximately 110 m^3/day to 150 m^3/day for construction activities (e.g., dust suppression, clay mixing and fire protection). Construction water use is expected to peak at approximately 750 m^3/day. Water usage will be lower during the winter season (December through to March) when construction activities will be less. The water may also be used for commissioning activities including

hydrostatic testing of the WWTP storage tanks, the leachate collection and piping systems. Construction water will be sourced from an existing intake on the Ottawa River to fill temporary storage containers.

The intake of water from the Ottawa River for construction purposes (i.e., up to a maximum of 276,000 m^3/yr based on the peak daily usage) is anticipated to have a negligible effect on the overall Ottawa River annual flow rate of 25 billion m^3/yr (as recorded at the Des-Joachims monitoring point) and on the downstream hydrology. The proposed diverted annual volume for construction represents 0.0011% of the total annual flow rate of the Ottawa River at Des-Joachims using conservative assumptions of annual volumes based on peak daily flow and construction taking place during throughout the winter months. Actual water use for construction is anticipated to be lower than proposed; for example, during winter months, site activities do not require as much water as during the open water construction periods.

Similarly, changes to the hydrology within the Perch Creek and Perch Lake Watershed as a result of the intake of water from the Ottawa River for construction activities at the SSA are anticipated to be minor as the annual intake amount is approximately 15% of the mean annual outflow from the Perch Creek and Perch Lake Watershed. Water is used for various construction activities, such as dust management control. Water used for dust management will primarily evaporate or infiltrate and any associated runoff will be collected and conveyed to the SWMPs. Overall, water use for construction activities was determined to have a negligible effect on hydrology.

- **Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch lake (via a transfer line) and the discharge of non-contact water to the adjacent wetlands may cause changes to water levels, flows and channel and bank stability in downstream waterbodies and water levels in the adjacent wetlands.**

The NSDF Project will generate two water streams which will have the potential to impact water flows and levels in wetlands including:

- treated effluent from the WWTP which will be routed to the exfiltration gallery or Perch Lake; and
- non-contact water (i.e., water that has not been contaminated through contact with the ECM) which will be managed through a series of SWMPs.

A Surface Water Management Plan will be implemented to mitigate effects from wastewater discharges. Most of the wastewater flow will be generated from non-contact water produced during active filling of the ECM; contributions by leachate and decontamination activities represent a small fraction of the overall wastewater that will be treated by the WWTP. The total annual volume of water to be treated is 11,000 m^3. The volume represents approximately 0.6% of the average total outflow from Perch Lake (1,700,000 m^3/yr), or 0.5% of the average total outflow from Perch Creek (2,200,000 m^3/yr). Operational treated effluent discharge is expected to be a maximum of approximately 11 m^3/hr with an average effluent discharge rate below 1 m^3/hr. Flow rates within Perch Creek are approximately 252 m^3/hr; the maximum effluent discharge rate is roughly 4% of the average Perch Creek flows and approximately 11.5% of East Swamp weir flows. During the operations phase, the additional infiltration applied at the exfiltration gallery results in a localized increase in water table elevation of up to 1 m compared to the current conditions (see Section 5.3.2.6).

An exfiltration gallery is proposed at the discharge outlet for the treated effluent to promote the exfiltration of treated water into the local groundwater regime. Treated effluent will also be discharged directly to Perch Lake via a transfer line. The transfer line to Perch Lake has been designed to manage the full annual volume of treated effluent, if required, which will prevent the potential for overland flow at the exfiltration gallery.

The major flow system for all three SWMPs, which manage non-contact water, discharge on the NSDF Project site and from there flow into the adjacent wetlands. The SWMP outlet structures are located within the NSDF Project site boundary and are 5 m or more from the edge of the site, which in these locations follows a 30 m setback from the wetland. Flows from the SWMPs are dispersed by level spreaders that provide an even, flow distribution with an appropriately wide dispersal pattern before travelling 35 m or more overland to the edge of the wetland.

Annual maintenance activities will identify any erosion problems. Facility inspections will be completed twice annually to confirm that inlets and outlets are clear of debris and to confirm that there are no major erosion issues at the inlet or outlet. In addition, a maintenance review will be completed after major storm events and after the annual spring melt to confirm there are no major erosion issues at the dispersion outlets. Overall, changes to downstream discharge, water levels and channel and bank stability resulting from operational discharges of treated effluent and non-contact water will be localized to the receiving wetland. Therefore, this interaction was determined to have a negligible effect on hydrology.

5.4.1.5.2.3 Primary Pathways

The following primary pathways were identified as having residual effects on hydrology, and are therefore carried forward to the residual effects analysis.

- **The construction of the NSDF Project will physically alter drainage patterns in the Perch Creek and Perch Lake Watershed, and may change downstream discharge, water levels and channel and bank stability, and water levels in adjacent wetlands.**
- **The installation of the ECM will physically alter drainage patterns and may change downstream discharge, water levels in adjacent wetlands channel and bank stability during operations, closure, and post-closure.**

5.4.1.6 Residual Effects Analysis

5.4.1.6.1 Methods

The design of the SWMPs and associated systems use standard surface water management principles by controlling erosion, capturing sediment and allowing infiltration of non-contact water. The current SWMP footprints reflect the overall storage required to control closure flows to pre-development levels for the 2-year through to 100-year rainfall events at the site. This volume also contains the storage required for sediment control during construction and water quality control during operations. Where drainage crosses roadways, culverts are sized to convey the 25-year design event without road overtopping. Three SWMPs provide both quality and quantity control during construction, operations and closure phases. Flows from the ponds will be dispersed by a form of level spreader to provide even flow distribution to wetlands with an appropriate dispersal pattern to limit erosion and scouring of the wetland.

Closure activities include the installation of a final cover over the ECM to limit ponding and water infiltration into the waste. The final cover system will be constructed at slopes between 5% (overall slope for the top slope portion of the final cover) and 25% (4H:1V) for the side slope portion of the final cover. The top slopes and side slopes of the final cover are designed to be flat enough to satisfy slope stability factor of safety criteria and erosion control criteria. Runoff control for the final cover is designed to limit ponding and infiltration of water into the ECM, erosion of the final cover and waste material, and destabilization of the structure. The ECM design approach is to control the direction and velocity of the runoff to prevent erosion and abrasion of the final cover. During the closure

phase, surface water within the extents of the ECM will be conveyed through a series of rip-rap lined down-drains and lined channels into the ECM perimeter road ditch which drains into SWMPs #2 and #3 before being discharged to the wetland receiving waters and ultimately, Perch Creek.

The collection, conveyance and/or detention of runoff for the SSA upon closure of the ECM was modelled using Visual Otthymo 4.0 software for 1:2 year, through to the 1:100-year storm events. Rainfall intensity data were sourced from the Town of Arnprior. Modelling simulations included consideration of 6-hour, 12-hour and 24-hour Soil Conservation Service Type II storm distributions but since the 12-hour distribution generated the highest peak flows it was used in the conveyance and pond designs.

5.4.1.6.2 Application Case Results

5.4.1.6.2.1 Construction Phase

The SWMPs are designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during operations, closure and post-closure. The current SWMP footprints reflect the overall storage required to control post-closure flows to pre-development levels for the 2-year through to 100-year rainfall events at the site. This volume also contains the storage required for sediment control during construction and water quality control during operations. The target surface water quality objective of 60% TSS removal that provides basic water quality treatment for discharge to the receiving wetland is provided in the *Stormwater Management Planning and Design Manual* (MOE 2003). SWMP #1 will meet 80% TSS removal which will provide enhanced water quality treatment. SWMP #2 will provide 76% TSS removal and SWMP #3 will provide 60% TSS removal during operations, which will be sufficient because the receiving waterbody is a wetland and not a watercourse. The wetland functions as a sediment trap that will provide additional treatment prior to surface water reaching any watercourses in wetlands.

During the construction phase, erosion and sediment control measures will be in place to mitigate the effects of soil erosion and sediment transport. The measures include the use of erosion control blankets, as needed, to control erosion on steep slopes, check dams in ditches and swales, and the three proposed SWMPs that will be constructed to serve as interim sediment control facilities during construction, and then as surface water management facilities during the operations, expansion and post-closure periods. Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site (i.e., CNL's Management of Land and Habitat Procedure) will be used around disturbed areas, where appropriate. Furthermore, an Environmental Management Plan has been developed as part of the design plan for the site outlining the erosion and sediment control measures and SWMP construction schedule discussed. It also outlines administrative protocols such as training, contractor document submissions and staffing required for effective surface water management throughout all phases of the NSDF Project.

Site operations include surface water management for the ECM and all external areas. Surface water from all external areas will be conveyed by ditches, swales and culverts to SWMPs that will address water quality and water quantity criteria established for the wetland receiving waters and, ultimately, Perch Creek. Contact water, which is exposed to waste within the ECM, will drain from the active cells of the ECM and be conveyed to the WWTP. Non-contact water drainage from completed cells and yet-to-be completed cells will be directed either by gravity to the external surface water management system or to temporary holding ponds within the ECM, then pumped to the three SWMPs.

Facility inspections will be completed on a defined schedule to confirm that inlets and outlets are clear of debris and to confirm that there are no major erosion issues at the inlet or outlet. As well, the integrity of berms and outlet structures will be confirmed by visual inspections (e.g., to identify any animal burrowing activity or active soil erosion). Inspections will also include an annual sediment level monitoring component within each pond to identify sediment accumulation rates that may require clean-out requirements. If necessary, pond sediment will be extracted by excavation equipment and will be disposed of based on sediment sampling, testing and classification according to MECP standards, or stockpiled, dewatered and reused on-site for the daily ECM cover operations. Sediment removal will follow procedures identified in the *Stormwater Management Planning and Design Manual* (MOE 2003).

All proposed physical works are located within the SSA, affecting a relatively small area (5.1%) of the total contributing basin area for Perch Creek (720 ha; Robertson and Barry 1985). Any changes to existing drainage patterns will largely be restricted to this small sub-basin. In addition, the change from the forest cover under the existing conditions to the final cover of the ECM will result in decreased infiltration and increased runoff volumes from the footprint of the NSDF Project. Furthermore, all non-contact and contact water will be managed within the SSA, as per the Surface Water Management Plan that will be developed, reducing the potential for the NSDF Project to affect downstream discharge, water levels and channel and bank stability. Overall, changes to downstream discharge, water levels and channel and bank stability resulting from construction of the NSDF Project will be localized to the receiving wetlands. Therefore, this interaction was determined to have a negligible effect on hydrology.

5.4.1.6.2.2 Operations Phase

Phase 1 operations of the facility (the first 20-25-year operational period) is identified as the worst-case scenario for surface water runoff from the SSA. The Phase 1 and 2 excavations will be completed simultaneously, however during Phase 1 operation the Phase 2 excavation will be covered with an impermeable liner. The critical flow period throughout the life cycle is seen here where Phase 1 is operational and the Phase 2 excavation is impermeable.

The scenario was modelled using Visual Otthymo 4.0 software for the 1:2 year, through to the 1:100-year storm events. Summary results for the 12-hour event-controlled run-off from the entire site during Phase 1 operations are presented in Table 5.4.1-14 below (AECOM 2019). For comparison, pre-development results are also presented.

Table 5.4.1-14: Hydrologic Model Results for Base Conditions and Phase 1 Operations from the NSDF

Model Output Peak Runoff Flow Rate	Storm Event		
	1:2 Year	1:5 Year	1:100 Year
Pre-development (m^3/s)	0.42 m^3	0.83 m^3	2.38 m^3
Operational Phase 1 (m^3/s)	0.62 m^3	0.78 m^3	1.75 m^3

Though the SWMPs have been designed to control post-development flows to pre-development runoff rates they have not been designed to limit the operational Phase 1 run-off associated with the 1:2-year storm event. Pre-development runoff rates from that event have been modelled as 0.42 m^3/s, under Phase 1 operations this flow rate increases to 0.62 m^3/s. This ditches around the site are designed to safely convey the additional volumes and increased flow rates.

5.4.1.6.2.3 Post-closure Phase

During the post-closure phase, runoff from the site is transported by culverts and ditches to three SWMPs located to the North, West and South, these ponds collect and control much of the runoff from the site. There is however a combined 2.2 ha area with uncontrolled overland flow from the site (referred to as #4). Therefore, four distinct drainage areas can be modelled. SWMP #1 is within a 7.2 ha area which is located in the northern section of the site and captures runoff from the buildings and parking lots in that area. Runoff from this catchment is collected in SWMP #1 and ultimately discharges to the East Swamp. SWMP #2 is within an 18.7 ha area which captures runoff from lay down areas and the ECM mound, and ultimately discharges to the Perch Lake Swamp wetland complex. SWMP #3 located to the east is within a 5.4 ha catchment area which collects runoff from the ECM mound and ultimately discharges through SWMP#3 to the Perch Lake Swamp wetland complex (Figure 5.4.1-6).

Tables 5.4.1-15 through 5.4.1-18 provide a summary of the controlled post-development (i.e., closure phase) runoff rates for the SWMPs and the entire site (AECOM 2019). A comparison of the peak discharge rates pre-development versus post-development for the entire site is provided in Table 5.4.1-19. Overall, the results show that the surface water management system is designed so that flows during the closure phase are controlled to pre-development levels; preventing increased erosion rates in the receiving waterbodies due to increased discharge rates.

Table 5.4.1-15: Hydrologic Model Results for Controlled Post-development SWMP #1

Model Output	Storm Event		
	1:2 Year	1:5 Year	1:100 Year
Peak Runoff Flow Rate (m^3/s)	0.12 m^3	0.14 m^3	0.22 m^3
Time to Peak (hours)	6.83	6.92	6.75
Total Area Runoff (m^3)	1,650 m^3	2,553 m^3	5,335 m^3

Table 5.4.1-16: Hydrologic Model Results for Controlled Post-development SWMP #2

Model Output	Storm Event		
	1:2 Year	1:5 Year	1:100 Year
Peak Runoff Flow Rate (m^3/s)	0.28 m^3	0.40 m^3	0.63 m^3
Time to Peak (hours)	6.75	6.83	6.67
Total Area Runoff (m^3)	3,132 m^3	5,225 m^3	12,005 m^3

Table 5.4.1-17: Hydrologic Model Results for Controlled Post-development SWMP #3

Model Output	Storm Event		
	1:2 Year	1:5 Year	1:100 Year
Peak Runoff Flow Rate (m^3/s)	0.02 m^3	0.19 m^3	0.27 m^3
Time to Peak (hours)	6.58	6.67	6.58
Total Area Runoff (m^3)	914 m^3	1,593 m^3	3,736 m^3

The change in catchment areas between pre-development and post-development prevent a direct comparison by drainage areas, however an overall look at the site discharge allows for such a comparison. The ultimate condition runoff for the 1:2 year, 1:5 year and 1:100 year are summarized in Table 5.4.1-18.

Table 5.4.1-18: Hydrologic Model Results for Post-Closure Conditions from the NSDF

Model Output	Storm Event		
	1:2 Year	1:5 Year	1:100 Year
Peak Runoff Flow Rate	0.43 m^3/s	0.75 m^3/s	1.20 m^3/s
Total Area Runoff	5,856 m^3	9,648 m^3	21, 926 m^3

Table 5.4.1-19: Comparison of Peak Discharge Rates Pre development versus Post development for the NSDF

Peak Runoff Rates	Storm Event		
	1:2 Year	1:5 Year	1:100 Year (12 hr duration)
Pre-development	0.42 m^3/s	0.83 m^3/s	2.38 m^3/s
Post-development	0.43 m^3/s	0.75 m^3/s	1.20 m^3/s

5.4.1.7 Prediction Confidence and Uncertainty

The hydrologic model is considered to provide a reasonable prediction of the current surface water runoff rates and volumes, as well as the increases expected due to development of the site. The surface water runoff was modelled using Visual Otthymo 4.0 software for the 2-year through to 100-year rainfall events and the regional storm event for the area was also modelled along with the probable maximum precipitation. Visual Otthymo is a hydrologic management model that is capable of simulating runoff from single storm events. It is well suited to hydrologic studies of watersheds and sub-watersheds surface water designs and surface water management design. Rainfall intensity data inputted into the model was sourced from the Town of Arnprior as the storm data were more recent than that available from Environment Canada for the area. This rainfall distribution is a synthetic distribution and presents a heavy front-loaded storm with reduced infiltration leading to higher runoffs than may be seen with intensities more evenly distributed throughout the storm. This results in conservative model outputs with the resultant surface water management systems capable of handling larger storm events than those modelled.

5.4.1.8 Monitoring and Follow-up

Monitoring and follow-up programs for hydrology are related to operational performance monitoring (i.e., verify the SWMPs are performing as designed) and environmental monitoring (i.e., confirm that the ecological function and structure of the wetland system is maintained; Table 5.4.1-20).

Table 5.4.1-20: Monitoring and Follow-up Programs for Hydrology

Valued Component	Project Phase and Potential Effect	Monitoring Program Objective	Conceptual Monitoring Program	Suggested Duration	Implementing Program
Hydrology	The installation of the ECM will physically alter drainage patterns, and may change downstream discharge, water levels in adjacent wetlands and channel and bank stability.	Operational monitoring – Verify the SWMPs are performing as designed.	Monitoring of water levels and sediment build up in the SWMPs.	The water level at the SWMPs will be monitored during construction and operations. The need for and duration of monitoring will be revaluated based on an annual review of monitoring data.	Integrated into the NSDF Project Environmental Protection Plan to be developed and implemented for the NSDF Project.
		Environmental monitoring – Confirm that the ecological function and structure of the wetland system is maintained.	Monitoring of wetland water elevations and surface water flows to verify changes from the presence of the ECM.	Water level and surface water flows monitoring of the wetland system will be initiated pre-construction (baseline) and continue through construction and operations. The need for and duration of monitoring will be evaluated based on an annual review of monitoring data.	Water level and surface water flows monitoring of the wetland system will be integrated into the CNL Environmental Monitoring Program.

ECM = engineered containment mound; SWMP = surface water management pond.

5.4.1.9 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Hydrology, which includes surface water quantity, flow and direction, is recognized as an important component of the environment that may be affected by the NSDF Project and changes to hydrology could, in turn, lead to effects on other VCs selected for assessment. Acknowledging that changes to hydrology are considered to be important aspects of the natural and human environment, hydrology is referred to as an intermediate component. The hydrology assessment also does not include the assessment of the significance of these changes; rather, results of the analysis of changes in measurement indicators for hydrology are provided to other disciplines for inclusion in their assessment (Table 5.4.1-3).

All physical works are located within the SSA, affecting a relatively small area (5.1%) of the total contributing basin area for Perch Creek (720 ha). The total annual volume of water to be treated is approximately 11,000 m^3. The volume represents approximately 0.006% of the average total outflow from Perch Lake (1,700,000 m^3/yr), or 0.005% of the average total outflow from Perch Creek (2,200,000 m^3/yr). Operational treated effluent discharge is expected to be less than 1 m^3/hr. Flow rates within Perch Creek are approximately 252 m^3/hr; the effluent discharge rate is roughly 0.4% of the average Perch Creek flows and approximately 11.5% of East Swamp weir flows. Furthermore, the receiving wetlands are expected to buffer the discharge, further reducing flow rates into Perch Creek.

Residual effects to the hydrology VC are associated with the operational phase and the eventual closure of the NSDF Project, which will physically alter drainage patterns in the Perch Creek basin. In addition, the change from the forest cover under the existing conditions to the final cover of the ECM will result in decreased infiltration and increased runoff volumes from the footprint of the NSDF Project. The main physical works related to the NSDF Project is the ECM, the WWTP and supporting infrastructure. The design of the SWMPs and associated systems use standard surface water management principles by controlling erosion, capturing sediment and allowing infiltration of non-contact water. The current SWMP footprints reflect the overall storage required to control closure flows to pre-development levels for the post-development flows to pre-development levels for the 2-year through to 100-year rainfall events at the site. Where drainage crosses roadways, culverts are sized to convey the 25-year design event without road overtopping. A summary of residual effects is included in Table 5.4.1-21.

Closure activities include the installation of a final cover over the ECM to limit ponding and water infiltration into the waste. Modification to the drainage ditches and conveyance channels will be made to promote positive drainage from the site and limit erosion or abrasion of the final cover. During the closure phase, all surface water within the extents of the ECM will be conveyed through a series of rip-rap lined channels and down-drains into the ECM perimeter road ditch which drains into SWMP #2 and SWMP #3 before being discharged to the wetland receiving waters and ultimately, Perch Creek. Modelling results show that the surface water management system is designed so that flows during the closure phase are controlled to pre-development levels; thus, preventing increased erosion rates in the receiving waterbodies due to increased discharge rates.

Monitoring and follow-up programs for hydrology are related to operational monitoring (i.e., verify the SWMPs are performing as designed) and environmental monitoring (i.e., confirm that the ecological function and structure of the wetland system is maintained.

Table 5.4.1-21: Summary of Predicted Residual Adverse Effects for Hydrology Valued Components

Valued Component	Residual Adverse Effects	Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation
Hydrology	The construction of the NSDF Project will physically alter drainage patterns in the Perch Creek and Perch Lake Watershed and may change downstream discharge, water levels, channel and bank stability, and water levels in adjacent wetlands.	Construction	■ Site Preparation ■ Construction of the ECM ■ Development of surface water management structures ■ Construction of the WWTP and other support facilities ■ On-site road and access development ■ Construction of transfer line and Perch Lake diffuse	■ The NSDF Project footprint has been designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. ■ A 30 m buffer will be established along identified wetlands near the SSA; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion. ■ Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site will be used during construction around disturbed areas, where appropriate. ■ During the construction phase, erosion and sediment control measures in place to mitigate the effects of sediment transport include the use of erosion control blankets, as needed, to control erosion on steep slopes, check dams in ditches and swale. ■ Surface water from all external areas will be conveyed by ditches, swales and culverts to SWMPs to address water quality and water quantity criteria established for the wetland receiving waters and, ultimately, Perch Creek. ■ Where drainage crosses roadways, culverts are sized to convey the 25-year design event without road overtopping. ■ The SWMPs are designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during operations, closure and post-closure. ■ Annual maintenance activities will identify any erosion problems. ■ Inspections will be undertaken and maintenance activities completed, as required, after major storm events and after the annual spring melt to confirm there are no major erosion issues.

Table 5.4.1-21: Summary of Predicted Residual Adverse Effects for Hydrology Valued Components

Valued Component	Residual Adverse Effects	Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation
Hydrology	The installation of the site grading and final cover of the ECM and decommissioning of infrastructure will physically alter the Perch Creek watershed area and drainage patterns, and may change downstream discharge, water levels and channel and bank stability and water levels in adjacent wetlands.	Operations, Closure and Post-closure	■ Installation of the final cover of the ECM, restoration and grading of the site ■ Continued operation of surface water management structures	■ The final cover and site grading is designed to promote positive drainage from the SSA and reduce erosion or abrasion of the final cover. ■ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound and minimize leachate generation. ■ The final cover system design incorporates a series of shallow, trapezoidal, rip-rap lined drainage channels that are designed to convey water via drainage channels that are designed to convey water at low velocity. ■ The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the final cover and underlying waste materials, destabilization of the ECM structure and damage to access roads. ■ The ECM final grading and drainage plan includes collection ditches along the top of the ECM berm road to collect side slope drainage. ■ The SWMPs are designed to address erosion and sediment control concerns by providing water quality/quantity controls during operations, closure and post-closure. ■ Environmental monitoring will be completed as required during the institutional control period for the NSDF Project to confirm that the final cover is functioning as intended.

ECM = engineered containment mound.

5.4.2 Surface Water Quality

5.4.2.1 Scope of the Assessment

Section 5.4.2 focuses on surface water quality and follows the overall environmental assessment approach and methods described in Section 5.1. The assessment is completed in the key steps listed below:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries, and assessment cases** for the surface water quality assessment (refer to Sections 5.4.2.2 Valued Components and Section 5.4.2.3 Assessment Boundaries). The VCs and measurement indicators used to assess Project-related changes to surface water quality are described, along with the spatial and temporal boundaries at which the assessment occurred and the assessment cases considered.
- **Step 2 – Describe the existing conditions** (refer to Section 5.4.2.4 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation).
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 5.4.2.5 Project Interactions and Mitigation). NSDF Project components and/or activities with the potential to affect surface water quality are identified and mitigation developed to limit or avoid effects is presented. A pathways analysis is then used to focus further assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects to surface water quality. Where effects are adequately mitigated and do not require further analysis (i.e., where mitigation removes the pathway altogether and limits the effects to minor changes), rationale for concluding the assessment at this stage is articulated. Primary pathways that may lead to residual effects to surface water quality after incorporating mitigation are carried forward to Step 4 for further analysis and residual effects characterization.
- **Step 4 – Present the methods and results of the residual effects analysis** (refer to Section 5.4.2.6 Residual Effects Analysis). The residual effects analysis section outlines the methods used to predict and characterize residual effects to surface water quality from primary effects pathways. The analysis results for a select group of COPCs screened into the assessment are also presented including the characterization of incremental effects from the NSDF Project, as well as cumulative effects of the NSDF Project in combination with other reasonably foreseeable developments (if applicable). The analysis results for each of the COPCs screened into the assessment are presented in the Surface Water Quality Technical Supporting Document. A key outcome of this section is the predicted changes to surface water quality that are passed on to other disciplines for their assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty** (refer to Section 5.4.2.7 Prediction Confidence and Uncertainty). The prediction confidence and uncertainty section evaluates the available literature, data, and models used for the assessment, and describes the level of certainty that can be placed on predicted residual effects. This section will also identify how the uncertainty has been managed so that the effects are not underestimated.
- **Step 6 – Classify and determine the significance of the predicted residual effects**. This step was not required as the surface water quality VC is an intermediate component which does not include an assessment endpoint to determine significance.

- **Step 7 – Identify monitoring and follow-up** required to confirm effects predictions and address uncertainty (refer to Section 5.3.2.8 Monitoring and Follow-up).
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** of residual effects on surface water quality (refer to Section 5.4.2.9 Conclusions).

Section 5.4.2 also describes how the input from engagement influenced the scope of the surface water quality assessment. Information and areas of interest raised by the public, communities of interest, and Indigenous Peoples during engagement that influenced the scope of the surface water quality assessment are summarized in Table 5.4.2-1. Other general areas of interest and questions raised during the engagement that pertain to the surface water quality assessment (if any) are documented in CNL's Indigenous Engagement Report (CNL 2021) and CNL's Stakeholder's Activity Reports (CNL 2017a,b, 2019a).

Table 5.4.2-1: Summary of Areas of Interest Raised During Engagement Activities that Influenced the Scope of the Surface Water Quality Assessment

Areas of Interest	How the Area of Interest was Included in the Assessment
Potential for contamination in the Ottawa River from the NSDF Project.	The spatial boundaries of the assessment were selected to include consideration of potential effects to the Ottawa River. Surface water quality modelling was completed to estimate contaminant concentrations within the Perch Creek basin, which flows directly into the Ottawa River. Meeting effluent discharge targets within the Perch Creek and Perch Lake Watershed is considered to be protective of the Ottawa River. The Regional Study Area was expanded to include a reach of the Ottawa River extending 8 km downstream of the CRL site in response to comments received from Indigenous communities and organizations, and the public.

5.4.2.2 Valued Components

Valued Components (VCs) refer to environmental features that may be affected by a development and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community, or the public (The Agency 2018). Surface water quality is recognized as an important component of the environment that may be affected by the NSDF Project and changes to surface water quality could, in turn, lead to effects on other VCs selected for assessment. For example, changes to the characteristics of surface water quality have a large influence on aquatic, human, and wildlife health. Subsequently, changes to these characteristics by NSDF Project activities could affect aquatic organisms and the use of water as a drinking water source for people or wildlife (Table 5.4.2-2). The assessment of surface water quality focused on predicting changes in the concentrations of selected non-radiological and radiological parameters to the receiving environment as a result of the NSDF Project. The selected parameters (or Constituents of Potential Concern [COPC]) were identified through a screening process of the WWTP design and waste characterization information for the NSDF Project, which focussed on those that were known to be important to human and aquatic life. More detail is provided in Section 5.4.2.6.1.4. Changes to radiological parameters are discussed in Section 5.7 (Ambient Radioactivity and Ecological Health).

Acknowledging that changes to surface water quality are important aspects of the natural and human environment, surface water quality is referred to as an intermediate component (i.e., it does not have an assessment endpoint). Changes to intermediate component VCs must be understood to facilitate assessment of project interactions. The surface water quality assessment, therefore, is analyzed for incremental and cumulative (if applicable) changes in the relevant measurement indicators associated with surface water quality (Table 5.4.2-3). The changes are characterized in terms of magnitude, duration, and geographic extent, but they are not classified using rankings for effects criteria. For example, the magnitude of change in a water quality

parameter may be described as the relative change from baseline; however, this change would not be classified (or ranked) as low, moderate, or high. The surface water quality assessment also does not include the assessment of the significance of these changes; rather, assessment results for surface water quality (i.e., projected changes in water quality measurement indicators) are provided to other disciplines for inclusion in their assessment (Table 5.4.2-3).

Table 5.4.2-2: Valued Components for the Surface Water Quality Assessment

Valued Component	Rationale for Selection
Surface Water Quality	■ Water quality to support aquatic and human health is defined by the concentration or value of various physical and chemical constituents of water, such as temperature, suspended particulate matter, major ions (e.g., chloride, potassium), nutrients (e.g., nitrogen, phosphorus), metals, trace organic compounds, and radiological compounds that occur in dissolved or soluble form (e.g., aluminum and iron) and suspended matter (comprising inorganic or organic material). ■ Changes in the quality of water can affect aquatic and terrestrial sustainability and biodiversity, and the use of water for recreational purposes or as a drinking water source for people and wildlife. ■ Societal values concerning changes in water quality are an important consideration in understanding potential effects of the NSDF Project.

Table 5.4.2-3: Measurement Indicators for the Surface Water Quality Assessment

Valued Component	Measurement Indicators	Discipline Assessments where Effects on Surface Water Quality are Considered
Surface Water Quality	Concentrations of non-radiological and radiological constituents in surface water, which will be compared to baseline concentrations and effluent discharge targets.	■ Section 5.5 Aquatic Environment ■ Section 5.6 Terrestrial Environment ■ Section 5.7 Ambient Radioactivity and Ecological Health ■ Section 5.8 Human Health

5.4.2.3 Assessment Boundaries

5.4.2.3.1 Spatial Boundaries

The spatial boundaries selected for the surface water quality assessment were chosen because they permit description of existing conditions in sufficient detail to enable potential Project-VC interactions and effects to be identified, understood and assessed, including the contribution of the NSDF Project to cumulative effects. The spatial boundaries selected for the surface water quality are consistent with the hydrology and aquatic biodiversity assessment are presented on Figure 5.4.1-1 and are described below:

- **Site Study Area (SSA):** the SSA is the NSDF Project footprint (i.e., where NSDF Project activities would be undertaken including proposed facilities, buildings, and infrastructure).
- **Local Study Area (LSA):** The LSA is defined as the area within which there is potential for measurable changes to measurement indicators resulting from the proposed NSDF Project activities. The LSA includes the SSA and is bounded by Perch Lake and Perch Creek, and adjacent wetlands and swamps.

- **Regional Study Area (RSA):** The RSA is defined as the area within which the potential effects of the NSDF Project may interact with the effects of other existing or reasonably foreseeable developments. The RSA is determined by the spatial extent of the Perch Creek and Perch Lake Watershed and includes Perch Lake and its tributaries and Perch Creek. The RSA also includes a portion of the Ottawa River (i.e., roughly 8 km downstream in the Ottawa River to Harrington Bay).

5.4.2.3.2 Temporal Boundaries

Temporal boundaries (i.e., project phases) establish the timeframe during which NSDF Project effects are assessed. The temporal boundary represents the timeframe during which project activities are actively occurring and considers the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a project activity or stressor (which is related to the project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the NSDF Project or if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the NSDF Project:

- **Construction phase**: This phase includes site preparation and all activities associated with the construction of the NSDF Project. This phase includes activities such as installing the necessary supporting and/or ancillary facilities and infrastructure to facilitate NSDF Project operations, inactive commissioning and systems testing, and transportation of construction materials. Construction activities are expected take place from 2022 to 2024.
- **Operations phase**: This phase includes all activities associated with waste placement, water management, Wastewater Treatment Plant (WWTP) operations, vehicle movements into and from the SSA, and maintenance activities. Operations activities are expected to last approximately 50 years (i.e., 2025 to 2070).
- **Closure phase:** This phase includes activities necessary to complete the installation of the final cover and implementation of long-term monitoring. Closure activities are expected to start in 2070 and continue through to 2100, after which the NSDF Project will transfer into the post-closure phase.
- **Post-closure phase:** This phase has two discrete periods: institutional control and post-institutional control. The institutional control period includes implementation of controls throughout 2100 to 2400 (i.e., 300 years). During institutional control, environmental monitoring will continue to demonstrate compliance with the environmental assessment predictions. Post-institutional control occurs after year 2400 and continues indefinitely.

The assessment of potential effects to the receiving surface water environment is focused on the construction and operations phases. The assessment of potential effects during the closure and post-closure phases is presented in Section 5.7 (Ambient Radioactivity and Ecological Health) and Section 5.8 (Human Health).

5.4.2.3.3 Assessment Cases

The assessment cases considered in the surface water quality assessment include the Base Case and Application Case:

- **Base Case –** This scenario represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural, mining and residential and recreational development. Current effects from the existing CRL facilities and operations, for example, are considered part of the Base Case.
- **Application Case –** This scenario represents predictions of the effects of the Base Case combined with the effects that may result from the NSDF Project. The Application Case considers potential effects from the NSDF Project during construction through the operations phase. The assessment of potential effects during the Closure/Post-closure phases is presented in Section 5.7 (Ambient Radioactivity and Ecological Health).
- **Reasonably Foreseeable Development (RFD) Case –** This scenario represents predictions of the cumulative effects of the Application Case, which includes the Base Case, plus projects that are currently under application review or that have officially entered a regulatory application process and are therefore considered reasonably foreseeable.
- RFDs expected within the CRL site (i.e., the RSA) that may interact with surface water quality include new or upgrades to research and development facilities, construction and operations of the SMR, new support infrastructure, and on-going decommissioning and environmental remediation activities. New support infrastructure and research and development facilities will generally be located within existing disturbed areas on the CRL site (i.e., minimal disturbance to largely undeveloped areas) where erosion and sediment control practices and surface water management systems already in place will be implemented. Disturbance of an approximately 3.5 ha may be required for development of the SMR based on the candidate site selected, but no watercourses are identified within any of the three candidate sites (Global First Power 2019); therefore, the footprint of the SMR will be approximately 10% of the footprint of the SSA. The Project Description document for the SMR notes that the nearest waterbody to Site A is “No Name” Lake within the Perch Creek and Perch Lake Watershed and the nearest waterbody to Sites B and C is the Ottawa River within the Ottawa River direct watershed. It is noted that a small amount of radioactive liquid waste from decontamination activities during the operations of the SMR will be monitored and stored in a holding tank, for further processing (Global First Power 2019). A septic field may be used to manage sewage the SMR site, depending on the candidate site chosen that would follow required standards and would be located approximately 2 km from the NSDF Project site. Consequently, potential effects from revitalization activities and through development of the SMR are not expected to spatially overlap with potential effects to surface water quality from the NSDF Project.
- The NSDF Project will enable the remediation of contaminated lands and legacy waste management areas, and decommissioning of outdated infrastructure at the CRL site and CNL’s other business locations to support future CNL work. The end-state plan for the CRL site will be to return lands disturbed by site activities to a condition that is physically stable and safe in keeping with the land use and landscape of the day. Therefore, decommissioning and environmental remediation activities are anticipated to positively affect surface water quality.

5.4.2.4 Description of the Environment

Surface water monitoring at on-site lakes and streams, off-site streams, and locations in the Ottawa River both upstream and downstream of the CRL site is routinely conducted to describe the radiological and non-radiological water chemistry in the LSA and RSA (Figure 5.4.1-1). Monitoring of radiological and non-radiological parameters is performed in accordance with CNL's *Environmental Monitoring Program* (CNL 2018a). Methods for the collection of *in situ* field data and water samples follow approved methods in the *Protocol for the Sampling and Analysis of Industrial/Municipal Waste Water* (MOECC 2016) with minor modifications. As part of the surface water quality monitoring program design, CNL has provided a characterization of the naturally occurring and existing baseline metal, organic, and radionuclide constituents in surface water and sediments within the CRL site in *Environmental Risk Assessment of Chalk River Laboratories* (CNL 2019b).

Regional and local surface water quality data described in the *Chalk River Laboratories: A Description of the Environmental Baseline for Environmental Assessments* (AECL 2008) and in the *Environmental Monitoring in 2018 at Chalk River Laboratories* (CNL 2019c) are included in the following sections. The available existing Base Case conditions for Perch Lake and Perch Creek are also summarized. The focus of this description is on the non-radiological parameters, with a brief summary of the radiological parameters; a fuller description of the monitoring locations for radiological parameters and the existing Base Case conditions for the radiological parameters is provided in Section 5.7.4.5.

5.4.2.4.1 Ottawa River Watershed

The CRL site, as well as the surrounding area, is located entirely within the Ottawa River watershed. The Chalk River and Petawawa River are the two major downstream tributaries near the CRL site. Surface drainage from approximately 18% of the CRL site flows through Perch Creek and subsequently into the Ottawa River (CNL 2019c), which includes the CRL Built-Up Area Drainage Basin, where most of the operational nuclear and industrial facilities are located. The CRL Built-Up Area Drainage Basin also includes several landfill facilities, including the non-radiological landfill currently in operation, and two groundwater contaminant plumes from the National Research Experimental and National Research Universal reactor facilities that slowly discharge to the Ottawa River through regions of the riverbed. Wastewater effluents and streams with the potential to release contaminants to the Ottawa River are subject to routine monitoring, as appropriate, providing a means of measuring and controlling releases to the environment (CNL 2019c).

Sampling for non-radiological parameter concentrations for the Ottawa River is conducted at one location adjacent to the CRL site (i.e., CRL Water Intake) and at several locations upstream and downstream of the CRL site as part of the Provincial Water Quality Monitoring Network (PWQMN). Due to the lack of PWQMN stations near the Perch Creek confluence, PWQMN data are not applicable in establishing existing surface water quality conditions for the RSA. The PWQMN stations that were ultimately removed from further consideration included Petawawa (16 km downstream of the CRL site) and the Mattawa River situated approximately 108 km northeast of Perch Lake just before its confluence with the Ottawa River.

Sampling locations for radiological parameters of surface water include Rolphton (28 km upstream), Deep River (9 km upstream), CRL Intake, Pointe au Bapteme (CRL downstream boundary), Highview (8 km downstream), Harrington Bay (9 km downstream), Fort William (14 km downstream), Petawawa (18 km downstream), and Pembroke (28 km downstream). Only monitored radiological concentrations at the CRL Intake location were used in establishing the baseline Ottawa River radiological concentrations for surface water quality modelling. No sampling for radiological parameters is undertaken at the Perch Creek outlet to the Ottawa River. A data summary for the radiological parameters measured at these stations is provided in Table 5.7.4-9.

Table 5.4.2-4 provides a summary of Ottawa River water quality monitoring results for non-radiological parameters at the CRL water intake and compares data collected in 2018 to annual average water quality data for the previous five years where data were available (i.e., 2011 to 2015 or 2014 to 2018). Some of the annual averaged concentrations provided for several parameters are higher than surface water quality guidelines (e.g., CCME [1999]); these elevated parameters include aluminum, copper, lead, zinc, and iron. These data provided the existing baseline condition data for the Ottawa River used in the surface water quality assessment.

Table 5.4.2-4: Summary of Ottawa River Water Quality Monitoring Results from 2010 to 2018 at CRL Water Intake

Parameter	Unit	2010	2011	2012	2013	2014	2015	2016	2017	2018	Previous 5-Year Average[a]
pH	pH	7.10	6.91	7.06	6.97	6.79	6.84	6.69	6.66	6.94	6.78[b]

Table 5.4.2-4: Summary of Ottawa River Water Quality Monitoring Results from 2010 to 2018 at CRL Water Intake

Parameter	Unit	2010	2011	2012	2013	2014	2015	2016	2017	2018	Previous 5-Year Average[(a)]
Temperature Influent Mean	°C	9.02	7.15	6.46	7.71	8.13	8.95	9.0	8.1	6.1	7.7[(b)]

Source: CNL (2018a)

Note: Shading = summary concentration higher than surface water quality guideline value (e.g., CCME [1999]).

(a) Averages were determined by setting the SRI to zero.

(b) Averages were calculated from 2014 to 2018 data.

(c) Five-year averages were calculated from 2011 to 2015 data for parameters that were not sampled in 2016, 2017, and 2018.

µS/cm = microSiemens per centimetre; µg/L = micrograms per litre; SRI = smallest reportable increment; T = trace amount; V = data that has been averaged and includes one or more, but not all, measurements that were either a trace amount, below detection limits, below critical levels, or were a smallest reportable increment; <= less than.

5.4.2.4.2 Perch Creek and Perch Lake Watershed

The SSA is located within the Perch Creek and Perch Lake Watershed, which drains to the Ottawa River (Figure 5.4.1-2). The Perch Creek and Perch Lake Watershed represents the LSA for this project because most of the drainage from the SSA will be directed to the Perch Creek and Perch Lake Watershed. Additionally, this watershed contains many of the site's operating waste management areas; in particular, the waste management areas of the earliest vintage in the evolution in waste storage practices at CRL, including the Liquid Dispersal Areas. Because of its history, this basin is the most historically affected region of the CRL site.

Physical characteristics of Perch Lake include a wetted area of approximately 45 ha, a drainage area of 730 ha and a mean depth of 2 m (Robertson and Barry 1985). A recent bathymetric survey completed in 2018 identified a maximum depth of 4 m, and confirmed that most of the lake is shallow, less than 3 m in depth (CNL 2018b). Based on the 2018 bathymetric survey, the contour of the lake remains similar to that of the 1985 study, and as such, it can be assumed that the hydrology of Perch Lake has remained relatively constant over the past 30 years (i.e. no significant change in annual flow and water volume).

Most of Perch Lake is open water except for littoral zones along the shore, including a region of floating, emergent, and submerged vegetation, which amounts to about 30% of the lake's surface (Yankovich et al. 2000). The outer fringe of this zone is known as Perch Lake Marsh. Due to the physical connectivity between the marsh and the lake, this open marsh may be part of the lake. To the north, there are extensive wetlands, notably Perch Lake Swamp, South Swamp, East Swamp, and West Swamp. The lake is confined in part by sand outcrops along the northern and southern shores, and by bedrock along the western shores. The northern shoreline of Perch Lake was altered in the 1960s with the construction of the Perch Lake Ring Road. As part of this construction activity, sand fill was used to create a 1 to 2 m berm along this stretch of shoreline. There are no other documented alterations to Perch Lake, and as such it is anticipated that the physical characteristics of the lake have not appreciably been modified (CNL 2018b).

Perch Lake is characterized by high levels of nutrients (Yankovich et al. 2000) and can be described as dystrophic-eutrophic because it shows clear signs of nutrient enrichment, with approach to maturity in lake evolution. The water in Perch Lake is highly coloured water with an acidic pH (ranging from 5.5 to 6.8) and a low total suspended solids content. The colour of the water is the result of humic and fulvic acids. On average, the lake is frozen from late November to April. Following melting of the ice, the water warms up rapidly and summer temperatures can exceed 30°C; the highest temperature recorded was 34°C. During summer, the deeper

parts of the lake become stratified with surface water temperatures about 5°C higher than the deep-water zone (Yankovich et al. 2000). The bottom waters of Perch Lake often become depleted in oxygen in summer and in winter, but without reaching full anaerobic conditions; no massive fish kills have been observed during these conditions.

Perch Creek is the dominant surface water feature that drains the Perch Creek and Perch Lake Watershed directly into the Ottawa River. The upper third of Perch Creek is characterized by a low gradient, supporting extensive emergent vegetation and a thick layer of organic detritus. Below the Perch Creek weir, there is a substantial increase in overhead riparian cover and stream gradient. A series of small waterfalls (or cascades) and run sequences grade into slow-run sequences grade into slow flowing water in the lower reach of the creek. Substrate is predominately rock, gravel and coarse in the middle section of the creek, transitioning to a dominance of finer-grained material (e.g., silt) in the lower reach of the creek.

Surface water sampling locations are monitored routinely by CRL throughout the Perch Creek and Perch Lake Watershed (Figure 5.4.1-3). Monitoring data for these sampling stations includes a range of select non-radiological and radiological parameters (Table 5.4.2-5). Within the LSA, the closest monitored surface waters to the SSA are the East Swamp weir (ESW), Perch Lake Inlet #2 (PL2), and Perch Creek weir (PCW; Figure 5.4.1-3). The ESW is located immediately west of the SSA. This monitoring location is downstream of the CRL Liquid Dispersal Area, Laundry Pit, Reactor Pit 2, and Chemical Pit. The PL2 monitoring location is further downstream and receives discharge from the East Swamp Stream, South Swamp Stream, and Main Stream. The PCW monitoring station represents a downstream location of Perch Lake and is the final monitoring station in Perch Creek prior to its confluence with the Ottawa River. Perch Lake (PL4), is characterized as a reference sampling location for the Perch Creek and Perch Lake Watershed. It is located at Inlet 4 along the southern perimeter of Perch Lake which drains a sub-watershed not affected by CNL operations. Perch Lake is not routinely monitored; however, for the purposes of the EIS, aquatic monitoring, including sampling for field and laboratory non-radiological and radiological water quality data, was conducted in Spring 2018.

In order to assess the effects of non-radiological and radiological contaminants and physical stressors on surface water quality, the monitoring results were screened against the Risk Benchmark values (RBs) for non-radiological parameters adopted by the CRL site listed in Table 5.4.2-5 and No Effects Concentrations (NEC) for radiological parameters listed in Table 5.4.2-6. The tables include existing baseline concentrations in the Perch Creek and Perch Lake Watershed.

The Risk Benchmarks for non-radiological constituents are based on the Lowest Observable Effect Level (LOEL) with acute exposure at which population level effects may occur. They are based on:

- Federal and provincial guidelines for acute exposure; and
- Lowest observable effect concentrations from the literature.

Exceedance of an RB does not necessarily indicate that ecological effects would occur, but instead indicates that there may be some potential for effects (CNL 2019b).

The NEC for radiological constituents represents the concentration below which no adverse effects are expected at the population level. The NECs are derived from radiation benchmarks established for the protection of biota (i.e., 100 microGray per hour [µGy/hr] for terrestrial biota and 400 µGy/hr for aquatic biota). An exceedance of a NEC does not indicate an effect, rather that there may be the potential for effects.

Some non-radiological parameters in the Perch Lake and Perch Creek watershed have been identified as having high existing environmental concentrations compared to screening criteria from federal and provincial water quality guidelines for chronic exposure. These non-radiological parameters are closely monitored in surface waters at the CRL site and (i.e., 2010 to 2017). In 2018, parameters having elevated concentrations included pH, copper, aluminum, barium, iron, lead, manganese, phosphorus, and silver (CNL 2018b). Barium, iron, lead, phosphorus, and silver concentrations were consistently elevated in the Perch Lake and Perch Creek watershed. In most cases, with the exception of iron, these metals were present at concentrations similar to those seen in reference (i.e., unaffected) monitoring locations in the Perch Creek and Perch Lake Watershed (CNL 2019b), indicating that these parameters are naturally elevated in the basin (or outside of the guideline range as for pH). Aluminum, copper, and manganese concentrations are elevated at a limited number of sampling locations (CNL 2018b).

Other parameters, such as chromium, lead, and nickel, were measured in 2018 at concentrations that were notably higher than previous years at all monitoring stations; in particular, copper concentrations measured at PL1 and PCW in 2018 are notably higher than previous years. All other non-radiological parameters were present at levels comparable to those observed in previous years and at the reference locations (i.e., Perch Lake Inlet 4).

Concentrations of non-radiological parameters do not exceed the risk benchmarks, with the exception of lead, which with a concentration of 8 µg/L slightly exceeds the risk benchmark of 7 µg/L (Table 5.4.2-5). As noted above, lead concentrations are similar to those at locations in the Perch Lake Basin that are unaffected by CRL operations.

The existing baseline radiological parameter concentrations for the sampling stations within the Perch Creek and Perch Lake Watershed show localized exceedances above NEC for gross beta (as strontium-90). An exceedance of a NEC does not necessarily indicate that ecological effects would occur, but instead indicates that there may be some potential for effects (CNL 2019b). A more detailed discussion of baseline radioactivity in surface waters within the Perch Creek and Perch Lake Watershed is provided in Section 5.7.4.5.

Table 5.4.2-5: Summary of Existing Baseline Water Quality in the Perch Creek and Perch Lake Watershed and Risk Benchmark Values for Non radiological Parameters

Monitoring Parameters	Units	Existing Baseline Concentration Range[a]	Risk Benchmark[b]	Risk Benchmark Reference
Non-radiological Parameters				
Aluminum	µg/L	<MDL – 545	100	AESRD (2014)
Ammonia	mg/L	No data	No data	-
Antimony	µg/L	0.027 – 0.050	180	Suter and Tsao (1996)
Barium	µg/L	17 – 18	110	Suter and Tsao (1996)
Boron	µg/L	6.5 – 13.1	29,000	CCME (1999)
Cadmium	µg/L	0.013 – 0.058	1	CCME (1999)
Calcium	mg/L	7.0 – 7.6	No data	-
Chloride	mg/L	0.25 – 273	640	CCME (1999)
Chromium	µg/L	0.768 – 1.38	1,700	Suter and Tsao (1996)
Cobalt	µg/L	0.24 – 0.45	1,500	Suter and Tsao (1996)
Copper	µg/L	<MDL – 51	Narrative[c]	AESRD (2014)

Table 5.4.2-5: Summary of Existing Baseline Water Quality in the Perch Creek and Perch Lake Watershed and Risk Benchmark Values for Non radiological Parameters

Monitoring Parameters	Units	Existing Baseline Concentration Range[(a)]	Risk Benchmark[(b)]	Risk Benchmark Reference
Fluoride	mg/L	No data	3	SCHER (2011)
Hardness	mg/L	4 – 337	No data	-
Iron	mg/L	1.65 – 2.87	3.4	SAVEX (2013)
Lead	µg/L	<MDL – 8	7	AESRD (2014)
Magnesium	mg/L	1.829 – 2.530	No data	-
Manganese	µg/L	52 – 130	2,300	Suter and Tsao (1996)
Mercury	µg/L	<MDL – 0.027	2.4	Suter and Tsao (1996)
Molybdenum	µg/L	0.3	16,000	Suter and Tsao (1996)
Nickel	µg/L	<MDL – 4	1,400	Suter and Tsao (1996)
Nitrate	mg/L	<MDL – 0.12	550	CCME (1999)
Nitrite	mg/L	No data	Narrative[(d)]	AESRD (2014)
Phosphorus	mg/L	<MDL – 0.2	No data	-
Potassium	mg/L	0.647 – 1.038	No data	-
Selenium	µg/L	<MDL – 3	20	Suter and Tsao (1996)
Silver	µg/L	1	4.1	Suter and Tsao (1996)
Sodium	mg/L	2.1 – 24.6	No data	-
Strontium	µg/L	16 – 110	15,000	Suter and Tsao (1996)
Sulfate	mg/L	0.85 – 3.80	No data	-
Thallium	µg/L	0.02	110	Suter and Tsao (1996)
Tin	µg/L	0.002	2,700	Suter and Tsao (1996)
Uranium	µg/L	<MDL – 0.11	33	CCME (1999)
Vanadium	µg/L	<MDL – 4	280	Suter and Tsao (1996)
Zinc	µg/L	<MDL – 25	120	Suter and Tsao (1996)

a) Existing baseline water quality data ranges for all assessment nodes between 2010 to 2018 (CNL 2015b, CNL 2019b).

b) Risk benchmarks apply to the select non-radiological parameters for the entire CRL site.

c) Other factors need to be considered in the risk assessment (e.g., water hardness).

d) The risk benchmark varies with chloride (AESRD 2014). For chloride concentrations greater than 10 mg/L, the nitrite risk benchmark concentration = 0.6 mg N/L.

MDL = method detection limit; µg/L = micrograms per litre; mg/L = milligrams per litre.

Table 5.4.2-6: Summary of Existing Baseline Water Quality in the Perch Creek and Perch Lake Watershed and No Effects Concentrations for Radiological Parameters

Monitoring Parameters	Units	Existing Baseline Concentration Range[a]	No Effects Concentration[b]	No Effects Concentration Reference
Radiological Parameters				
Carbon-14	Bq/L	<MDL	164	CNL (2019b)
Caesium-137	Bq/L	<MDL – 0.5	72.7	CNL (2019b)
Cobalt-60	Bq/L	<MDL – 0.54	135	CNL (2019b)
Gross Alpha as Americium-241	Bq/L	0.0037 – 0.3[d]	0.385[c,e]	ERICA (2019)
Gross Beta as Strontium-90	Bq/L	0.001 – 923	183[f]	CNL (2019b)
Tritium	Bq/L	15 – 7,443	17,400,000	CNL (2019b)

a) Existing baseline water quality data ranges for all assessment nodes between 2010 to 2018 (CNL 2015a, CNL 2019b).

b) No Effects Concentrations apply to the select radiological parameters for the entire CRL site

c) No effect concentration for americium-241. Americium-241 is present in low concentrations in groundwater in the lower Perch Creek and Perch Lake Watershed downgradient of Legacy Waste Management Areas.

d) Outliers for gross alpha has been removed from the dataset.

e) The concentration is the Environmental Media Concentration from the Erica Tool multiplied by a factor of 40.

f) Strontium-90 is the main contributor to gross beta in Perch Lake and Perch Creek watershed. The no effect concentration for Strontium-90 (183 Bq/L).

MDL = method detection limit; Bq/L = Becquerels per litre

5.4.2.5 Project Interactions and Mitigation

5.4.2.5.1 Methods

This section describes the process by which interactions between NSDF Project components and activities and surface water quality were identified and evaluated. Potential effects pathways to surface water and mitigation developed to eliminate and/or reduce these effects are presented in this section. An assessment of these pathways then focuses on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects are adequately mitigated, they are not carried forward for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether). Primary pathways that may lead to residual effects after incorporation of mitigation are then further characterized in subsequent subsections of the assessment. As such, the “Project Interactions and Mitigation” section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all phases of the NSDF Project. The next step in the analysis was the development of environmental design features and mitigation that could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects to surface water quality. Environmental design features included NSDF Project design elements, environmental best practices, and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the NSDF Project’s engineering and environmental teams, combined with input from Project specific or regional engagement with other interested parties. The environmental design features and/or mitigation were selected considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effects pathways.

Potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments, and the effectiveness of environmental design features and mitigation:

- **No linkage:** This pathway is removed by environmental design features or mitigation such that the NSDF Project would not be expected to result in a measurable environmental change relative to existing conditions, and therefore would have no residual effects to surface water quality.
- **Secondary pathway:** The pathway could result in a measurable minor environmental change but would have a negligible residual effect on surface water quality relative to existing conditions and/or guideline values. Additionally, the pathway is not expected to contribute cumulatively to other NSDF Project effects or to the effects of other previous, existing, or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway:** The pathway is likely to result in an environmental change relative to the existing conditions and/or guideline values and could contribute to residual effects to surface water quality.

Environmental design features and mitigation that have been or could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to surface water quality through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways were carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the NSDF Project.

5.4.2.5.2 Results

Pathways through which all stages of the NSDF Project may interact and result in changes to measurement indicators for surface water quality are provided in Table 5.4.2-7.

This page intentionally left blank

Table 5.4.2-7: Pathways Analysis for the Surface Water Quality Valued Components – Construction, Operations, Closure and Post closure

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Project activities during the construction phase: ■ Site Preparation ■ Construction of the ECM ■ Blasting (as required) ■ Development of surface water management structures ■ Construction of the WWTP and other support facilities ■ On-site road and access development	Changes to local hydrology from surface disturbances may cause changes to water levels, flows, channel and bank stability, and sediment yield, at downstream locations, affecting water quality	■ The NSDF Project has been designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials	No Linkage
	Changes to the hydrology within the Perch Creek and Perch Lake Watershed as a result of the intake of water from the Ottawa River for construction activities may cause changes to surface water quality	■ A 30 m buffer will be established along identified wetlands near the SSA; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion ■ Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site will be used during construction around disturbed areas, where appropriate ■ During the construction phase, erosion and sediment control measures will include the use of erosion control blankets to control erosion on steep slopes, and the use of check dams in ditches and swale ■ Surface water from all external areas will be conveyed by ditches, swales and culverts to surface water management ponds to address water quality and water quantity criteria established for the wetland receiving waters and, ultimately, Perch Creek ■ Where drainage crosses roadways, culverts will be sized to convey the 25-year design event without road overtopping ■ The surface water management ponds have been designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during operations, closure, and post-closure. ■ Annual inspections and maintenance activities will identify and address any erosion problems ■ Inspections will be undertaken, and maintenance activities completed, as required, after major storm events and after the annual spring melt to confirm there are no major erosion issues	No Linkage
	Surface water drainage through the SSA during construction of the ECM may transport blasting residuals and metals directly into downstream waterbodies, affecting surface water quality	■ A blasting plan, as part of the EPP, will be developed by the Contractor and implemented for the NSDF Project ■ Runoff from the SSA will be managed (e.g., surface water management ponds) to avoid adverse environmental effects in downstream waterbodies ■ Additional guidance for the NSDF Project blasting limits will be obtained from *OPSS 120 – General Specification for the Use of Explosives* (OPSS 2014) ■ Blasting activities will follow industry standard Best Management Practices, and applicable federal regulations and DFO guidelines for use of explosives ■ Any runoff in contact with blasting residues at the SSA will be managed where appropriate (e.g., surface water management ponds) during the construction phase	No Linkage
	The high-pressure horizontal directional drilling installation of the transfer line to Perch Lake may result in a release of drilling mud (i.e., frac-out), which may cause changes to surface water quality	■ The transfer line to Perch Lake will be installed using high-pressure horizontal directional drilling methods. The mitigation described in the DFO *Ontario Operational Statement – High-Pressure Directional Drilling* (DFO 2007) will be applied, including creation of, and adherence to, a Frac-out Response Plan and Spill Contingency Plan during installation, and full-time environmental monitoring during all phases of transfer line works within the Perch Lake Swamp. The monitoring will evaluate adherence to environmental protection measures and provide for observations to identify signs of surface frac-out of drilling mud. Evidence of frac-out will trigger implementation of the Frac-out Response Plan	Secondary

Table 5.4.2-7: Pathways Analysis for the Surface Water Quality Valued Components – Construction, Operations, Closure and Post closure

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Project activities during the construction phase: ■ Site Preparation ■ Construction of the ECM ■ Blasting (as required) ■ Development of surface water management structures ■ Construction of the WWTP and other support facilities ■ On-site road and access development	Physical disturbances in Perch Lake from the installation of diffuser and transfer line construction and footprint may affect water quality	■ The selection of final routing alignment and foundation design considered the routing alignments and foundation designs that would result in the least potential for in-lake environmental effects ■ Work will be completed within the in-water work timing window of July 16 to March 14 to avoid spawning and egg/larval development periods for spring spawning fish species (DFO 2013; MNRF 2013); the construction duration is anticipated to be short term (i.e., <30 days) ■ Mitigation, including erosion and sediment control practices (e.g., silt fences, silt curtains), will be used during construction around disturbed areas, where appropriate. Key fish habitat protection measures will include turbidity curtains to isolate any suspended sediments to the construction work areas within the lake ■ Industrial equipment will be well maintained and free of leaks, invasive species, and noxious weeds. Machinery will be operated from above the high-water mark or from a barge to minimize the disturbance of the lakebed, riparian area, and shoreline. Vegetative mats and riparian protection measures will be used when mobilizing to and from the site ■ Clearing of any riparian vegetation and organic materials will be minimized, materials removed will be salvaged and replaced once the NSDF Project is completed. Disturbed riparian areas and shorelines will be re-vegetated and restored to the original stable gradient and contour. All construction materials will be removed from site upon completion of the NSDF Project ■ A site-specific Erosion and Sediment Control Plan will be developed and implemented for this activity ■ A site-specific ‘Spill Management Plan’ will be developed and implemented for this activity. Any refueling will occur at least 30 m away from the lake or waterbodies ■ Mitigation as described for drilling activities in the DFO *Ontario Operational Statement - High-Pressure Directional Drilling* (DFO 2007) will be followed ■ Environmental monitoring of ESC measures will be completed by a qualified professional. Environmental monitoring will include turbidity and total suspended solids monitoring; the monitoring details will be described in an ‘Erosion and Sediment Control Plan’ provided by the Project contractor prior to construction	Secondary
■ Project activities during the construction phase (as listed above) and;	Discharge of domestic wastewater may cause a downstream change in surface water quality	■ The grey water/sanity sewage will be managed through a gravity sewer network connected to the two sewage disposal systems as described in Section 3.4.4.4. These systems are completely separate from the ECM leachate and other contact water sewer conveyance for the on-site WWTP ■ Sewage discharges to the sewage disposal systems will conform with CNL’s *Acceptability Criteria for Routine and Non-Routine Discharge of Liquids on the CRL Site* (CNL 2015b)	No Linkage

Table 5.4.2-7: Pathways Analysis for the Surface Water Quality Valued Components – Construction, Operations, Closure and Post closure

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
▪ Hauling of construction materials ■ Project activities during the operations phase: ▪ Phased development of disposal cells in the ECM ▪ On-site transportation of waste and placement in the ECM ▪ Progressive closure of disposal cells and installation of final cover ▪ Operation of the WWTP ▪ Existing presence of fencing around perimeter of ECM ▪ Surface water management ▪ Domestic waste (solid and liquid) management; and, ▪ Routine operational management and monitoring activities.	Non-radiological air emissions and dust emissions (including sulphur dioxide, nitrogen oxides and particulate matter) and subsequent deposition may cause a change in surface water quality	■ Implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018c), which includes operational control monitoring and verification monitoring ■ The NSDF *Environmental Protection Plan* (AECOM 2018a) includes: ▪ restricting or suspending activities if unacceptable amounts of dust are generated due to winds or other site conditions ▪ use of water spraying or misting techniques (e.g., water trucks) as the primary dust control method ▪ use of fixatives (e.g., chemical suppressant) for dust control, and for use as daily ECM cover ▪ suspension of excavating, loading, hauling and disposal operations when wind speeds exceed the specified criterion ▪ vehicles that come into contact with potential contamination sources will be required to pass through the vehicle decontamination facility ■ On-site vehicles and equipment engines will meet Tier 2 emission standards and be maintained in good working order ■ Idling of vehicles will be limited on-site	Secondary
	Surface water runoff from the SSA can contain contaminants and suspended solids, which can affect water quality	■ Procedures for surface water management will be developed and implemented for the NSDF Project ■ The target surface water quality objective is provided in *Stormwater Management Planning and Design Manual* (MOE 2003). ■ Surface water from all external areas will be conveyed by ditches, swales and culverts to surface water management ponds that will address water quality and water quantity criteria established for the wetland receiving waters and, ultimately, Perch Creek ■ The surface water management ponds are designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during operations, closure and post-closure ■ The current surface water management pond design reflects the overall storage required to control post-closure flows to predevelopment levels for the 2-year through to 100-year rainfall events at the site. This volume also contains the storage required for sediment control during construction and water quality control during operations ■ Where drainage crosses roadways, culverts are sized to convey the 25-year design event without road overtopping ■ For each surface water management pond, the water level will be sampled to estimate the inflow and outflow of each pond ■ The outlet water quality will be sampled periodically to confirm that surface water discharges meet applicable environmental criteria	No Linkage

Table 5.4.2-7: Pathways Analysis for the Surface Water Quality Valued Components – Construction, Operations, Closure and Post closure

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Project activities during the operations and closure phases: ■ Surface water management ■ Operation of the WWTP ■ Discharge of treated effluent from the WWTP	Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) may cause changes to water levels, flows, and channel and bank stability, and scouring of the wetland, affecting water quality at downstream locations	■ Discharge of treated effluent to the exfiltration gallery area will help to reduce water loss from the hydrogeological system. ■ Design consideration was given during the selection of the discharge location of treated effluent for environmental effects of scour on the receiving waterbodies. As such, the preferred design (i.e., discharge to the exfiltration gallery and Perch Lake diffuser) was chosen as the favourable alternative as they resulted in negligible scour potential ■ Outlet flows from all three surface water management ponds will be dispersed by level spreaders that will provide an even flow distribution to the wetlands with an appropriately wide dispersal pattern ■ The WWTP system's outlet will utilize a headwall structure, which will discharge to a level spreader for the purposes of preventing erosion and sedimentation at the outlet for the exfiltration gallery ■ The outlet locations of the surface water management ponds are limited by the site boundary (i.e., greater than 5 m separation required) so there will be no discharge from the spreaders directly to the wetland ■ Annual inspections and maintenance activities will identify and address any erosion problems ■ Inspections will be undertaken and maintenance activities completed, as required, after major storm events and after the annual spring melt to confirm there are no major erosion issues	No Linkage

	Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) can cause changes to downstream surface water quality	■ The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses best available technology that is economically achievable and capable of meeting regulatory requirements
		■ Effluent discharge targets for wastewater discharges are protective of the environment and human health
		  ▪ Discharge targets for non-radiological contaminants are sourced from federal and provincial guidelines for protection of aquatic biota.
		  ▪ Discharge targets for radionuclides are the Canadian Drinking Water Guidelines with the exception of tritium for which a site-specific target is developed (Section 3.4.2.5.1)
		■ Treated effluent will be sampled to confirm it meets treatment targets before release to the environment
		■ When applied, the proposed exfiltration gallery will promote the exfiltration of treated water into the local groundwater regime where further retention of radioactivity by the geosphere is anticipated
		■ The Perch Lake diffuser design provides additional dilution of treated effluent at the point of release
		■ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water quality
		■ Appropriate procedures will be in place to effectively identify spill occurrences in the event treated effluent is released to areas other than directly to the exfiltration gallery or to Perch Lake and initiate appropriate emergency responses
			Primary

	Leakage of leachate from the ECM during the operations and closure phases may cause changes to downstream surface water quality	■ Design of the ECM includes base contours developed using a herringbone pattern with ridges and valleys to promote leachate transport to the leachate collection system for removal ■ The base liner design includes primary and secondary liner systems designed to have redundancy in case of premature degradation and are a combination of natural and synthetic barrier systems. These include a compacted clay liner (CCL), two geosynthetic clay liners (GCL) and an HDPE geomembrane ■ Clay materials were selected for the CCL and GCL components of the liner system as these materials are anticipated to maintain their function as hydraulic barriers throughout and beyond the design life of the disposal facility (i.e., 550 years) ■ The HDPE geomembrane design for the liner will be compatible with the leachate generated by the waste and provide a long service life ■ The base liner system will include an underlying compacted clay liner to supplement the primary and secondary liner system ■ The leachate collection system design will provide accessible access points for inspections, maintenance, repairs, and replacements ■ Appropriate responses to leachate leakage and contamination will be implemented as described in the Operations and Maintenance Plan and Contingency Plan	No Linkage

Table 5.4.2-7: Pathways Analysis for the Surface Water Quality Valued Components – Construction, Operations, Closure and Post closure

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
	Physical disturbances in Perch Lake from the installation of diffuser and transfer line construction and footprint may affect water quality	■ Installation of drill pilings to be completed by staged construction and restricted to the vicinity of the barge location where installation is occurring ■ Active work areas in the lake will be contained by turbidity curtains to isolate and limit the extent of any suspended sediments ■ Use of heavy machinery along the shoreline will be mitigated using erosion and sediment control measures	Secondary
	The high-pressure horizontal directional drilling installation of the transfer line to Perch Lake may result in a release of drilling mud (i.e., frac-out), which may cause changes to surface water quality	■ On-going environmental monitoring will be conducted during drilling activities ■ Mitigation as described for drilling activities in the DFO *Ontario Operational Statement - High-Pressure Directional Drilling* (DFO 2007) will be followed	Secondary
Project activities during the operations and closure phases: ■ Surface water management ■ Operation of the WWTP ■ Discharge of treated effluent from the WWTP	Temperature changes in Perch Lake as a result of the direct discharge of treated effluent from the WWTP to Perch Lake may result in thermal effects (e.g., degassing) in the lake	■ The temperature of the treated effluent to be released to Perch Lake will be routinely monitored. The monitoring at the WWTP will be used to identify treated effluent conditions (elevated temperature conditions) that will prohibit its release to Perch Lake so that it can be held in storage until it can be released ■ Most of the discharge transfer line between the WWTP and Perch Lake will be buried below the frost line. Additionally, the transfer line will be double-walled with an air space between inner and outer wall for most of its length ■ The design of the submerged diffuser will result in the rapid dispersal of treated effluent in Perch Lake during discharge	No Linkage
	Temperature changes in Perch Lake or other surface water bodies as a result of the direct discharge of discharge from the surface water management ponds may result in thermal effects to water quality (e.g., degassing) in the receiving water bodies	■ There are no direct discharges of SWMPs to surface water bodies, including Perch Lake	No Linkage
Project activities during the closure and post-closure phases: ■ Installation of final ECM cover, restoration and grading of the site ■ On-going long-term performance monitoring, transfer of NSDF Project into institutional control	Installation of the final cover of the ECM and decommissioning of Project infrastructure may change downstream discharge, water levels, and channel/bank stability, affecting surface water quality	■ The final cover is designed to promote positive drainage from the SSA and reduce erosion or abrasion of the cover ■ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound and minimize leachate generation ■ The cover system design incorporates a series of shallow, trapezoidal, riprap-lined drainage channels that are designed to convey water at low velocity ■ The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the cover and underlying waste materials, destabilization of the ECM structure, and damage to access roads ■ The ECM final grading and drainage plan includes collection ditches along the top of the ECM berm road to collect side slope drainage ■ Environmental monitoring will be completed as required during the institutional control period for the NSDF Project to confirm that the final cover is functioning as intended	Secondary
Project activities during the closure and post-closure phases: ■ Installation of final cover, restoration and grading of SSA ■ On-going long-term performance monitoring, transfer of NSDF Project into institutional control	Leakage of leachate from the ECM after the end of the post-institutional control period (i.e., after Year 2400) from liner and final cover degradation as a result of normal evolution can cause changes to downstream surface water quality	The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the ECM and minimize leachate generation The final cover system design incorporates a series of shallow, trapezoidal, riprap-lined drainage channels that are designed to convey water at low velocity The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the final cover and underlying waste materials, destabilization of the ECM structure and damage to access roads ■ The ECM final grading and drainage plan also includes collection ditches along the top of the ECM berm road to collect side slope drainage. ■ The design life for the ECM is 550 years to meet the required time period to allow for radioactive decay of the waste placed in the facility (i.e., until it has decayed to levels that do not present a risk to the public and environment) ■ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water and groundwater quality	Primary

ECM = engineered containment mound; WWTP = Wastewater Treatment Plant; SSA = Site Study Area; ESC = erosion and sediment control; HDPE = high density polyethylene; DFO = Fisheries and Oceans Canada; LLW = low-level waste.

5.4.2.5.2.1 No Linkage Pathways

The following pathways were assessed as having no measurable environmental change relative to Base Case values and therefore would have no effects to surface water quality.

- **Changes to local hydrology from surface disturbances may affect downstream water levels, flows, channel and bank stability, and sediment yield, affecting surface water quality**

The sediment quality conditions in Perch Lake and at the Ottawa River have been determined in previous programs. Current data are not available for Perch Lake or Perch Creek, but in-river sediments in the Ottawa River have been evaluated more recently (CNL 2015a). 'Offshore' sediment surveys have been conducted at a location adjacent to the process sewer outfall at CRL, particularly to evaluate historic sediment contamination that was limited to a small zone around the immediate diffuser discharge area. The results of the offshore sediment evaluation have concluded a negligible (and declining) risk to aquatic biota in the river, in terms of radiological and non-radiological sediment chemistry, sediment toxicity, and biotic population and community assessments.

Sediment quality data in Perch Lake are less available and are not routinely monitored under the current annual environmental programs. However, Perch Lake possesses a sustainable aquatic community structure, which has persisted through elevated contaminant exposure in the upper watershed resulting from historic contamination due to releases from Waste Management Areas and Liquid Dispersal Areas. The projected potential contribution from the NSDF Project to exposure of aquatic species in East Swamp is expected to be less than 1% of the current levels of exposures, which provides further confidence that sediment quality in Perch Lake and its downstream waters is not anticipated to be affected. Sediment quality constituents of potential concern (COPCs) in Perch Lake and Perch Creek have been identified, but are limited to chromium and copper and several sediment polycyclic aromatic hydrocarbons, and 'on-site' specific benchmarks and background levels have been formalized (CNL 2019b). These benchmarks will provide a useful reference should sediment quality monitoring be required.

The following mitigation will be implemented for the NSDF Project to limit changes to sediment quality to Perch Lake, its downstream watershed, and ultimately, the Ottawa River. During construction, erosion and sediment control practices (e.g., surface water management ponds, silt fences, runoff management) consistent with those applied at the CRL site during construction around disturbed areas, will be integrated into the NSDF Project, where appropriate. These practices will include erosion control blankets, to control erosion on steep slopes, ditches, swales and culverts for the conveyance of surface runoff to surface water management ponds, which will be designed to manage flows to control erosion potential and sediment transport through augmenting settlement by flow control.

During operations, the surface water management system established in the construction phase will control clean surface water quantity and quality while preventing contact with contaminated areas. The surface water management system will include surface water management ponds that will have the storage capacity to manage flows up to back-to-back 100-year rainfall events at the site, and a WWTP for the treatment of site leachate and wastewater (e.g., infiltration and suspended particulate settling) prior to discharge to the downstream receiving watershed and, ultimately, Perch Creek. Additionally, the design of discharge from the surface water management ponds will be dispersed by level spreaders to an even flow distribution to wetlands with an appropriately wide dispersal pattern, further reducing erosion potential.

As a result of the mitigation applied on-site during the life of the NSDF Project, water quality projections in Perch Lake and its downstream flow-paths over the life of the NSDF Project are expected to remain within Risk Benchmark values or existing baseline concentrations. In addition, flows from the NSDF Project to the Perch Creek and Perch Lake Watershed flow regime are expected to be minor (i.e., approximately 0.63% of the average total outflow from Perch Lake will be sourced from contact surface water from the SSA). Overall, this pathway was determined to have no linkage to effects on surface water quality.

- **Changes to the hydrology within the Perch Creek and Perch Lake Watershed as a result of the intake of water from the Ottawa River for construction activities may cause changes to surface water quality**

The NSDF Project construction phase will be carried out from 2022 to 2024. During the construction phase, CNL anticipates an average daily usage of approximately 110 m^3/day to 150 m^3/day for construction activities (e.g., dust suppression, clay mixing and fire protection). Construction water use is expected to peak at approximately 750 m^3/day. Water usage will be lower during the winter season (December through to March) when construction activities will be less. The water may also be used for commissioning activities during construction including hydrostatic testing of the WWTP storage tanks, the leachate collection, and piping systems. Construction water will be sourced from the Ottawa River and accessed via overland hoses and pipes to fill temporary storage containers.

The intake of water from the Ottawa River for construction purposes (i.e., up to a maximum of 276,000 m^3/yr based on the peak daily usage) is anticipated to have a negligible effect on the overall Ottawa River annual flow rate of 25 billion m^3/yr (as recorded at the Des-Joachims monitoring point) and the downstream hydrology. The proposed diverted annual volume for construction represents 0.0011% of the total annual flow rate of the Ottawa River at Des-Joachims using conservative assumptions of annual volumes based on peak daily flow and construction taking place throughout the winter months. Actual water use for construction is anticipated to be lower than proposed; for example, during winter months, site activities do not require as much water as during the open water construction periods. Consequently, no changes to surface water quality in the Ottawa River are anticipated.

Similarly, changes to the surface water quality within the Perch Creek and Perch Lake Watershed as a result of the intake of water from the Ottawa River for construction activities at the SSA are as the annual intake amount is approximately 15% of the mean annual outflow from the Perch Creek and Perch Lake Watershed. Water is used for various construction activities, such as dust management control. Water used for dust management will primarily evaporate or infiltrate and any associated runoff will be collected and conveyed to the SWMPs. Overall, water use for construction activities was determined to have a no linkage to effects on surface water quality.

- **Surface water drainage through the SSA during construction of the ECM may transport blasting residuals and metals directly into downstream waterbodies, affecting surface water quality**

Use of ammonium nitrate/fuel oil and water-resistant bulk emulsion explosives during the construction of the ECM has the potential to affect surface water quality in the Perch Creek and Perch Lake Watershed through runoff coming into contact with residual nitrogen material (e.g., nitrate and ammonia) in the construction area. A blasting plan will be developed by the Contractor as part of the EPP for the NSDF Project, which will comply with existing guidelines (Wright and Hopky 1998; DFO 2019; OPSS 2014). Any runoff in contact with blasting residues at the SSA will be managed according to the NSDF *Surface Water Management Plan* (AECOM 2019) (e.g., surface water management ponds and associated systems) during the construction phase. In addition, the potential for

transporting blasting residuals into downstream waterbodies is minimized as blasting operations are limited to a relatively short period of time during the construction phase.

Any runoff in contact with blasting residues at the SSA will be managed according to the NSDF *Surface Water Management Plan* (AECOM 2019) (e.g., directed to surface water management ponds and associated systems to enhance settling of particulates in the ponds) during the construction phase. In addition, the potential for transporting blasting residuals into downstream waterbodies is minimized as blasting operations are limited to a relatively short period of time during the construction phase.

Consequently, the use of explosives for the development of the ECM in the SSA is considered to potentially influence runoff quality with respect to minor increases in nitrate and ammonia concentrations for a short period in the construction phase. As such, this interaction is determined to have no linkage to effects on surface water quality in the receiving and downstream environment.

- **Discharge of domestic wastewater may cause a downstream change in surface water quality**

The NSDF Project's sanitary conveyance system is designed to convey the peak sewage flows generated by up to 65 full-time employees (although this will be adjusted based on operational demand) who will work at the NSDF Project. The NSDF sanitary sewage will be managed through a gravity sewer network connected to a sewage disposal system. This system is independent of the ECM leachate and other contact water sewer conveyance for the on-site WWTP.

There are two site sewage disposal systems proposed to service the NSDF Project. A detailed description of the systems is presented in Section 3.4.4.4.

Sewage discharges to the sewage disposal systems will conform to CNL requirements for discharge to septic systems provided in CNL's Environmental Protection Program procedure, *Acceptability Criteria for Routine and Non-Routine Discharge of Liquids on the CRL Site* (CNL 2015b). As such, discharge of treated domestic wastewater for the NSDF Project to downstream locations is considered to have no linkage to effects on surface water quality.

- **Surface water runoff from the SSA can contain contaminants and suspended solids, which can affect water quality**

A variety of mitigation strategies will be implemented during all project phases to reduce the potential for changes to soil, water and vegetation quality from surface water runoff from the CRL site. These include surface water management, erosion and sediment control measures, surface water management ponds, maintenance and inspection activities, and monitoring.

Site operations include surface water management for the ECM and all external areas. Surface water from all external areas will be conveyed by ditches, swales and culverts to surface water management ponds that will address water quality and water quantity criteria established for the wetland receiving waters and, ultimately, Perch Creek. Contact water, which is exposed to waste within the ECM, will drain from the active cells of the ECM and be conveyed to the WWTP. Non-contact water drainage from completed cells and yet-to-be completed cells will be directed either by gravity to the external surface water management system or to temporary holding ponds within the ECM, then pumped to the three surface water management ponds.

During the construction phase, erosion and sediment control measures will be in place to mitigate the effects of soil erosion and sediment transport. The measures include use of erosion control blankets, as needed, to control erosion on steep slopes. Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site (i.e., CNL's *Management of Land, Habitat and Wildlife* procedure [CNL 2018d]) will be used around disturbed areas within the CRL site, where appropriate. Furthermore, an Environmental Management Plan has been developed as part of the design plan for the site outlining the erosion and sediment control measures and surface water management pond construction schedule discussed. It additionally outlines administrative protocols such as training, contractor document submissions and staffing required for effective surface water management throughout all phases of the NSDF Project.

The surface water management ponds are designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during operations, closure and post-closure. The current surface water management pond footprints reflect the overall storage required to control post-closure flows to predevelopment levels for the 2-year through to 100-year rainfall events at the site. This volume also contains the storage required for sediment control during construction and water quality control during operations. The target surface water quality objective of 60% TSS removal that provides basic water quality treatment for discharge to the receiving wetland is provided in the *Stormwater Management Planning and Design Manual* (MOE 2003). Surface water management pond #1 will meet 80% total suspended solids removal which will provide enhanced water quality treatment. Surface water management pond #2 will provide 76% removal and SWMP #3 will provide 60% total suspended solids removal during operations which will be sufficient because the receiving waterbody is a wetland and not a watercourse. The wetland functions as a sediment trap that will provide additional treatment prior to surface water reaching any watercourses in wetlands.

Roadway, sidewalk and parking lot winter maintenance activities that may release road salt to the environment, include snow plowing/shoveling and de-icing practices, salt and sand storage and snow stockpiling, and removal and disposal. The winter maintenance practices outlined in the current *CRL Salt Management Plan* (AECL 2013) provide for effective management of salt use and will be applied to the NSDF Project as necessary. As per the plan, the application of road salt in the SSA will be to be limited as salt residual within contact water and/or leachate may compromise the treatment effectiveness of the WWTP systems. Instead, alternative products in winter road management, such as a sand-stone mixtures, are currently being considered.

Facility inspections will be completed on a defined schedule to confirm that inlets and outlets are clear of debris and to confirm that there are no major erosion issues at the inlet or outlet. As well, the integrity of berms and outlet structures will be confirmed by visual inspections that would identify soil erosion. Inspections will identify sediment clean-out requirements. Sediments will be extracted by excavation equipment and will be disposed of based on sediment sampling, testing and classification according to Ministry of Environment, Conservation and Parks standards or stockpiled, dewatered, and reused on-site for daily ECM cover operations. The sediment removal assessment follows procedures identified in the *Stormwater Management Planning and Design Manual* (MOE 2003).

The implementation of proposed mitigation at the CRL site will reduce the potential for changes to soil, water and vegetation quality from runoff from the CRL site. This pathway was determined to have no linkage to effects to surface water quality.

- **Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) and the discharge of non-contact water to the adjacent wetlands may cause changes to water levels, flows, and channel and bank stability, affecting water quality at downstream locations**

The NSDF Project will generate two water streams which will have the potential to impact water flows and levels in wetlands including:

- treated effluent from the WWTP which will be routed to the exfiltration gallery or directly to Perch Lake; and
- non-contact water (i.e., water that has not been contaminated through contact with the ECM), which will be managed through a series of SWMPs.

The NSDF *Surface Water Management Plan* (AECOM 2019) will be implemented to mitigate effects from wastewater discharges. Most of the wastewater flow will be generated from non-contact water produced during active filling of the ECM; contributions by leachate and decontamination activities represent a small fraction of the overall wastewater that will be treated by the WWTP. The total annual volume of water to be treated is 11,000 m^3. The volume represents approximately 0.6% of the average total outflow from Perch Lake (1,700,000 m^3/yr), or 0.5% of the average total outflow from Perch Creek (2,200,000 m^3/yr). Operational treated effluent discharge is expected to be a maximum of approximately 11 m^3/hr with an average effluent discharge rate below 1 m^3/hr. Flow rates within Perch Creek are approximately 252 m^3/hr; the maximum effluent discharge rate is roughly 0.4% of the average Perch Creek flows and approximately 11.5% of East Swamp weir flows. During the operations phase, the additional infiltration applied at the exfiltration gallery results in a localized increase in water table elevation of up to 1 m compared to the current conditions (see Section 5.3.2.6).

An exfiltration gallery is proposed at the discharge outlet for the treated effluent to promote the exfiltration of treated water into the local groundwater regime. Treated effluent will also be discharged directly to Perch Lake via a transfer line. The transfer line to Perch Lake has been designed to manage the full annual volume of treated effluent, if required, which will prevent the potential for overland flow at the exfiltration gallery.

The major flow system for all three SWMPs, which manage non-contact water, will outlet to adjacent wetlands and will be dispersed by level spreaders that will provide an even flow distribution to the wetlands with an appropriately wide dispersal pattern. Current SWMPs outlet locations are limited by the site boundary (greater than 5 m separation required) so that there is no discharge from the spreader directly to the wetlands. Local topography between the level spreaders and the wetlands, as well as any setbacks, has influenced the location of the on-site level spreaders.

Annual inspection and maintenance activities will be undertaken by CRL to identify any erosion problems. Facility inspections will be completed twice annually to confirm that inlets and outlets are clear of debris and to confirm that there are no major erosion issues at the inlet or outlet. In addition, inspections and maintenance activities will be completed after major storm events and after the annual spring melt to confirm there are no major erosion issues at the dispersion outlets.

As a result of the design of the WWTP and surface water management pond outlets, discharges from these facilities to receiving wetlands and Perch Lake are not predicted to result in appreciable changes to water levels, flows, and channel and bank stability, that would affect water quality at downstream locations. As a result, this pathway was determined to have no linkage to effects to surface water quality.

- **Temperature changes in Perch Lake as a result of the direct discharge of treated effluent from the WWTP to Perch Lake may result in thermal effects (e.g., degassing) in the lake**

Federal and provincial guidelines exist for discharges to receiving waterbodies. These are described in Environment Canada (2014).

The Canadian Council of Ministers of the Environment (CCME 1999) requirements can be summarized as follows:

- Discharges to receiving waters should be such that thermal stratification and subsequent turnover periods are not altered significantly from those existing prior to the operational discharge period.
- Discharges to receiving waters should not affect the thermal condition such that the maximum weekly average temperature is exceeded.
- Discharges to receiving waters should be such that the short-term exposures to maximum temperatures are not exceeded. Exposures should not be so lengthy or frequent as to adversely affect aquatic species determined to be valued in the receiving waterbody.

The Ontario Provincial Water Quality Objective (PWQO) for temperature (MOEE 1994) provides specific guidelines for temperature as a result of discharges to a receiving waterbody in Ontario. It requires that:

- the natural thermal regime of any body of water shall not be altered to impair the quality of the natural environment;
- the temperature at the edge of a mixing zone shall not exceed the natural ambient water temperature at a representative control location by more than 10ºC; and
- the maximum temperature of the receiving body of water, at any point in the thermal plume outside a mixing zone, shall not exceed 30ºC or the temperature of a representative control location plus 10 degrees or the allowed temperature difference, whichever is the lesser temperature.

To mitigate the potential for thermal effects in Perch Lake during periods of direct discharge to the lake, a combination of design aspects, monitoring, and adaptive management processes will mitigate any potential for adverse thermal effects to water quality. Further, during summer months under dry conditions, most discharge is expected to be directed to the exfiltration gallery instead of to Perch Lake.

The WWTP is designed to accommodate temperatures ranging from 0°C to 38°C; however, the temperature of the treated effluent to be discharged to Perch Lake will largely be dependent on the ambient conditions and the length of storage in the collection tanks and break tanks within the WWTP. The potential worst-case condition is expected to be during warm summer periods, especially if treated effluent is stored for extended periods allowing the temperature of the stored water to increase. To mitigate the potential for temperature build-up in the collection tanks, water storage times will be reduced. It is understood that under these warm conditions, the surface waters in Perch Lake will be warm, with some thermal stratification in the deeper zones of the lake. Mitigating elevated temperature conditions in the treated effluent to be discharged will manage large temperature differentials between the treated effluent discharge and Perch Lake around the diffuser; however, disruption of the thermal profile around this discharge is expected. This disruption will result in mixed conditions, with no anticipated adverse effect to water quality.

The treated effluent transfer line from the WWTP to Perch Lake comprises two key sections: a section between the WWTP and the point in the upstream pumping location, and the section downstream of the pumping location to the submerged diffuser. Between pumping periods, treated effluent may remain in the transfer line within these two sections. For most of these pipeline sections, the high-density polyethylene (HDPE) pipe will be buried below the frost line (below 2 m depth) and the pipe will be double walled with an air space between inner and outer wall for most of its length. Due to adiabatic conditions between the ground and pipe, the temperature of any remaining treated effluent in the transfer line in these sections is anticipated to gradually become consistent with the ground temperature around the transfer line; treated effluent remaining in the section of the pipe near Perch Lake will gradually assume the same water temperature as the lake at the same depth. During treated effluent to discharge, the small diameter transfer line results in water transfers between the WWTP and Perch Lake being relatively rapid; marked temperature changes during pumping are not anticipated; treated effluent temperatures at the point of release in Perch Lake are expected to be similar to the release point in the WWTP.

The design of the submerged diffuser will result in the rapid dispersal of treated effluent in Perch Lake during discharge. This will minimize the area in the lake that may be thermally affected.

Further monitoring of temperature of the stored treated effluent to be discharged directly to Perch Lake and at the point of release and at the edge of the mixing zone in Perch Lake. The monitoring at the WWTP will be used to identify treated effluent conditions (elevated temperature conditions) that will prohibit its release to Perch Lake so that it can be held in storage until it can be released. Monitoring at the edge of the mixing zone will provide confidence in the dispersion of the treated effluent, and that the thermal regime integrity in Perch Lake is maintained.

It is expected that the temperature of the treated effluent discharged directly to Perch Lake will be similar to the surface water temperatures in Perch Lake during discharge under most seasonal conditions. During warm summer conditions, minimizing storage periods in the collection tanks at the WWTP will reduce temperature build-up in the treated effluent. The design of the WWTP, including the number and capacity of collection tanks and the treated effluent transfer system, and the water transfer line and submerged diffuser will limit the potential for changes to the thermal regime in Perch Lake outside the Federal and Provincial guidelines during periods of operational discharge. As such, this pathway is determined to have no linkage to surface water quality.

- **Temperature changes in Perch Lake or other surface water bodies as a result of the direct discharge of discharge from the surface water management ponds may result in thermal effects to water quality (e.g., degassing) in the receiving water bodies**

The primary application of all three SWMPs is to manage non-contact water at the NSDF Project. The SWMPs will flow to adjacent wetlands and will be dispersed by level spreaders that will provide an even flow distribution to the wetlands. The SWMPs will therefore not discharge directly to a water body, including Perch Lake. As such, this pathway is determined to have no linkage to surface water quality.

- **Leakage of leachate from the ECM during the operations and closure phases may cause changes to downstream surface water quality.**

Design of the ECM includes base contours that have been developed using a herringbone pattern with ridges and valleys to promote leachate transport to the leachate collection system for removal. The base liner design includes both primary and secondary liner systems that are a combination of natural and synthetic barrier systems, which will be designed to provide redundancy in case of premature degradation. The primary liner includes a leachate collection system with the secondary liner housing a leak detection system. The composite

base liner contains perforated high-density polyethylene (HDPE) collection and pipes. The HDPE geomembrane was selected as it is compatible with the leachate generated by the waste and is expected to perform as an effective hydraulic and diffusion barrier over the 550-year design life (see Section 3.4.1.4). The base liner system includes an underlying compacted clay liner to supplement the primary and secondary liner system. The leachate collection system design provides access points for inspections, maintenance, repairs and replacements.

The primary liner system will contain the leachate collection system and will convey leachate to a single collection point for removal from the mound, for transfer to the WWTP for treatment. The primary liner system serves as the primary source of protection for the natural environment below the mound from leachate migration. The secondary liner system will contain the leak detection system, which will be used to detect leaks in the unlikely event that the primary liner system fails. Leachate collected by the leachate collection system will be pumped to the on-site WWTP for treatment.

Perimeter berms consist of three main geotechnical elements, or layers, each contributing to the soundness and integrity of the berm itself and the whole ECM. A *Slope Stability Analysis* (AECOM 2018b) was completed to provide the information needed to support the design of the base slopes, sidewalls and side slopes of the ECM. The *Slope Stability Analysis* (AECOM 2018b) addresses the range of anticipated loading conditions, under both short-term and long-term scenarios, to confirm that the slope designs will satisfy minimum factor-of-safety requirements for stability. Size and shape of the berms and each of the elements and layers were determined using a seismic design basis, including the National Building Code of Canada (NBCC).

The implementation of the above mitigation will limit the potential for changes to groundwater and surface water quality from the NSDF Project. As such, this pathway is determined to have no linkage to surface water quality.

5.4.2.5.2.2 Secondary Pathways

The following pathways were assessed as potentially having a measurable minor change to the receiving environment, but resulting in a negligible effect to surface water quality relative to the Base Case.

- **The installation of the final cover of the ECM and decommissioning of NSDF Project infrastructure may change downstream discharge, water levels, and channel and bank stability, affecting surface water quality.**

Closure activities include the installation of an engineered cover and a final cover over the ECM to limit ponding and water infiltration into the waste. Modification to the drainage ditches and conveyance channels will be made to promote positive drainage from the site and limit erosion or abrasion of the final cover. Runoff control for the final cover is designed to limit ponding and infiltration of water into the ECM, erosion of the final cover and waste material, and destabilization of the structure. The ECM design approach is to control the direction and velocity of the run-off to prevent erosion and abrasion of the final cover. Any surface water infiltrating the final cover will be collected by the leachate collection system and sent to the WWTP. The three surface water management ponds will remain to promote infiltration and settlement of suspended solids and restrict discharge rates to the nearby wetland. Decommissioning of the WWTP and all associated surface water management structures will be completed after the leachate quantity and quality no longer requires treatment. If the WWTP is required beyond its design life, the unit would be refurbished to enable continued treatment of leachate or other treatment options investigated. Environmental monitoring will be completed as required during the institutional control period for the NSDF Project to confirm that the final cover is functioning as intended.

Mitigation associated with the installation of a final cover over the ECM and decommissioning of the NSDF Project infrastructure to manage hydrological changes through surface disturbance during these closure activities is expected to limit potential changes to downstream discharge, water levels, and channel and bank stability in Perch Creek. As such, negligible effects are predicted to surface water quality in the receiving and downstream environment.

- **Non-radiological air emissions and dust emissions (including nitrogen and sulphur oxides, and particulate matter) and subsequent deposition may cause a change in surface water quality.**

The construction and operation phase of the NSDF Project will generate non-radiological air and dust emissions such as carbon monoxide, sulphur oxides (includes sulphur dioxide), nitrogen oxides (includes nitrogen dioxide), particulate matter less than 2.5 microns in diameter ($PM_{2.5}$) or less than 10 microns in diameter (PM_{10}) and suspended particulate matter (SPM). Air emissions, such as sulphur oxides and nitrogen oxides, can result from the use of fossil fuels in generators, vehicles, and machinery. Vehicle exhaust and fugitive dust from unpaved and paved roads are the largest contributors of particulate matter (SPM, PM_{10} and $PM_{2.5}$) during both construction and operations phases (Section 5.2.1.6.2).

Implementation of applicable mitigation is anticipated to limit predicted residual effects from NSDF Project emissions to air quality (and subsequently to surface water quality) include meeting Tier 2 emission standards for on-site vehicles and equipment engines, use of vehicles that are maintained in good working order and idling of vehicles on site will be limited consistent with CNL's Environmental Protection Program. Dust control will be conducted to support waste placement operations in accordance with the *Dust Management Plan* (AECOM 2018c) during loading, transportation, placement, and compaction operations. Work areas that have the potential for generating dust will require implementation of dust suppression applications. The primary dust control method will include water spraying or misting techniques (e.g., water trucks). Fixatives (e.g., chemical suppressant) may also be used for dust control and for use as daily ECM cover. Water application and the use of fixatives will be controlled to limit potential effects on leachate and surface water runoff generated by the ECM.

Predicted concentrations for the Application Case during both construction and operations phases are below applicable air quality guidelines and/or standards with the exception of nitrogen dioxide, which will not meet the 2020 1-hour Canadian Ambient Air Quality Standards (Section 5.2.1.6.2, Table 5.2.1-14). The contributing factor to the high magnitude nitrogen dioxide emissions is the heavy-duty construction equipment and the conservative assumption that all equipment will run simultaneously and continuously during working hours. In reality, individual equipment will be idling or off for varying parts of the workday that cannot be predicted but will result in lower emissions than currently estimated. The likelihood that all equipment operates simultaneously for an hour or more along with unfavourable weather conditions to produce the maximum concentrations modelled is very low. With the implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018c) and through the implementation of the *Dust Management Plan* (AECOM 2018c) for the NSDF Project, air and dust emissions and subsequent deposition are expected to result in minor and local changes to water quality relative to Base Case conditions. Therefore, this pathway was determined to have negligible effects on surface water quality.

- **Physical disturbances in Perch Lake from the installation of diffuser and transfer line construction and footprint may affect water quality.**

Water management strategies for treated effluent include the use of a proposed discharge transfer line (320 m) with a diffuser positioned in Perch Lake (Figure 5.5.2.1). As part of the installation of the discharge transfer line, the open water section of the transfer line will include a foundation installed with steel pile supports for both the

transfer line and diffuser. This design was selected from four discharge options and was considered both technically and economically feasible. The preferred design to support the transfer line was also chosen over a gravel fill foundation, as it provided a much smaller footprint on the lakebed. The discharge transfer line will be constructed using 0.10 m diameter pipe and will be supported by approximately five pairs of piles spaced at approximately 50 m intervals along the discharge transfer line. The submerged diffuser will comprise one 28.2 mm (inside diameter) port, extending 0.8 m above the lakebed sediments to limit disturbance. The diffuser will rest on a pile cap supported by approximately four piles. The footprint of the discharge transfer line was estimated using the entire pipe length across Perch Lake of 320 m multiplied by a pipe diameter of 0.10 m, resulting in a conservative estimation of the permanent footprint of the transfer line as 32 m^2. Additional details regarding the transfer line are available in Section 3.4.2.6.2.

Of the 320 m transfer line length, approximately 23 m of the discharge line will be within the riparian marsh/shoreline area of the lake. Excavation and dredging activities will be required for a shallow trench (2 m deep by 2 m wide) for the placement of the discharge transfer line (total affected area would less than 46 m^2). Vegetated materials and organic debris will be stockpiled during dredging/excavation and then used to remediate disturbed areas as construction stages are completed.

The construction (temporary) footprint for the installation of the transfer line will be minimized where possible. Within the riparian marsh/shoreline section of the transfer line, vegetation mats will be used to mitigate disturbance to shoreline areas from any heavy equipment. The construction (temporary) footprint also includes a barge launch pad within a footprint of approximately 300 m^2 (i.e., 10 m × 30 m), occupying a riparian / shoreline area and possibly extending into the water to a depth of less than 1 m. The barge launch pad will be required to support the barge and drill rig assembly. The launch pad will be lined with geogrid/geotextile material and gravel. The pad will be removed post-construction and affected riparian and shoreline areas will be remediated through the re-vegetation of the disturbed area.

For the open water section of the transfer line in Perch Lake, drill pilings are expected to be completed by staged construction and therefore, it is assumed that an active work area at any given time will be restricted to the vicinity of the barge location where a pile or piles will be installed (Golder 2018). These active work areas will be contained by turbidity curtains to isolate and limit the extent of any suspended sediments (i.e., 5 m wide temporary work area).

Potential changes in sediment concentrations from the use of heavy machinery during the construction period will be mitigated using erosion and sediment control measures, such as turbidity curtains for the duration of the construction. Best management practices will be followed, including those identified in the NSDF *Environmental Protection Plan* (AECOM 2018a). Prior to construction, an Environmental Protection Plan will be developed by the Contractor listing measures for erosion and sediment control as well as spill management.

With the application of best management practices and associated mitigation and monitoring during installation and post-installation activities (removal of the turbidity barriers), changes to water quality (e.g., elevated total suspended sediment) will be limited to the area of installation that will be bound by turbidity curtains. Limited measurable changes to water quality outside of the turbidity curtains is expected, but any changes, such as elevated total suspended sediment concentrations, would be expected to be temporary in duration. Overall, changes to water quality in Perch Lake from the placement of the discharge transfer line are expected to be minor and have negligible residual effects on surface water quality.

- **The high-pressure horizontal directional drilling installation of the transfer line to Perch Lake may result in a release of drilling mud (i.e., frac-out), which may cause changes to surface water quality.**

With high pressure drilling operations, there is a risk of the drilling mud entering the environment through tunnel collapse, spills or frac-out (the rupture of mud to the ground surface). On-going environmental monitoring during drilling works can limit the effects of a frac-out and having an appropriate response plan in place can reduce the environmental effects of frac-out. Drilling mud is considered a deleterious substance that can adversely affect aquatic organisms and habitat. Specifically, inputs of drilling mud to aquatic habitat may result in adverse effects such as fish egg suffocation and reduction of plant and insect productivity (Falk and Lawrence 1973; Land 1974; Ferrante 1981).

The mitigation described for drilling activities in the DFO *Ontario Operational Statement - High-Pressure Directional Drilling* (DFO 2007) will be followed. This mitigation includes siting of the transfer line and access to temporary laydown and staging areas largely within a previously established access road right-of-way (Perch Lake Ring Road), minimization of vegetation removal beyond previously disturbed areas, creation of, and adherence to an emergency frac-out response plan and spill contingency plan during installation, and full-time environmental monitoring during all phases of transfer line works within the Perch Lake Swamp. The monitoring activities will monitor for adherence to environmental protection measures and provide for observations for signs of surface frac-out of drilling mud. Evidence of frac-out will trigger implementation of the frac-out response plan.

Additional mitigation strategies will include:

- Machine operation will take place on land above the high-water mark of Perch Lake.
- Drilling machinery will be clean and leak free.
- Service, washing, refuelling and storage of operational liquids for the machinery will be kept at a distance from surface water features to ensure spills do not drain into the waterbody. Emergency spill kits will be kept available at the working site in the event of a fluid leak or spill. Potential pathways for spilled products (e.g., storm drains) should be mapped and plans put in place to prevent entry of deleterious products into the storm drain system.
- Where possible, drilling will be timed to occur during daylight hours, which will increase the probability of visually identifying a frac-out of drilling mud.
- Disposal of drilling mud, cuttings, and all waste will be directed to appropriate disposal facilities. All waste materials will be contained in a dugout or holding basin away from wetlands or other surface water features, or storm drains, to avoid entering natural surface water features, until they can be transported for disposal.
- Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CNL site will be used during construction of the transfer line to Perch Lake as the exit point for drilling will be within the Perch Lake riparian area.
- On-going monitoring will occur during all phases of drilling works, including fluid pressure (by drillers) and changes in turbidity in local surface water features (by environmental monitors) that would indicate surface migration (frac-out) of drilling mud.
- Material and equipment required to contain and cleanup a frac-out event will be located in close proximity to the working area. In the event of frac-out, the following processes will be followed:

- Stop work. Contain drilling mud. Take care that cleanup effort does not result in damage to Perch Lake Swamp or Perch Lake.
- Containment booms, silt fences, and other appropriate erosion control measures will be deployed to prevent further migration to surrounding areas. Erosion control equipment will be on-site and ready for deployment.
- Notify the CNL facilities representative on-site.
- Drillers to evaluate data and circumstances leading to the loss of circulation and if possible, implement methods to seal the fracture.
- All spills will be evaluated, and work will cease, if frac-out cannot be stopped and/or thresholds of environmental regulations are exceeded (i.e., relevant water quality benchmarks in the surrounding wetlands and/or Perch Lake). A directional drilling contingency plan will be implemented if drilling is unsuccessful along the designated corridor. Enactment of this contingency plan will require review by the responsible parties with CNL prior to initiation.

The implementation of mitigation and monitoring during the drilling of the transfer line to Perch Lake will reduce the potential for a frac-out event. Some localized effects around the drilling zones may occur, but these events will be quickly identified, and the application of mitigation associated with the management and response plans would limit any effects to small, if measurable, and temporary changes to surface water.

5.4.2.5.2.3 Primary Pathways

The following primary pathways were identified as having the potential to result in residual effects to surface water quality:

- **Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) can cause changes to downstream surface water quality.**
- **Leakage of leachate from the ECM during the post-closure phase (i.e., after Year 2400) from liner and final cover degradation as a result of normal evolution can cause changes to downstream surface water quality.**

However, only the primary pathway associated with the discharge of treated effluent from the WWTP to the exfiltration gallery and to Perch Lake has been carried forward to the residual effects analysis in this section. The primary pathway associated with the leakage of leachate from the ECM in the closure/post-closure phases of the Project is discussed in Section 5.7 (Ambient Radioactivity and Ecological Health).

5.4.2.6 Residual Effects Analysis

Residual effects to surface water quality are limited to operational discharges of treated effluent from the WWTP to the exfiltration gallery and to Perch Lake, and it's potential to change surface water chemistry in the receiving and downstream environment. This assessment includes an assessment focused on select non-radiological constituents, and a small number of radiological constituents.

5.4.2.6.1 Methods

5.4.2.6.1.1 Model Overview

The effect of the NSDF Project to surface water quality on the receiving and downstream environment was modelled using the GoldSim. GoldSim is a graphical Windows-based simulation software package developed by the GoldSim Technology Group. The GoldSim model was employed as a "graphical spreadsheet" to estimate non-radiological and radiological contaminant concentrations at focal surface water assessment nodes within the Perch Creek Basin catchment based on an instantaneous mixing zone mass balance approach. The model was run using site specific information, and projected flow data and projected wastewater effluent quality and quantity data for select COPCs provided by previous hydrologic studies, recent water quality reports, and the NSDF Project Description.

The following list summarizes the water quantity and quality reference documents used to characterize the surface water quality GoldSim model:

- Water Quantity:
  - Average monthly flow rates and precipitation data from 1969 to 1980 for five Perch Lake inlets (PL1, PL2, PL3, PL4, and PL5) and one outlet flow (PL0; Robertson and Barry 1985);
  - Monthly flow rates based on annual averages for Main Stream Culvert (MSC), South Swamp Weir (SSW), and East Swamp Weir (ESW) (CNL 2016c);
  - Projected leachate and contact wastewater generation rates as a result of normal operation and back-to-back 100-year storm events (AECOM 2019);
  - Perch Creek catchment annual flow rates downstream of Perch Lake Outlet (CNL 2016c); and
  - Average annual Ottawa River flow rates (Table 5.4.1-3).
- Water Quality:
  - Average annual non-radiological water chemistry existing environmental concentrations at surface water model nodes of interest from 2010 to 2018 (CNL 2018e, CNL 2017c, CNL 2019b);
  - Non-radiological and radiological WWTP projected treated effluent concentrations and effluent discharge targets (AECOM 2019);
  - Non-radiological and radiological monitored water chemistry for Perch Lake from a 2018 lake survey (CNL 2018b).

5.4.2.6.1.2 Model Scenarios

The GoldSim model is designed to simulate operating conditions during years 45 to 50 of the NSDF Project when the greatest amount of contact water requires treatment and when the largest volume of treated effluent from the WWTP is expected to be generated. The construction phase from 2022 to 2024 was removed from consideration as a model scenario because of its time-period (as COPCs are not expected to be generated in reasonable quantities during construction to affect receiving and downstream water quality as described in Section 5.4.2.6.2). The ECM will have a final waste capacity of 1,000,000 m^3 and will be comprised of ten cells – each with an average surface area of approximately 12,000 m^2. The model implicitly considers the contact water that is generated over the surface area of the ECM by including the back-to-back 100-year freshet storm event flows with normal operating condition flows. Thus, the normal operating condition is represented as one single annual discharge of 13,320 m^3/yr, which is comprised of:

- two weeks of 22.5 m^3/hr discharge (at 8 hours per day) corresponding to the storm event (i.e. 2,520 m^3/yr); and
- 120 days of 11.25 m^3/hr discharge (at 8 hours per day) corresponding to normal operating conditions spread over mid-March to October (i.e. 10,800 m^3/yr).

The combination of these discharge conditions represents a single bound annual discharge scenario that results in a cumulative discharge volume of 13,320 m^3. This volume is an 18% increase above the annual estimated discharge wastewater volume of 11,230 m^3, which represents the maximum projected wastewater volume generated over the life of the NSDF (AECOM 2018d). The volume generated for the back to back 100-year storm event (i.e., 2,520 m^3) represents 70% of the volume estimated for back to back 100-year storm, based on 1,800 m^3 generated for the NSDF Project from a 100-year storm event over a 24-hr period (AECOM 2018d). For the purposes of the assessment, it was assumed that the WWTP would only need to discharge at a higher rate for two weeks to reduce the volume of wastewater to a manageable volume to allow normal operating conditions to resume.

Using the single annual discharge condition as a baseline, the GoldSim model was run using two scenarios as detailed in the following sections.

Scenario 1

- Total annual WWTP discharge of 13,320 m^3/yr
- 50% discharge to East Swamp Wetland via the exfiltration gallery and 50% discharge to Perch Lake

This scenario divides the total annual discharge equally between the exfiltration gallery and Perch Lake (direct pumping to Perch Lake via transfer line). The exfiltration gallery is considered to be the downstream portion of East Swamp (upstream of East Swamp weir) and the outfall location is considered to be at the northeastern shoreline of Perch Lake.

Scenario 2

- Total annual WWTP discharge of 13,320 m^3/yr (same as Scenario 1)
- 100% discharge to Perch Lake

This scenario discharges 100% of the total annual discharge directly into Perch Lake at the deepest location in the lake.

5.4.2.6.1.3 Model Inputs and Assumptions

GoldSim was run for the two scenarios using monthly time steps for 15 years to illustrate concentration trends. The mass balance calculations assumed year-to-year continuous time series of seasonal effluent discharge from mid-March to October, instantaneous and complete mixing, and contaminants were modelled to be fully conservative (no decay and no sorption).

The model considered several nodes upstream of Perch Lake, namely, Main Stream Culvert (MSC), South Swamp Weir (SSW), and East Swamp Weir (ESW), which correspond to the surface water quality monitoring stations as shown on Figure 5.4.1-1. Similarly, downstream nodes relative to Perch Lake include Perch Creek weir (PCW) and Perch Creek Outlet (PCO) where PCO is assumed to be fully mixed at the confluence with the Ottawa River (OR).

The 1985 water balance study provided monthly estimates of inflow and outflow at the Perch Lake inlets and outlets for the model. Model inflow rates for Perch Lake inflows were assumed to be representative of a typical predominately natural watershed with high snowmelt flows occurring in April.

The 1985 water balance study estimated an annual average flow rate at the outlet of Perch Lake of approximately 1,788,000 m^3/yr – a reasonable estimate in comparison to the annual average flow rate at the same outlet of 1,700,000 m^3/yr provided by CNL (CNL 2016c). CNL also provided an estimate of the average annual flow rate at the outlet of Perch Creek of 2,210,000 m^3/yr (CNL 2016c).

Existing environmental water quality conditions for Perch Lake were limited to a baseline survey completed in 2018. Existing water quality conditions in Perch Lake were therefore derived from the flow-weighted sum of average measured parameter concentrations from the inflow monitoring stations to Perch Lake, PL1, PL2, PL3, PL4, and PL5. Relative to the total inflow to Perch Lake, PL1 received a weighting of 15%, PL2 received a weighting of 67%, and PL3 through PL5 combined received a weighting of 18%. The total incoming concentration was used to estimate an initial mass loading (model input) into Perch Lake based on the lake's 900,000 m^3 volume. The 2018 data for Perch Lake provided a basis for comparison of the flow-weighted data.

5.4.2.6.1.4 Model Screening for Constituents of Potential Concern

The COPCs included for further analysis in the GoldSim model represent a collection of key parameters that have undergone an iterative screening process throughout the life of the NSDF Project using best available information from WWTP design and waste characterization documents at the time. The initial list of COPCs for modelling focussed on those that were known to be important to human and aquatic life, and radiological parameters that have been conventionally monitored for decades by CNL. The final list of COPCs represented a total of 40 different non-radiological and radiological parameters.

Non-radiological COPCs were screened in or out based on the following screening factors:

1) Availability of Projected Wastewater Characteristics
2) Treatment Requirement
3) High Existing Environmental Conditions
4) Potential for Nutrient Enrichment Effects on Trophic States
5) Ionic Composition
6) Potential for Effects on Aquatic Life

Organic compounds were not included in the modelling as these compounds are generally only present in trace amounts, with no obvious source in the waste inventory.

Based on the above approach, the following non-radiological parameters screened into the surface water quality assessment:

- major ions – sodium, potassium, calcium, magnesium, fluoride, sulphate, and chloride (including hardness);
- nutrients – nitrate, nitrite, and phosphorus; and
- metals – aluminum, antimony, barium, boron, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, molybdenum, nickel, selenium, silver, strontium, thallium, tin, uranium, vanadium, and zinc.

Radiological COPCs were screened based on the following:

1) The predicted treated effluent concentration for a radionuclide was greater than 1% of the No Effect Concentration (NEC) for that radionuclide.
2) Where NEC were not available for a radionuclide, screening was based on human exposure factors consistent with Arcadis and Quintessa (2020) or if it was present in elevated concentrations in surface water within the Perch Creek and Perch Lake Watershed.
3) Radionuclides of public interest or site focus.

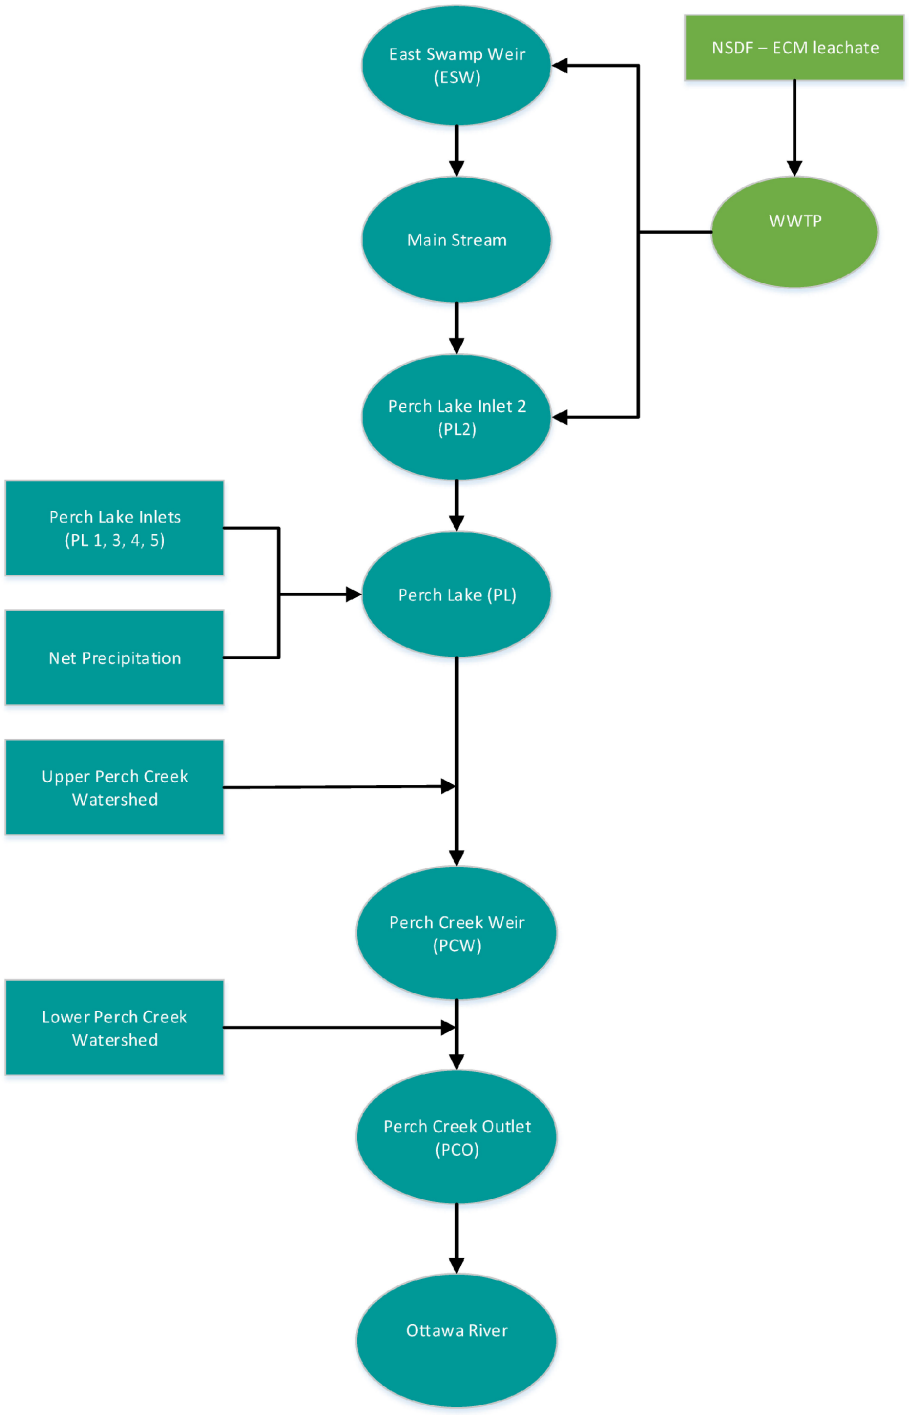
The following radiological parameters screened into the surface water quality assessment:

- Carbon-14 – the predicted treated effluent concentration exceeds 1% of the NEC for biota.
- Caesium-137 – although treated effluent concentration is well below 1% of the NEC, it is present in slightly elevated concentrations in surface water within the Perch Creek and Perch Lake Watershed.
- Cobalt-60 – the predicted treated effluent concentration exceeds 1% of the NEC for biota.
- Gross Beta (noting that strontium-90 is the main contributor to the gross beta concentrations) – although the treated effluent concentration for strontium-90 is well below 1% of the NEC, it is present in elevated concentrations in surface water within the Perch Creek and Perch Lake Watershed.
- Tritium – is of public interest. The predicted treated effluent concentration also approaches 1% of the NEC.

5.4.2.6.1.5 Model Inputs for the Treated Effluent Discharge

For the majority of the COPCs in the assessment, the maximum projected wastewater concentration was lower than the effluent discharge target (e.g., antimony). Although in this situation targeted treatment of this COPC would not be required prior to discharge, mass loading inputs to the water quality model for the operational discharge scenarios used the effluent discharge target. This approach applied a high level of conservatism to the modelling assessment.

For a subset of the COPCs (i.e., aluminum, cobalt, iron, manganese, nitrate, nitrite, sulphate and cobalt-60), the maximum projected wastewater concentration was higher than the treated effluent discharge trigger (e.g., aluminum: wastewater concentration = 150 micrograms per litre [µg/L]; treated effluent discharge trigger = 50 µg/L). This means that treatment of the COPCs is required prior to discharge being acceptable. For these COPCs, the mass loading input to the water quality model for the operational discharge scenarios used the treated effluent discharge target concentration and assumes that the treated effluent discharge will consistently meet the effluent discharge target. This approach applied a lower level of conservatism to the modelling assessment for these COPCs.



In a few instances (e.g., ammonia, phosphorus, uranium), the maximum projected wastewater concentration was not available. In these cases, the treated effluent discharge target was assigned to the treatment specifications. For these COPCs, the mass loading input for each modelling scenario used the treated effluent discharge target. For phosphorus, despite the maximum projected wastewater concentration not being available, there is confidence in the ability of the WWTP to meet the treated effluent discharge target. The WWTP treatment process for phosphorus is chemical precipitation by ferric chloride. If higher than normal phosphorus concentrations are measured in the wastewater feed to the WWTP treatment process, the ferric chloride precipitation process can be optimized for enhance phosphorus removal. If phosphorus concentrations in water in the Final Effluent Tank prior to discharge exceeds the effluent discharge target, this water will be returned to the beginning of the treatment process for further treatment.

5.4.2.6.1.6 Model Output

The assessment nodes at which water quality concentrations were estimated are listed as follows and as illustrated in the annual average water balance on Figure 5.4.2-1:

1) ESW: East Swamp Weir;
2) PL2: Perch Lake Inlet #2;
3) PL: Perch Lake;
4) PCW: Perch Creek Weir;
5) PCO: Perch Creek Outlet; and
6) OR: Ottawa River.

The Ottawa River assessment node is located 8 km downstream of the CRL Built-up Area, where it is assumed that any discharge from the Perch Creek and Perch Lake Watershed has been completely mixed.

Model results for the COPCs are presented by node and model scenario. All modelled concentrations are inclusive of the existing baseline concentrations (at nodes where existing baseline information was available). Where existing baseline data were not available, the modelled results were limited to providing only an indication of incremental increase to that parameter concentration at the assessment node. The modelled results for the screened COPCs at each assessment node in the Perch Creek and Perch Lake Watershed downstream of the NSDF Project are presented as the average, 95th percentile, and maximum concentrations as these statistical values are used to further classify the COPCs for monitoring requirements and to determine the likelihood of environmental (e.g., aquatic) effects. These summary statistics were generated from the modelled monthly concentrations over the 15-year run time during operating conditions associated with years 45 to 50 of the NSDF Project. This specific operations focus in the modelling is associated with the highest amount of contact water that requires treatment and when the largest volume of treated effluent from the WWTP is expected to be generated for discharge. All resultant modelled concentrations for each COPC were evaluated against the respective effluent discharge target (if available) and their risk benchmark or no effects concentration.

5.4.2.6.2 Application Case Results

This section provides a summary of the modelling results for a select group of COPCs based on discernible trends in the results. The more detailed GoldSim surface water quality modelling results for each of the screened non-radiological and radiological COPCs are presented in detail the Surface Water Quality Technical Supporting Document (Golder 2019b).

- Overall, the water quality modelling results indicated the following water quality projections for the Perch Creek and Perch Lake Watershed and the Ottawa River:
- Incremental changes to water quality during discharges under both discharge scenarios resulting from the operation of the NSDF Project are not expected to result in adverse effects throughout the Perch Creek and Perch Lake Watershed.
- In Scenario 1 where 50% of the discharge is directed to East Swamp Wetland (ESW) via the exfiltration gallery and 50% is directed to Perch Lake (PL), a distinct reducing COPC concentration gradient is evident between ESW and PL, which decreases further to Perch Creek Outlet (PCO).
- In Scenario 2 where 100% of the discharge is directed to Perch Lake, COPC concentrations at East Swamp Wetland (ESW) and Perch Lake Inlet 2 (PL2) remain at ambient concentrations while concentrations at PL increase relative to ambient concentrations. After Perch Lake (PL), a decreasing concentration gradient towards Perch Creek Outlet (PCO) is evident.
- Projected changes to Ottawa River (OR) quality as a result of the NSDF Project during operations are negligible. For most COPCs, incremental changes in concentration as a result of the NSDF Project are not expected to be measurable in the Ottawa River, recognizing that the annual average Perch Creek flow rate (2.3 million m^3/yr) represents less than 0.01% of annual average Ottawa River flow rate (approximately 25,000 million m^3/yr). The Ottawa River is expected to adequately rapidly assimilate the discharge from the Perch Creek and Perch Lake Watershed under all scenarios, such that aquatic life and drinking water sources are unlikely to be affected as a result of the NSDF Project discharges. Therefore, the Ottawa River water quality is expected to remain at its existing baseline conditions through the entire NSDF Project operations lifespan.

Under both operations scenarios, the modelling results indicated four clear trends in modelled COPC concentrations at the assessment nodes in the Perch Creek and Perch Lake Watershed:

- The discharge of treated effluent under both scenarios resulted in a negligible change to COPC concentrations at ESW, PL2, and PL (i.e., within 10% of baseline conditions). This was observed for the following COPCs: barium, cadmium (Table 5.4.2-8), iron, lead, and silver (Table 5.4.2-9). For these COPCs, the existing baseline concentrations at each assessment node were higher than the treated effluent discharge target.

Table 5.4.2-8: Water Quality Modeling Results for Cadmium

Cadmium	Units	ESW	PL2	PL[(a)]	PCW	PCO	OR
Criteria	µg/L	EDT: 0.09[(b)]; RB: 1.0					
Existing Baseline Concentration	µg/L	0.052	0.058	0.049	0.013	0.013[(c)]	0.026
Scenario 1 - 50% to Exfiltration Gallery, 50% Direct Discharge to Perch Lake							
Mean	µg/L	0.056	0.062	0.040	0.031	0.028	0.026
95th Percentile	µg/L	0.065	0.062	0.043	0.039	0.038	0.026
Maximum	µg/L	0.065	0.062	0.043	0.039	0.038	0.026
Scenario 2 - 100% Direct Discharge to Perch Lake							
Mean	µg/L	0.052	0.062	0.040	0.031	0.028	0.026
95th Percentile	µg/L	0.052	0.062	0.043	0.039	0.038	0.026
Maximum	µg/L	0.052	0.062	0.043	0.039	0.038	0.026

(a) Perch Lake existing baseline concentration based on a flow-weighted calculation using all available upstream data sources. Existing baseline cadmium concentrations in Perch Lake only available in 2018 (average = 0.004 µg/L). The flow-weighted average data for PL used in the modelling assessment over the lake-specific measured data for conservatism.

(b) The effluent discharge target for cadmium is hardness dependent as per CCME (1999) guidelines.

(c) PCO existing baseline concentrations were assigned PCW existing baseline concentrations since the PCO location is just downstream of the PCW location.

ESW = East Swamp weir; PL2 = Perch Lake Inlet #2; PL = Perch Lake; PCW = Perch Creek weir; PCO = Perch Creek outlet; OR = Ottawa River; µg/L = micrograms per litre; EDT = treated effluent discharge target; RB = risk benchmark.

Table 5.4.2-9: Water Quality Modeling Results for Silver

Silver	Units	ESW	PL2	PL[(a)]	PCW	PCO	OR[(b)]
Criteria	µg/L	EDT: 0.1; RB: 4.1					
Existing Baseline Concentration	µg/L	1.000	1.000	1.000	1.000	1.000[(c)]	No data
Scenario 1 - 50% to Exfiltration Gallery, 50% Direct Discharge to Perch Lake							
Mean	µg/L	0.890	1.040	0.740	0.573	0.516	NCB
95th Percentile	µg/L	1.000	1.047	0.798	0.728	0.699	NCB
Maximum	µg/L	1.000	1.047	0.798	0.728	0.700	NCB
Scenario 2 - 100% Direct Discharge to Perch Lake							
Mean	µg/L	1.000	1.047	0.740	0.573	0.516	NCB
95th Percentile	µg/L	1.000	1.047	0.798	0.728	0.699	NCB
Maximum	µg/L	1.000	1.047	0.798	0.728	0.700	NCB

Note: Shading = concentration higher than the treated effluent discharge target.

(a) Perch Lake existing baseline concentration based on a flow-weighted calculation using all available upstream data sources. Existing baseline silver concentration specifically in Perch Lake only available in 2018 (average = 1.000 µg/L), which was consistent with the flow-weighted calculation.

(b) All OR results are based on an assumed zero existing baseline concentration due to absent measured existing baseline concentration data.

(c) PCO existing baseline concentrations were assigned PCW existing baseline concentrations since the PCO location is just downstream of the PCW location.

A modelled result showing '**NCB'** indicates that an incremental increase in silver is expected not to be measurable, so the projection is no change from existing baseline concentrations.

ESW = East Swamp weir; PL2 = Perch Lake Inlet #2; PL = Perch Lake; PCW = Perch Creek weir; PCO = Perch Creek outlet; OR = Ottawa River; µg/L = micrograms per litre; EDT = treated effluent discharge target; RB = risk benchmark.

- The discharge of treated effluent under Scenario 1 resulted in an incremental increase in COPC concentration at ESW and PL2 whereas the discharge of treated effluent under Scenario 2 resulted in no incremental change in COPC concentration at ESW and PL2. This was observed for ammonia, antimony, boron, calcium, chloride, cobalt (Table 5.4.2-10), fluoride, magnesium, manganese, mercury, molybdenum, nickel, nitrate, nitrite, phosphorus, potassium, selenium, sodium, strontium (Table 5.4.2-11), sulphate, thallium, tin, uranium, vanadium, zinc, carbon-14, caesium-137 (Table 5.4.2-12), cobalt-60, and tritium. The higher projected COPC concentrations at ESW and PL2 in the combined discharge scenario (Scenario 1) compared to the direct discharge to Perch Lake (Scenario 2) suggest that the assimilation of treated effluent for these COPCs through the exfiltration gallery is not as pronounced as it is via direct discharge to Perch Lake. With the exception of the modelled COPC concentrations at ESW and PL2 during operations for the combined discharge, all other modelled concentrations were similar to existing baseline concentrations at the Perch Creek assessment nodes.

Table 5.4.2-10: Water Quality Modeling Results for Cobalt

Cobalt	Units	ESW	PL2	PL[(a)]	PCW	PCO	OR[(b)]
Criteria	µg/L	EDT: 0.9**;** RB: 1,500					
Existing Baseline Concentration	µg/L	0.450	0.330	0.351	0.240	0.240[(c)]	No data
Scenario 1 - 50% to Exfiltration Gallery, 50% Direct Discharge to Perch Lake							
Mean	µg/L	0.505	0.356	0.278	0.215	0.194	NCB
95th Percentile	µg/L	0.609	0.366	0.299	0.274	0.263	NCB
Maximum	µg/L	0.611	0.366	0.299	0.274	0.264	NCB
Scenario 2 - 100% Direct Discharge to Perch Lake							
Mean	µg/L	0.450	0.351	0.278	0.215	0.194	NCB
95th Percentile	µg/L	0.450	0.351	0.299	0.274	0.263	NCB
Maximum	µg/L	0.450	0.351	0.299	0.274	0.264	NCB

(a) Perch Lake existing baseline concentration based on a flow-weighted calculation using all available upstream data sources. Existing baseline cobalt concentration data for Perch Lake only available in 2018 (average = 0.1 µg/L). The flow-weighted average data for PL used in the modelling assessment over the lake-specific measured data for conservatism.

(b) All OR results are based on an assumed zero existing baseline concentration due to absent measured existing baseline concentration data.

(c) PCO existing baseline concentrations were assigned PCW existing baseline concentrations since the PCO location is just downstream of the PCW location.

A modelled result showing '**NCB'** indicates that an incremental increase in cobalt is expected not to be measurable, so the projection is no change from existing baseline concentrations. ESW = East Swamp weir; PL2 = Perch Lake Inlet #2; PL = Perch Lake; PCW = Perch Creek weir; PCO = Perch Creek outlet; OR = Ottawa River; µg/L = micrograms per litre; EDT = treated effluent discharge target; RB = risk benchmark.

Table 5.4.2-11: Water Quality Modeling Results for Strontium

Strontium	Units	ESW	PL2	PL[a]	PCW	PCO	OR
Criteria	µg/L	EDT: 1,500[b]; RB: 15,000					
Existing Baseline Concentration	µg/L	39.5	44.5	45.0	43.4	43.4[c]	28.3
Scenario 1 - 50% to Exfiltration Gallery, 50% Direct Discharge to Perch Lake							
Mean	µg/L	218.0	73.2	53.4	41.3	37.2	28.3
95th Percentile	µg/L	555.9	99.7	57.4	53.1	51.0	28.3
Maximum	µg/L	563.6	100.5	57.4	53.1	51.0	28.3
Scenario 2 - 100% Direct Discharge to Perch Lake							
Mean	µg/L	39.5	61.6	53.4	41.3	37.2	28.3
95th Percentile	µg/L	39.5	61.6	57.4	53.1	51.0	28.3
Maximum	µg/L	39.5	61.6	57.4	53.1	51.0	28.3

(a) Perch Lake existing baseline concentration based on a flow-weighted calculation using all available upstream data sources. Existing baseline strontium concentration specifically in Perch Lake only available in 2018 (average = 41.0 µg/L). The flow-weighted average data for PL used in the modelling assessment over the lake-specific measured data for conservatism.

(b) No effluent discharge target is specified for Strontium. A COPC screening limit of 1,500 µg/L is reported from *Environmental Risk Assessment of Chalk River Laboratories* (CNL 2019b).

(c) PCO existing baseline concentrations were assigned PCW existing baseline concentrations since the PCO location is just downstream of the PCW location.

ESW = East Swamp weir; PL2 = Perch Lake Inlet #2; PL = Perch Lake; PCW = Perch Creek weir; PCO = Perch Creek outlet; OR = Ottawa River; µg/L = micrograms per litre; EDT = treated effluent discharge target; RB = risk benchmark.

Table 5.4.2-12: Water Quality Modeling Results for Caesium 137

Caesium-137	Units	ESW	PL2	PL[a]	PCW	PCO	OR
Criteria	Bq/L	EDT: 10; NEC: 73					
Existing Baseline Concentration	Bq/L	0.152	0.010	0.010	0.007	0.007[b]	0.005
Scenario 1 - 50% to Exfiltration Gallery, 50% Direct Discharge to Perch Lake							
Mean	Bq/L	1.356	0.099	0.086	0.067	0.060	0.005
95th Percentile	Bq/L	3.634	0.282	0.106	0.089	0.086	0.005
Maximum	Bq/L	3.686	0.288	0.106	0.089	0.086	0.005
Scenario 2 - 100% Direct Discharge to Perch Lake							
Mean	Bq/L	0.152	0.018	0.086	0.067	0.060	0.005
95th Percentile	Bq/L	0.152	0.018	0.106	0.089	0.086	0.005
Maximum	Bq/L	0.152	0.018	0.106	0.089	0.086	0.005

(a) Perch Lake existing baseline concentration based on a flow-weighted calculation using all available upstream data sources. Existing baseline caesium-137 concentration specifically in Perch Lake only available in 2018 (average = 0.028 Bq/L). The flow-weighted average data for PL used in the modelling assessment over the lake-specific measured data.

(b) PCO existing baseline concentrations were assigned PCW existing baseline concentrations since the PCO location is just downstream of the PCW location.

ESW = East Swamp weir; PL2 = Perch Lake Inlet #2; PL = Perch Lake; PCW = Perch Creek weir; PCO = Perch Creek outlet; OR = Ottawa River; Bq/L = Becquerels per litre; EDT = treated effluent discharge target; NEC = no effects concentration.

- Modelled COPC concentrations showed a notable incremental increase at PL2 for both discharge scenarios during the operation of the NSDF Project, but not at ESW. The COPCs included chloride (Table 5.4.2-13), nitrate, selenium, strontium, and gross beta (Table 5.4.2-14). The source of this elevated concentration at PL2 is attributed to high existing baseline concentrations at MSC measured in 2018, which was incorporated into the flow weighted existing baseline concentration calculations for PL2. These elevated concentrations then attenuated with progression through Perch Lake to PCO.

Table 5.4.2-13: Water Quality Modeling Results for Chloride

Chloride	Units	ESW	PL2	PL[(a)]	PCW	PCO	OR[(b)]
Criteria	mg/L	EDT: 120; RB: 640					
Existing Baseline Concentration	mg/L	15.7	54.0	40.7	19.9	19.9[(c)]	No data
Scenario 1 - 50% to Exfiltration Gallery, 50% Direct Discharge to Perch Lake							
Mean	mg/L	28.5	107.5	62.9	48.6	43.7	NCB
95th Percentile	mg/L	52.6	107.7	67.9	61.3	58.9	NCB
Maximum	mg/L	53.1	107.7	67.9	61.4	59.0	NCB
Scenario 2 - 100% Direct Discharge to Perch Lake							
Mean	mg/L	15.7	107.4	62.9	48.6	43.7	NCB
95th Percentile	mg/L	15.7	107.4	67.9	61.3	58.9	NCB
Maximum	mg/L	15.7	107.4	67.9	61.4	59.0	NCB

(a) Perch Lake existing baseline concentration based on a flow-weighted calculation using all available upstream data sources. Existing baseline chloride concentration specifically in Perch Lake only available in 2018 (average = 26.2 mg/L). The flow-weighted average data for PL used in the modelling assessment over the lake-specific measured data for conservatism.

(b) All OR results are based on an assumed zero existing baseline concentration due to absent measured existing baseline concentration data.

(c) PCO existing baseline concentrations were assigned PCW existing baseline concentrations since the PCO location is just downstream of the PCW location.

A modelled result showing 'NCB' indicates that an incremental increase in chloride is expected not to be measurable, so the projection is no change from existing baseline concentrations.

ESW = East Swamp weir; PL2 = Perch Lake Inlet #2; PL = Perch Lake; PCW = Perch Creek weir; PCO = Perch Creek outlet; OR = Ottawa River; milligrams per litre; EDT = treated effluent discharge target; RB = risk benchmark.

Table 5.4.2-14: Water Quality Modeling Results for Gross Beta

Gross Beta	Units	ESW	PL2	PL[(a)]	PCW	PCO	ORC
Criteria	Bq/L	**EDT: 5**; NEC: 183					
Measured Background Concentration	Bq/L	293	17	11	9	9[(b)]	0.041
Scenario 1 - Nine Closed Cells, One Active Cell, 50% to Exfiltration Gallery, 50% Direct Discharge to Perch Lake							
Mean	Bq/L	258	37	28	22	20	0.043
95th Percentile	Bq/L	293	37	30	28	26	0.046
Maximum	Bq/L	293	37	30	28	26	0.046
Scenario 2 - Nine Closed Cells, One Active Cell, 100% Direct Discharge to Perch Lake							
Mean	Bq/L	293	37	28	22	20	0.043
95th Percentile	Bq/L	293	37	30	28	26	0.046
Maximum	Bq/L	293	37	30	28	26	0.046

Note: Shading = exceedance of effluent discharge target.

(a) Perch Lake existing baseline concentration as-modelled is based on a flow-weighted calculation using all available upstream data sources. Existing baseline Gross Beta concentration specifically in Perch Lake only available in 2018 (average = 14 Bq/L). The flow weighted average data for PL used in the modelling assessment over the lake specific measured data.

(b) PCO existing baseline concentrations were assigned PCW existing baseline concentrations since the PCO location is just downstream of the PCW location.

Bq/L = Becquerels per litre; EDT = treated effluent discharge target; NEC = no effects concentration.

- Modelled COPC concentrations measured above their respective risk benchmarks or no effect concentrations. With the exception of COPCs that had baseline concentrations above their treated effluent discharge targets and risk benchmarks (e.g., iron, barium, lead, phosphorus, silver, and gross beta – above effluent discharge targets; aluminum and copper – above risk benchmarks), some COPCs were predicted to be above their treated effluent discharge targets at intermittent cases. These included sulphate (Table 5.4.2-15) and nitrite at ESW (at the 95th and maximum concentrations under scenario 1, and selenium at PL2 (under both scenarios for average, 95th and maximum concentrations). Manganese was measured above the treated effluent discharge target under existing baseline conditions at PCW and PCO.

Table 5.4.2-15: Water Quality Modeling Results for Sulphate

Sulfate	Units	ESW	PL2	PL[(a)]	PCW	PCO	OR[(b)]
Criteria	mg/L	EDT: 128; RB: No data					
Existing Baseline Concentration	mg/L	1.99	1.41	1.25	2.79	2.79[(c)]	No data
Scenario 1 - 50% to Exfiltration Gallery, 50% Direct Discharge to Perch Lake							
Mean	mg/L	79.22	6.60	5.69	4.41	3.97	0.000
95th Percentile	mg/L	225.45	18.23	6.93	5.88	5.65	0.001
Maximum	mg/L	228.79	18.61	6.94	5.89	5.65	0.001
Scenario 2 - 100% Direct Discharge to Perch Lake							
Mean	mg/L	1.99	1.50	5.69	4.41	3.97	0.000
95th Percentile	mg/L	1.99	1.50	6.93	5.88	5.65	0.001
Maximum	mg/L	1.99	1.50	6.94	5.89	5.65	0.001

Note: Shading = concentrations higher than treated effluent discharge target.

(a) Perch Lake existing baseline concentration based on a flow-weighted calculation using all available upstream data sources. Existing baseline sulfate concentration specifically in Perch Lake only available in 2018 (average = 2.33 mg/L). The flow-weighted average data for PL used in the modelling assessment over the lake-specific measured data.

(b) All OR results are based on an assumed zero existing baseline concentration due to absent measured existing baseline concentration data.

(c) PCO existing baseline concentrations were assigned PCW existing baseline concentrations since the PCO location is just downstream of the PCW location.

ESW = East Swamp weir; PL2 = Perch Lake Inlet #2; PL = Perch Lake; PCW = Perch Creek weir; PCO = Perch Creek outlet; OR = Ottawa River; mg/L = milligrams per litre; EDT = treated effluent discharge target; RB = risk benchmark.

5.4.2.7 Prediction Confidence and Uncertainty

Predicted residual effects are not expected to be underestimated due to following factors that have contributed to conservatism in the modelling projections:

- For the majority of the COPCs in the assessment, the maximum projected wastewater concentration was lower than the effluent discharge target.
  - For a subset of the COPCs (i.e., aluminum, cobalt, iron, manganese, nitrate, nitrite, sulphate, and cobalt-60), the maximum projected wastewater concentration was higher than the treated effluent discharge trigger (e.g., aluminum: wastewater concentration = 150 µg/L; treated effluent discharge trigger = 50 µg/L).
  - In a few COPC instances (e.g., ammonia, uranium), the maximum projected wastewater concentration was not available. In these cases, the treated effluent discharge target was assigned to the modelling assessment.
  - For one COPC (e.g., phosphorus), the maximum projected wastewater concentration was not available; however, based on the treatability of phosphorus in wastewater a treated effluent discharge target was assigned to the discharge that is expected to be achievable.
- In each discharge scenario, the water quality model was run without decay or sorption mechanisms, whereas in actuality concentrations may be subject to chemical, physical, radioactive decay, and biological processes that can remove them from the mass balance as they progress downstream.
- Background concentrations obtained from previous reports were typically presented as averages from 2010 to 2018, which include data measured below detection. For data measured below detection, the detection level was used in the averaging calculation; the true existing baseline concentrations may not have been as high as used. Nonetheless, these as-stated averages used in the model are considered a conservative estimate of the existing baseline concentrations.

Further discussion on the prediction confidence and uncertainty in the assessment is presented in the technical support document appended to this section.

5.4.2.8 Monitoring and Follow-up

Routine surface water quality monitoring will be integrated into CNL's Environmental Monitoring Program, which will be continued for the NSDF Project. The effluent water quality monitoring will be integrated into the CRL Effluent Verification Monitoring Program.

As part of the Environmental Monitoring Program, surface water monitoring in the receiving environment at the assessment nodes and effluent quality monitoring at the WWTP discharge point for radiological and non-radiological parameters will continue through the operations phase (Table 5.4.2-16) and be undertaken through closure, and post closure. The Environmental Monitoring and Effluent Verification Monitoring will be used the verify the surface water management ponds are performing as designed, mitigation associated with operation of the NSDF Project is effective, effluent discharge targets developed for the NSDF Project are achievable and sustainable at the WWTP, and that water quality in the Perch Creek and Perch Lake Watershed remains within predicted concentrations.

Table 5.4.2-16: Monitoring and Follow up Programs for Surface Water Quality

Valued Component	Project Phase and Potential Effect	Monitoring Program Objective	Conceptual Monitoring Program	Suggested Duration	Implementing Program
Surface Water Quality	■ Discharge of treated effluent from the WWTP to the exfiltration gallery and/or Perch Lake can cause changes to downstream surface water quality ■ Leakage of leachate from the ECM during the post-closure phase (i.e., after Year 2400) from liner and final cover degradation as a result of normal evolution can cause changes to downstream surface water quality.	Environmental monitoring – Verify environmental assessment predictions related to surface water quality	Monitor the quality of surface water surrounding the ECM footprint area to evaluate whether the quality of the water is affected by the ECM or by operation of surface water management pond(s)	Water quality monitoring will continue through operations, closure and post-closure (institutional control). The number of parameters and locations may change based annual review of monitoring data	Surface water monitoring in the receiving environment is integrated into the CNL Environmental Monitoring Program
		■ Operational monitoring – Verify the surface water management pond is performing as designed. ■ Demonstrate compliance with effluent discharge targets developed for the NSDF Project	■ Each pond weir outlet water quality will be sampled to identify if any contact surface water or leachate contamination of the non contact surface water is entering the surface water management ponds and to confirm total suspended solid concentrations. ■ WWTP effluent verification monitoring consistent with CSA Standard N288.5-11 (CSA Group 2011).	■ Routine visual inspections and surface water sampling during operations, closure and post-closure (institutional control) as required ■ Effluent monitoring will continue throughout operation of the WWTP	Effluent water quality monitoring will be integrated into the CRL Radioactive Effluent Verification Monitoring Program

WWTP = Wastewater Treatment Plant; CSA = Canadian Standards Association.

5.4.2.9 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Surface water quality is recognized as an important component of the environment that may be affected by the NSDF Project and changes to surface water quality could, in turn, lead to effects on other VCs selected for assessment. Acknowledging that changes to surface water quality are important aspects of the natural and human environment, surface water quality is referred to as an intermediate component. Results of the analysis of changes in measurement indicators for surface water quality are provided to other disciplines for inclusion in their assessment (Table 5.4.2-3).

The potential for residual effects to surface water quality from the operation and closure of the NSDF Project is primarily associated the operation of the WWTP and treated and untreated effluent discharge to the Perch Creek and Perch Lake Watershed during the operations, and runoff from the ECM during post-closure phases (Table 5.4.2-20). During operations and closure, treated effluent is discharged to the Perch Creek and Perch Lake Watershed via two discharge scenarios:

- to the East Swamp Wetland through an exfiltration gallery; and
- directly to Perch Lake via direct discharge to a submerged diffuser in the deepest part of the lake.

The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses best demonstrated available technology that is economically achievable and capable of meeting regulatory requirements. In addition, effluent discharge targets for wastewater discharges are protective of the environment and human health. Discharge targets for non-radiological contaminants are sourced from federal and provincial guidelines for protection of aquatic biota. Discharge targets for radionuclides are the Canadian Drinking Water Guidelines, except for tritium for which a site-specific target has been developed (Section 3.4.2.5.1). Treated effluent will be sampled and confirmed that it meets treatment targets before release to the environment.

The GoldSim surface water quality mass balance model assessment resulted in the following key projections for operational discharge to the Perch Creek and Perch Lake Watershed:

- Incremental changes to water quality during discharges under both discharge scenarios resulting from the operation of the NSDF Project are not expected to result in adverse effects throughout the Perch Creek and Perch Lake Watershed.
- The Ottawa River is expected to rapidly assimilate all discharge from the Perch Creek and Perch Lake Watershed under both discharge scenarios. COPCs from the discharge are expected not to be measurable beyond existing baseline conditions in Ottawa River after the Perch Creek confluence. Aquatic life and drinking water sources are unlikely to be affected.
- Aluminum, copper and gross beta are predicted to exceed risk benchmarks or no effects concentrations for the operations phase. However, modelled exceedances of aluminum and copper are due to baseline concentrations at the East Swamp Weir, Perch Lake, Perch Creek Weir, Perch Creek Outlet, and in the Ottawa River, which were measured above risk benchmarks in baseline conditions. Modelled concentrations of gross beta (as Strontium 90) above no effects concentrations are limited to East Swamp Weir, which is due to elevated baseline concentrations above No Effects Concentrations.

- There were no incremental changes to barium, cadmium, iron, lead, and silver concentrations resulting from the operation of the NSDF Project throughout the Perch Creek and Perch Lake Watershed during discharges under both discharge scenarios.
- Baseline and modelled aluminium, barium, copper, iron, lead, silver, and gross beta (as Strontium-90) were present in concentrations above the treated effluent discharge target and/or the risk benchmark/no effects concentration (i.e., aluminium, copper), and will remain so during the operation of the NSDF Project.
- Incremental changes were projected under Scenario 1 (50% discharge via the exfiltration gallery and 50% direct discharge to Perch Lake) in East Swamp Weir (ESW) and Perch Lake Inlet #2 (PL2) to varying levels for most of the COPCs, with no change at these locations in Scenario 2 (direct discharge to Perch Lake). These COPCs include ammonia, antimony, boron, calcium, chloride, cobalt, fluoride, magnesium, manganese, mercury, molybdenum, nickel, nitrate, nitrite, phosphorus, potassium, selenium, sodium, strontium, sulphate, thallium, tin, uranium, vanadium, zinc, carbon-14, caesium-137, cobalt-60, and tritium. However, most of the COPC concentrations in Scenario 1 remained below treated effluent discharge targets and risk benchmarks/no effects concentrations. Any incremental COPC changes under Scenario 1 attenuated downstream of Perch Lake to the Ottawa River, with the incremental changes to the COPCs for Scenario 2 generally consistent with those for Scenario 1.
- Projected chloride, nitrate, selenium, strontium, and gross beta concentrations at Perch Lake Inlet 2 (PL2) under both scenarios indicated a non-Project related elevation in concentration at this location. This elevation was attributed to a high existing baseline concentration at MSC, which was incorporated into the flow-weighted concentration calculations for PL2. These COPCs remained below treated effluent discharge targets and risk benchmarks and no effect concentrations, except for selenium, which was above the treated effluent discharge target at PL2 for both discharge scenarios.

During the post-closure phase (i.e., after the end of the 300-year institutional control period in Year 2400), leakage of leachate from the ECM from liner and final cover degradation as a result of normal evolution can cause changes to downstream surface water quality. The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound and minimize leachate generation. The assessment of surface water quality in the post closure phase is summarized in Section 5.7.6.1.2.2 of the EIS and detailed in the *Post-Closure Safety Assessment* (PostSA; Arcadis and Quintessa 2020).

Surface water monitoring in the receiving environment is integrated into the CNL Environmental Monitoring Program. The effluent water quality monitoring will be integrated into the CRL Effluent Verification Monitoring Program.

Table 5.4.2-17: Summary of Predicted Residual Adverse Effects for Surface Water Quality Valued Component

Valued Components	Residual Adverse Effects	Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation

Surface Water Quality	Adverse changes to downstream surface water quality from the discharge of treated effluent from the WWTP to the exfiltration gallery and/or Perch Lake	Operations and Closure	Discharge of treated effluent to the Perch Creek and Perch Lake Watershed	■ The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses best available technology that is economically achievable and capable of meeting regulatory requirements
				■ Effluent discharge targets for wastewater discharges are protective of the environment and human health
				  ▪ Discharge targets for non-radiological contaminants are sourced from federal and provincial guidelines for protection of aquatic biota
				  ▪ Discharge targets for radionuclides are the Canadian Drinking Water Guidelines with the exception of tritium for which a site-specific target is developed (Section 3.4.2.5.1)
				■ Treated effluent will be sampled to confirm it meets treatment targets before release to the environment
				■ When applied, the proposed exfiltration gallery will promote the exfiltration of treated water into the local groundwater regime where further retention of radioactivity by the geosphere is anticipated
				■ The Perch Lake diffuser design provides additional dilution of treated effluent at the point of release
				■ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water quality
				■ Appropriate procedures will be in place to effectively identify spill occurrences in the event treated effluent is released to areas other than directly to the exfiltration gallery or to Perch Lake and initiate appropriate emergency responses

Table 5.4.2-17: Summary of Predicted Residual Adverse Effects for Surface Water Quality Valued Component

Valued Components	Residual Adverse Effects	Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation
Surface Water Quality	Leakage of leachate from the ECM after the 300-year post-closure phase (i.e., after Year 2400) from liner and final cover degradation as a result of normal evolution can cause changes to downstream surface water quality	Post-closure	Liner and final cover degradation as a result of normal evolution	■ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound and minimize leachate generation ■ The final cover system design incorporates a series of shallow, trapezoidal, riprap-lined drainage channels that are designed to convey water at low velocity ■ The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the final cover and underlying waste materials, destabilization of the ECM structure and damage to access roads ■ The ECM final grading and drainage plan also includes collection ditches along the top of the ECM berm road to collect side slope drainage ■ The design life for the ECM is 550 years to meet the required time period to allow for radioactive decay of the waste placed in the facility (i.e., until it has decayed to levels that do not present a risk to the public and environment) ■ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water and groundwater quality

CRL = Chalk River Laboratories; ECM = engineered containment mound; NSDF = Near Surface Disposal Facility; LLW = low-level waste

5.5 Aquatic Environment

This section of the Environmental Impact Statement (EIS) for the Canadian Nuclear Laboratories (CNL) Near Surface Disposal (NSDF) Project seeks to understand and characterize potential residual effects of the NSDF Project on aquatic biodiversity at the Chalk River Laboratories (CRL) site. Effects of the NSDF Project are considered in the context of cumulative effects from other previous, existing and reasonably foreseeable developments on the aquatic environment.

5.5.1 Scope of the Assessment

This section focuses on aquatic biodiversity, which includes fish and fish habitat. The aquatic biodiversity assessment follows the overall environmental assessment approach and methods described in Section 5.1 Environmental Assessment Approach. The assessment was completed following the key steps listed below.

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases for the aquatic biodiversity assessment** (refer to Sections 5.5.2 Valued Components and Section 5.5.3 Assessment Boundaries). The VCs and measurement indicators used to assess Project-related changes to the aquatic biodiversity are described, along with the spatial and temporal boundaries at which the assessment occurred and the assessment cases considered.
- **Step 2 – Describe the existing conditions** (refer to Section 5.5.4 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation). The existing conditions provide a reference to which the effects of the NSDF Project can be compared.
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 5.5.5 Project Interactions and Mitigation). Project components and/or activities with the potential to affect aquatic biodiversity are identified, and mitigation developed to limit or avoid effects is presented. A pathways analysis is then used to focus further assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects to aquatic biodiversity. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways were not identified for aquatic biodiversity; therefore, no residual effects are carried forward for further analysis and characterization.
- **Step 4 – Present the methods and results of the residual effects analysis**. This step was not required as no primary pathways were identified in the aquatic environment assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty.** This step was not required as no primary pathways were identified in the aquatic environment assessment.
- **Step 6 – Classify and determine the significance of the predicted residual effects**. This step was not required as no primary pathways were identified in the aquatic environment assessment.
- **Step 7 – Identify monitoring and follow-up** required to confirm effects predictions and address uncertainty (refer to Section 5.5.6 Monitoring and Follow-up).
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** (refer to Section 5.5.7 Conclusions).

Information and areas of interest raised by the public, communities of interest, and Indigenous Peoples during engagement that influenced the scope of the aquatic biodiversity assessment are summarized in Table 5.5.1-1. Other general areas of interest and questions raised during the engagement that pertain to the surface water quality assessment (if any) are documented in CNL's Indigenous Engagement Report (CNL 2021) and CNL's Stakeholder's Activity Reports (CNL 2017a,b, 2019a).

Table 5.5.1-1: Summary of Areas of Interest Raised During Engagement Activities that Influenced the Scope of the Aquatic Biodiversity Assessment

Area of Interest	How the Area of Interest Was Included in the Assessment
Effects to fish from potential for contamination in the Ottawa River from the NSDF Project.	The spatial boundaries of the assessment were selected to include consideration of potential effects to the Ottawa River. Surface water modelling was completed to estimate contaminant concentrations within the Perch Creek and Perch Lake Watershed[(a)], which flows directly into the Ottawa River. Meeting effluent discharge targets within the Perch Creek and Perch Lake Watershed is considered to be protective of fish in the Ottawa River. The Regional Study Area was expanded to include reach of the Ottawa River extending 8 km downstream from CNL in response to comments received from Indigenous communities and organizations and the public.
Effects to fish species of interest to Indigenous Peoples.	Brown bullhead was added to the aquatic environment assessment as a VC in the assessment as a species of interest to Indigenous Peoples that has been observed in Perch Creek and Perch Lake Watershed.

a) Includes contributing watercourses and waterbodies within the Perch Creek and Perch Lake Watershed, including Perch Creek, Perch Lake, East Swamp Stream, and Main Stream.

5.5.2 Valued Components

Valued Components (VCs) refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Fish and fish habitat are recognized as important components of the aquatic environment that may be affected by the NSDF Project and changes to fish and fish habitat could, in turn, lead to effects on other VCs, such as land and resource use (Section 5.9). The assessment assumed that waterbodies and watercourses in the Perch Creek and Perch Lake watershed contain fish and habitat that are part of, or support a fishery, and that all fish within waters potentially affected by the NSDF Project are subject to the application of the *Fisheries Act*. As environmental features of the assessment for the Project, fish and fish habitat also fall within the scope of the protections of Section 35 of the *Fisheries Act*, including the prohibition against causing harmful alteration, disruption and destruction of fish and fish habitat.

Inclusion of a Fish Habitat VC describes any watercourse, waterbody, or wetland providing functions for life history stages of fish. The Fish Habitat VC was combined VCs describing the fish community and species of concern or value to examine potential changes to the fish community that use watercourses and waterbodies within the Perch Creek and Perch Lake Watershed, including large-bodied and small-bodied species, species occupying various trophic levels (e.g., carnivores, invertivores and herbivores) and species that use shoreline habitat near Pointe au Baptême in the Ottawa River (Table 5.5.2-1). The study species were summarized within a Fish Community VC for all contributing watercourses and waterbodies within the Perch Creek and Perch Lake Watershed. Brown Bullhead (*Ictalurus nebulosus*) was also selected as an individual species VC because it is a resident large-bodied species that is dominant in the fish community of Perch Lake. Brown Bullhead was recommended as a VC by Indigenous Peoples (summarized in Section 6.3.2). A similar approach was taken for the selection of aquatic biodiversity VCs for the Environmental Risk Assessment completed for the NSDF Project

(summarized in Section 5.7); where species were selected to assess exposures to water, as well as ingestion of aquatic biota (Table 5.5.2-2).

Although residual effects to hydrology and water quality are not anticipated for the Ottawa River, species of conservation concern that may occur at downstream locations in the Ottawa River are included within the aquatic biodiversity assessment for the NSDF Project. These species include Lake Sturgeon (*Acipenser fulvescens*), American Eel (*Anguilla rostrata*), River Redhorse (*Moxostoma carinatum*) and Northern Brook Lamprey (*Ichthyomyzon fossor*) (see Government of Canada 2015, 2016; Government of Ontario 2019) (Table 5.5.2-1). Both Northern Brook Lamprey and River Redhorse are currently designated as species of 'Special Concern' under *Ontario Regulation (O. Reg.) 230/08 Species at Risk in Ontario List,* and under Schedule 1 (i.e., list of species at risk) of the *Species at Risk Act* (SARA). Lake Sturgeon is currently designated as 'Endangered' under the Species at Risk in Ontario List and as 'Threatened' by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC), and is eligible for an amendment to Schedule 1 of SARA. The American Eel is currently designated as 'Endangered' under the Ontario *Endangered Species Act, 2007,* and as 'Threatened' by COSEWIC, and is eligible for an amendment to Schedule 1 of the SARA.

Table 5.5.2-1: Valued Components for Aquatic Biodiversity Assessment

Valued Component	Rationale for Selection
Perch Creek and Perch Lake Watershed Fish Habitat (i.e., Fish Habitat)[a]	■ Wetlands, lakes, streams and rivers provide a diversity of functions for life history stages of fish species and forage fish species. ■ The NSDF Project may affect existing availability of the spatial and temporal distribution of habitat, which can subsequently affect land and resource use.
Perch Creek and Perch Lake Watershed Fish Community (i.e., Fish Community)[a]	■ Up to 15 species have been documented within the Perch Creek and Perch Lake Watershed, some of which may use habitat in the Ottawa River at the mouth of Perch Creek. ■ Species in potentially affected waters are protected under the Fisheries Act., for example, Northern Pike (Esox lucius), Brown Bullhead (Ameiurus nebulosus) and supporting forage fish species. ■ Societal values concerning changes in local fisheries species are an important consideration in understanding potential effects of the NSDF Project.
Perch Creek and Perch Lake Watershed Brown Bullhead [a]	■ Brown Bullhead (*Ictalurus nebulosus*), a species of 'bullhead catfish', is a warm water native species to Ontario and resident of Perch Lake where it is a dominant species in the fish community. ■ Brown Bullhead is a valued species by Indigenous Peoples.
Fish Species of Conservation Concern	■ The Lake Sturgeon (*Acipenser fulvescens*) population in the Ottawa River is designated as Threatened by COSEWIC; threats to the Lake Sturgeon include overexploitation, dams, habitat degradation, contaminants and introduced species; commercial fishing was the most significant factor that caused the historical decline of populations. ■ American Eel (*Anguilla rostrata*) is designated as Threatened by COSEWIC; threats include dams which can impede upstream migration of juvenile eels; impeded access to the Ottawa River, Lake Ontario and Lake Champlain resulted in substantial cumulative loss of formerly productive rearing habitat in the St. Lawrence River watershed. ■ The Northern Brook Lamprey (*Ichthyomyzon fossor*) population in the Ottawa River is designated as special concern under Schedule 1 of SARA; lampricide (chemical used to target lamprey larvae) use to manage invasive Sea Lamprey (*Petromyzon marinus*) is the main threat for Northern Brook Lamprey. ■ River Redhorse (*Moxostoma carinatum*) is designated as special concern under Schedule 1 of SARA; principal threats are habitat degradation through siltation, agricultural and urban pollution, and instream barriers such as dams, which restrict access to spawning areas and can change flow regimes during spawning periods.

a) Includes contributing watercourses and waterbodies within the Perch Creek and Perch Lake Watershed, including Perch Lake, Perch Creek, East Swamp Stream, and Main Stream.

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future generations. The assessment endpoints and measurement indicators identified for the aquatic biodiversity VCs are presented in (Table 5.5.2-2).

The assessment endpoint for fish and fish habitat is maintenance of self-sustaining and ecologically effective fish populations, which are important components of on-going fisheries productivity. Self-sustaining fish populations are healthy and viable and, by definition, robust and capable of withstanding environmental change and accommodating stochastic (i.e., random variable) processes (Reed et al. 2003).

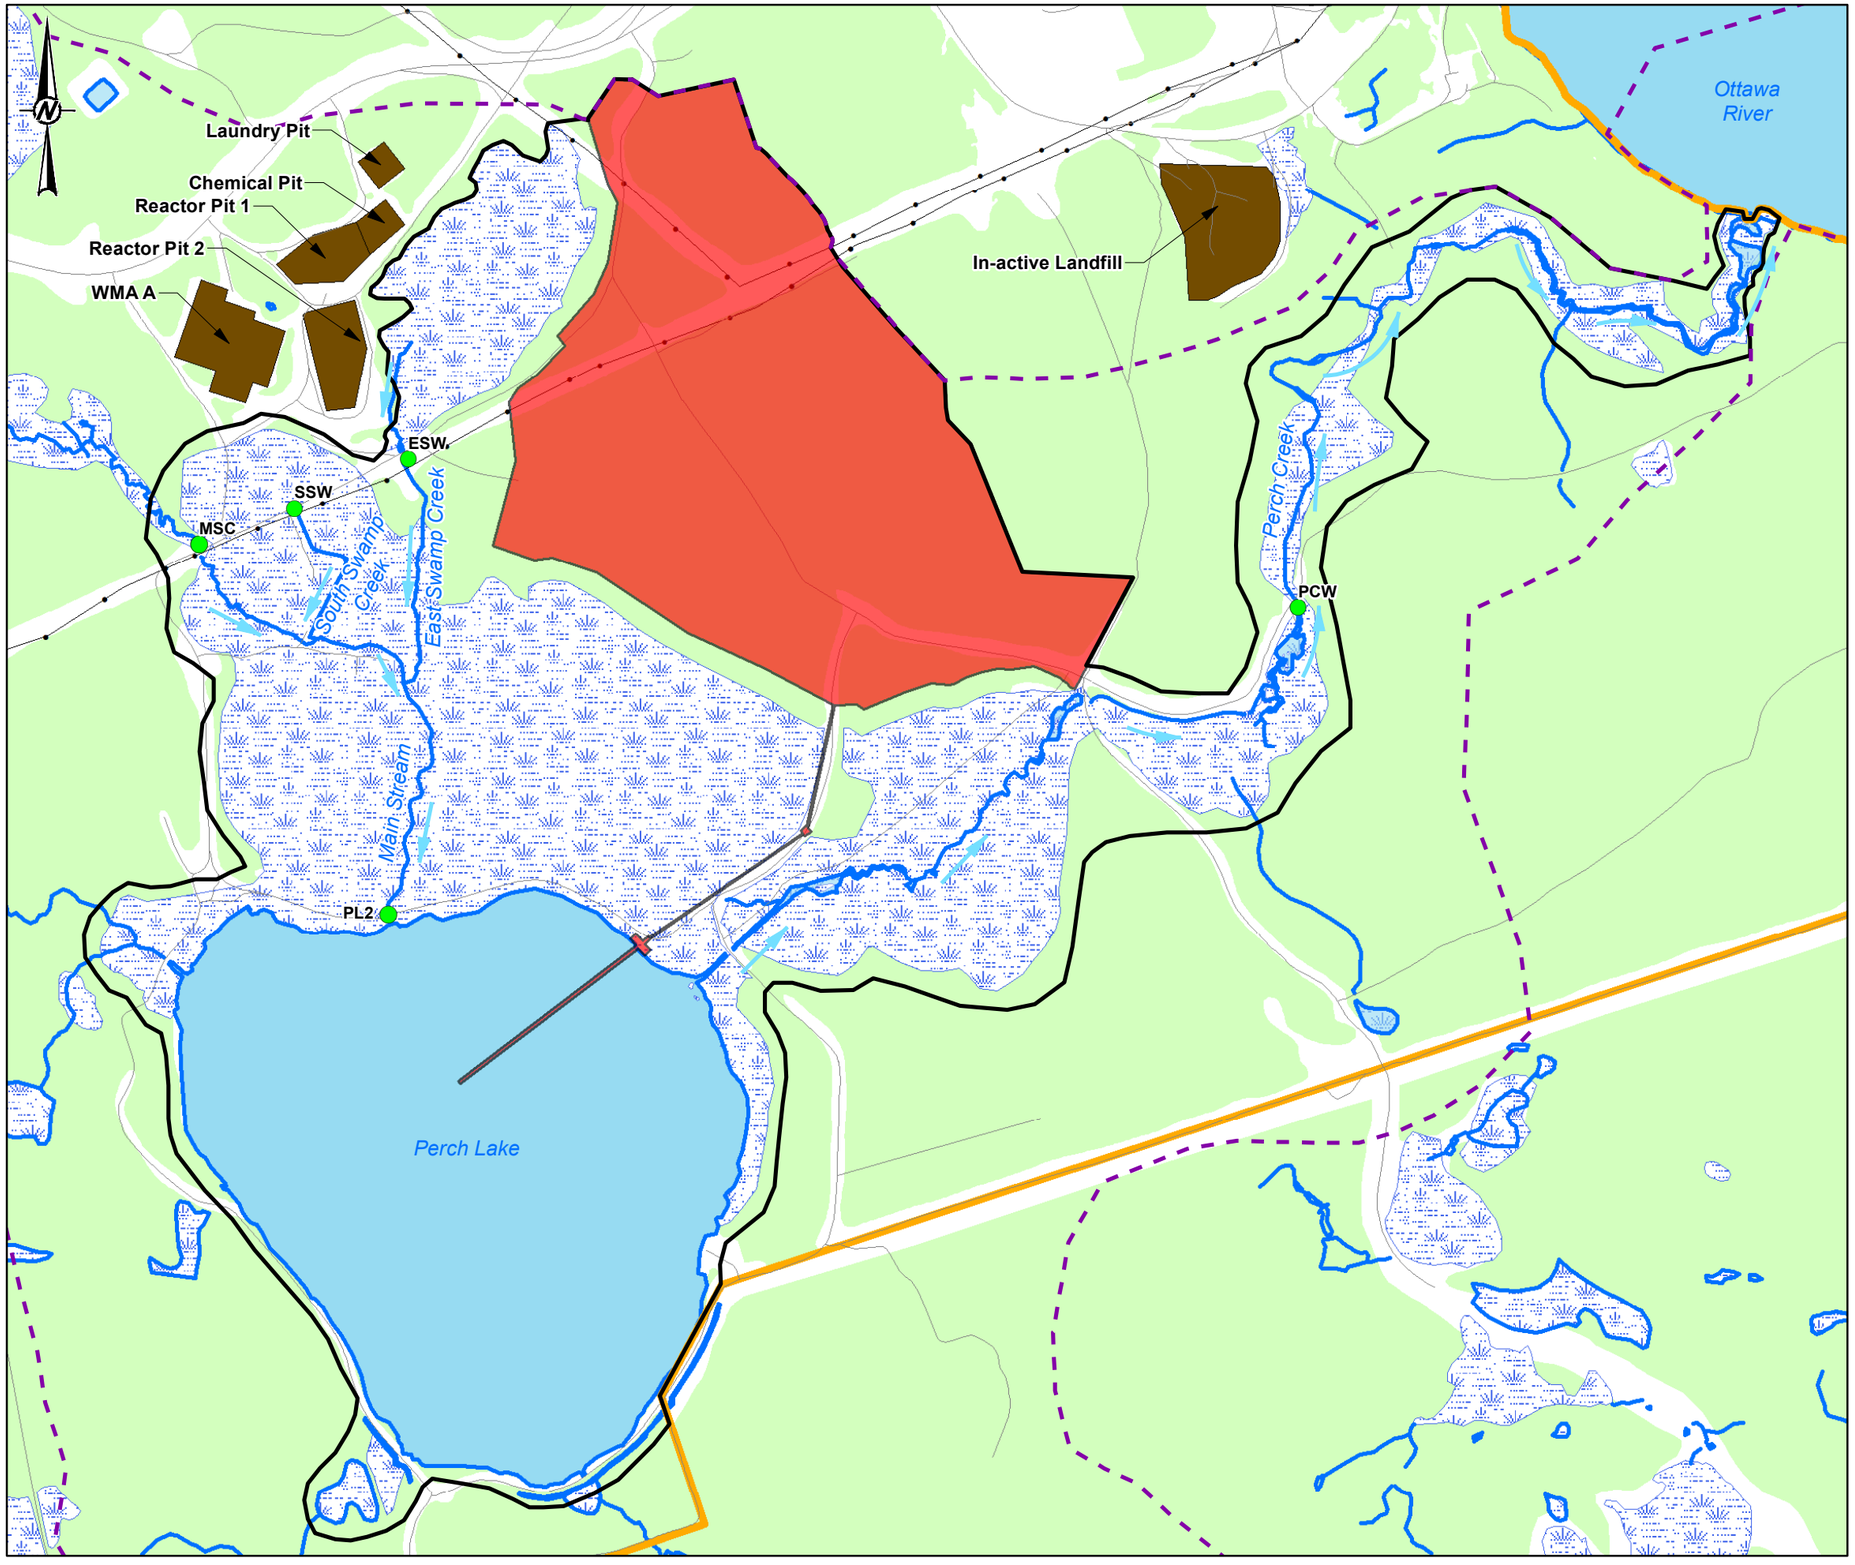
Habitat availability, habitat distribution, and survival and reproduction were selected as the measurement indicators for the aquatic biodiversity species VCs (Table 5.5.2-2). The measurement indicators are defined as follows:

- Habitat availability: Changes to the amount of habitat (e.g., by altering flows or abundance of food) and quality of habitat (e.g., by altering water quality).
- Habitat distribution: Changes to spatial configuration and connectivity of habitats.
- **Survival and reproduction**: Changes to abundance caused by altering survival and/or recruitment (i.e., demographic parameters).

Table 5.5.2-2: Assessment Endpoints and Measurement Indicators for the Aquatic Biodiversity Assessment

Valued Component	Assessment Endpoints	Measurement Indicators
Perch Creek and Perch Lake Watershed[(a)] Fish Habitat	■ On-going support of fisheries productivity	■ Habitat availability (quality and quantity) ■ Habitat distribution
Perch Creek and Perch Lake Watershed[(a)] Fish Community	■ Self-sustaining and ecologically effective fish populations ■ On-going fisheries productivity	■ Habitat availability (quality and quantity) ■ Habitat distribution ■ Survival and reproduction
Brown Bullhead of the Perch Creek and Perch Lake Watershed[(a)]	■ As above	■ As above
Fish Species of Conservation Concern	■ Self-sustaining and ecologically effective fish populations	■ Habitat availability (quality and quantity) ■ Habitat distribution ■ Survival and reproduction

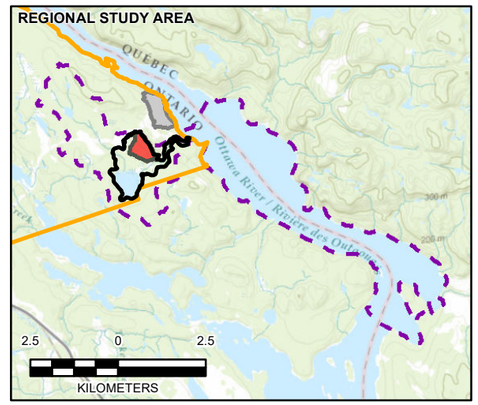
a) Includes watercourses and waterbodies within the Perch Creek and Perch Lake Watershed, including Perch Lake, Perch Creek, East Swamp Stream, and Main Stream.



5.5.3 Assessment Boundaries

5.5.3.1 Spatial Boundaries

The spatial boundaries selected for the aquatic biodiversity assessment were chosen because they permit description of existing conditions in sufficient detail to enable potential Project-VC interactions and effects to be identified, understood and assessed, including understanding and assessing the contribution of the NSDF Project to cumulative effects. The spatial boundaries selected for the aquatic biodiversity assessment are the same as those identified for hydrology and surface water quality and are presented on Figure 5.5.3-1 and are described below.



- **Site Study Area (SSA):** The SSA is the NSDF Project footprint (i.e., where NSDF Project activities would be undertaken including proposed facilities, buildings and infrastructure).
- **Local Study Area (LSA):** The LSA is defined as the area within which there is potential for measurable changes to measurement indicators resulting from the proposed NSDF Project activities. The LSA includes the SSA and is bounded by Perch Lake and Perch Creek, and adjacent wetlands and swamps.
- **Regional Study Area (RSA):** The RSA is defined as the area within which the potential effects of the NSDF Project may interact with the effects of other existing or reasonably foreseeable developments. The RSA is determined by the spatial extent of the Perch Creek and Perch Lake Watershed, which includes Perch Lake and its tributaries and Perch Creek. The RSA also includes a portion of the Ottawa River (i.e., roughly 8 km downstream in the Ottawa River to Harrington Bay).

5.5.3.2 Temporal Boundaries

Temporal boundaries (i.e., project phases) establish the timeframe during which NSDF Project effects are assessed. The temporal boundary represents the timeframe during which project activities are actively occurring and considers the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a project activity or stressor (which is related to the Project phases) plus the time required for the residual effect to be reversed. In some cases, residual effects may be irreversible within the temporal boundaries of the project or if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the NSDF Project.

- **Construction phase**: This phase includes site preparation and all activities associated with the construction of the NSDF Project. This phase includes activities such as installing the necessary supporting and/or ancillary facilities and infrastructure to facilitate NSDF Project operations, inactive commissioning and systems testing, and transportation of construction materials. Construction activities are expected take place from 2022 to 2024.
- **Operations phase**: This phase includes all activities associated with waste placement, water management, Wastewater Treatment Plant (WWTP) operations, vehicle movements into and from the SSA, and maintenance activities. Operations activities are expected to last approximately 50 years (i.e., 2025 to 2070).
- **Closure phase:** This phase includes activities necessary to complete the installation of the final cover and implementation of long-term monitoring. Closure activities are expected to start in 2070 and continue through to 2100, after which the NSDF Project will transfer into the post-closure phase.
- **Post-closure phase:** This phase has two discrete periods: institutional control and post-institutional control. The institutional control period includes implementation of controls throughout 2100 to 2400 (i.e., 300 years). During institutional control, environmental monitoring will be completed as required to confirm that the final cover is functioning as intended and to demonstrate compliance with the environmental assessment conditions. Post-institutional control occurs after year 2400 and continues indefinitely.

The temporal boundaries for the aquatic biodiversity assessment include consideration of effects of the NSDF Project from construction through post-closure.

5.5.3.3 Assessment Cases

The assessment cases considered in the aquatic biodiversity assessment are the Base Case and Application Case (the Reasonably Foreseeable Developments Case has not been considered for the reasons outlined below).

- **Base Case:** This scenario represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural, mining and residential and recreational development. Current effects from the existing CRL facilities and operations, for example, are considered part of the Base Case.
- **Application Case:** This scenario represents predictions of the effects of the Base Case combined with the effects that may result from the NSDF Project. The Application Case considers potential effects from the NSDF Project during construction through to the closure and post-closure phases.

- **Reasonably Foreseeable Development (RFD) Case**: This scenario represents predictions of the cumulative effects of the Application Case, which includes the Base Case, plus projects that are currently under application review or that have officially entered a regulatory application process and are therefore considered reasonably foreseeable. Because RFDs will have no spatial overlap or are likely to positively affect the fish and fish habitat, an RFD Case is not presented as part of this assessment.

  RFDs expected within the CRL site (i.e., the RSA) that may interact with the aquatic environment include new or upgrades to research and development facilities, construction and operations of the SMR, new support infrastructure, and on-going decommissioning and environmental remediation activities. New support infrastructure and research and development facilities will generally be located within existing disturbed areas on the CRL site (i.e., minimal disturbance to largely undeveloped areas) where erosion and sediment control practices and surface water management systems already in place will be implemented. Disturbance of an approximately 3.5 ha may be required for development of the SMR based on the candidate site selected, but no watercourses are identified within any of the three candidate sites (Global First Power 2019). The Project Description document for the SMR notes that the nearest water body to Site A is “No Name” lake within the Perch Creek and Perch Lake Watershed and the nearest water body to Sites B and C is the Ottawa River within the Ottawa River direct watershed. It is noted that a small amount of radioactive liquid waste from decontamination activities during the operations of the SMR will be monitored and stored in a holding tank, for further processing (Global First Power 2019). A septic field may be used to manage sewage the SMR site, depending on the candidate site chosen that would follow required standards and would be located approximately 2 km from the SSA. Accordingly, potential effects from revitalization activities are not expected to spatially overlap with potential effects to aquatic biodiversity from the NSDF Project.

  The end-state plan for the CRL site will be to return lands disturbed by site activities to a condition that is physically stable and safe in keeping with the land use and landscape of the day. Therefore, decommissioning and environmental remediation activities are anticipated to positively affect fish and fish habitat.

5.5.4 Description of the Environment

5.5.4.1 Methods

This section describes the setting and characterization for the aquatic biodiversity as relevant for the assessment of effects from the NSDF Project. It describes the existing conditions (i.e., Base Case) against which potential changes from the NSDF Project are compared and evaluated. Existing fish and fish habitat conditions within and surrounding the CRL site, including the Ottawa River, were obtained from published reports and available baseline data.

The baseline study conducted as part of this EIS focuses on methods which assess the conditions of fish in Perch Lake at the community level by examining changes to community structure. As such, the description of fish habitat, communities, and species present in the Perch Creek and Perch Lake watershed of the RSA takes into account a community-based approach in assessing the potential residual effects of the NSDF Project on aquatic biodiversity. This conventional approach is appropriate to determine the long-term ecological effects of contaminants to non-human biota (Canadian Standards Association’s Standards N288.4-10 *Environmental Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [CSA Group 2010]).

5.5.4.2 Results

5.5.4.2.1 Fish Habitat

The NSDF Project is located primarily within the Perch Creek and Perch Lake Watershed of the RSA (Figure 5.5.3-1) at the southern edge of the Canadian Shield in the Ottawa River valley (Robertson and Barry 1985) and includes contributing watercourses and waterbodies within the watershed of Perch Creek. Ground surface elevations range from a low of approximately 160 metres above sea level (masl) within the low-lying and relatively flat terrain bordering the north side of Perch Lake, to a high of 196 masl along the crest of the ridge to the east of Emergency Road #3 that separates the Perch Creek and Perch Lake Watershed and Ottawa River Watershed. The watershed includes the Waste Management Areas (WMAs) A and B, the Reactor and Laundry Pits and the Liquid Dispersal Area. From Perch Lake, surface water (Perch Creek) flows in a north-easterly direction through Perch Creek to its confluence with the Ottawa River. The Perch Creek basin drains approximately 18% of CRL site area and drains to the Ottawa River through Perch Lake and Perch Creek (CNL 2016a).

The CRL site is located adjacent to the reach of the Ottawa River extending approximately 90 km between La Passe and the Des-Joachins hydroelectric dam. This reach consists of several “lakes” separated by short rapids. The river section near the CRL site is 200 to 400 m wide, slow-moving and with a steeply sloped shoreline, extending to a depth of 55 m. There is a shallow shelf extending across Pointe au Baptême (approximately 125 m wide) where Perch Creek enters the Ottawa River. The river bottom across the shelf is predominately fine substrate, with average depths of 1 m to 3.5 m and aquatic vegetation is abundant around the shoreline. Based on daily flow measurements of the Ottawa River taken at the Des-Joachims Generating Station (just north [upstream] of the NSDF site) from the time period of June 1950 to December 2016, flow rates for the river range from 336 m^3/s (minimum flow rate) to 1,560 m^3/s (maximum flow rate) (also see Section 5.4.1.4.2.2). The mean flow rate is 807 m^3/s. The flow past the Des-Joachims hydroelectric dam is regulated according to the demands of the generating station.

Physical characteristics of Perch Lake include a wetted area of approximately 45 ha, a drainage area of 730 ha and a mean depth of 2 m (Robertson and Barry 1985). A recent bathymetric survey completed in 2018 identified a maximum depth of 4 m, and confirmed that most of the lake is shallow, less than 3 m in depth (CNL 2018a). In late summer and fall, the water level usually drops by as much as 0.25 m. Most of Perch Lake is open water except for littoral zones along the shore, including a region of floating, emergent and submerged vegetation, which amounts to about 30% of the lake’s surface (Yankovich et al. 2000). Substrates within the lake are primarily organic sediments and surrounding shoreline soils are a mixture of sand and soils (CNL 2018a). The lake is confined, in part, by sand outcrops along the northern and southern shores, and by bedrock along the western shores.

The dominant vegetation form in Perch Lake is a floating-leafed plant cover of fragrant water-lily (*Nymphaea odorata*) and watershield (*Brasenia schreberi*). Closer to the shore, narrow leafed emergent bands of slender sedge (*Carex lasiocarpa*), twig rush (*Cladium mariscoides*) and broad-leaved arrowhead (*Sagittaria latifolia*) grow in profusion in the shallow water, as does common cattail (*Typha latifolia*) and pickerelweed (*Pontederia cordata*). In the deeper water beyond, fully or partially submerged vegetation is dominated by common bladderwort (*Utricularia vulgaris*), flat-leafed bladderwort (*Utricularia intermedia*), fennel leafed pondweed (*Potamogeton pectinatus*), big-leaf pondweed (*Potamogeton amplifolius*) and stoneworts (*Chara* sp.), grow along the bottom. Along the north shore and elsewhere, a broad-leafed emergent cover of pickerelweed contrasts with water-lilies. The outer fringe of this zone is known as Perch Lake Marsh. This open marsh may be considered to be part of the lake, with which it is physically continuous.

Previous water quality monitoring of Perch Lake recorded high nutrient levels that indicate a eutrophic condition of the lake (Yankovich et al. 2000). Total phosphorus background concentrations in Perch Lake typically range between 0.01 mg/L to 0.07 mg/L based on monitoring results from 2012 to 2017 (CNL 2018a). In May 2018, surface water measurements in Perch Lake averaged approximately 0.02 mg/L (CNL 2018b). The upper range of historical concentrations of total phosphorous indicate a eutrophic condition because those concentrations fall between 0.035 mg/L to 0.1 mg/L (as defined for eutrophic states in CCME 1999 and Wetzel 2001).

Perch Lake, like other lakes in the region, undergoes an open water condition (April to October) and ice-covered condition (November to March) throughout a yearly cycle. Following melting of the ice during spring, the water warms up rapidly and summer surface temperatures can exceed 30°C; the highest recorded temperature was 34°C (Yankovich et al. 2000). During summer, water temperatures in the lake can stratify with surface water temperatures about 5°C higher than lower depth strata (Yankovich et al. 2000). In summer 2017, lake stratification was observed during fish sampling conducted on Perch Lake (surface temperature = 26.1°C, bottom temperature = 19.6°C) (CNL 2017c). However, the strength of the temperature gradient and the duration of thermal stratification would be limited in magnitude depending on climate conditions during any given year (e.g., where high winds would promote mixed scenarios).

Dissolved oxygen (DO) levels may also stratify concurrently with changes in water temperatures, with reduced DO concentrations near the bottom of the lake. In summer 2017, DO concentration gradients were observed during fish sampling conducted on Perch Lake (surface DO = 5.8 mg/L, bottom DO = 0.2 mg/L) and Toussaint Lake (surface DO = 6.7 mg/L, bottom DO = 0.3 mg/L) (CNL 2017c). The depth stratum of the reduced DO levels (i.e., the hypolimnion) in Perch Lake was approximately from 2.5 m to 4.0 m. However, the duration of the anoxic period in the lower depth strata of Perch Lake is unknown for summer 2017. Prolonged periods of low DO levels (e.g., less than 3 mg/L) near the lake bottom may restrict sensitive fish species and developmental stages to higher in the water column, exposing biota to higher seasonal peak temperatures (e.g., Fang and Stefan 2000; Roberts et al. 2012).

Water quality samples were also collected in May 2018 (spring conditions) from multiple station locations within Perch Lake (CNL 2018a; also summarized in EIS Section 5.4). In-situ water quality measured at four locations in the lake at the time of the water quality sampling was reflective of spring water temperatures and consistent with a warm-cool water thermal regime characterized by small lakes in the region (i.e., temperatures ranged from 12.0ºC to 22.8ºC). Dissolved oxygen and pH were both within the guidelines for the protection of aquatic life (CCME 1999; DO >5.5 mg/L and pH = 6.5 to 9.0) at the majority of stations and depth sampled. Exemptions were bottom water quality readings at two stations in Perch Lake where DO concentrations were as low as 4.7 mg/L and pH values were as low as 6.26.

Dissolved oxygen concentrations can also diminish in ice-covered lakes during the winter due to sedimentary oxygen demand and water column oxygen demand (reviewed in Fang and Stefan 2000). In particular, shallow (4 m maximum depth), eutrophic lakes in winter are prone to low DO concentrations below 2.0 mg/L near the end of an extended ice cover period. Previous under-ice measurements of Perch Lake in late winter show that bottom waters can become depleted in oxygen in winter, as low as 4.0 mg/L (CNL 2019b), however, there have been no reported ‘fish kills’ during these conditions to the knowledge of the authors of this assessment. Prolonged reductions in winter DO levels below 3 mg/L has the potential to reduce available habitat and cause chronic stress for populations in the lake.

From Perch Lake, mean historical annual flows at the outlet are 0.057 m^3/s based on the 11-year average water budget (1969 to 1980) for the hydrologic year (September 1 to August 31; see Section 5.4.1.4.2.3). Flow rates from the Perch Creek weir were also measured by CNL from 2009 to 2015 (see Table 5.4.1-6). The highest flows

typically occur in conjunction with spring melt (i.e., freshet) events in April, while lower flows are encountered during the summer season, particularly in August. The overall annual mean flow from years 2009 to 2015 was estimated to be approximately 0.063 m^3/s. Downstream of the outlet, Perch Creek ranges from 5 m to 10 m in width and generally has a depth of less than 1 m. The Perch Creek weir is located at the downstream extent of adjacent wetlands, approximately 700 m downstream of Perch Lake (Photo 5.5.4-1).

Photo 5.5.4-1: Upstream View of the Perch Creek Weir, August 2012

Below the Perch Creek weir, the creek enters a mixed deciduous woodlot and overhead cover increases substantially (Sowden and Power 1981). Stream gradient also increases sharply, exceeding a 10% slope in sections. A series of small waterfalls (or cascades) occur just downstream of the weir, which is expected to be a barrier to upstream movements of fish species from the Ottawa River, preventing access to upper Perch Creek and Perch Lake. The waterfalls then lead to a pool riffle sequence, followed by slow-flowing water in the lower reach of the creek. The substrate in the middle reach is rock, gravel and coarse sand; whereas the substrate in the lower section of the creek is dominated by silt and sand substrate. The overall slope of Perch Creek is approximately 3%.

To the north of Perch Lake are extensive wetlands, notably Perch Lake Swamp, South Swamp and East Swamp. The fish habitat potential of wetlands such as Perch Lake Swamp and East Swamp is predicted to be low. These wetlands may support small-bodied fish during spring conditions and potentially through the summer in areas defined by a stream bed and banks where flows are sustained over the summer. From East Swamp, the outlet stream starts immediately above a small weir where groundwater influences may sustain flows in upper sections of the creek throughout the year (CNL 2017c). Pools above and below the weir may provide year-round habitat for fish (Photo 5.5.4-2). East Swamp Stream flows for approximately 350 m before entering Main Stream, which then flows for approximately 375 m before entering Perch Lake. The main tributary stream of Perch Lake is Main Stream, which is approximately 2 km in length. Substrates for East Swamp Stream and Main Stream are predominately fines (e.g., silts, sands) (CNL 2017c).

Photo 5.5.4-2: Downstream View of the East Swamp Stream Weir, November 2017

Brown Bullhead Habitat

Brown Bullhead require warm water temperatures, shallow lakes and streams with sand or fine substrates and cover (e.g., aquatic plants, woody debris) (Holm et al. 2009 and Eakins 2021), and Perch Lake and the connecting creeks provide such habitats to support all life stages of Brown Bullhead. As an opportunistic bottom feeding fish, Brown Bullhead have a varied diet of insects, crustaceans, smaller fish and plants that would be available within the waterbodies of the study area (Yankovich 2003). The shallow and vegetated shorelines of Perch Lake and the connecting creeks provide suitable spawning habitats for nest building as well as suitable cover for nursery and rearing habitats (Langhorne et al. 2001). Water depth within Perch Lake is suitable to support an overwintering population (i.e., there is sufficient under-ice water and dissolved oxygen levels to sustain the population through the winter). Brown Bullhead are also very tolerant of low dissolved oxygen levels and a range of temperatures (Scott and Crossman 1998).

5.5.4.2.2 Perch Creek and Perch Lake Watershed Fish Community

An inventory of fish in nine waterbodies within the CRL site was performed in summer 1980 (Sowden and Power 1981), with follow-up inventory investigations performed in 1996 and 1997 (CG&S 1997, 1998), 2016 and 2017 (CNL 2017c) and in 2018 (CNL 2018c). The baseline inventory data, although a portion of it over 20 years old, provides a historical baseline description that can be used to characterize the potential distribution of species in the assessment area. Current distributions reflect the introduction of Northern Pike to Perch Lake in the mid-to-late 1980s (Yankovich et al. 2000). Natural colonization of the lake by other species in the Ottawa River are unlikely given the small waterfalls on Perch Creek acting as a natural barrier for upstream movements of fish.

Waterbodies that were sampled as part of historical baseline studies include: Ottawa River, Perch Lake, Lower Bass Lake, Upper Bass Lake, Maskinonge Lake, Duke Stream Marsh, Perch Creek (Perch Lake outlet), Main Stream (tributary to Perch Lake), and East Swamp Stream (tributary to Perch Lake) (Figure 5.5.3-1 and Figure 5.4.1-2). Sampling gear types included experimental gill nets, hoop net traps, beach seines, minnow traps, and backpack electrofishers. Historical data on distribution, diet and growth of locally occurring fish species, with a focus on environments below waste disposal sites are provided in more detail in Sowden and Power (1981).

Forty-one fish species were collected during the 1980 field program, including 13 species collected in the Perch Creek and Perch Lake Watershed (Table 5.5.4-1; Sowden and Power 1981). One species (Blacknose Shiner) recorded in Perch Lake during earlier investigations (Ophel and Fraser 1971, as cited in Sowden and Power 1981) was not captured in the watershed in 1980, and two species (Rosyface Shiner and Threespine Stickleback) were recorded near the mouth of Perch Creek but not in the creek or upstream locations. Within the Perch Creek basin, seven species were exclusive to lower Perch Creek, including Common Shiner, Longnose Dace, Fallfish, White Sucker, Johnny Darter, Logperch and Mottled Sculpin. It is assumed that species found in lower Perch Creek below the Perch Creek weir, also occur in the Ottawa River near the outlet of Perch Creek (e.g., shelf habitat near Pointe au Baptême) to meet their life history requirements (e.g., for foraging, overwintering). Species with relatively wide distributions in the Perch Creek and Perch Lake Watershed and also dominant species in upper Perch Creek included Fathead Minnow, Pearl Dace and Creek Chub. Abundant cyprinid species in Perch Lake included Bluntnose Minnow and Pearl Dace, and the dominant large-bodied species in the lake included Yellow Perch (40.4% of catch), Brown Bullhead (24.2% of catch) and Pumpkinseed (15.5% of catch). The dominant species in Main Stream were Pearl Dace and Fathead Minnow, and the only species captured in East Swamp Stream was Pearl Dace.

Table 5.5.4-1: Distributions For Focal Species in Small Watercourses and Waterbodies at the CRL Site

Common Name	Scientific Name	Trophic Category[a]	Feeding Habitat[a]	Occurrence at Nine Waterbodies and Watercourses (Sowden and Power 1981)	Occurrence at Main Stream and Upper Perch Creek (CG&S 1997, 1998)	Occurrence at Perch Lake, Toussaint Lake, Main Stream and East Swamp Stream (CNL 2017c; 2018c)
Common Shiner	*Luxilus cornutus*	Invertivore herbivore	Generalist	Lower Perch Creek	—	—
Blacknose Shiner[b]	*Notropis heterolepsis*	Invertivore-herbivore	Generalist	Ottawa River (shoreline)	Upper Perch Creek	—
Rosyface Shiner	*Notropis rubellus*	Invertivore	Specialist	Ottawa River (shoreline near Perch Creek)	—	—
Bluntnose Minnow	*Pimetheles notatus*	Omnivore	Generalist	All locations sampled except Upper Bass Lake and tributaries to Perch Lake	Upper Perch Creek	—
Fathead Minnow	*Pimetheles promelas*	Omnivore	Generalist	Duke Stream Marsh, Main Stream, Perch Lake, upper Perch Creek	Main Stream, Upper Perch Creek	—
Longnose Dace	*Rhinichthys cataractae*	Insectivore	Benthic	Lower Perch Creek	—	—
Creek Chub	*Semotilus atromaculatus*	Omnivore	Generalist	Perch Lake, upper/lower Perch Creek, Ottawa River in vicinity of Perch Creek	Main Stream, Upper Perch Creek	—
Fallfish	*Semotilus corporalis*	Invertivore-carnivore	Generalist	Ottawa River (shoreline) and lower Perch Creek	—	—
Pearl Dace	*Semotilus margarita*	Invertivore	Water column	Perch Lake, Main Stream, East Swamp Stream and lower/upper Perch Creek	Main Stream, Upper Perch Creek	Main Stream, East Swamp Stream
White Sucker	*Catostomus commersonii*	Omnivore	Benthic	Widely distributed, but not recorded above upper Perch Creek	—	—
Brown Bullhead[c]	*Ictalurus nebulosus*	Omnivore	Benthic	Perch Lake, upper/lower Perch Creek, Maskinonge Lake and Ottawa River	Upper Perch Creek	Perch Lake
Threespine Stickleback[d]	*Gasterosteus aculeatus*	Invertivore-carnivore	Generalist	Ottawa River (shoreline near Perch Creek)	—	—

Table 5.5.4-1: Distributions For Focal Species in Small Watercourses and Waterbodies at the CRL Site

Common Name	Scientific Name	Trophic Category[a]	Feeding Habitat[a]	Occurrence at Nine Waterbodies and Watercourses (Sowden and Power 1981)	Occurrence at Main Stream and Upper Perch Creek (CG&S 1997, 1998)	Occurrence at Perch Lake, Toussaint Lake, Main Stream and East Swamp Stream (CNL 2017c; 2018c)
Pumpkinseed	*Lepomis gibbosus*	Invertivore-carnivore	Generalist	Perch Lake, upper/lower Perch Creek, Maskinonge Lake, Lower Base Lake and Upper Base Lake	Upper Perch Creek	Perch Lake
Yellow Perch	*Perca flavescens*	Invertivore-carnivore	Water column	Widely distributed, but not recorded in Duke Stream Marsh and in Perch Lake tributaries	—	Perch Lake
Northern Pike[e]	*Esox lucius*	Carnivore- insectivore	Benthic	—	—	Perch Lake
Johnny Darter	*Etheostoma nigrum*	Invertivore	Benthic	Maskinonge Lake, Upper Base Lake, Ottawa River (near Perch Creek) and Lower Perch Creek	—	—
Logperch	*Percina caprodes*	Invertivore	Benthic	Ottawa River (near Perch Creek) and lower Perch Creek	—	—
Mottled Sculpin	*Cottus bairdii*	Invertivore	Benthic	Maskinonge Lake, Ottawa River (near Perch Creek) and lower Perch Creek	—	—

a) Considers species descriptions in Scott and Crossman (1973).

b) Blacknose Shiner reported in Perch Lake by Ophel and Fraser (1971).

c) Valued component species

d) Species documented in the Ottawa River near the mouth of Perch Creek but not collected in the Perch Creek and Perch Lake Watershed in summer 1980 or earlier.

e) Northern Pike, a top carnivore, was introduced to Perch Lake in the late 1980s (Yankovich et al. 2000), and populations have persisted through to 2018 (CNL 2018c)

— = not collected.

Following the baseline investigations by Sowden and Power (1981), Northern Pike was introduced to or recolonized Perch Lake, in the late 1980s, causing changes to the population dynamics of local species of fish (Yankovich et al. 2000). The once abundant population of Yellow Perch described in Sowden and Power (1981), was reduced in size, and forage species, such as Creek Chub, Bluntnose Minnow, Fathead Minnow, Pearl Dace and Blacknose Shiner were similarly affected (Yankovich et al. 2000). However, Perch Lake continues to support a large-bodied fish community that is similar to that recorded in 1980 (CNL 2017c), which includes a mix of coolwater species such as Perch, and warmwater species such as Brown Bullhead and Pumpkinseed (Table 5.5.4-1). All previously recorded large-bodied species were captured by gill netting in summer 2016. Of 230 fish captures in total, Brown Bullhead was the most abundant species (56% of catch), followed by Yellow Perch (38% of catch) and Pumpkinseed (2% of catch). Northern Pike was only 4% of the fish catch. A suite of methods was deployed in Perch Lake in 2018, including hoop nets, angling and minnow traps, capturing 208 fish in total. Fishing efforts confirmed the presence of relatively few Northern Pike (i.e., only one fish captured). Abundant species included Pumpkinseed (58% of catch), Brown Bullhead (23% of catch) and Yellow Perch (19% of catch) within Perch Lake (see Table 5.5.4-1; CNL 2018c).

Electrofishing of streams in the Perch Creek and Perch Lake Watershed in 1996 and 1997 characterized a community of fish dominated by Fathead Minnow, Creek Chub and Pearl Dace in Main Stream, and a community dominated by Creek Chub and Blacknose Shiner in upper Perch Creek (CG&S 1997, 1998; see Table 5.5.4-1). Other species captured in upper Perch Creek included Fathead Minnow, Pearl Dace, Pumpkinseed and Brown Bullhead. Only one species of small-bodied fish, Pearl Dace[1], was captured in Main and East Swamp Streams using dip nets in 2017 (CNL 2017c; Photo 5.5.4-3).

Photo 5.5.4-3: Pearl Dace Captured in East Swamp Stream During Sampling in Summer 2017

[1] Fish in Main and East Swamp Streams were initially identified as Finescale Dace (*Chrosomus neogaeus*) (CNL 2017c), but upon review were later classified as Pearl Dace.

Changes in the general structure of the fish community structure over time have been minor. Any temporal changes may be related to historical effects of the Northern Pike introduction (or colonization) and trends in annual hydrology. For streams, factors influencing the presence of fish appear to be related to flow conditions (e.g., volume), the presence of available refugia, such as pools, during the summer and winter, and the connectivity to Perch Lake (CG&S 1998). Although on-going environmental monitoring indicates that surface water quality of the Perch Creek and Perch Lake Watershed continues to be affected by past operations of the WMAs, the potential risk to negatively affecting fish has been deemed low (CNL 2015a, 2016a, 2019c). The potential risk to fish in the Perch Creek and Perch Lake Watershed will continue to be assessed through the conduct of the CRL Environmental Risk Assessment on a five-year cycle.

Major changes to fish productivity and community structure over time have not been observed, suggesting that the historical effects of past operations on water quality pose minimal risk to the fish community and populations in Perch Lake (CNL 2017c, CNL 2018b,c).

Brown Bullhead

Brown Bullhead is a native Ontario fish with historical populations documented within the Ottawa River, Perch Lake and the connecting tributaries (Sowden and Power 1981; CG&S 1997, 1998; CNL 2017c; 2018c; and Rubex and Qadri 1982). Historical baselines studies describe Brown Bullhead as a relatively abundant species in Perch Lake, numerically representing 24% of the fish community (Yankovich 2003). Population sizes in Perch Lake may have also increased over time. Yancovich (2003) suggested that the Brown Bullhead population increased approximately 80% following the colonization of Perch Lake by Northern Pike in the late 1980s. The fish catch in 2016 suggested a relative abundance of 56% Brown Bullhead and that Brown Bullhead was the dominant large-bodied species in Perch Lake. However, the most recent sampling in 2018 suggests a community structure more similar to historical estimates with 23% of the fish catch as Brown Bullhead (CNL 2018c). A total of 47 Brown Bullhead were collected during the 2018 fish community survey and they were the second most abundant species capture after Pumpkinseed (CNL 2018c).

A summary of Brown Bullhead body length measurements is presented in Table 5.5.4-2. Fish lengths reported in historical studies are, on average, 110 to 187 mm (Sowden and Power 1981; Yanchovich 2003). In 2018, the total length of captured fish was, on average, 182 mm. Both historical and recent measurements of mean lengths are less than the Ontario average length of 280 mm (Holm et. al. 2009). Whole body weights for the 2018 fish catch ranged from 21.0 g to 78.6 g, and the condition factor (K = weight /length^3 * 100) of those fish was calculated as K= 1.14 (± 1 standard error [SE] of 0.017) (Table 5.5.4-2), which is within the range of previously recorded K values for Brown Bullhead in Perch Lake (Figure 5.5.4-1). Average condition factor of Brown Bullhead reported in Yanchovich (2003) was 1.30 (± 1 SE of 0.021).

Table 5.5.4-2: Summary of Brown Bullhead Length and Condition Factor Collected in Perch Lake in 1981, 1997, 2003 and 2018

Variable	Sampling Years		
	1981	2003	2018
Length (mm)			
Average	187	159	182
Standard Error	5.2	2.1	4.9
Minimum	134	-	120
Maximum	313	-	262
n	72	46	47

Variable	Sampling Years		
	1981	2003	2018
Condition Factor (K)			
Average	-	1.30	1.14
Standard Error	-	0.021	0.000
Minimum	-	0.98	0.00
Maximum	-	1.63	0.00
n	-	46	0

Notes: n = sample size; - =data not available; [(a)] K = weight /length^3 * 100

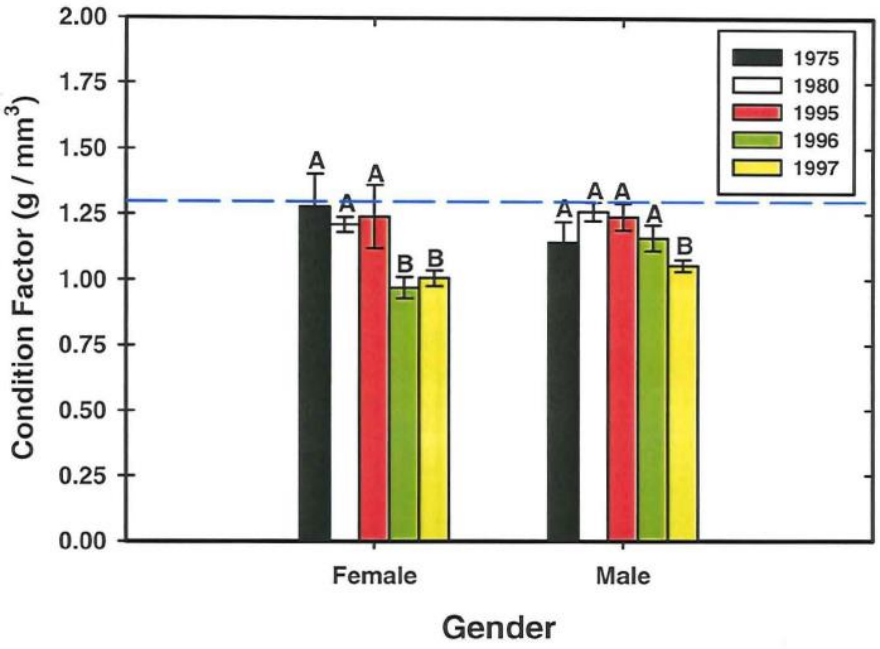

Figure 5.5.4-1: Brown Bullhead Historical Condition Factor by Gender (Yanchovich 2003)

Notes: The blue dashed line is the typical condition factor (K) as reported in (Carlander 1969). Letters indicate bars that are statistically the same and different (Yanchovich 2003).

5.5.4.2.3 Species of Conservation Concern

Based on historical reports of fish sampling in the Ottawa River, four fish species of conservation concern occur or have the potential to occur in the river reach adjacent to the CRL site (e.g., Allumette Lake). These species include Lake Sturgeon (*Acipenser fulvescens*), American Eel (*Anguilla rostrate*), River Redhorse (*Moxostoma carinatum*) and Northern Brook Lamprey (*Ichthyomyzon fossor*).

Lake Sturgeon

Lake Sturgeon is a member of the family Acipenseridae, and is Ontario's largest and longest-lived fish species (Golder 2011). Lake Sturgeon can reach 3 m in length and live to over 100 years in Ontario. They are a bottom-dwelling fish found in large rivers and lakes, at depths generally between 5 and 10 m. Spawning occurs in the spring in fast-flowing water at depths between 0.6 and 5 m over hard-pan clay, sand, gravel and boulders. The distribution of Lake Sturgeon once extended from western Alberta to the St. Lawrence drainage in Quebec, and from southern Hudson Bay drainages to the lower Mississippi drainage. Lake Sturgeon currently inhabit at least 229 waters (128 lakes and reservoirs and 101 rivers) in Ontario. Commercial fishing is thought to be the most significant factor that caused the historical decline of populations.

Lake Sturgeon are known to be present in the Ottawa River near the CRL site based on previous baseline and monitoring studies (e.g., Sowden and Power 1981; SENES 2010, CNL 2016a, CNL 2018c, CNL 2018d). The species has also been previously recorded in the Ottawa River reach adjacent to the CRL site (reviewed in Golder 2011). Lake Sturgeon have been known to spawn in the Allumette Rapids, downstream of the CRL site (SENES 2010). Lake Sturgeon are not listed under SARA but are designated as Threatened under the Ontario *Endangered Species Act, 2007.*

In order to track the effect of CNL's existing operations on the Lake Sturgeon population in the Ottawa River, monitoring of fish impinged into the National Research Universal reactor's water intake is conducted annually (CNL 2016b). Typically, few individual fish are impinged. Since monitoring began, the maximum number impinged in a single year was 10 in 2004, with every other year averaging 2 individuals. Impingement of sturgeon will continue to be monitored as long as water is being drawn from the Ottawa River at a rate strong enough to impinge fish.

In 2008, Pratt concluded that the population of Lake Sturgeon in the middle of the Ottawa River (Lac Colounge, Lower and Upper Allumette Lake) is increasing with greater than 5,000 individuals (Pratt 2008). While there are low numbers in many reaches of the Ottawa River, in the section of the Ottawa River where CRL sits, called Allumette Lake, there is a relatively healthy population of Lake Sturgeon (Pratt 2008; Haxton 2008). Studies along the Ottawa River show that Lake Sturgeon in this area prefer depths of 12 m to 20 m and are rarely found at depths of 35 to 50 m. Younger, smaller fish are more often found in more shallow regions while larger fish inhabit the deepest depth strata (Haxton 2011). The stable, self-sustaining Lake Sturgeon population adjacent to the CRL site coupled with CRL's consistently low impingement numbers of this species provides evidence that the CRL site has had minimal negative effect on the local population of Lake Sturgeon.

American Eel

The American Eel is in the order Anguilliformes, family Anguillidae. Anguilla eels are termed freshwater eels, although some species (including the American Eel) are able to complete their entire life cycle in saltwater (COSEWIC 2006). The American Eel spawn in the Sargasso Sea in the southern North Atlantic Ocean. The historic Canadian range includes all accessible fresh water, estuaries and coastal marine waters connected to the Atlantic Ocean, up to the mid-Labrador coast. Continental shelves, where Niagara Falls is the natural distributional limit in the Great Lakes, are used by juvenile eels arriving from the spawning grounds, and by mature eels just prior to the spawning migration. Eels in the continental growth phase do not show consistent habitat preference. They are primarily benthic, using substrate and bottom debris as protection and cover.

American Eel are known to be present in the Ottawa River near the CRL site (Sowden and Power 1981; SENES 2010a, CNL 2018d). American eels were previously considered abundant in this stretch of the river and have been reported in Maskinonge Lake on the CRL site but have not been observed during recent creel surveys in the region (SENES 2010). American Eel is not a federally listed species under SARA but is considered Endangered under the Ontario *Endangered Species Act, 2007*. Efforts to reintroduce American Eels to the Ottawa River were completed in 2017, as a collaborative project with Ottawa Riverkeeper and Canadian Wildlife Federation (Ottawa Riverkeeper 2017).

Dams and other barriers are the primary threat to the persistence of American Eel populations (COSEWIC 2006). Barriers generate habitat loss and fragmentation for upstream migrants and produce turbine mortality for downstream migrants. The Ottawa River is currently blocked by 19 major-dams, only the Hydro Ottawa Chaudière dam is equipped with an eel ladder and turbine by-passes for migration movements (Ottawa Riverkeeper 2017).

Northern Brook Lamprey

The Northern Brook Lamprey is a freshwater, non-parasitic fish from the family Petromyzontidae (DFO 2016a). Northern Brook Lamprey live up to seven years as ammocoetes (larval lampreys), burrowed in soft sediments of streams where they are relatively protected before metamorphosis. The adult Northern Brook Lamprey has a non-parasitic adult stage and its fertility is relatively low (i.e., it has a lower reproductive capacity compared to other lamprey species). The Northern Brook Lamprey migrates up streams to spawn near the end of its life.

In Canada, the Northern Brook Lamprey lives in rivers and lakes in the Great Lakes and Upper St. Lawrence system. Although Northern Brook Lamprey may be present in the Ottawa River reach adjacent to the CRL site (SENES 2010; CNL 2018d), there are no records of the species near the CRL site based on previous baseline and monitoring studies. Furthermore, the species has not been recorded in the river reach adjacent to the CRL site based on Fisheries and Oceans Aquatic Species at Risk (DFO 2018), and the list of Species at Risk in Ontario (Government of Ontario 2019). The application of lampricide to manage the invasive Sea Lamprey is the main threat for Northern Brook Lamprey in the Great Lakes systems (DFO 2016a). Northern Brook Lamprey are considered as species of Special Concern under both SARA and the Ontario *Endangered Species Act, 2007*.

River Redhorse

The River Redhorse is a member of the genus Moxostoma in the Catostomidae family. The River Redhorse is a long-lived species that requires a variety of connected habitats to complete its life stages (DFO 2016b). The preferred spawning habitat for the River Redhorse is moderate to large rivers with a moderate to swift current, riffle-run habitat, and clean gravel, cobble, or boulder substrate. Upon spawning, approximately mid-June, the species can be found in deeper, slower current areas with abundant aquatic vegetation and softer substrates through the summer.

This species has a disjunct distribution in Canada (DFO 2016b). It occurs in southern Ontario (Grand River, Thames River) and eastern Ontario (Bay of Quinte, Trent River, Mississippi River, Madawaska River, and throughout the Ottawa River system). It also occurs in southern and southwestern Quebec (Coulonge River, Gatineau River, Noire River, Ottawa River and Richelieu River). The species has a wide distribution throughout the Ottawa River and its tributaries.

River Redhorse are expected to be present near the CRL site (SENES 2010, CNL 2018d). River Redhorse is designated as a species of Special Concern under SARA and the Ontario *Endangered Species Act, 2007*.

The species was previously recorded in the Ottawa River reach near the CRL site, as noted on the Fisheries and Oceans Aquatic Species at Risk (DFO 2018), and in the list of Species at Risk in Ontario (Government of Ontario 2019). The nearest area of the Ottawa river containing critical habitat for River Redhorse is approximately 20 km downstream of the CRL site (Figure 5.5.4-2). The principal threats affecting the future persistence of River Redhorse populations are habitat degradation through siltation, agricultural and urban pollution, and instream barriers such as dams, which restrict access to spawning areas and can change flow regimes during spawning periods (DFO 2016b).

5.5.5 Project Interactions and Mitigation

5.5.5.1 Methods

This section describes the process by which interactions between NSDF Project components and activities on the aquatic environment were identified and evaluated. Potential effects pathways were identified, and mitigation developed to eliminate or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated, pathways are not forwarded for further analysis (i.e., secondary pathways where mitigation will remove the pathway altogether), and the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment, as required. As such, the Project Interactions and Mitigation section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all phases of the NSDF Project. The next step in the analysis was the development of environmental design features and mitigation that could be incorporated into the NSDF Project to eliminate or reduce adverse effects to the aquatic biodiversity. Environmental design features included project design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the Project's engineering and environmental teams, combined with project-specific input from engagement with other interested parties. The design features and mitigation were selected considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effects pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments, and the effectiveness of environmental design features and mitigation:

- **No linkage:** The pathway is removed by environmental design features or mitigation such that the NSDF Project would not be expected to result in a measurable environmental change relative to Base Case values and therefore would have no residual effects to aquatic biodiversity.
- **Secondary pathway:** The pathway could result in a measurable minor environmental change, but would have a negligible residual effect on aquatic biodiversity relative to Base Case or available guideline values, and is not expected to contribute cumulatively to other Project effects or to the effects of other previous, existing or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway:** The pathway is likely to result in an environmental change relative to the Base Case or available guideline values that could contribute to residual effects to aquatic biodiversity.

Environmental design features and mitigation that have been or could be incorporated into the NSDF Project to eliminate and reduce adverse effects were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and were demonstrated to have a negligible residual effect to aquatic biodiversity through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways were carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the NSDF Project.

5.5.5.2 Results

Pathways through which all phases of the NSDF Project may interact with and result in changes to measurement indicators for aquatic biodiversity are provided in Table 5.5.5-1.

Table 5.5.5-1: Pathways Analysis for Aquatic Biodiversity Valued Component

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment[(a)]
■ Project activities during the construction phase: ▪ Site Preparation ▪ Construction of the ECM ▪ Blasting (as required) ▪ Development of surface water management structures ▪ Construction of the WWTP and other support facilities ▪ On-site road and access development ▪ Construction of the transfer line and Perch Lake diffuser ▪ Domestic waste (solid and liquid) management	Change to local hydrology from surface disturbances may cause changes to water levels, flows and channel/bank stability at downstream locations, affecting water and sediment quality, and fish habitat quality	■ The NSDF Project footprint (SSA) has been designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily/interim cover daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. ■ A 30 m buffer will be established along identified wetlands near the SSA; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion ■ Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site will be used during construction around disturbed areas, where appropriate. ■ During the construction phase, erosion and sediment control measures include the use of erosion control blankets to control erosion on steep slopes, and the use of check dams in ditches and swale. ■ Surface water from all external areas will be conveyed by ditches, swales and culverts to surface water management ponds (SWMPs) to address water quality and water quantity criteria established for the wetland receiving waters. ■ Where drainage crosses roadways, culverts are sized to convey the 25-year design event without road overtopping. ■ The SWMPs are designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during operations, closure and post-closure. ■ Annual maintenance activities will identify any erosion problems. ■ Inspection and maintenance reviews will be completed after major storm events and after the annual spring melt to confirm there are no major erosion issues.	No Linkage
	Changes to the hydrology within the Perch Creek and Perch Lake Watershed as a result of the intake of water from the Ottawa River for construction activities may cause changes to surface water quality and fish habitat quality		
	Surface water drainage through the SSA during construction of the ECM may transport blasting residuals and metals directly into downstream waterbodies, affecting surface water and sediment quality (i.e., fish habitat quality), and fish survival and reproduction	■ A blasting plan, as part of the EPP, will be developed by the Contractor and implemented for the NSDF Project. ■ Runoff from the SSA will be managed (e.g., SWMPs) to avoid adverse environmental effects in downstream waterbodies. ■ Additional guidance for the NSDF Project blasting limits will be obtained from *OPSS 120 – General Specification for the Use of Explosives* (OPSS 2014). ■ Blasting activities will follow industry standard Best Management Practices, applicable federal regulations, and Fisheries and Oceans Canada guidelines for use of explosives (Wright and Hopky 1998). ■ Set-back distances required for blasting will be identified in the blasting plan (as part of the EPP to be developed by the Contractor).	No Linkage
	Blasting near fish-bearing waterbodies may result in pressure changes, vibrations (“noise”) and affect fish survival and reproduction.		No Linkage

Table 5.5.5-1: Pathways Analysis for Aquatic Biodiversity Valued Component

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment[(a)]
■ Project activities during the construction phase: ▪ Site Preparation ▪ Construction of the ECM ▪ Blasting (as required) ▪ Development of surface water management structures ▪ Construction of the WWTP and other support facilities ▪ On-site road and access development ▪ Construction of the transfer line and Perch Lake diffuser ▪ Domestic waste (solid and liquid) management	Physical change to fish habitat and temporary riparian area disturbances from the installation of diffuser and transfer line construction and footprint may affect fish and fish habitat	■ The selection of final routing alignment and foundation design considered an assessment of environmental effects of alternate routing alignments and foundation designs ■ All in-water work will target the timing window of July 16 to October 1 to avoid critical fish spawning and egg/larval development periods for spring spawning fish species (DFO 2013, MNR 2013) while being protective of turtle overwintering habitats in and around Perch Lake. The construction duration is anticipated to be short term (i.e., <30 days). ■ Mitigation, including erosion and sediment control practices (e.g., silt fences, silt curtains), will be used during construction around disturbed areas, where appropriate. Key fish habitat protection measures will include turbidity curtains to isolate any suspended sediments in the construction work areas within the lake. ■ Industrial equipment will be well maintained and free of leaks, invasive species and noxious weeds. Machinery will be operated from above the high-water mark or from a barge to minimize the disturbance of the lakebed, riparian area, and shoreline. Vegetative mats and riparian protection measures will be used when mobilizing to and from the site. ■ Clearing of any riparian vegetation and organic materials will be minimized, materials removed will be salvaged and replaced once the project is completed. Disturbed riparian areas and shorelines will be re-vegetated and restored to the original stable gradient and contour. All construction materials will be removed from site upon completion of the project. ■ A site-specific Erosion and Sediment Control Plan will be developed and implemented for this activity. ■ A site-specific 'Spill Management Plan' will be developed and implemented for this activity. Any refuelling will occur at least 30 m away from the lake or waterbodies. ■ Mitigation as described for drilling activities in the DFO Ontario High-Pressure Directional Drilling Operational Statement (DFO 2007) will be followed. ■ Environmental monitoring of ESC measures will be completed by a qualified professional. Environmental monitoring will include turbidity and total suspended solids monitoring; the monitoring details will be described in an 'Erosion and Sediment Control Plan' provided by the Project contractor prior to construction.	Secondary
	Non-radiological air emissions and dust emissions (including sulphur dioxide, nitrogen oxides and particulate matter) and subsequent deposition may cause a change in surface water quality and fish habitat quality	■ Implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018e), which includes operational control monitoring and verification monitoring. ■ The EPP, which will be developed by the Contractor, will align with CNL's Environmental Monitoring Programs and with the NSDF *Dust Management Plan* (AECOM 2018a) will include dust management mitigation measures and will include: ▪ restricting or suspending activities if unacceptable amounts of dust are generated due to winds or other site conditions; ▪ use of water spraying or misting techniques (e.g., water trucks) as the primary dust control method; ▪ use of fixatives (e.g., chemical suppressant) for dust control and for use as daily/interim cover daily ECM cover; ▪ suspension of excavating, loading, hauling and, and disposal operations when wind speeds exceed the specified criterion; and ▪ vehicles that have come into contact with potential contamination sources will be required to pass through the vehicle decontamination facility. ■ On-site vehicles and equipment engines will meet Tier 2 emission standards as described in Section 5.2 and be maintained in good working order. ■ Idling of vehicles will be limited on-site.	Secondary
	Discharge of domestic wastewater/sanitary sewage may cause a change in surface water and sediment quality, affecting fish habitat quality	■ The grey water/sanity sewage will be managed through a gravity sewer network connected to the two sewage disposal systems as described in Section 3.4.4.4. These systems are completely separate from the ECM leachate and other contact water sewer conveyance for the on-site WWTP. ■ Sewage discharges to the sewage disposal systems will conform with CNL's procedure *Acceptability Criteria for Routine and Non-Routine Discharge of Liquids on the CRL Site* (CNL 2015b).	No Linkage

Table 5.5.5-1: Pathways Analysis for Aquatic Biodiversity Valued Component

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment[(a)]

■ Project activities during the construction phase (as listed above)
■ Project activities during the operations phase:
  ■ Phased development of disposal cells in the ECM
  ■ On-site transportation of waste and placement in the ECM
  ■ Progressive closure of disposal cells and installation of final cover
  ■ Operation of the WWTP
  ■ Existing presence of fencing around perimeter of ECM
  ■ Surface water management
  ■ Domestic waste (solid and liquid) management; and,
  ■ Routine operational management and monitoring activities.
	Surface water runoff from the SSA can contain contaminants and suspended solids, which can affect water quality, ultimately leading to changes to fish habitat quality, survival and reproduction	■ Procedures for surface water management will be developed and implemented for the NSDF Project.
		■ The target surface water quality objective is provided in *Stormwater Management Planning and Design Manual* (MOE 2003).
		■ Surface water from all external areas will be conveyed by ditches, swales and culverts to SWMPs that will address water quality and water quantity criteria established for the wetlands and Perch Lake receiving waters and, ultimately, Perch Creek.
		■ The SWMPs are designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during operations, closure and, and post-closure.
		■ The current SWMP designs reflect the overall storage required to control post-closure flows to predevelopment levels for the 2-year through to 100-year rainfall events at the site. This volume also contains the storage required for sediment control during construction and water quality control during operations.
		■ Where drainage crosses roadways, culverts are sized to convey the 25-year design event without road overtopping.
		■ For each SWMP the water level will be sampled to estimate the inflow and outflow of each pond.
		■ The outlet water quality will be sampled periodically to confirm that surface water discharges meet applicable environmental criteria.
			No Linkage

	Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) can cause changes to downstream surface water quality, which can affect fish habitat quality, survival and reproduction	■ The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses best available technology that is economically achievable) and, and capable of meeting regulatory requirements.
		■ Effluent discharge targets for wastewater discharges are protective of the environment and human health.
		  ■ Discharge targets for non-radiological contaminants are sourced from federal and provincial guidelines for protection of aquatic biota.
		  ■ Discharge targets for radionuclides are the Canadian Drinking Water Guidelines with the exception of tritium for which a site-specific target is developed (Section 3.4.2.5.1).
		■ Treated effluent will be sampled to confirm that it meets effluent discharge targets before release to the environment.
		■ When applied, the proposed exfiltration gallery will promote the exfiltration of treated water into the local groundwater regime where further retention of radioactivity by the geosphere is anticipated.
		■ The Perch Lake diffuser design provides additional dilution of treated effluent at the point of release
		■ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water quality.
		■ Appropriate procedures will be in place to effectively identify spill occurrences in the event treated effluent is released to areas other than directly to the exfiltration gallery and initiate appropriate emergency responses.
			Secondary

	Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) and the discharge of non-contact water to adjacent wetlands can cause changes to hydrology, resulting in scouring of the wetlands, which can affect fish habitat quality at downstream waterbodies	■ Discharge of treated effluent to the exfiltration gallery area will help to reduce water loss from the hydrogeological system. ■ Design consideration was given during the selection of the discharge location of treated effluent for environmental effects of scour on the receiving waterbodies. As such, the preferred design (i.e., discharge to the exfiltration gallery and Perch Lake diffuser) was chosen as the favourable alternative as they resulted in negligible scour potential. ■ Outlet flows from all three SWMPs will be dispersed by level spreaders that will provide an even flow distribution to the adjacent wetlands with an appropriately wide dispersal pattern. ■ The WWTP system's outlet utilizes a headwall which discharges to a level spreader for the purposes of preventing erosion and sedimentation at the outlet for the exfiltration gallery. ■ The outlet locations of the SWMPs are limited by the site boundary (greater than 5 m separation required) so that there is no discharge from the spreader directly to a waterbody. ■ Annual inspection and maintenance activities will identify any erosion problems. ■ Inspections will be undertaken and maintenance activities completed, as required, after major storm events and after the annual spring melt to confirm there are no major erosion issues.	No Linkage

Table 5.5.5-1: Pathways Analysis for Aquatic Biodiversity Valued Component

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment[a]
■ Project activities during the operations and closure phases: ▪ Surface water management ▪ Operation of the WWTP ▪ Discharge of treated effluent from the WWTP	Discharge of treated effluent through the Perch Lake diffuser may create an area of turbulence that affects water quality, affecting fish habitat quality	■ The final design considered an evaluation that addressed the environmental effects through alternate routing alignments and foundation designs that resulted in a favourable alternative that addressed economic, environmental and technical factors. ■ The diffuser will be positioned in the water column and designed to avoid excess sediment mobilization and turbulence. ■ Discharge will be directed through properly designed structures to the lake environment to prevent erosion and sediment entrainment in the receiving waters. ■ The diffuser discharge ports will be located 0.8 m above the lakebed to minimize erosion. ■ Direct discharge flow rates will be developed and maintained to address erosion concerns.	Secondary
	Leakage of leachate from the ECM during the operations and closure phases may cause changes to groundwater quality, affecting surface water quality in East Swamp Stream and downstream waterbodies, which can affect fish habitat quality, survival and reproduction	■ Design of the ECM includes base contours developed using a herringbone pattern with ridges and valleys to promote leachate transport to the leachate collection system for removal. ■ The base liner design includes primary and secondary liner systems designed to have redundancy in case of premature degradation and are a combination of natural and synthetic barrier systems. These include a compacted clay liner (CCL), two geosynthetic clay liners (GCL) and an HDPE geomembrane. ■ Clay materials were selected for the CCL and GCL components of the liner system as these materials are anticipated to maintain their function as hydraulic barriers throughout and beyond the design life of the disposal facility (i.e., 550 years). ■ The HDPE geomembrane design for the liner will be compatible with the leachate generated by the waste and provide a long service life. ■ The base liner system will include an underlying compacted clay liner to supplement the primary and secondary liner system. ■ The leachate collection system design will provide accessible access points for inspections, maintenance, repairs and replacements. ■ Appropriate responses to leachate leakage and contamination will be implemented as described in the Operations and Maintenance Plan and Contingency Plan	No Linkage
	The installation of the final cover of the ECM and decommissioning of NSDF Project infrastructure may change downstream discharge, water levels and, and channel/bank stability, affecting surface water and sediment quality (i.e., fish habitat quality)	■ The final cover is designed to promote positive drainage from the SSA and reduce erosion or abrasion of the final cover. ■ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound and minimize leachate generation. ■ The final cover system design incorporates a series of shallow, trapezoidal and lined drainage channels designed to convey water at low velocity. ■ The perimeter road ditch will route runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the final cover and underlying waste materials, destabilization of the ECM structure and, and damage to access roads. ■ The ECM final grading and drainage plan includes collection ditches along the top of the ECM berm road to collect side slope drainage. ■ Environmental monitoring will be completed as required during the institutional control period for the NSDF Project to confirm that the final cover is functioning as intended.	No Linkage
	Leakage of leachate from the ECM during the post-closure phase (i.e., after Year 2100 to 2400) from liner and final cover degradation as a result of normal evolution may cause changes to groundwater quality and downstream surface water quality in adjacent wetlands, affecting fish habitat quality, survival and reproduction.	■ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the ECM and minimize leachate generation. ■ The final cover system design incorporates a series of shallow, trapezoidal, riprap-lined drainage channels that are designed to convey water at low velocity. ■ The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the final cover and underlying waste materials, destabilization of the ECM structure and damage to access roads. ■ The ECM final grading and drainage plan also includes collection ditches along the top of the ECM berm road to collect side slope drainage. ■ The design life for the ECM is 550 years to meet the required time period to allow for radioactive decay of the waste placed in the facility (i.e., until it has decayed to levels that do not present a risk to the public and environment). ■ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water and groundwater quality.	Secondary

a) All pathways assessed were determined to provide ‘No Linkage’ for Species of Conservation Concern VC and assessment designations are provided for Fish Habitat and Fish Community VCs.

WWTP = Wastewater Treatment Plant; ECM = engineered containment mound; SSA = Site Study Area; SWMPs = surface water management ponds; EPP = Environmental Protection Plan; OPSS = Ontario Provincial Standard Specification; DFO = Fisheries and Oceans Canada; <= less than; TSS = total suspended solids; HDPE = high-density polyethylene.

5.5.5.2.1 No Linkage Pathways

The following pathways were assessed as having no measurable effect on habitat availability, survival, and/or reproduction, and therefore, the pathways have no linkage to residual effects on aquatic biodiversity VCs.

- **Changes to local hydrology from surface disturbances may cause changes to water levels, flows and channel/bank stability at downstream locations, affecting water and sediment quality, and fish habitat quality.**
- **The installation of the final cover of the engineered containment mound (ECM) and decommissioning of NSDF Project infrastructure may change downstream discharge, water levels and channel/bank stability, affecting surface water and sediment quality (i.e., fish habitat quality).**

Changes to surface flows, water levels and water quality from NSDF Project construction and decommissioning are expected to be limited using environmental design features and mitigation. The NSDF Project footprint was designed to be as small as possible to limit disturbance to the natural environment to the extent feasible and will avoid stream and wetland habitats. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily/interim ECM cover. This approach reduces the required area for the laydown and stockpile of materials. In addition, a 30-m buffer is established along the identified wetlands near the NSDF Project; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion.

All proposed physical works are located within the SSA, affecting a relatively small area (5.1%) of the total contributing basin area for Perch Creek (720 ha; Robertson and Barry 1985). The total land area to be cleared is up to 37.4 ha, of which 35.6 ha is within the boundary of the Perch Creek and Perch Lake Watershed representing 4.8% of the contributing basin area (746 ha). The remaining small footprint (1.8 ha) will overlap with the CRL Built Up Area drainage basin. Any changes to existing drainage patterns will largely be restricted to the Perch Creek and Perch Lake Watershed. The total annual volume of water to be treated is 11,000 m^3. The volume represents approximately 0.6% of the average total outflow from Perch Lake (1,700,000 m^3/yr), or 0.5% of the average total outflow from Perch Creek (2,200,000 m^3/yr). Operational treated effluent discharge is expected to be less than 11 m^3/hr. Flow rates within Perch Creek are approximately 252 m^3/hr; the effluent discharge rate is roughly 0.4% of the average Perch Creek flows and approximately 11.5% of East Swamp weir flows. Furthermore, the receiving wetlands are expected to buffer the discharge, further reducing flow rates into Perch Creek.

All non-contact and contact water will be managed within the SSA, as per the Surface Water Management Plan that has been developed, reducing the potential for the NSDF Project to affect downstream discharge, water levels and channel/bank stability. Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site will be used during construction and decommissioning around disturbed areas.

Closure activities include the installation of an engineered cover and a final cover over the ECM to limit ponding and water infiltration into the waste. Modification to the drainage ditches and conveyance channels will be made to promote positive drainage from the site and limit erosion or abrasion of the final cover. Runoff control for the final cover is designed to limit ponding and infiltration of water into the ECM, erosion of the final cover and waste material, and destabilization of the structure. The ECM design approach is to control the direction and velocity of the run-off to prevent erosion and abrasion of the final cover. Any surface water infiltrating the final cover will be collected by the leachate collection system and sent to the WWTP. The three SWMPs will remain to promote

infiltration and settlement of suspended solids and restrict discharge rates to the nearby wetland. Decommissioning of the WWTP and all associated surface water management structures will be completed after the leachate quantity and quality no longer requires treatment. If the WWTP is required beyond its design life, the unit would be refurbished to enable continued treatment of leachate or other treatment options investigated. Environmental monitoring will be completed throughout the 300-year institutional control period for the NSDF Project to confirm that the final cover is functioning as intended.

Implementation of the above described mitigation measures for the NSDF Project are expected to limit changes to downstream discharge, water levels and, and channel/bank stability in affected streams such that residual effects are not predicted for fish habitat quality. As such, this pathway was identified as a no linkage pathway for aquatic biodiversity VCs.

- **Changes to the hydrology within the Perch Creek and Perch Lake Watershed as a result of the intake of water from the Ottawa River for construction activities may cause changes to surface water quality and fish habitat quality.**

The NSDF Project construction phase will be carried out from 2022 to 2024. During the construction phase, CNL anticipates an average daily usage of approximately 110 to 150 m^3/day for construction activities (e.g., dust suppression, clay mixing and fire protection). Construction water use is expected to peak at approximately 750 m^3/day and to be lower during the winter season (December through to March) when construction activities will be less. The water may also be used for commissioning activities including: hydrostatic testing of the WWTP storage tanks, the leachate collection and piping systems. Construction water will be sourced from the Ottawa River and accessed via overland hoses and pipes to fill temporary storage containers.

The intake of water from the Ottawa River for construction purposes (i.e., up to a maximum of 276,000 m^3/yr based on the peak daily usage) is anticipated to have a negligible effect on the overall Ottawa River annual flow rate of 25 billion m^3/yr (as recorded at the Des-Joachims monitoring point) and on the downstream hydrology. The proposed diverted annual volume for construction represents 0.0011% of the total annual flow rate of the Ottawa River at Des-Joachims using conservative assumptions of annual volumes based on peak daily flow and construction taking place during the winter months. Actual water use for construction is anticipated to be lower than proposed; for example, during winter months, site activities do not require as much water as during the open water construction periods. Consequently, no changes to aquatic biodiversity VCs in the Ottawa River are anticipated.

Similarly, changes to the surface water quality within the Perch Creek and Perch Lake Watershed as a result of the intake of water from the Ottawa River for construction activities at the SSA are not anticipated. Water is used for various construction activities, such as dust management control. Water used for dust management will primarily infiltrate or evaporate, any associated runoff will be collected and conveyed to the SWMPs. Overall, the water use for construction activities pathway was determined to be a no linkage pathway for aquatic biodiversity VCs.

- **Surface water drainage through the SSA during construction of the engineered containment mound (ECM) may transport blasting residuals and metals directly into downstream waterbodies, affecting surface water and sediment quality (i.e., fish habitat quality), and fish survival and reproduction.**

Use of ammonium nitrate/fuel oil and water-resistant bulk emulsion explosives during the construction of the ECM has the potential to affect surface water quality in the Perch Creek and Perch Lake Watershed through runoff coming into contact with residual nitrogen material (e.g., nitrate and ammonia) in the construction area. A blasting plan will be developed by the Contractor as part of the EPP for the Project, which will comply with existing guidelines (Wright and Hopky 1998; DFO 2019; OPSS 2014). Any runoff in contact with blasting residues at the SSA will be managed according to the Surface Water Management Plan (e.g., SWMPs and associated systems) during the construction phase. In addition, the potential for transporting blasting residuals into downstream waterbodies is minimized as blasting operations are limited to a relatively short period of time during the construction phase.

The use of explosives for the development of the ECM in the proposed NSDF Project is considered to potentially influence runoff quality with respect to minor increases in nitrate and ammonia concentrations for a short period in the construction phase. Therefore, the use of explosives for the development of the proposed NSDF Project is unlikely to result in changes in fish habitat quality in East Swamp Stream and downstream locations, including Perch Lake and Perch Creek. This pathway was determined to have no linkage to aquatic biodiversity VCs.

- **Blasting near fish-bearing waterbodies may result in pressure changes and vibrations (“noise”) and affect fish survival and reproduction**

Use of explosives near fish-bearing waters has the potential to injure or kill fish. Detonation of explosives in or near water creates compressive shock waves that rapidly rise to high peak pressures then rapidly decrease to below ambient hydrostatic pressure (Wright and Hopky 1998). The rapid decrease in pressure produced by blasting has the potential to negatively affect fish in the vicinity by damaging the swim bladder and other soft organs (Wright 1982). Fish eggs in the area affected by pressure waves can be damaged by the movement of the substrate in which they are embedded (Wright 1982).

The NSDF Project will avoid any effects to fish and fish habitat through the implementation of set-back distances and by avoiding construction and related blasting activities in waterbodies and watercourses. A detailed blasting plan will be developed by the Contractor as part of the EPP and will contain contingencies and mitigations to reduce the potential for harm to fish and fish habitat. The blasting plan will comply with Fisheries and Oceans Canada *Guidelines for the Use of Explosives in or Near Canadian Fisheries Waters* (Wright and Hopky 1998). Additional guidance will be obtained from *OPSS 120 – General Specification for the Use of Explosives* (OPSS 2014).

The anticipated quantities of blasted rock are approximately 170,000 m^3. There will also be an allowance made for additional trench blasting that may be required to facilitate utility runs. It is anticipated that the majority of blasted rock will be recycled for use within the construction of the engineered containment mound. Rock that cannot be recycled for reuse will either be stored at the CRL site or cleared for off-site use. Set-back distances required for blasting will be determined and included in the Blasting Plan. Charge sizes, blasting sequences and any additional measures required to deaden vibrations (i.e., strategic positioning of aggregate material) will be described in the Blasting Plan.

The use of explosives for the development of the proposed NSDF Project is predicted to not measurably change survival or reproduction measurement indicators for fish species in the LSA. It is therefore anticipated that this pathway has no linkage with aquatic biodiversity VCs.

- **Discharge of domestic wastewater/sanitary sewage may cause a change in surface water and sediment quality, affecting fish habitat quality.**

The NSDF's sanitary conveyance system is designed to convey the peak sewage flows generated by up to 65 full-time employees (although this will be adjusted based on operational demand) who will work at the NSDF Project. The NSDF sanitary sewage will be managed through a gravity sewer network connected to a sewage disposal system. This system is completely separate from the ECM leachate and other contact water sewer conveyance for the on-site WWTP.

There are two site sewage disposal systems proposed to service the NSDF site. A detailed description of the system is presented in Section 3.4.4.4.

Sewage discharges to the sewage disposal systems will conform to CNL requirements for discharge to septic systems provided in the NSDF *Environmental Protection Plan* (AECOM 2018b) and *Acceptability Criteria for Routine and Non-Routine Discharge of Liquids on the CRL Site* procedure (CNL 2015b). As such, discharge of treated domestic wastewater for the NSDF Project to downstream locations is considered to have no linkage to effects on aquatic biodiversity VCs.

- **Surface water runoff from the SSA can contain contaminants and suspended solids, which can affect water quality, ultimately leading to changes to fish habitat quality, survival and reproduction.**

A variety of mitigation strategies will be implemented during all project phases to reduce the potential for changes to soil, water and vegetation quality from surface water runoff from the CRL site. These include surface water management, erosion and sediment control measures, SWMPs, maintenance and inspection activities, and monitoring.

Site operations include surface water management for the ECM and all external areas. Surface water from all external areas will be conveyed by ditches, swales and culverts to SWMPs that will address water quality and water quantity criteria established for the wetland receiving waters and, ultimately, Perch Creek. Contact water, which is exposed to waste within the ECM, will drain from the active cells of the ECM and be conveyed to the WWTP. Non-contact water drainage from completed cells and yet-to-be completed cells will be directed either by gravity to the external surface water management system or to temporary holding ponds within the ECM, then pumped to the three SWMPs.

During the construction phase, erosion and sediment control measures will be in place to mitigate the effects of soil erosion and sediment transport. The measures include use of erosion control blankets, as needed, to control erosion on steep slopes. Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site (i.e., CNL's *Management of Land, Habitat and Wildlife* procedure [CNL 2018f] will be used around disturbed areas within the CRL site, where appropriate. Furthermore, an Environmental Management Plan has been developed as part of the design plan for the site outlining the erosion and sediment control measures and SWMP construction schedule discussed. It additionally outlines administrative protocols such as training, contractor document submissions and staffing required for effective surface water management throughout all phases of the NSDF Project.

The SWMPs are designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during operations, closure and post-closure. The current SWMP footprints reflect the overall storage required to control post-closure flows to predevelopment levels for the 2-year through to 100-year rainfall events at the site. This volume also contains the storage required for sediment control during construction and water quality control during operations. The target surface water quality objective of 60% TSS removal that provides basic water quality treatment for discharge to the receiving wetland is provided in the *Stormwater Management Planning and Design Manual* (MOE 2003). The SWMPs #1 will meet 80% total suspended solids removal which will provide enhanced water quality treatment. SWMP #2 will provide 76% TSS removal and SWMP #3 will meet 60% total suspended solids removal during operations which will be sufficient because the receiving waterbody is a wetland and not a watercourse. The wetland functions as a sediment trap that will provide additional treatment prior to stormwater reaching any watercourses in wetlands.

Roadway, sidewalk and parking lot winter maintenance activities that may release road salt to the environment, include snow plowing/shoveling and de-icing practices, salt and sand storage and snow stockpiling, and removal and disposal. The winter maintenance practices outlined in the current CRL *Salt Management Plan* (AECL 2013) provide for effective management of salt use and will be applied to the NSDF Project as necessary. As per the plan, the application of road salt in the SSA will be to be limited as salt residual within contact water and/or leachate may compromise the treatment effectiveness of the WWTP systems. Instead, alternative products in winter road management, such as a sand-stone mixtures, are currently being considered.

Facility inspections will be completed on a defined schedule to confirm that inlets and outlets are clear of debris and to confirm that there are no major erosion issues at the inlet or outlet. As well, the integrity of berms and outlet structures will be confirmed by visual inspections that would identify soil erosion. Inspections will identify sediment clean-out requirements. Sediments will be extracted by excavation equipment and will be disposed of based on sediment sampling, testing and classification according to Ministry of Environment, Conservation and Parks standards or stockpiled, dewatered and reused on-site for daily ECM cover operations. The sediment removal assessment follows procedures identified in the *Stormwater Management Planning and Design Manual* (MOE 2003).

The implementation of proposed mitigation at the SSA will reduce the potential for changes to soil, water and vegetation quality from surface water runoff from the NSDF Project. As such, this pathway was determined to have no linkage to aquatic biodiversity VCs.

- **Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) and the discharge of non-contact water to adjacent wetlands can cause changes to hydrology, resulting in scouring of the wetlands, which can affect fish habitat quality at downstream waterbodies.**

The NSDF Project will generate two water streams which will have the potential to impact water flows and levels in wetlands including:

- treated effluent from the WWTP which will be routed to the exfiltration gallery or Perch Lake; and
- non-contact water (i.e., water that has not been contaminated through contact with the ECM) which will be managed through a series of SWMPs.

A Surface Water Management Plan will be implemented to mitigate effects from wastewater discharges. Most of the wastewater flow will be generated from non-contact water produced during active filling of the ECM; contributions by leachate and decontamination activities represent a small fraction of the overall wastewater that will be treated by the WWTP. The total annual volume of water to be treated is 11,000 m^3. The volume represents approximately 0.6% of the average total outflow from Perch Lake (1,700,000 m^3/yr), or 0.5% of the average total outflow from Perch Creek (2,200,000 m^3/yr). Operational treated effluent discharge is expected to be a maximum of approximately 11 m^3/hr with an average effluent discharge rate below 1 m^3/hr. Flow rates within Perch Creek are approximately 252 m^3/hr; the maximum effluent discharge rate is roughly 0.4% of the average Perch Creek flows and approximately 11.5% of East Swamp weir flows. During the operations phase, the additional infiltration applied at the exfiltration gallery results in a localized increase in water table elevation of up to 1 m compared to the current conditions (see Section 5.3.2.6).

An exfiltration gallery is proposed at the discharge outlet for the treated effluent to promote the exfiltration of treated water into the local groundwater regime. Treated effluent will also be discharged directly to Perch Lake via a transfer line. The transfer line to Perch Lake has been designed to manage the full annual volume of treated effluent, if required, which will prevent the potential for overland flow at the exfiltration gallery.

The major flow system for all three SWMPs, which manage non-contact water, will outlet to adjacent wetlands and will be dispersed by level spreaders that will provide an even flow distribution to the wetlands with an appropriately wide dispersal pattern. Current SWMPs outlet locations are limited by the site boundary (greater than 5 m separation required) so that there is no discharge from the spreaders directly to the wetlands. Local topography between the level spreaders and the wetlands, as well as any setbacks, has influenced the location of the on-site level spreaders.

Annual maintenance activities will identify any erosion problems. Facility inspections will be completed twice annually to confirm that inlets and outlets are clear of debris and to confirm that there are no major erosion issues at the inlet or outlet. In addition, inspection and maintenance reviews will be completed after major storm events and after the annual spring melt to confirm there are no major erosion issues at the dispersion outlets. Overall, changes to downstream discharge, water levels and channel and bank stability resulting from operational discharges of treated effluent and non-contact water will be localized to the receiving wetland. As a result of the design of SWMP outlets and the proposed low discharge rates (i.e., 1 m^3/hr), the discharge of treated effluent and non-contact water to receiving wetlands is not predicted to result in changes to water levels, flows and channel/bank stability, that would affect habitat quality at downstream locations. As a result, this pathway was determined to have no linkage to aquatic biodiversity VCs.

- **Leakage of leachate from the ECM during the operations and closure phases may cause changes to groundwater quality, affecting water surface water quality in downstream waterbodies, which can affect fish habitat quality, survival and reproduction.**

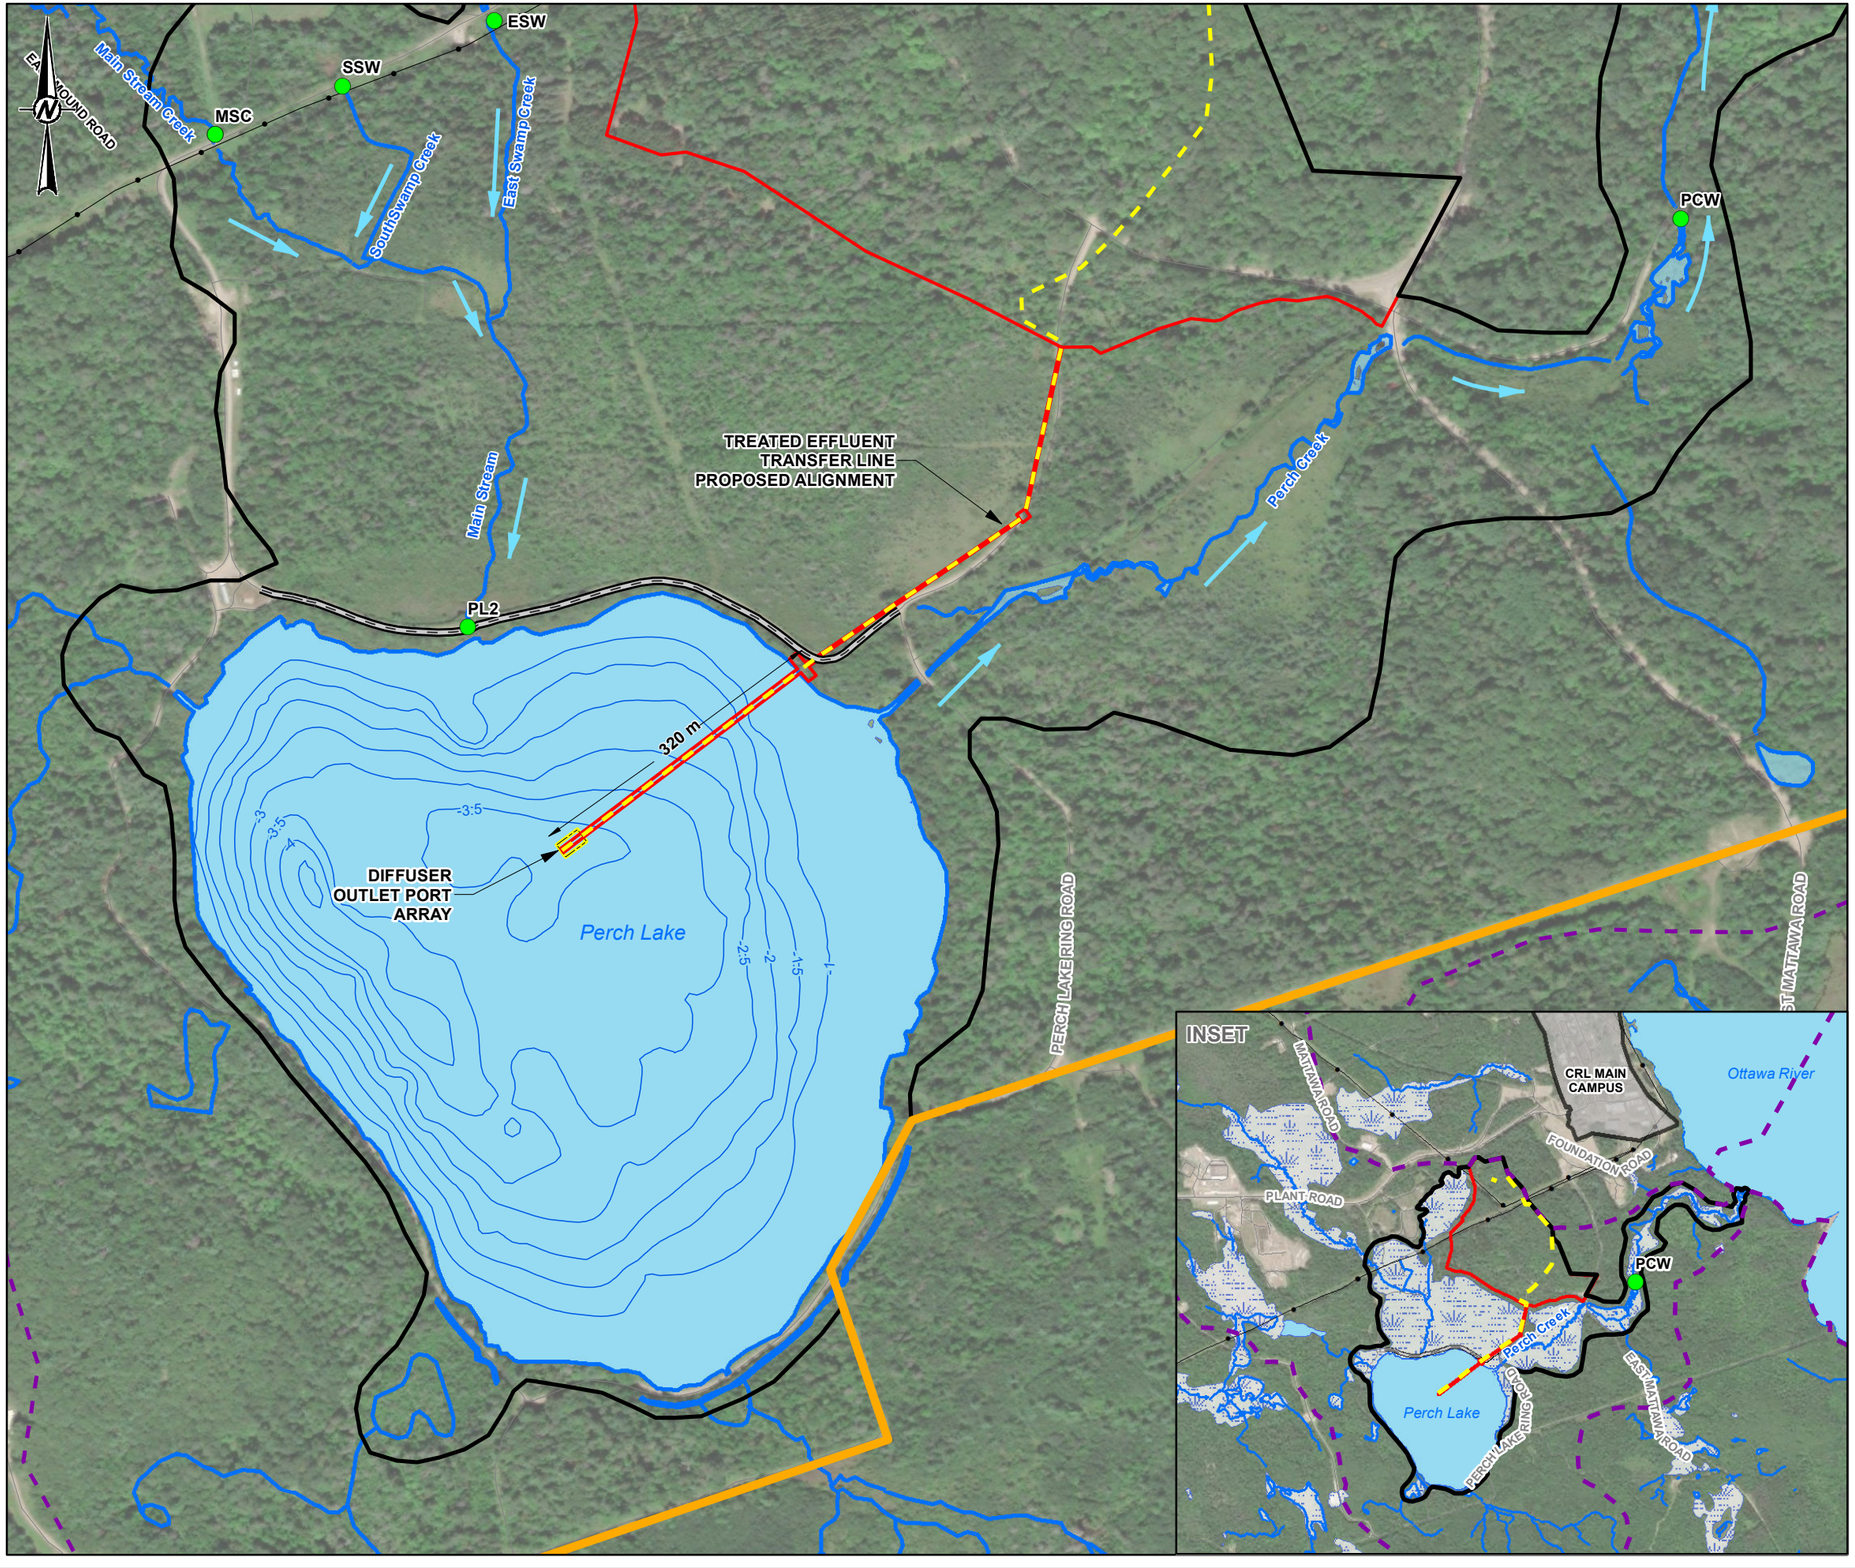
Design of the ECM includes base contours that have been developed using a herringbone pattern with ridges and valleys to promote leachate transport to the leachate collection system for removal. The base liner design includes both primary and secondary liner systems that are designed to provide redundancy in case of premature degradation and are a combination of natural and synthetic barrier systems. The primary liner includes a leachate collection system with the secondary liner housing a leak detection system. The composite base liner contains perforated high-density polyethylene (HDPE) collection and pipes. The HDPE geomembrane was selected as it is compatible with the leachate generated by the waste and is expected to perform as an effective hydraulic and diffusion barrier over the 550-year design life (see Section 3.4.1.4). The base liner system includes an underlying

compacted clay liner to supplement the primary and secondary liner system. The leachate collection system design provides access points for inspections, maintenance, repairs and replacements.

The primary liner system will contain the leachate collection system and will convey leachate to a single collection point for removal from the mound, for transfer to the WWTP for treatment. The primary liner system serves as the primary source of protection for the natural environment below the mound from leachate migration. The secondary liner system will contain the leak detection system, which will be used to detect leaks in the unlikely event that the primary liner system fails. Leachate collected by the leachate collection system will be pumped to the on-site WWTP for treatment.

Perimeter berms consist of three main geotechnical elements, or layers, each contributing to the soundness and integrity of the berm itself and the whole ECM. A *Slope Stability Analysis* (AECOM 2018c) was completed to provide the information needed to support the design of the base slopes, sidewalls and side slopes of the ECM. The Slope Stability Analysis addresses the range of anticipated loading conditions, under both short-term and long-term scenarios, to confirm that the slope designs will satisfy minimum factor-of-safety requirements for stability. Size and shape of the berms and each of the elements and layers were determined using a seismic design basis, including the National Building Code of Canada.

The implementation of the above mitigation will limit the potential for changes to groundwater and surface water quality from the NSDF site. As such, this pathway is determined to have no linkage with aquatic biodiversity VCs as there will be no measurable effects on fish habitat quality and survival and reproduction measurement indicators.



5.5.5.2.2 Secondary Pathways

The following pathways were assessed as potentially having a minor effect on habitat availability, survival, and/or reproduction; however, the pathways result in a negligible residual effect on the aquatic biodiversity VCs relative to the Base Case.

- **Physical change to fish habitat and temporary riparian area disturbances from the installation of diffuser and transfer line construction and footprint that may affect fish and fish habitat.**

Water management strategies for treated effluent include the use of a proposed discharge transfer line (320 m) with a diffuser positioned in Perch Lake (Figure 5.5.5-1). As part of the installation of the discharge transfer line, the open water section of the transfer line will include a foundation installed with steel pile supports for both the transfer line and diffuser. This design was selected from four discharge options and was considered both technically and economically feasible. The preferred design to support the transfer line was also chosen over a gravel fill foundation, as it provided a much smaller footprint on the lakebed. The discharge transfer line will be constructed using 0.10 m diameter pipe and will be supported by approximately five pairs of piles spaced at approximately 50 m intervals along the discharge transfer line. The submerged diffuser will comprise one 28.2 mm (inside diameter) port, extending 0.8 m above the lakebed sediments to limit disturbance. The diffuser will rest on a pile cap supported by approximately four piles. The footprint of the discharge transfer line was estimated using the entire pipe length across Perch Lake of 320 m multiplied by a pipe diameter of 0.10 m, resulting in a conservative estimation of the permanent footprint of the transfer line as 32 m^2. Additional details regarding the transfer line are available in Section 3.4.2.6.2.

IF THIS MEASUREMENT DOES NOT MATCH WHAT IS SHOWN, THE SHEET SIZE HAS BEEN MODIFIED FROM: 25mm 0

This page intentionally left blank

Of the 320 m transfer line length, approximately 23 m of the discharge line will be within the riparian marsh/ shoreline area of the lake. Excavation and dredging activities will be required for a shallow trench (2 m deep by 2 m wide) for the placement of the discharge transfer line (total affected area would less than 46 m²). Vegetated materials and organic debris will be stockpiled during dredging/excavation and then used to remediate disturbed areas as construction stages are completed.

The construction (temporary) footprint for the installation of the transfer line will be minimized where possible. Within the riparian marsh/shoreline section of the transfer line, vegetation mats will be used to mitigate disturbance to shoreline areas from any heavy equipment. The construction (temporary) footprint also includes a barge launch pad within a footprint of approximately 300 m² (i.e., 10 m × 30 m), occupying a riparian / shoreline area and possibly extending into the water to a depth of less than 1 m. The barge launch pad will be required to support the barge and drill rig assembly. The launch pad will be lined with geogrid/geotextile material and gravel. The pad will be removed post-construction and affected riparian and shoreline areas will be remediated through the re-vegetation of the disturbed area.

For the open water section of the transfer line in Perch Lake, drill pilings are expected to be completed by staged construction and therefore, it is assumed that an active work area at any given time will be restricted to the vicinity of the barge location where a pile or piles will be installed (Golder 2018). These active work areas will be contained by turbidity curtains to capture and limit the extent of any suspended sediments (i.e., 5 m wide temporary work area). Construction activities will also avoid any sensitive periods for resident fish species. Specifically, in-water construction work will be completed within the recommended timing window of July 16 to March 14 to avoid any effects to spawning and egg/larval development of spring spawning fish species in Perch Lake (i.e., in-water work will avoid the restricted period of March 15 to July 15; DFO 2013).

Potential changes in sediment concentrations from the use of heavy machinery during the construction period will be mitigated using erosion and sediment control measures, such as turbidity curtains for the duration of the construction. Best management practices will be followed, including those identified in the NSDF *Environmental Protection Plan* (AECOM 2018b). Prior to construction, an Environmental Protection Plan will be developed by the Contractor listing measures for erosion and sediment control as well as spill management. With the application of best management practices and relevant mitigation applied, no measurable residual effects to fish habitat and fish community assessment endpoints are anticipated from construction. There will be no measurable changes to the productivity of the fishery in Perch Lake. The Project has a relatively small permanent footprint of the lake bottom (i.e., 32 m²) and any changes to fish habitat quantity and quality during construction, such as elevated levels of suspended sediments, would be temporary in duration. Overall, changes to habitat quality in Perch Lake from the placement of the discharge transfer line are expected to have negligible residual effects on the Fish Community VC, including Brown Bullhead, and the Fish Habitat VC, and are expected to have no linkage to the Fish Species of Conservation Concern VC.

- **Discharge of treated effluent through the Perch Lake diffuser may create an area of turbulence that affects water quality, affecting fish habitat quality.**

Water management strategies for the discharge of treated effluent include discharging a portion of the treated effluent through a transfer line with a diffuser located in a deep location of Perch Lake. The discharge transfer line will connect to a discharge point that rests on a pile cap. The submerged diffuser will extend vertically 0.8 m above the lakebed sediments to avoid disturbance of the substrates. The average discharge rate from the diffuser is anticipated to be 11.25 m³/hr (Golder 2019), a small proportion of the annual average flow at the Perch Lake outlet which is approximately 205.2 m³/hr (CNL 2017c). At the diffuser outlet the velocities are anticipated to be

5.01 m/s and above background standing water conditions (i.e., mean of 0.034 m/s during open water) from the discharge port in the mixing zone (Golder 2019). However, the diffuser was designed to reduce the effects of increased velocity within the lake through a vertical design of the diffuser that will reduce turbulence or sediment mobilization of the lakebed. Through consideration of a design to minimize erosion of the lakebed sediments, negligible residual effects to the Fish Community VC, including Brown Bullhead, and the Fish Habitat VC are anticipated as a result of the operation of the diffuser in Perch Lake. This pathway was determined to be a no linkage pathway for the Fish Species of Conservation Concern VC.

- **Non-radiological air emissions and dust emissions (including sulphur dioxide, nitrogen oxides and particulate matter) and subsequent deposition may cause a change in surface water quality and fish habitat quality.**

The construction and operations phases of the NSDF Project will generate non-radiological air and dust emissions such as carbon monoxide, oxides of sulphur (includes sulphur dioxide), oxides of nitrogen (includes nitrogen dioxide), particulate matter less than 2.5 microns in diameter ($PM_{2.5}$) and suspended particulate matter (SPM). Air emissions can result from the use of fossil fuels in generators, vehicles and machinery. Vehicle exhaust and fugitive dust from unpaved and paved roads is the largest contributor to particulate matter (SPM, PM_{10} and $PM_{2.5}$) during both construction and operations (see Section 5.2.1.6.2).

Implementation of mitigation measures are anticipated to limit predicted residual effects from NSDF Project emissions to air quality (and subsequently to aquatic biodiversity VCs) include: meeting Tier 2 emission standards for on-site vehicles and equipment engines, use of vehicles that are maintained in good working order and idling of vehicles on site will be limited consistent with CNL's Environmental Protection Program. Dust control will be conducted to support waste placement operations in accordance with the *Dust Management Plan* (AECOM 2018a) during loading, transportation, placement and compaction operations. Work areas that have the potential for generating dust will require implementation of dust suppression techniques. The primary dust control method will include water spraying or misting techniques (e.g., water trucks). Water application is controlled to avoid generation of free liquids. Fixatives (e.g., chemical suppressant) may also be used for dust control and for use as daily ECM cover. The use of fixatives is reviewed prior to application for potential effects on leachate and surface water runoff generated by the ECM.

Predicted concentrations for the Application Case during both construction and operations phases are below applicable air quality guidelines and/or standards with the exception of nitrogen dioxide, that will not meet the 2020 1-hour CAAQS (Section 5.2.1.6.2, Table 5.2.1-14). The contributing factor to the high magnitude nitrogen dioxide emissions is the heavy-duty construction equipment and the conservative assumption that all equipment will run simultaneously and continuously during working hours. In reality, individual equipment will be idling or off for varying parts of the workday that cannot be predicted but will result in lower emissions than currently estimated. The likelihood that all equipment operates simultaneously for an hour or more along with unfavourable weather conditions to produce the maximum concentrations modelled is very low. With the implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018e) and through the implementation of the *Dust Management Plan* (AECOM 2018a) for the NSDF Project, air and dust emissions and subsequent deposition are expected to result in minor and local changes to water quality relative to Base Case conditions. Therefore, this pathway was determined to have negligible effects on the Fish Habitat VC and the Fish Community VC, including Brown Bullhead, for contributing waterbodies and watercourses within the Perch Creek and Perch Lake Watershed. This pathway was also determined to have no linkage to the Fish Species of Conservation Concern VC.

- **Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) can cause changes to downstream surface water quality, which can affect fish habitat quality, survival and reproduction.**

The WWTP for the NSDF Project will be a new, stand-alone facility with a new discharge point. The WWTP will treat leachate generated in the ECM during the operations and closure phases. The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses best available technology that is economically achievable and capable of meeting regulatory requirements.

The radionuclide concentrations in wastewater will be a combination of the leachate concentrations and the leachate volume, combined with the contact water and decontamination volumes. The contact water is assumed to have very low radionuclide concentrations because of the effects of daily ECM cover and water management practices within the disposal cell. Decontamination water is assumed to have the same radiological and chemical characteristics as the wastewater from the ECM. In the absence of quantitative information, non-radiological waste constituents were developed from information gathered from other sites and the expected characteristics of wastes to be disposed of in the NSDF. These values present a reasonable and conservative estimate of concentrations in wastewater such that the WWTP design is capable of treating wastewater to meet effluent discharge targets (as described in Section 3.4.2.2, Tables 3.5.3-2 and 3.5.3-3).

Treated effluent will be sampled and confirmed that it meets effluent discharge targets before release to the environment. A portion of the treated effluent from the WWTP will be released to an exfiltration gallery to promote the exfiltration of treated water into the local groundwater regime; from here, small quantities of residual contaminants will migrate from the East Swamp Wetland to East Swamp Stream. The remaining treated effluent will be released into Perch Lake using a submerged diffuser. It is anticipated that the diffuser placement will result in a ten-fold dilution of any treated effluent discharge to Perch Lake within 100 m of the discharge (Golder 2019). The East Swamp Stream flows into Main Stream and then Perch Lake, which is connected to the Ottawa River through Perch Creek.

Both aquatic and terrestrial species will be exposed to contaminated surface water and sediment in the East Swamp Stream, Perch Lake, Perch Creek, and possibly the Ottawa River. Doses to non-human biota were calculated based on water concentrations from East Swamp Stream. Although dilution will occur in Perch Lake, Perch Creek and the Ottawa River, the exposure limits within the aquatic environment was conservatively assessed to match that of East Swamp Stream during the period of leachate management system and WWTP operations. Doses to non-human biota were calculated based on the waterborne and airborne emissions from the ECM and assessed against the most conservative criteria available such as Environmental Quality Guidelines (CCME 2019) for non-radiological contaminants and No-Effect Concentrations for non-human biota derived for the boreal Canadian Shield forest ecosystem (Arcadis 2019) for radiological contaminants. The NSDF Project is confident that there will be no adverse effects to biota during operations phase by ensuring that releases and subsequent environmental concentrations are below the relevant guidelines or are below levels that would result in potential adverse effects on aquatic life as summarized in Section 5.7.6.2.1.

Many of the site's existing WMAs, including WMAs A and B and the Liquid Dispersal Area (which includes Reactor Pit 1, Reactor Pit 2 and the Chemical Pit) may also affect the Perch Creek and Perch Lake Watershed. Contaminants are transported by groundwater to nearby wetlands, including East Swamp and via the transfer discharge line directly into Perch Lake, which will be the recipient waterbodies for the NSDF Project wastewater. Contaminants released into the Perch Lake then migrate to Perch Creek from where they reach the Ottawa River,

which is the ultimate receptor for all CRL discharges. The NSDF Project's contribution to potential effects on populations of non-human biota in the Perch Creek and Perch Lake Watershed does not result in unacceptable cumulative effects. Estimated doses resulting from historic contamination, due to releases from WMAs and Liquid Dispersal Areas, fall below benchmark values for Perch Lake and Perch Creek. Potential contribution from the NSDF to exposure of aquatic species in East Swamp is less than 1% of the current levels of exposures.

For non-radiological and radiological constituents, two surface water model scenarios were completed for a select group of constituents of potential concern (COPCs) as defined in Section 5.4.2.6.1.4 and Section 5.7.6.2.1. Key elements of the COPCs selection process included identifying those COPCs that were expected to change as a result of the NSDF Project, those with available guidelines, treatment requirements, high existing environmental conditions, potential for nutrient effects, water properties and those that were expected to be toxic to aquatic organisms. The selected non-radiological COPCs included: aluminum, ammonia, antimony, boron, barium, calcium, cadmium, chloride, chromium, cobalt, copper, fluoride, iron, lead, manganese, magnesium, mercury, molybdenum, nickel, phosphorus, potassium, selenium, silver, sodium, strontium, sulfate, thallium, tin, uranium, vanadium and zinc. Radiological COPCs included: carbon-14, cesium-137, cobalt-60, gross beta and tritium.

The predicted radiological and non-radiological concentrations for the COPCs were compared to effluent discharge targets[2] and to local background at the six water quality nodes (i.e., East Swamp weir, Perch Lake Inlet 2, Perch Lake, Perch Creek weir, Perch Creek Outlet and the Ottawa River; Section 5.4.2.6.2 and Tables 5.4.2-9 to 5.4.2-18). The predicted concentrations for most COPCs met the effluent targets at all sampling nodes, with the exception of aluminum, barium, copper, iron, lead, manganese, phosphorus, selenium and silver. However, predicted concentrations were generally similar to local background concentrations at these nodes with the exception of selenium concentrations that were predicted to exceed local ambient concentrations. Predicted selenium concentrations were less than the United States Environmental Protection Agency guidelines for protection of aquatic life and therefore are predicted to not result in adverse effects on aquatic life.

For most COPCs, the incremental changes in concentration as a result of the NSDF Project are expected not to be measurable in the Ottawa River. COPCs that increase above background in the Ottawa River included only tritium and gross beta. However, these increases are expected to be within the uncertainty bounds of the surface water quality modelling. Further, results of the radiological dose assessment for the operations phase and post-closure phase also indicates that doses to ecological health VCs are below their respective No Effect Concentrations (see Section 5.7.8). As such, changes to surface water quality (and habitat quality) from the discharge of treated effluent are expected to have negligible residual effects on Fish Community VC, including Brown Bullhead, and the Fish Habitat VCs. The discharge of treated effluent is not expected to have a residual effect on the Fish Species of Conservation Concern VC.

- **Leakage of leachate from the ECM during the post-closure phase (i.e., after Year 2100 to 2400) from liner and final cover degradation as a result of normal evolution may cause changes to groundwater quality and downstream surface water quality in wetlands, affecting fish habitat quality, survival and reproduction.**

Potential impacts on aquatic biota from failure of cover and liner as a result of normal evolution are assessed in Section 5.7.6.3.2.1. No adverse effects are predicted to aquatic biodiversity VCs.

[2] Effluent discharge targets for radiological COPCs were composed of No Effect Concentrations for the protection of aquatic biota (See Section 5.4.2.6.1).

5.5.5.2.3 Primary Pathways

No pathways were identified as having a primary linkage to aquatic biodiversity VCs. As such, a residual effects analysis and assessment of significance is not required for the aquatic biodiversity assessment.

5.5.6 Monitoring and Follow-up

There are no monitoring or follow-up programs planned that will directly sample fish or survey fish habitat for the NSDF Project. The focus of planned monitoring will include routine monitoring of surface water quality parameters as measurement indicators of fish habitat and fish community assessment endpoints. Monitoring will verify the effects predictions and provide data to evaluate changes to measurement indicators. Routine surface water quality monitoring includes stations on East Swamp Stream, Perch Lake and Perch Creek. Operational monitoring will be completed to verify the SWMPs are performing as designed and to demonstrate compliance with effluent discharge targets developed for the NSDF Project. Surface water monitoring also includes the Ottawa River receiving environment at multiple locations downstream of CRL. The Ottawa River is expected to adequately rapidly assimilate any discharge from the Perch Creek and Perch Lake Watershed to existing conditions in the river, such that aquatic biodiversity VCs are unlikely to be affected. The number and type of parameters and number of sampling locations may change based on annual review of monitoring data. For additional information on the monitoring programs to be developed and implemented for surface water quality, see Section 5.4.2.8 and Table 5.4.2-16, respectively.

If the environmental monitoring program for surface water quality identifies that adverse environmental effects are greater than predicted, then CNL will evaluate the need for revised mitigation actions and management practices to manage effects. CNL's evaluation process for monitoring data include environmental performance criteria that are based on statistical measures and ecological health benchmarks. An exceedance of environmental performance criteria triggers CNL's non-conformance and corrective action process and includes notifying management and further investigation. Where the need for revised mitigation is identified they will be developed and implemented. The evaluation process is documented in CNL's *Environmental Monitoring Program* (CNL 2018g).

5.5.7 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Aquatic biodiversity is an important component of the environment, and potential effects to aquatic biodiversity were evaluated using a suite of aquatic biodiversity VCs selected for the NSDF project. The selected aquatic biodiversity VCs were as follows: the Perch Creek and Perch Lake Watershed Fish Community and Fish Habitat, Brown Bullhead, and Fish Species of Conservation Concern in the Ottawa River.

Assessment endpoints for aquatic biodiversity VCs were on-going fisheries productivity, and the maintenance of self-sustaining and ecologically effective fish populations as important components of on-going fisheries productivity, and these assessment endpoints were evaluated through the study of measurement indicators for the aquatic biodiversity VCs. The environmental assessment for aquatic biodiversity relied, in part, on water quality and water quantity results for describing habitat quality and quantity, and survival and reproduction indicators.

The following conclusions were determined during the aquatic biodiversity assessment:

- No primary pathways (measurable residual effects) were identified for aquatic biodiversity VCs for the NSDF Project.
- Secondary pathways (negligible or no-measurable residual effects) were not identified for aquatic biodiversity in the Ottawa River, including the Species of Conservation Concern VC.
- Five secondary pathways were identified that may result in negligible (i.e., non-measurable) residual effects to the assessment endpoints of Fish Habitat and Fish Community VCs for the Perch Creek and Perch Lake Watershed.
- Secondary pathways included those related to surface water changes and related effects to the fish community in Perch Lake.
- Secondary pathways also included physical disturbances to fish habitat resulting from the construction, installation and operation of the effluent transfer line and diffuser in Perch Lake.

In summary, results of the aquatic environment assessment identified only negligible residual effects on aquatic biodiversity VCs as a result of the NSDF Project. The potential for residual effects will be addressed through the implementation of mitigation, monitoring, and environmental design features, which are well-understood and include existing practices at the CRL site.

The secondary pathways related to the transfer line construction, installation and operation will be mitigated through standard best management practices and design considerations such as sediment and erosion controls, limited footprints and duration of construction within the in-water work timing window for the Perch Lake fish species, and by the design of the diffuser to limit turbulence on the lakebed. In addition to planned construction monitoring for the effluent transfer line and diffuser, routine and operational monitoring of surface water quality parameters will be completed as measurement indicators of aquatic biodiversity endpoints. Effluent water quality monitoring will be integrated into CNL's Effluent Verification Monitoring Program.

Mitigation related to potential changes in surface water quality include those finalized within procedural controls and plans developed and applied for the NSDF Project, such as the following:

- CNL's procedure for Management and Monitoring of Emissions (CNL 2018e)
- CNL Environmental Protection Procedures (as part of CNL Environmental Program)
- CNL Effluent Verification Monitoring Program
- Operations and Maintenance Plan (to be developed by CNL)
- Environmental Management Plan (as part of CNL Environmental Program)

An Environmental Protection Plan will be developed for the NSDF Project by the Contractor prior to construction and will include blasting, dust, sediment and erosion, and spill management measures and controls.

5.6 Terrestrial Environment

This section of the Environmental Impact Statement (EIS) for the Canadian Nuclear Laboratories (CNL) Near Surface Disposal Facility (NSDF) Project seeks to understand and characterize potential residual effects of the NSDF Project on terrestrial biodiversity, including potential effects to the ecological and biological processes that connect species with each other and their abiotic environment. Effects of the NSDF Project are considered in the context of cumulative effects from other previous, existing and reasonably foreseeable developments on terrestrial biodiversity.

5.6.1 Scope of the Assessment

Section 5.6 focuses on providing an assessment for terrestrial biodiversity. Terrestrial biodiversity includes all upland vegetation communities and wetlands, as well as terrestrial wildlife taxa (e.g., mammals, birds) and wildlife taxa with terrestrial and aquatic life history requirements (e.g., reptiles). Effects of the NSDF Project on aquatic biodiversity (e.g., fish) are assessed in Section 5.5. The terrestrial biodiversity assessment follows the overall environmental assessment approach and methods described in Section 5.1. The assessment was completed following the key steps listed below:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** for the terrestrial biodiversity assessment (refer to Sections 5.6.2 Valued Components and Section 5.6.3 Assessment Boundaries). The VCs and measurement indicators used to assess Project-related changes to terrestrial biodiversity are described, along with the spatial and temporal boundaries at which the assessment occurred and the assessment cases considered.
- **Step 2 – Describe the existing conditions** (refer to Section 5.6.4 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation). The existing conditions provide a reference to which the effects of the NSDF Project can be compared.
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 5.6.5 Project Interactions and Mitigation). Project components and/or activities with the potential to affect terrestrial biodiversity are identified, and mitigation developed to limit or avoid effects is presented. A pathways analysis is then used to focus further assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Pathways that may lead to residual effects to terrestrial biodiversity after incorporating mitigation are carried forward to Step 4 for further analysis.
- **Step 4 – Present the methods and results of the residual effects analysis** for the terrestrial biodiversity assessment (refer to Section 5.6.6 Residual Effects Assessment Methods and 5.6.7 Residual Effects Assessment Results).
- **Step 5 – Describe the level of certainty and management of uncertainty** of residual effects (refer to the subsections titled Prediction Confidence and Uncertainty under Section 5.6.7). This step in the assessment evaluates the available literature, data and models used for the assessment and describes the level of certainty that can be placed on predicted residual effects. It provides a precautionary evaluation of potential

residual effects of the NSDF Project and aims to overestimate potential effects where uncertainty is present. It also identifies how uncertainty was managed for each VC so that the predicted effects of the NSDF Project are not underestimated.

- **Step 6 – Classify and determine the significance of the predicted residual effects** (refer to the subsections titled Residual Effects Classification and Sections and Determination of Significance under Section 5.6.7). This step describes the methods and presents the results of a residual effects classification and determination of significance for each terrestrial biodiversity VC. The residual effects classification uses a common set of criteria, direction, magnitude, geographic extent, duration, reversibility, frequency and likelihood to classify effects, and significance is determined in a binary fashion for each VC (i.e., either significant or not significant).
- **Step 7 – Identify monitoring and follow-up** required to confirm effects predictions and address uncertainty (refer to Section 5.6.8 Monitoring and Follow-up).
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** of residual effects on terrestrial biodiversity (refer to Section 5.6.9 Conclusions).

Each assessment step integrates information from regulatory guidelines, scientific literature, the experience of the professionals conducting the assessment and issues raised during engagement. Information and concerns raised by the public, communities of interest, and Indigenous Peoples during engagement that influenced the scope of the terrestrial biodiversity assessment are summarized in Table 5.6.1-1. Other general concerns and questions raised during the engagement that pertain to the human health assessment are documented in CNL's in CNL's Indigenous Engagement Report (CNL 2021) and CNL's Stakeholder's Activity Reports (CNL 2017a,b, 2019).

Table 5.6.1-1: Summary of Issues Raised during Engagement Activities that Influenced the Scope of the Terrestrial Biodiversity Assessment

Issue	How the Issue Was Included in the Assessment
Inclusion of migratory birds in the assessment	Because of their ecological importance and because they are protected by federal legislation (Migratory Birds Convention Act, 1994 [MBCA]), the suite of migratory birds with the potential to be affected by the NSDF Project was included as a terrestrial biodiversity VC. Some individual migratory bird species that are federally listed species at risk were also included as VCs assessed at the species level.
Concern over the conversion of terrestrial habitat	An evaluation of the change in habitat availability and habitat distribution in the vicinity of the NSDF Project is completed for each of the wildlife species selected as VCs.
Concern with road mortality to Blanding's turtle and what can be done to reduce this risk	Increased risk of injury/mortality of Blanding's turtle on roads is a key interaction evaluated as part of the residual effects assessment. Mitigation to be implemented to reduce this risk is described and monitoring programs are recommended for Blanding's turtle.
Inclusion of bird and other species at risk in the assessment	The species-level assessment focused on species identified on Schedule 1 of the federal Species at Risk Act (SARA). Species at risk evaluated in the assessment include Canada warbler, eastern whip-poor-will, eastern wood pewee, wood thrush and golden-winged warbler, bats, Blanding's turtle, eastern milksnake and monarch butterfly. Most of the species-level VCs identified for the terrestrial biodiversity assessment are also useful indicators for broader groups of species.

VC = valued component.

5.6.2 Valued Components

VCs refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Identifying VCs helps to focus the assessment on the most important or representative components of the environment that are likely to be affected by the NSDF Project. This section describes how VCs were selected for the terrestrial biodiversity assessment and identifies the assessment endpoints and measurement indicators that were used to assess the effects of the NSDF Project on each VC. Because this assessment is for a designated project, as described in the *Canadian Environmental Assessment Act, 2012* (CEAA 2012) and is regulated by the Canadian Nuclear Safety Commission (CNSC), VC selection considered guidance from Appendix A of the CNSC's *REGDOC-2.9.1 Environmental Protection: Environmental Principles, Assessments and Protection Measures* (CNSC 2017). Specifically, VC selection focused on providing a *"*full accounting of effects on species with elevated conservation status and their habitat*"* (CNSC 2017).

Selection of VCs for the terrestrial biodiversity assessment was accomplished using a coarse and fine filter approach. Coarse filter VCs were identified to permit an assessment of the effects of the NSDF Project to terrestrial biodiversity broadly (e.g., large groups of species or the ecosystems and habitats that support groups of species), whereas fine filter VCs focus the assessment on individual species. Combined, the coarse and fine filter VCs are selected to provide a holistic assessment of the potential effects of the NSDF Project on terrestrial biodiversity.

To capture potential effects to terrestrial biodiversity broadly, the terrestrial vegetation communities potentially affected by the NSDF Project were selected as a VC (Table 5.6.2-1). Assessing and managing biodiversity at the ecosystem level (represented by vegetation communities) means that a large number of biodiversity features are addressed together. Terrestrial vegetation communities also represent the habitats that may support species with elevated conservation status. For example, effects of the NSDF Project on wildlife guilds (i.e., species that use the same resources, or that use different resources in related ways) that are dependent on very old growth trees, standing dead trees (i.e., "snags"), coarse woody debris and natural disturbance processes (e.g., fire, insects and disease) found in mature and older forests will be captured by the vegetation communities VC assessment. Vegetation community types present in the Regional Study Area (RSA; see Section 5.6.3.1) were included as part of the vegetation community VC. This assessment focuses on the ecological integrity of these communities, whereas potential effects from the NSDF Project on Indigenous Peoples traditional vegetation use are assessed in Section 5.9 Land and Resource Use and Section 6.0 Indigenous Interests.

Because of their ecological importance and because they are protected by federal legislation (*Migratory Birds Convention Act, 1994* [MBCA]), the suite of migratory birds with the potential to be affected by the NSDF Project was also included as a terrestrial biodiversity VC. The purpose of including the group of migratory birds together as a VC was to identify appropriate mitigation so that the NSDF Project would comply with the MBCA for all migratory birds. Section 5 of the MBCA prohibits the disturbance, destruction or removal of a nest or related shelter, or egg of a migratory bird, or possession of a live migratory bird, or a carcass, nest or egg of a migratory bird.

To complement the assessment of vegetation communities and migratory birds, some VCs were also identified at the species level. Consideration at the species level is also important to understand effects to biodiversity features that sometimes are distinct from effects to ecosystems and for which targeted actions at the species level may be required (e.g., as specified in federal action plans or recovery strategies developed for species at risk). Some individual migratory birds that are federally listed species at risk were also included as VCs that were assessed at the species level.

The species-level assessment focused on species identified on Schedule 1 of the federal *Species at Risk Act* (SARA). On a federal level, designations for species at risk occurring in Canada are initially determined by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC). If approved by the federal Minister of the Environment, species are added to the federal List of Wildlife Species at Risk under Schedule 1 of SARA. Once included on Schedule 1, it is prohibited to kill, harm, harass, capture, possess, collect, buy, sell or trade individuals, or to damage or destroy the residence of a species listed as Extirpated, Endangered or Threatened. Furthermore, for species that are included on Schedule 1 as Extirpated, Endangered or Threatened, species-specific critical habitat is protected on federal lands (such as the Chalk River Laboratories [CRL] site) once critical habitat is defined in a recovery strategy. Although species listed as Special Concern are not afforded the same degree of legal protection as those at higher threat levels, Section 65 of SARA requires that a management plan be developed that includes measures for the conservation of the species of Special Concern and their habitats. Federal landowners are expected to implement these measures.

Baseline biodiversity data have been collected at the CRL site since 2009, with targeted surveys for species at risk occurring annually since 2012. These surveys have determined that 23 terrestrial species at risk listed on Schedule 1 of SARA occur within the CRL site (Appendix 5.6-1).

All SARA-listed species identified in Appendix 5.6-1 with confirmed observation records within the CRL site were considered as potential VCs at the species level. Each species was evaluated to determine whether its presence was likely in the Site Study Area (SSA) or the Local Study Area (LSA) defined for the terrestrial biodiversity assessment (see Section 5.6.3.1). Species that are unlikely to occur in the LSA, for which habitat was not present in the LSA or for which effects of the NSDF Project were unlikely were excluded as VCs. Rationale for inclusion or exclusion of each species at risk identified during surveys undertaken in the CRL site is presented in Appendix 5.6-1. Species at risk identified as VCs for the terrestrial biodiversity assessment are presented in Table 5.6.2-1. Individual species for which the potential effects of the NSDF Project are similar were grouped into a single VC (e.g., bats; Table 5.6.2-1). Table 6.3.2-1 in Section 6 highlights how VCs identified by Indigenous communities and organizations are represented by the species that are evaluated in the NSDF EIS.

Table 5.6.2-1: Valued Components Selected for the Terrestrial Biodiversity Assessment

Valued Component	Rationale for Selection
Vegetation communities	▪ This VC broadly captures effects on terrestrial biodiversity. ▪ The NSDF Project is associated with footprint effects that will remove vegetation and result in physical losses of some vegetation communities (and related wildlife habitat).
Migratory birds	▪ Migratory birds and their nests are protected under the federal MBCA. ▪ There are numerous migratory bird species that breed, nest or could be present year-round in the vicinity of the NSDF Project. There is the potential for migratory birds to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads or loss of eggs in nests during tree clearing). ▪ Comment on the Project Description received by a member of the public specifically requested assessment of this VC.
Canada warbler	▪ Canada warbler (Cardellina canadensis) is federally listed as Threatened under SARA and is protected under the MBCA. It has legal individual and habitat protection provisions under SARA and individual and nest protection under the MBCA. ▪ The CRL site is federally owned; therefore, this species is afforded protection of critical habitat because it is listed as Threatened on Schedule 1 of SARA. Critical habitat has not yet been defined for this species in the federal recovery strategy. ▪ There is the potential for Canada warbler to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads or loss of eggs in nests during tree clearing). ▪ Canada warbler is an avian species VC recorded within the LSA that represents a guild of early successional habitat specialists requiring coniferous, deciduous, moist mixed forest and regenerating habitats.
Eastern whip-poor-will	▪ Eastern whip-poor-will (Antrostomus vociferus) is federally listed as Threatened under SARA and is protected under the MBCA. It has legal individual and habitat protection provisions under SARA and individual and nest protection under the MBCA. ▪ The CRL site is federally owned; therefore, this species is afforded protection of critical habitat because it is listed as Threatened on Schedule 1 of SARA. Critical habitat has been partially defined for this species in the federal recovery strategy (ECCC 2018a). ▪ There is the potential for eastern whip-poor-will to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads or loss of eggs in nests during tree clearing). ▪ Eastern whip-poor-will is a keystone avian species VC recorded within the LSA that represents a guild of aerial insectivores requiring open forest/edge habitat in drier deciduous and coniferous habitats.

Table 5.6.2-1: Valued Components Selected for the Terrestrial Biodiversity Assessment

Valued Component	Rationale for Selection
Eastern wood-pewee	▪ Eastern wood-pewee (Contopus virens) is federally listed as Special Concern under SARA and is protected under the MBCA. It has legal individual and nest protection under the MBCA. ▪ The CRL site is federally owned; therefore, Section 65 of SARA requires that habitat be managed for conservation of this species because it is listed as Special Concern on Schedule 1 of SARA. ▪ There is the potential for eastern wood-pewee to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads or loss of eggs in nests during tree clearing). ▪ Eastern wood-pewee is an avian species VC recorded within the LSA that represents a guild of forest edge habitat species.
Golden-winged warbler	▪ Golden-winged warbler (Vermivora chrysoptera) is federally listed as Threatened under SARA and is protected under the MBCA. It has legal individual and habitat protection provisions under SARA and individual and nest protection under the MBCA. ▪ The CRL site is federally owned; therefore, this species is afforded protection of critical habitat because it is listed as Threatened on Schedule 1 of SARA. Critical habitat has been partially defined for this species in the federal recovery strategy. ▪ There is the potential for golden-winged warbler to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads or loss of eggs in nests during tree clearing). ▪ Golden-winged warbler is a keystone avian species VC recorded within the LSA that represents a guild of edge habitat specialists.
Wood thrush	▪ Wood thrush (Hylocichla mustelina) is federally listed as Threatened under SARA and is protected under the MBCA. It has legal individual and habitat protection provisions under SARA and individual and nest protection under the MBCA. ▪ The CRL site is federally owned; therefore, this species is afforded protection of critical habitat because it is listed as Threatened on Schedule 1 of SARA. Critical habitat has not yet been defined for this species in the absence of a federal recovery strategy due to recent (2017) listing. ▪ There is the potential for wood thrush to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads or loss of eggs in nests during tree clearing). ▪ Wood thrush is an avian species VC recorded within the LSA that represents a guild of deciduous and mixedwood forest habitat specialists.

Table 5.6.2-1: Valued Components Selected for the Terrestrial Biodiversity Assessment

Valued Component	Rationale for Selection
Bats ▪ Little brown myotis ▪ Northern myotis ▪ Tri-colored bat	▪ Little brown myotis (Myotis lucifugus), northern myotis (Myotis septentrionalis) and tri-colored bat (Perimyotis subflavus) have observation records within the LSA. All three bat species are federally listed as Endangered and have legal individual protection provisions under SARA. ▪ The CRL site is federally owned; therefore, these bat species are afforded protection of critical habitat because they are listed as Endangered on Schedule 1 of SARA. Critical habitat has only partially been defined for hibernacula (i.e., overwintering sites), as the largest threat to these species is associated with that habitat. The destruction of maternity roosts is also a potential threat to bat populations. Hibernacula have not been found in the LSA or RSA and are unlikely to occur in the SSA. Maternity roosts are likely present and have the potential to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (i.e., loss of roosting bats during tree clearing). ▪ There is the potential for bats to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss (loss of roost trees) and mortality (i.e., loss of pre-volant juveniles in maternity roosts during tree clearing). ▪ The bats VC represents small mammal species recorded in the LSA that rely on standing dead trees (e.g., snags) for part of their life history (maternity roosting, diurnal roosting and evening roosting).
Blanding's turtle	▪ The Great Lakes / St. Lawrence population of Blanding's turtle (Emydoidea blandingii) is federally listed as Threatened and has legal individual and habitat protection provisions under SARA. COSEWIC (2016) has assessed the population as Endangered. ▪ The CRL site is federally owned; therefore, this species is afforded protection of critical habitat because it is listed as Threatened on Schedule 1 of SARA. Critical habitat has been identified within the CRL site based on the partial definition in the recovery strategy (ECCC 2018b). Grid squares that have been identified as containing critical habitat for Blanding's turtle are intersected by the NSDF Project (ECCC 2017). ▪ There is the potential for Blanding's turtle to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads and overwinter mortality from changes in the hydrology in wetlands). ▪ The Blanding's turtle is represented through effects on species at risk in the terrestrial environment. This species further acts as an indicator species representing reptile species (e.g., snapping turtle) that use a variety of wetland habitats for hibernation, mating, foraging, thermoregulation, staging prior to nesting and for movement. They use upland, relatively open areas with suitable substrate for nesting, overland migration, thermoregulation and foraging. Blanding's turtles display fidelity to their overwintering sites and nesting sites (i.e., use the same habitat year after year). ▪ Comments and questions raised at public information sessions expressed value of the Blanding's turtle. ▪ There are Blanding's turtle observation records congregated within various waterbodies and wetlands throughout the RSA and LSA. CNL baseline studies indicate that Blanding's turtles use the wetland habitats that surround the SSA.

Table 5.6.2-1: Valued Components Selected for the Terrestrial Biodiversity Assessment

Valued Component	Rationale for Selection
Eastern milksnake	▪ Eastern milksnake (Lampropeltis triangulum) has not been observed within the LSA but is potentially present because it has been confirmed elsewhere on the CRL site. It is federally listed as Special Concern on Schedule 1 under SARA. ▪ There is the potential for eastern milksnake to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads). ▪ The CRL site is federally owned; therefore, Section 65 of SARA requires that habitat be managed for conservation of this species because it is listed as Special Concern on Schedule 1 of SARA. ▪ Eastern milksnake represents reptile species that use a variety of microhabitats. The eastern milksnake is known to congregate in hibernacula over winter.
Monarch butterfly	▪ Monarch butterfly (Danaus plexippus) has not been observed within the LSA but is potentially present because it has been confirmed elsewhere on the CRL site. It is federally listed as Special Concern and is considered Endangered by COSEWIC. ▪ There is the potential for the monarch butterfly to be indirectly and directly affected by the NSDF Project through disturbance, habitat loss and mortality (e.g., vehicle strike on roads or loss of individuals during vegetation clearing). ▪ The CRL site is federally owned. Although species listed as Special Concern are not afforded the same degree of legal protection as higher threat levels, Section 65 of SARA requires that a management plan be developed that includes measures for the conservation of the species and their habitats. ▪ The iconic migratory butterfly relies on milkweed and represents other insects that use a variety of open habitats during the summer and early fall.

MBCA = *Migratory Birds Convention Act, 1994*; COSEWIC = Committee on the Status of Endangered Wildlife in Canada; LSA = Local Study Area (see Section 5.6.3.1); SARA = *Species at Risk Act*; VC = valued component; SSA = Site Study Area; ECCC = Environment and Climate Change Canada.

Most of the species level VCs identified for the terrestrial biodiversity assessment are useful indicators for broader groups of species. For example, eastern whip-poor-will (*Antrostomus vociferus*) represents a guild of species that forage on insects while flying and require edge habitat and forest openings (Table 5.6.2-1). Blanding's turtle (*Emydoidea blandingii*) is tied closely to wetland habitats and adjacent upland areas and can be used to represent other species at risk with similar requirements, such as snapping turtles. Bats rely on mature forests that contain wildlife trees for roosting habitat, and thus represent a variety of other wildlife tree secondary cavity users (i.e., species that use cavities created by primary cavity excavator species such as woodpeckers). Consequently, understanding the potential effects of the NSDF Project on the selected VCs provides inferences about effects on other wildlife species or guilds with similar life history traits and habitat requirements (Appendix 5.6-1).

A functioning ecosystem involves interactions of multiple species ranging in size and complexity from bacteria to apex wildlife predators. Each species is likely to respond differently to physical disturbances or different levels of contaminants present in their environment or environmental media. As such, the aquatic and terrestrial VCs selected for the Environmental Risk Assessment completed for the NSDF Project (summarized in Section 5.7) were selected to assess exposures to water and ingestion of aquatic biota. Wildlife species that receive most of their exposure from ingestion of terrestrial plants and animals were also considered.

Common nighthawk (*Chordeiles minor*), chimney swift (*Chaetura pelagica*), olive-sided flycatcher (*Contopus cooperi*) and western chorus frog (*Pseudacris triseriata*) were initially considered as VCs but were ultimately not carried forward to the effects assessment for the following reasons:

- A common nighthawk survey was conducted during the summer of 2013. The survey method was adapted from MNR (2013a). Because this species is territorial and responds to other calling individuals by making a "booming" sound, common nighthawk calls were also played (infrequently) to increase the detection of the species. A total of 43 survey points were surveyed twice. Each survey consisted of a three-minute listening period to detect nighthawks. No common nighthawks were heard during the surveys. Consequently, the proposed NSDF Project is not expected to affect common nighthawks. Additionally, eastern whip-poor-wills use similar habitats to common nighthawks and so can be considered a surrogate for determining effects on common nighthawks.
- A recent study conducted by Zanchetta et al. (2014) reports only 59 records of chimney swifts using trees for nesting or roosting between 1803 and 2013. Fitzgerald et al. (2014) and COSEWIC (2018) also conclude that the loss of nesting sites is not a primary factor limiting chimney swift populations in Ontario. Forest songbird surveys did not detect chimney swifts in the forested area of the SSA, LSA or RSA (CNL 2018a). Chimney swift detection is limited to the area near the roosting chimney. CNL properties (CRL sites and Nuclear Power Demonstration Closure Project property) have two significant roosting sites (stacks) used by the species. A research project in collaboration with Dr. Joe Nocera from the University of New Brunswick studied extensively the behaviour of the chimney swift roosting in both stacks. The study helped CNL to understand the importance of the stacks used as a major stop over during the spring migration. As a result, CNL has committed to preserve the stack on the Nuclear Power Demonstration site as part of the Nuclear Power Demonstration Closure Project. CNL is likely contributing to the recovery of the species by retaining the Nuclear Power Demonstration stack. No effects from the NSDF Project are anticipated for chimney swifts.
- The forest songbird survey effort conducted on the CRL site in 2013 and 2016 involved a total of 42 survey locations and a total 3,000 minutes of recording time. Olive-sided flycatcher was only recorded once on the CRL site during these surveys and was 4 km away from the proposed NSDF Project. There was one other observation of olive-sided flycatcher approximately 3 km away from the NSDF Project in 1997. Based on these results, olive-sided flycatchers are not likely using habitats in or near the NSDF Project, and no effects to this species are anticipated.
- There is uncertainty whether western chorus frogs have potential to occur in or near the NSDF Project. Crother (2012), Dodd (2013) and Frost (2013), all consider chorus frogs located in the Great Lakes St. Lawrence region to be the boreal chorus frog (*Pseudacris maculata*); this contradicts Platz (1989), who considers all chorus frogs in southern Ontario to be western chorus frog. Nevertheless, Platz's (1989) interpretation was used for the development of the Western Chorus Frog Recovery Strategy and so, to be conservative, CNL considered it possible that western chorus frogs may occur in or near the NSDF Project. Amphibian surveys were conducted at CRL in 2012 and 2016 and followed methods used in the Marsh Monitoring Program (Bird Studies Canada 2008). Surveys were conducted between April 20 and June 16 of both years. Western chorus frogs were not detected in 2012 or 2016 (CNL 2013, 2017c). In 2015, Environment and Climate Change Canada (ECCC; formerly Environment Canada) advised CNL that sightings of chorus frog (*Pseudacris triseriata* and *P. maculata*) had occurred in close proximity to the CRL site. Further discussion with ECCC in February 2017 provided a different and more adequate protocol for the

detection of the species. Changes to the current survey method were made immediately and this new protocol adopted for surveys conducted in 2017. Western chorus frogs were not detected in 2017 (CNL 2018a).

- Although habitats corresponding entirely to the definition of suitable wetland and terrestrial habitats in Table 3 of the Western Chorus Frog Recovery Strategy are not present at CRL, four areas were surveyed in 2017. Those four areas were selected as they resemble somewhat the definition of Table 3. The survey was conducted between April 12, 2017, and May 31, 2017. In addition to the Marsh Monitoring Program method where a three-minute recording period a set every hour between 20:00 and 23:00, the passive recorders were programmed to capture daytime callers. A five-minute audio file was collected every 30 minutes between 10:00 and 12:00 and between 16:00 and 18:00. All amphibian audio files were analyzed using Raven software. No western chorus frogs were detected. As such, CNL has committed to completing another amphibian survey in 2020. Because no western chorus frogs have been detected to date at CRL, the NSDF Project is not expected to affect this species.

Each VC for the terrestrial biodiversity assessment was assessed using the assessment endpoints and measurement indicators listed in Table 5.6.2-2. Assessment endpoints represent the key properties of each VC that should be protected. The assessment endpoint for terrestrial biodiversity is the maintenance of self-sustaining and ecologically effective vegetation communities or wildlife populations. Self-sustaining vegetation communities or wildlife populations are healthy and viable and, by definition, robust and capable of withstanding environmental change and accommodating stochastic processes (i.e., random environmental processes such as wildfire) (Reed et al. 2003). Maintaining viable wildlife populations is a conservation target frequently applied by conservation biologists and resource managers (Fahrig 2001; Nicholson et al. 2006; Ruggiero et al. 1994; With and Crist 1995).

Achieving viable wildlife populations, however, may not be sufficient to meet conservation objectives for other species that interact with the VCs being assessed (Soulé et al. 2005). For highly interactive VCs that have strong effects on ecosystem structure and function, the concept of ecologically effective populations was applied as part of the assessment endpoint for wildlife. Ecologically effective wildlife populations are populations of wildlife species that are large enough to maintain ecological function in an ecosystem.

Likewise, the maintenance of self-sustaining vegetation communities may not be sufficient to support their ecological function on the landscape; therefore, the concept of ecologically effective vegetation communities was applied as part of the assessment endpoint for vegetation communities. Ecologically effective vegetation communities are those that can support the range of native species and ecological and evolutionary processes normally provided by the ecosystem (Noss 1990).

An ecologically effective vegetation community or wildlife population differs from self-sustaining vegetation communities or wildlife populations if the abundance needed to maintain ecological function is greater than the abundance required to maintain viability for the long-term. The application of the concept of self-sustaining ecologically effective vegetation communities or wildlife populations is key to the significance determination for the terrestrial biodiversity assessment (Section 5.6.7).

Table 5.6.2-2: Assessment Endpoints and Measurement Indicators for the Terrestrial Biodiversity Assessment

Valued Component	Assessment Endpoints	Measurement Indicators
Vegetation communities	Maintenance of self-sustaining and ecologically effective vegetation communities	▪ Ecosystem availability ▪ Ecosystem distribution ▪ Ecosystem condition
Migratory birds	Maintenance of self-sustaining and ecologically effective populations	▪ Habitat availability ▪ Habitat distribution ▪ Survival and reproduction
Canada warbler *(Cardellina canadensis)*		
Eastern whip-poor-will *(Antrostomus vociferous)*		
Eastern wood-pewee *(Contopus virens)*		
Golden-winged warbler *(Vermivora chrysoptera)*		
Wood thrush *(Hylocichla mustelina)*		
Bats		
Blanding's turtle *(Emydoidea blandingii)*		
Eastern milksnake *(Lampropeltis Triangulum)*		
Monarch butterfly *(Danaus plexippus)*		

Two sets of measurement indicators were employed for terrestrial biodiversity VCs: those suitable for quantifying effects on vegetation communities and those suitable for quantifying effects on wildlife. Changes in these measurement indicators were used to evaluate potential changes in the status of each VC relative to the assessment endpoints. Each measurement indicator was assessed quantitatively where sufficient information existed to support a numerical assessment and qualitatively where necessary.

Ecosystem availability, ecosystem distribution and ecosystem condition were selected as the measurement indicators for the vegetation communities VC. The measurement indicators are defined as follows:

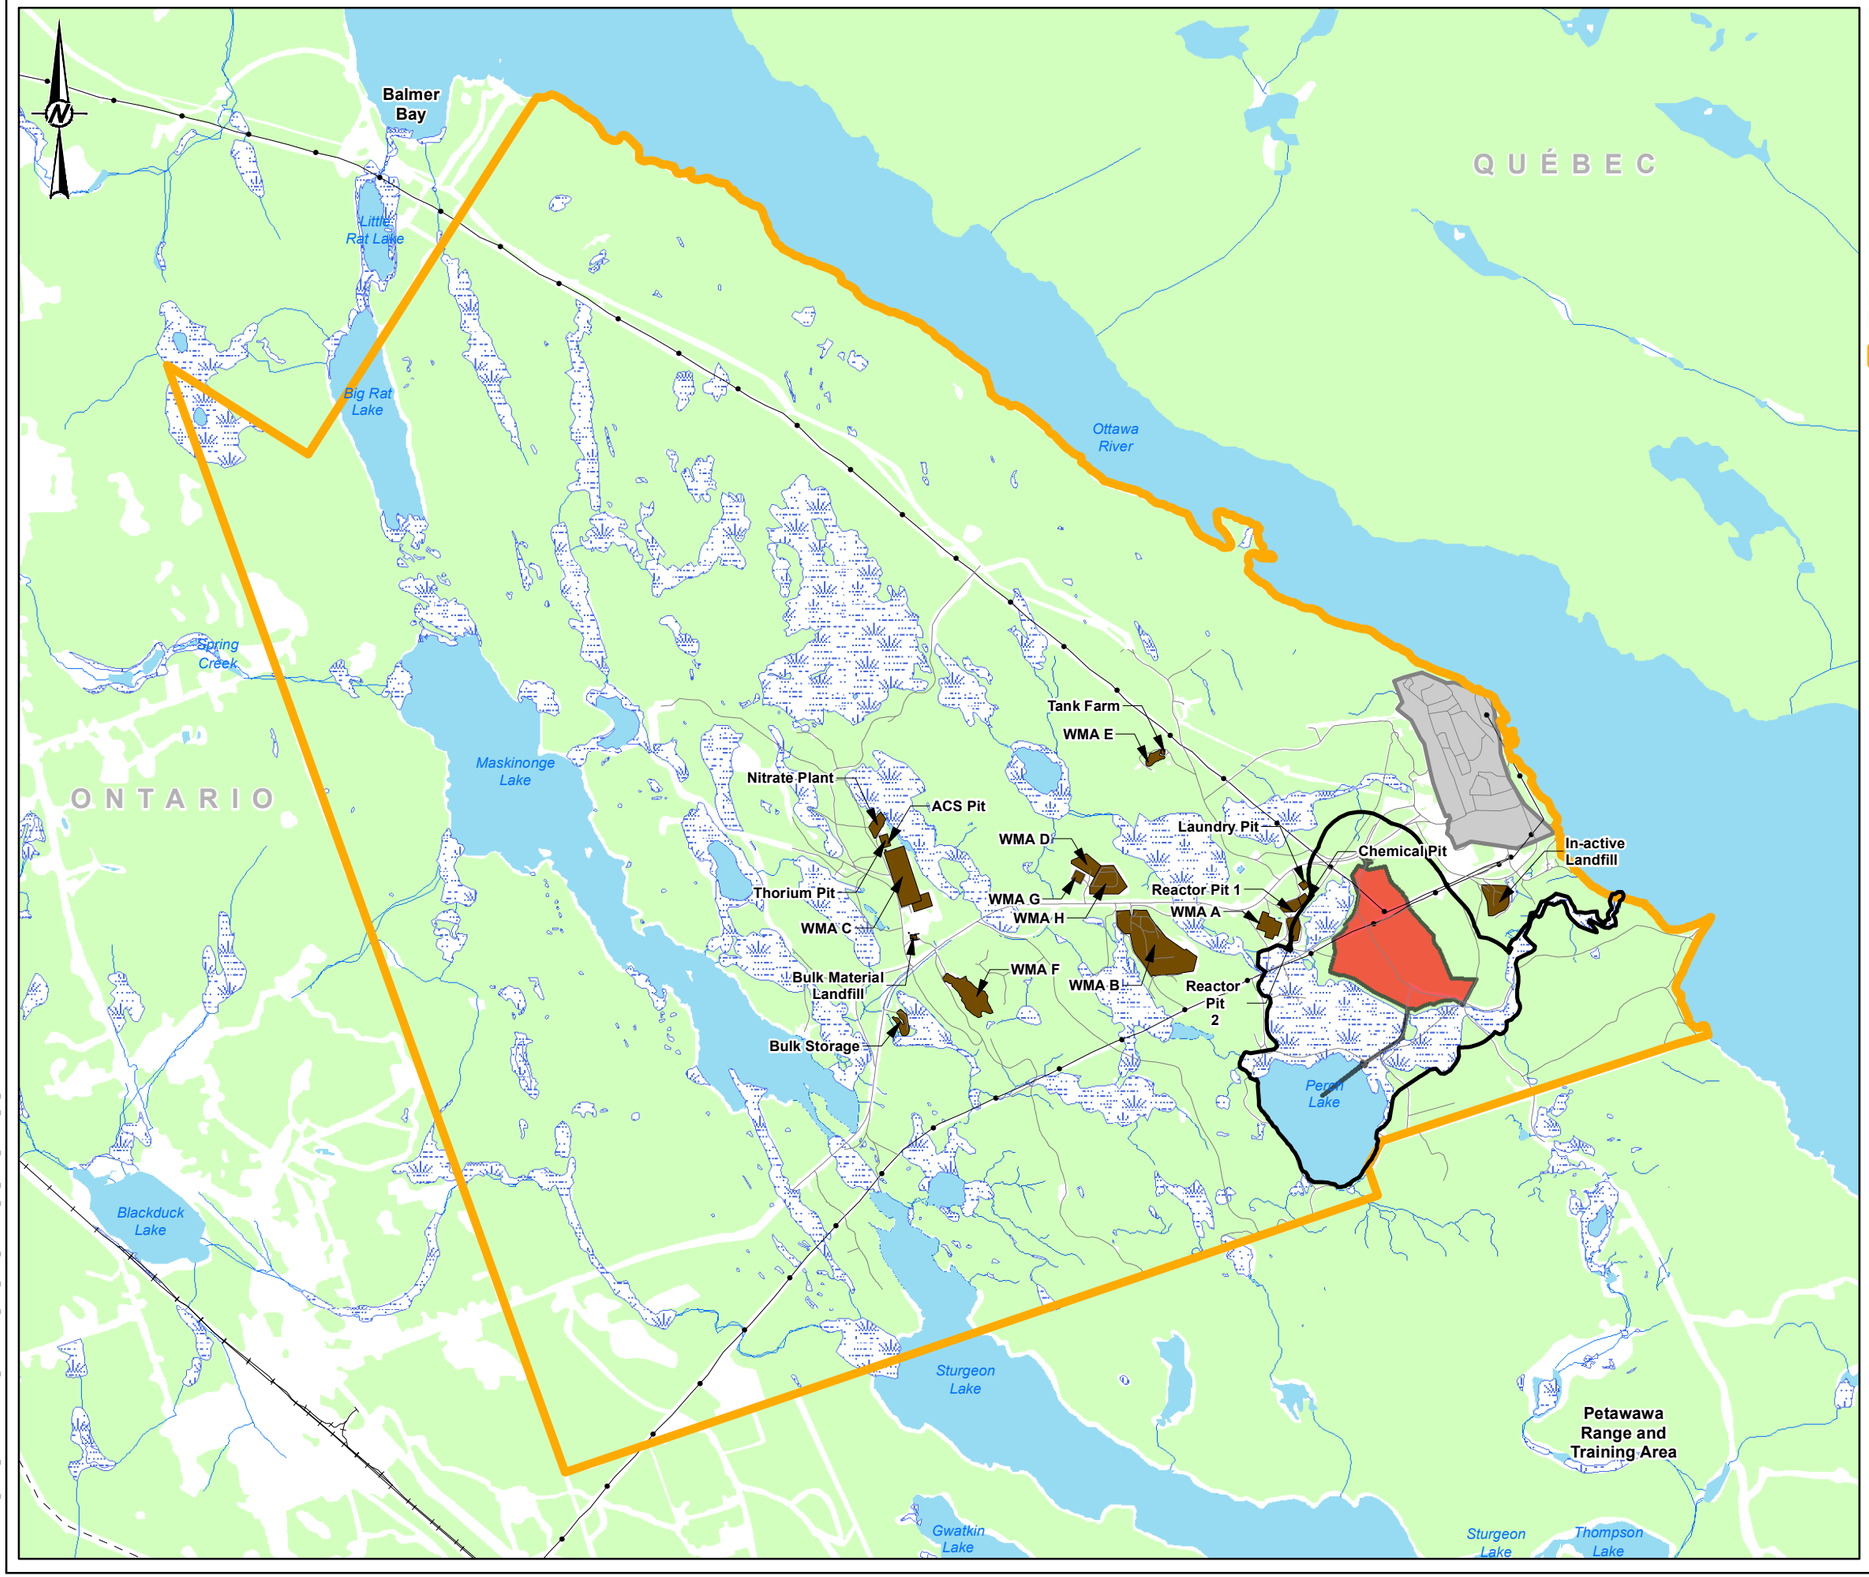
- **Ecosystem availability**: changes to the amount (e.g., hectares) of vegetation communities.
- **Ecosystem distribution**: changes in the way each vegetation community is distributed on the landscape. Ecosystem availability and distribution are linked, but distribution focuses on the spatial configuration (or arrangement) and connectivity of ecosystems, whereas availability focuses on the area of those ecosystems.
- **Ecosystem condition**: changes in native species richness, abundance and diversity. Ecosystem condition refers to the quality of habitat and is primarily affected by changes to structural stage and changes in the amount of moisture, amount of sunlight, competition with invasive species, dust deposition and contamination (e.g., radiological). The presence of invasive species may adversely affect ecosystem

condition. Mature forest stand age can be used as a broad indicator of ecosystem quality as wildlife habitat features required for a broad number of wildlife species, such as cavity trees and downed woody debris, are typically found in mature forest stands and less frequently found in younger seral (i.e., intermediate) stage stands. Maintenance of biodiversity in managed forest systems is an objective achieved through conservation of mature and old growth forest stands (Thompson 1997). The *Old Growth Policy for Ontario's Crown Forests* (MNR 2003) specifically describes the goal of ensuring old growth conditions and values are present in Crown forests for "conserving biological diversity at levels that maintain or restore ecological processes, while allowing for sustainable development now and in the future."

Habitat availability, habitat distribution, and survival and reproduction were selected as the measurement indicators for the terrestrial biodiversity species VCs. The measurement indicators are defined as follows:

- **Habitat availability**: changes to the size (e.g., hectares) and quality (e.g., probability of use by animals) of different habitats.
- **Habitat distribution**: changes to spatial configuration and connectivity of habitats and changes to the spatial distribution and movement of animals.
- **Survival and reproduction**: changes to abundance caused by altering mortality or recruitment rates.

5.6.3 Assessment Boundaries



5.6.3.1 Spatial Boundaries

The spatial boundaries selected for the terrestrial biodiversity assessment were chosen because they permit description of existing conditions in sufficient detail to enable potential project-VC interactions and effects to be identified, understood and assessed, including understanding and assessing the contribution of the NSDF Project to cumulative effects. The spatial boundaries selected for the terrestrial biodiversity assessment are presented on Figure 5.6.3-1 and are described below:

- **Site Study Area (SSA)**: The SSA is the NSDF Project footprint, which accounts for the direct physical disturbance and alteration of vegetation communities and wildlife habitat caused by construction and operations of the engineered containment mound (ECM) and related facilities, buildings and infrastructure. It also includes the two sections of East Mattawa Road that will be upgraded and form the north and south access roads to the ECM. These access road segments were included for terrestrial biodiversity because of the sensitivity of one VC species (Blanding's turtle) to road mortality. The SSA for terrestrial biodiversity encompasses approximately 37 hectares (ha) (Figure 5.6.3-1).
- **Local Study Area (LSA)**: The LSA is defined as the area within which there is potential for measurable changes to measurement indicators resulting from the proposed NSDF Project activities. The LSA includes the SSA (including the roads to the north and south) plus any surface waterbody (i.e., Perch Lake and Perch Creek) that was a potential discharge point for wastewater from the ECM. A 250 m buffer was applied to the SSA to capture effects from the NSDF Project that may extend beyond the footprint, including those caused by emissions of dust and sensory disturbance caused by noise and light (Figure 5.6.3-1). Any wetland feature that intersected the 250 m buffer area was included in the LSA to capture potential effects on Blanding's turtle. The resulting LSA encompasses approximately 210 ha.

- **Regional Study Area (RSA)**: The RSA is defined as the area within which the potential effects of the NSDF Project may interact with the effects of other existing or reasonably foreseeable developments. The RSA for terrestrial biodiversity is the CRL site boundary (Figure 5.6.3-1). This federally owned property is within the larger Ottawa Valley Forest Management Unit and comprises one of three parcels of federal lands within the unit (Van Dyke 2011). The RSA is approximately 4,000 ha and, because it contains the CNL nuclear facilities, it is managed differently from the surrounding landscape, which is provincial Crown land, or private land. The RSA was used as the scale at which cumulative effects to terrestrial biodiversity VCs were assessed. Beyond regional disturbance factors (e.g., forestry and climate change) were considered if they were likely to affect vegetation communities or populations of wildlife VCs that overlap with the RSA.

5.6.3.2 Temporal Boundaries

Temporal boundaries (i.e., project phases) establish the timeframe during which NSDF Project effects are assessed. The temporal boundary represents the timeframe during which project activities are actively occurring, and does not include the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a project activity or stressor (which is related to the project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the NSDF Project (e.g., residual effect lasts for thousands of years). The following phases were identified for the NSDF Project:

- **Construction Phase:** This phase includes site preparation and all activities associated with the construction of the NSDF Project. This phase includes activities such as installing the necessary supporting and/or ancillary facilities and infrastructure to facilitate NSDF Project operations, inactive commissioning and systems testing, and transportation of construction materials. Construction activities are expected to take place from 2022 to 2024.
- **Operations Phase:** This phase includes all activities associated with waste placement, water management, Wastewater Treatment Plant (WWTP) operations, vehicle movements into and from the SSA, and maintenance activities. The operations phase is expected to last approximately 50 years (i.e., 2025 to 2070).
- **Closure Phase:** This phase includes activities necessary to complete the installation of the final cover and implementation of long-term monitoring. Closure activities are expected to start in 2070 and continue through to 2100, after which the NSDF Project will transfer into the post-closure phase.
- **Post-closure Phase:** This phase has two discrete periods: institutional control and post-institutional control. The institutional control period includes implementation of controls throughout 2100 to 2400 (i.e., 300 years). During institutional control, environmental monitoring will be completed as required to confirm that the final cover is functioning as intended and to demonstrate compliance with the environmental assessment predictions. Post-institutional control occurs after year 2400 and continues indefinitely.

The temporal boundaries for the terrestrial biodiversity assessment consider all NSDF Project phases, from construction through post-closure.

5.6.3.3 Assessment Cases

The assessment cases considered in the terrestrial biodiversity assessment are the Base Case, Application Case and the Reasonably Foreseeable Developments Case.

- **Base Case:** This scenario represents existing conditions and characterizes effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances in the area, such as forestry, transportation, agricultural, mining and residential and recreational development. Current effects from the existing CRL facilities and operations, for example, are considered part of the Base Case.

  In 2019, CNL started implementing mitigation outlined in the *Blanding's Turtle Road Mortality Mitigation Plan* (Golder 2019a) to mitigate effects from existing operations and activities at the CRL site on Blanding's turtles in 2019. CNL is committed to continuing to implement mitigation in the *Blanding's Turtle Road Mortality Mitigation Plan* in the future to reduce Blanding's turtle road mortality to the extent possible. Monitoring of Blanding's turtles at CRL is on-going and will continue, and CNL is committed to implementing adaptive

management such that their existing and future operations do not adversely affect Blanding's turtles. Other actions beyond implementing the *Blanding's Turtle Road Mortality Mitigation Plan* will be undertaken, as required, to achieve this objective. These actions are being initiated prior to the NSDF Project. Consequently, the Base Case for Blanding's turtle is a predicted future case that incorporates mitigation that has been committed to and is being implemented by CNL. This predicted Base Case is the reference condition to which effects from the NSDF Project on Blanding's turtles are compared.

- **Application Case:** This scenario represents the effects of the Base Case combined with the effects that may result from the NSDF Project. The Application Case considers potential effects from the NSDF Project from the construction phase through the post-closure phase.
- **Reasonably Foreseeable Development (RFD) Case:** This scenario represents predictions of the cumulative effects of the Application Case, which includes the Base Case, plus projects that are currently under application review or that have officially entered a regulatory application process and are therefore considered reasonably foreseeable. RFDs expected within the CRL site (i.e., the RSA) that may interact with terrestrial biodiversity include new or upgrades to research and development facilities, construction and operations of the SMR, new support infrastructure, and on-going decommissioning and environmental remediation activities. Additional details on these proposed activities are provided in Section 5.6.7.11.

5.6.4 Description of the Environment

The RSA is in the Ontario Shield Ecozone and Georgian Bay Ecoregion 5E. This ecoregion has predominantly mixed forests characterized by a blend of northern and southern species, representative of the Great Lakes – St. Lawrence Forest Region (MNR 2007). Lakes and rivers comprise over 10% of the surface area, and wetlands are relatively rare, only covering 2.5% of this ecoregion. Characteristic tree species of Ecoregion 5E include conifers such as eastern white pine (*Pinus strobus*), red pine (*Pinus resinosa*), eastern hemlock (*Tsuga canadensis*) and black spruce (*Picea mariana*) and deciduous species such as yellow birch (*Betula alleghaniensis*) and sugar maple (*Acer saccharum*) (MNR 2007). The natural disturbance regime in this region is a combination of fire, wind and insect damage (MNRF 2019b). Wildlife are diverse and abundant, and characteristic regional species include eastern wolf (*Canis lupus lycaon*), American black bear (*Ursus americanus*), moose (*Alces americanus*), beaver (*Castor canadensis*), painted turtle (*Chrysemys picta*), common loon (*Gavia immer*), common raven (*Corvus corax*) and ruffed grouse (*Bonasa umbellus*) (MNR 2007).

Specific details about the terrestrial biodiversity present within the RSA and LSA are presented in annual monitoring reports produced by CNL (AECL 2013, 2014a; CNL 2015, 2016a,b,c, 2017d, 2018b) and reports prepared by consultants (CG&S 1997, 1998; North-South 2002; EcoMetrix 2013). These reports constitute the broader information about terrestrial biodiversity, including species of conservation concern, which is presented in Appendix 5.6-1 and was used to generate the list of terrestrial biodiversity VCs included in this assessment. The selected VCs are intended to focus the terrestrial biodiversity assessment, and this section therefore focuses on describing the environment (i.e., existing conditions) for each terrestrial biodiversity VC in the SSA, LSA and RSA.

Existing conditions for each VC represent the outcome of past and present effects on the environment. The level of effect within the SSA, LSA and RSA has varied over time. Although human occupation along the Ottawa River has been recorded from 4,000 to 5,000 years ago, the RSA was not affected by substantial industrial activity until the 1850s (AECL 2008). Fire was the primary disturbance factor in the RSA before the 1850s, although some selective logging for eastern white pine occurred in the RSA during the early 1800s.

The Mattawa Road opened as a winter road in 1854, permitting greater access into the RSA. Farmsteads were established in 1857 and the land was cleared of forests in many places (AECL 2014b). These small farms comprised most of the land use in the RSA until the federal government expropriated the land for construction of CRL in 1944 (AECL 2014b). Since the 1940s, land uses in the RSA have been limited to operations and activities undertaken at the CRL main campus and associated facilities (AECL 2008; SENES 2010). Vegetation clearing has been limited and the majority of the property has been undisturbed since the 1940s (i.e., for approximately 75 years), with the result that forests more than 75 years old are common.

Forest fires in the RSA have been limited, although several serious fires have occurred on the adjacent Garrison Petawawa (CNL 2018b). Fire suppression activities are regularly undertaken in the RSA because fire poses a safety hazard to the nuclear facilities at the CRL site (AECL 2008). The result is that the RSA currently serves as a refugium for vegetation communities and wildlife species associated with mature forests, including a number of species at risk. In absence of natural disturbances and in absence of activities mimicking natural disturbances (i.e., sustainable forest management practices), the current forest structure is not representative of a natural forest state.

Anthropogenic disturbance of the RSA and current activity (e.g., the CRL main campus area, access roads, firebreaks and Waste Management Areas [WMAs]) is largely concentrated in the southeast corner of the RSA. Disturbance in the form of roads is also primarily within the southern third of the property, with the main access road for employees (Plant Road) running east–west and numerous secondary roads branching off the Plant Road to specific destinations (i.e., ER-3 (Emergency Road), Foundation Road, Area B Road, Laundry Pit Loop, Power Line Road, Perch Lake Ring Road). There are two cleared and maintained hydroelectric corridors for the 115 kilovolt (kV) transmission lines through the CRL site, one spanning most of the north–south length of the property and the other spanning the southern east–west length of the property.

Overall, CNL's activities in the RSA have likely improved conditions for terrestrial biodiversity relative to conditions present in the 1940s (i.e., when much of the land was being cleared for agricultural use). Consequently, much of the RSA maintains high value for terrestrial biodiversity, including the VCs identified for this assessment. Within this context, and in cases where data were limited for some VCs, existing conditions were estimated using precautionary assumptions. For example, where suitable habitat was present for a VC, the VC was assumed to use the habitat, unless survey effort was available to demonstrate that the VC was absent. The following information sources were used to describe existing conditions for terrestrial biodiversity VCs:

- reconnaissance-level walk-through of the SSA by senior Golder biologist conducted on June 30, 2016;
- results of fieldwork undertaken annually by CNL staff in the LSA between 2012 and 2018, including forest songbird surveys (five acoustic recorders, 750 minutes of audio recording analyzed), amphibian surveys (seven acoustic recorders, 336 minutes of recording analyzed), wetland bird surveys (two acoustic recorders, 200 minutes of recording analyzed), bat surveys (three acoustic recorders, 128 minutes of recording analyzed; 21 visits to eight bat boxes), and Blanding's turtles (netting at six wetlands);
- studies published in scientific journals and reports;
- previous environmental assessments and terrestrial biodiversity surveys conducted within the RSA;
- federal recovery strategies for VCs available in ECCC's species at risk database (Government of Canada 2016);

- Forest Management Plan for the Ottawa Valley Forest (Van Dyke 2011);
- Forest Management Guide for Great Lakes – St. Lawrence Landscapes (MNRF 2019b);
- Forest Resource Inventory (FRI) geographic information system (GIS) spatial data (original source from Gendron Resource Surveys 1987);
- wetland GIS spatial data (received from CNL May 2016);
- road GIS spatial data (two datasets used and merged: received from CNL May 2016 and downloaded from the Land Information Ontario data warehouse (MNRF 2019c); and
- Ontario Ministry of Natural Resources and Forestry (MNRF) Natural Heritage Information Centre Make-a-Map: Natural Heritage Areas (MNRF 2019d).

A description of the existing conditions based on these information sources is provided for each terrestrial biodiversity VC in the sections below. Existing conditions are described according to the measurement indicators selected for each VC (see Section 5.6.2). Existing conditions for vegetation communities are described first because the maps generated to describe ecosystem availability and distribution for that VC are then used to describe habitat conditions for each species level VC.

For each wildlife VC, habitat mapping based on ecosystem data was used to provide spatially explicit descriptions of habitat availability and distribution under existing conditions, representing an estimate of suitable habitat available as a result of past and present development and activities. A review of habitat requirements and species ecology was completed for each wildlife VC to identify habitat that is most likely to be limiting for the species in the RSA and the loss of which would be most likely to result in change to the species' abundance in the RSA. The limiting habitat was selected as the focus of the assessment.

5.6.4.1 Vegetation Communities

5.6.4.1.1 Ecosystem Availability

Ecosystem availability was described using available FRI data. Vegetation communities are typically classified in central and southern Ontario using the Ecological Land Classification system; however, classification of "ecosite," a descriptive unit under the Ecological Land Classification system, is not included in the FRI spatial data available for the RSA. According to the *Forest Management Plan for the Ottawa Valley Forest* (Van Dyke 2011), ecosite descriptions have not been developed for any of the federally owned lands within the Ottawa Valley Forest Management Unit.

The FRI dataset available for the RSA consists of spatially explicit polygons (i.e., map units) that provide information on forest tree species composition, as well as other non-forested categories of land cover. The FRI data are typically derived by aerial photo interpretation with varying degrees of confirming derived habitat calls through field visitation (i.e., ground-truthing), depending on the age of the dataset; it is believed the FRI dataset for the RSA is based on mapping work conducted in 1987 and corrected in 2009; however, the dates associated with polygon delineation were not provided with the dataset. Forest cover information from the FRI dataset that was used for this assessment included forest unit (described below); forest tree species composition (as two-letter species codes); polygon / stand area (in hectares); and age (in years). It should be noted these data are intended to be used by forest managers to guide forestry activity, not specifically for assigning habitat classification. Forest units are categories of forest stands within the larger Forest Management Unit (i.e., the Ottawa Valley Forest in this case). These units have similar species composition, similar successional trends (from natural

and/or silvicultural disturbance) and are managed under the same silvicultural system (Van Dyke 2011). For the purposes of defining vegetation community types that are useful for classifying ecosystems and wildlife habitat value, the following categories were derived from FRI data:

- **Mixed forest:** forest stands containing deciduous and coniferous trees in upper canopy. The mixed forest communities identified that occur within the RSA include red oak (*Quercus rubra*) – eastern white pine forest. Dominant tree species in mixed stands surveyed as part of the North-South Environmental Inc. (North-South) survey work in 2002 were recorded as red maple (*Acer rubrum*), poplar (i.e., aspen sp. [*Populus* sp.]) and eastern white pine. Woody debris and snags (i.e., standing dead trees, with high wildlife nesting value) were reported as abundant in mixed and deciduous forest types. Dominant shrub layer species recorded in both mixed and deciduous forests included striped maple (*Acer pensylvanicum*), mountain maple (*Acer spicatum*), immature sugar maple (*Acer saccharum*) and red maple, birch (*Betula* sp.), balsam fir (*Abies balsamea*), eastern white pine, maple-leaved viburnum (*Viburnum acerifolium*), beaked hazelnut (*Corylus cornuta*), round-leaved dogwood (*Cornus rugosa*) and eastern leatherwood (*Dirca palustris*). Herbaceous species dominant in the understory include wild sarsaparilla (*Aralia nudicaulis*), large-leaved aster (*Eurybia macrophylla*), spinulose wood fern (*Dryopteris carthusiana*), northeastern lady fern (*Athyrium filix-femina* var. *angustum*), wild lily-of-the-valley (*Maianthemum canadense* ssp. *canadense*), eastern teaberry (*Gaultheria procumbens*) and late lowbush blueberry (*Vaccinium angustifolium*).
- **Deciduous forest:** forest stands containing only deciduous trees in upper canopy. The deciduous forest communities identified that occur within the RSA include sugar maple – large-toothed aspen (*Populus grandidentata*) forest, poplar – red maple forest with deciduous understory, and poplar – red maple – oak (*Quercus* sp.) forest. Dominant shrub layer species in these forests are similar to those in the mixed forests. Dominant tree species in deciduous stands surveyed as part of the North-South survey work in 2002 were recorded as red maple and poplar. Along Mattawa Road, forests containing maple and beech (*Fagus* sp.) and considered to have more southern Great Lakes influence are more common. Woody debris and snags were reported as abundant in mixed and deciduous forest types.
- **Coniferous forest:** forest stands containing only coniferous trees in upper canopy. The North-South survey work (North-South 2002) classified the forested area within the north portion of the SSA, north of the east–west transmission line right-of-way (ROW) and straddling the north–south transmission line ROW, as white pine / red pine forest. This community was characterized as having 20 to 40 cm diameter at breast height red pine and/or white pine in a closed canopy. White pine is sub-dominant, followed by red maple and, less commonly, by white birch (*Betula papyrifera*), white spruce (*Picea glauca*) and red oak. The tall shrub layer was determined to be very sparse in areas and consists of immature white pine, beaked hazelnut, striped maple and immature balsam fir. The herbaceous layer is dominated by eastern teaberry, wild sarsaparilla, late lowbush blueberry, white-grained mountain-ricegrass (*Oryzopsis asperifolia*), large-leaved aster and bracken fern (*Pteridium aquilinum*). Rock outcrops and woody debris were both noted to be common.

- **Wetlands:** primarily marsh and swamp type wetlands (with some bog and fen type) as determined through FRI and CNL wetland mapping based on surveys conducted by CG&S (1997, 1998). Wetlands are highly important wildlife habitat features and can be very sensitive to physical disturbances or changes to hydrological processes, depending on wetland type. For example, wetland plant species that are sensitive to nutrient enrichment can be out-competed by other more common species if nutrient levels are altered (Granger et al. 2005). Within the RSA, wetlands provide important habitat for bat foraging and maternity roosting (if mature treed swamps) and Blanding's turtle hibernation, mating, foraging, thermoregulation, staging prior to nesting and for movement.
- **Flooded areas:** saturated areas not included under the classification of wetlands or aquatic habitat that were mapped in the FRI dataset. This includes areas originally mapped and coded as FL (flooded), M1 (lowlands – emergent vegetation), M2 (lowlands – sedges, grasses) and M3 (lowlands – shrubs, herbs, sedges). Flooded areas constitute a minor component of the RSA (1 ha, or less than 1%).
- **Unclassified (cleared):** an FRI designation for non-forested areas created for uses other than timber production, including roads, hydroelectric corridors or any anthropogenically altered area cleared of trees (MNRF 2017). The North-South (2002) survey report provides information on the composition of the vegetation community within the hydroelectric corridors in the RSA. The dominant species are primarily herbaceous, as the ROWs must be operationally maintained at low vegetation height. Species recorded include the following native plants: sweet fern (*Comptonia peregrina*), bracken fern, spreading dogbane (*Apocynum androsaemifolium*), field horsetail (*Equisetum arvense*) and heart-leaved aster (*Symphyotrichum cordifolium*). On steep slopes where there is bare ground and sparse vegetation cover, there are patches of exposed sand that are described as reminiscent of sand barrens, a significant vegetation community in Ontario; however, their small size and lack of provincially significant species occurrence precludes them from being designated as such. In these steep, exposed sandy areas, dominant species recorded include dry spike sedge (*Carex siccata*) and common scouring rush (*Equisetum hyemale*).

The classification of forest stand types (mixed, deciduous and coniferous) was conducted using the composition of deciduous and/or coniferous tree species within each FRI polygon and assigning it as "mixed", "deciduous" or "coniferous." If a stand had both coniferous and deciduous tree species present based on the assessment conducted as part of FRI mapping, it was classified as "mixed"; if a stand had only deciduous or coniferous tree species present, it was classified as such. The FRI codes for forest units could not be used because each forest unit can consist of more than one forest type. For example, a single forest unit, such as Mixed Uniform Shelterwood, can contain mixed, coniferous and deciduous forest stands. Consequently, forest unit was not used to define the forest stand type, although forest units can inform species composition (Appendix 5.6-2).
Other information associated with each forested vegetation community category, such as leading tree species and stand age, was used to identify the availability of suitable habitat for wildlife VCs (refer to Section 5.6.7.1).

Spatial data delineating the availability of wetlands within the terrestrial biodiversity study areas was provided by CNL and merged with the FRI dataset. Where CNL-derived wetland polygons overlapped FRI unclassified area polygons (i.e., roads, hydroelectric corridors), the unclassified area designation took priority; otherwise, the CNL wetland layer took priority. The CNL wetland layer was considered a better overall spatial representation of wetlands in the RSA, although the FRI data were considered a better representation of disturbance.

Although there are coniferous tree plantations within the RSA and these were delineated by FRI mapping as separate FRI polygons, the species composition and inclusion of relatively old stand ages distinguish them from typical coniferous tree plantations in Ontario that are more heavily managed and frequently disturbed. For this reason, plantations are described and considered but were not distinguished as a distinct vegetation community—they were considered as either coniferous or mixed forests (depending on recorded tree species composition). Availability of vegetation communities within the RSA and LSA under existing conditions are presented in Table 5.6.4-1.

Table 5.6.4-1: Availability of Vegetation Communities under Existing Conditions

Vegetation Community	Description	RSA		LSA	
		Area (ha)	Percent (%)	Area (ha)	Percent (%)
Mixed forest	Forested areas with deciduous and coniferous tree composition	1,929	50.1	71	33.6
Deciduous forest	Forested areas with only deciduous tree composition	643	16.7	6	2.8
Coniferous forest	Forested areas with only coniferous tree composition	199	5.2	5	2.4
Wetlands	Marshes, swamps as determined through FRI and detailed survey and mapping (CG&S 1997, 1998)	522	13.5	61	29.0
Flooded areas	This includes areas originally mapped and coded as FL (flooded), M1 (lowlands – emergent vegetation), M2 (lowlands – sedges, grasses) and M3 (lowlands – shrubs, herbs, sedges)	1	<0.1	0	0.0
Unclassified (cleared)	Based on FRI data, indistinguishable among hydroelectric corridor, road surface, buildings; includes all anthropogenically altered ground surfaces	268	7.0	27	12.8
Aquatic habitat (lakes, streams)		274	7.1	41	19.4
Slivers/Gaps (GIS gaps in spatial data coverage)		16	0.4	0	0.0
Total		**3,853**	**100.0**	**210**	**100.0**

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

<= less than; FRI = Forest Resource Inventory; RSA = Regional Study Area; LSA = Local Study Area; GIS = geographic information system.

The RSA is primarily forested (72% of total area, including lake and stream features). Forests are predominantly mixedwood and deciduous, dominated by species such as aspen and red maple, with stands of eastern white pine and spruce species (*Picea* spp.) in some places. The RSA contains a number of small lakes and streams (e.g., Maskinonge Lake, Clear Lake, Chalk Lake, Perch Lake and Perch Creek), which make up 7% of the total area. Wetlands are also common, making up another 13.5% of the total RSA. The remaining 7% contains “unclassified” (i.e., anthropogenically modified) areas, consisting of roads, two 115 kV hydroelectric corridors, WMAs and all other developed areas such as the CRL main campus area.

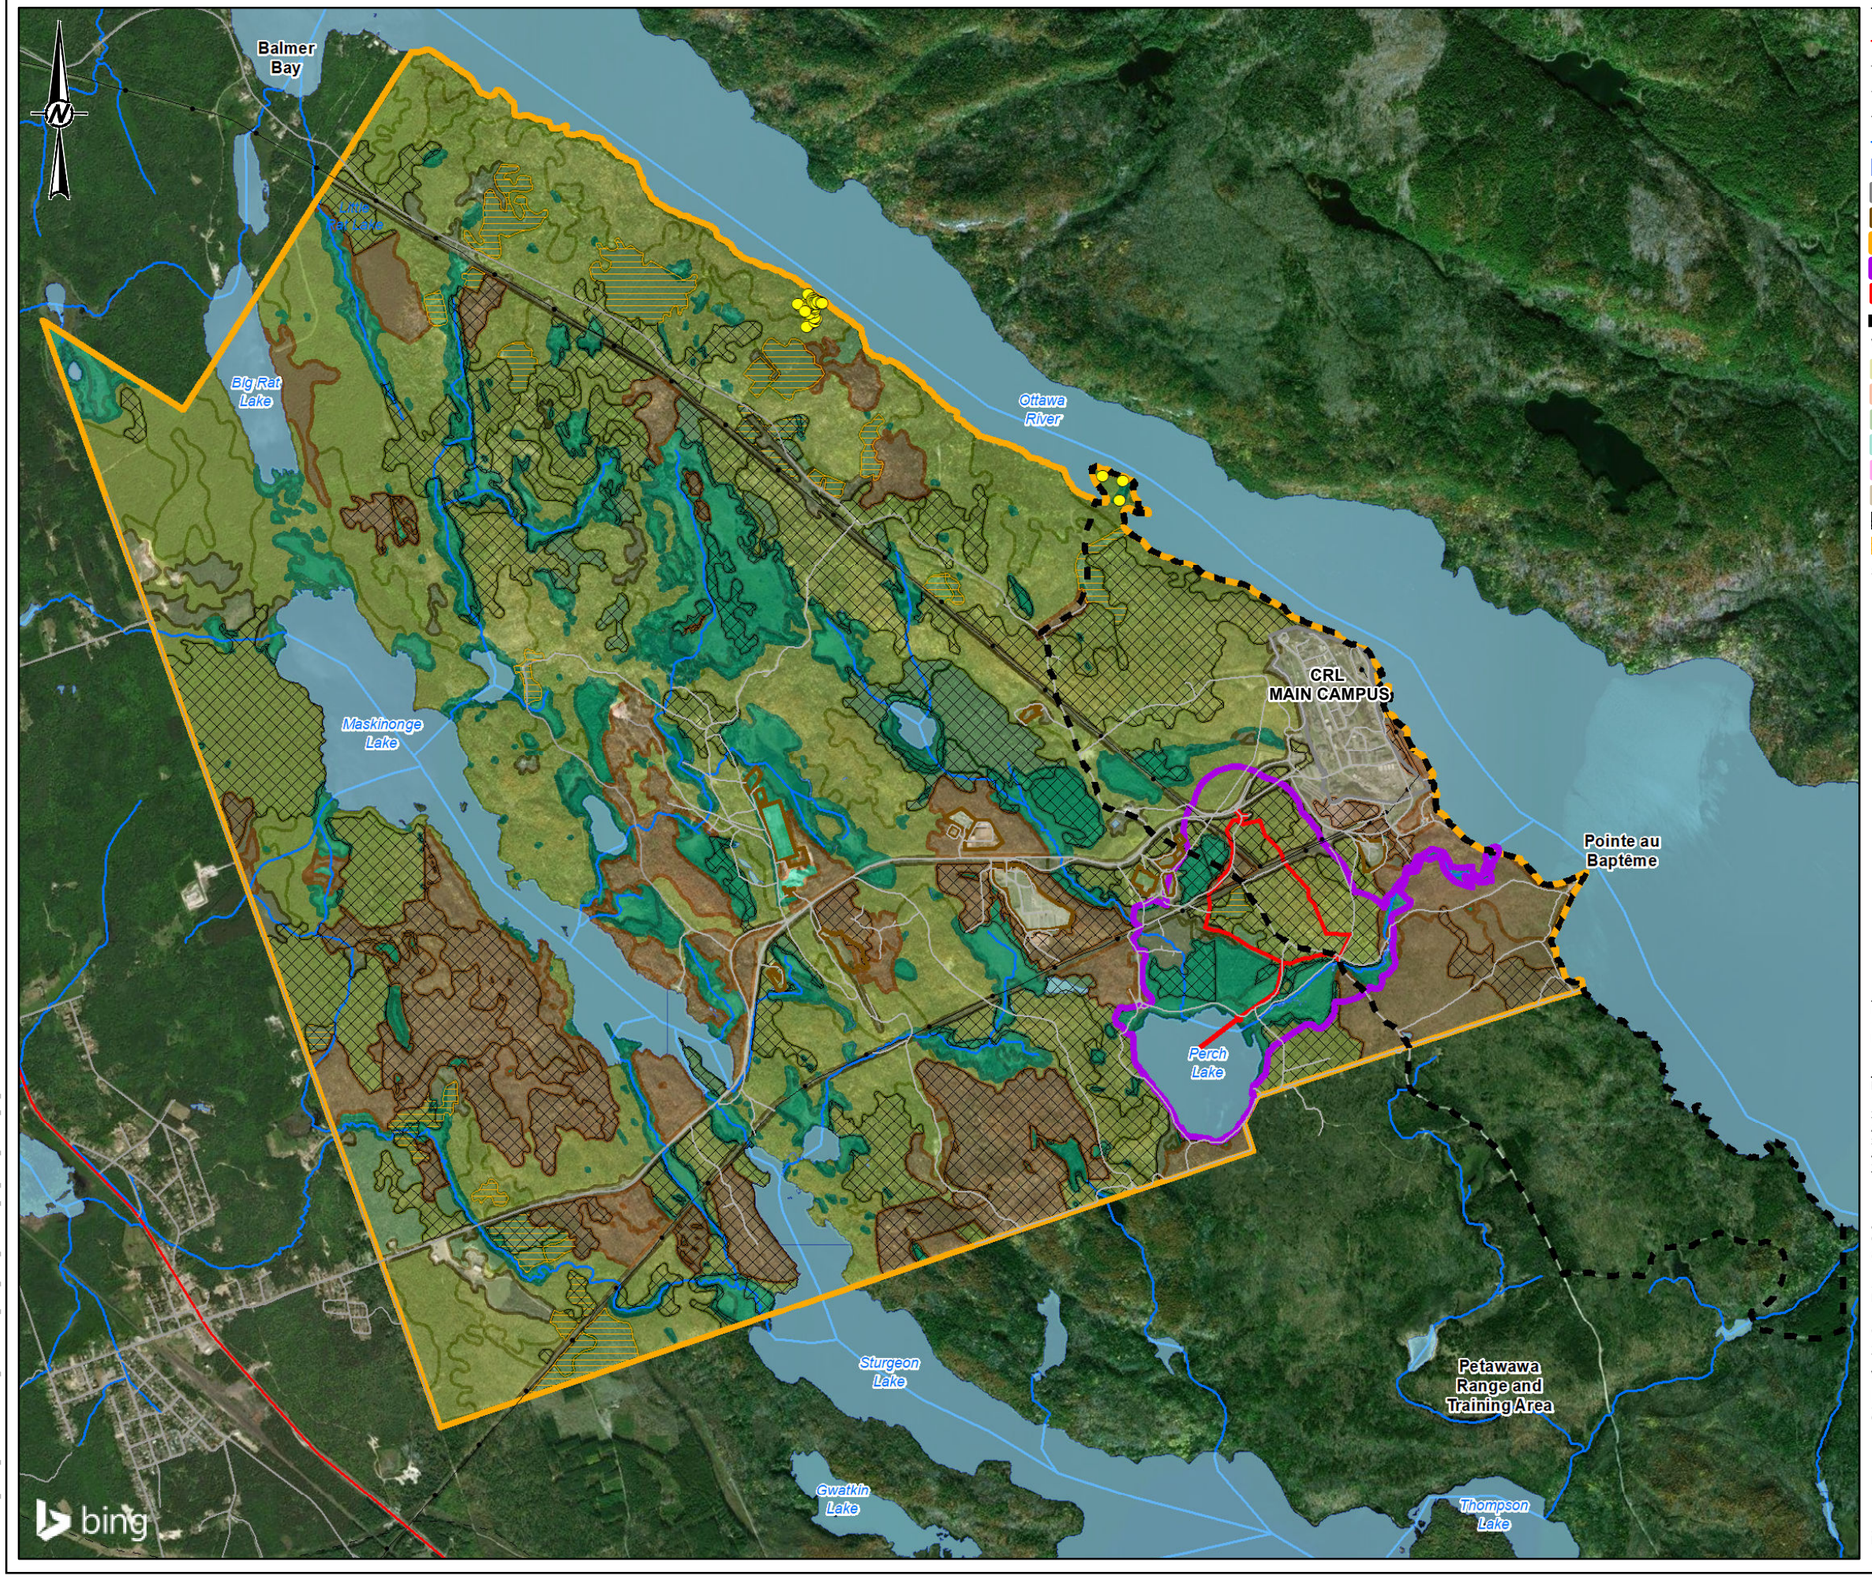
The LSA is located in the southeastern corner of the RSA, in a primarily undisturbed area adjacent the most heavily anthropogenically altered areas in the RSA, including the CRL main campus and various WMAs. The LSA is a mix of forested (38.8%) vegetation communities and wetlands (29%). The proportion of wetlands in the LSA is relatively high compared to the rest of the RSA and surrounding region in general, reflecting how the LSA for terrestrial biodiversity was derived (see Section 5.6.3.1). Wetlands consist of South Swamp to the south of the SSA, East Swamp to the northwest of the SSA (which will receive treated effluent released from the WWTP via the exfiltration gallery) and the marsh wetlands surrounding Perch Lake and Perch Creek. Aquatic habitat, largely

composed of Perch Lake and Perch Creek, covers 19.4% of the LSA. Anthropogenically altered (“unclassified”) areas in the form of roads, hydroelectric corridors and one inactive Liquid Dispersal Area (LDA; Reactor Pit 1) comprise the remaining 12.8% of LSA.

The SSA is approximately 38 ha and consists primarily of second-growth, mature, mixed forest, dominated by poplar species, red oak, eastern white pine and, and spruce species. It also contains a 1.2 km long segment of East Mattawa Road and two linear areas cleared as 30 to 45 m wide ROW for overhead hydroelectric lines. The East Mattawa Road corridor was not captured in the FRI data, but the hydroelectric corridors were. Inclusion of the true extent of East Mattawa Road would result in a minor decrease to the mixed forest total coverage of the SSA, because it bisects a mixed forest stand.

There are two areas of immature coniferous forest stands in the SSA: one is a tree research plantation containing 100% Norway spruce (*Picea abies*) and the other is a portion of a stand of spruce, balsam fir and larch species (*Larix* spp.). The Norway spruce research plantation is within the western portion of the SSA and was planted in the 1950s. Personnel with the Petawawa Research Forest have confirmed this plantation is no longer required for research purposes. There is also a portion of one deciduous forest stand, within the northwest end of the SSA, which contains poplar species, yellow birch and red oak.

There are no wetlands, flooded areas or aquatic habitat features within the majority of the SSA. However, the transfer line to Perch Lake intersects wetland and aquatic habitat. The surficial geology around the SSA consists primarily of sands, underlain by dense sandy silt till containing cobbles and boulders. Organic soils (e.g., peat) have deposited in the low-lying areas. The overburden thickness at the site typically ranges from approximately 0 to 10 m, depending on bedrock topography. The vegetation communities present within the SSA reflect these soil conditions.



In addition to mapping using FRI data, a spatial query of the MNRF Make-a-Map system for natural heritage areas was conducted to identify any designated provincially significant natural features that may be present within the RSA. These would include designated provincially significant wetlands and areas of natural and scientific interest. According to the query, there are no designated provincially significant natural features within the RSA (MNRF 2019d).

5.6.4.1.2 Ecosystem Distribution

Because the RSA has remained largely undisturbed since the 1940s, it consists primarily of natural vegetation communities distributed according to natural ecological patterns. Forested vegetation communities make up 72% of the RSA, with a mosaic of forested areas interspersed with wetland areas and lakes that make up a combined 20.6% of the total area (Table 5.6.4-1). The degree of anthropogenic disturbance is generally on a north–south gradient, with the most northern part of the RSA generally undisturbed (with the exception of a hydroelectric corridor) and the southern part of the RSA most disturbed, where the CRL main campus, main employee access road (Plant Road) and other secondary access roads, as well as other WMAs are located. Anthropogenically altered (“unclassified”) areas of the RSA comprise a total of 7% of the total area. Distribution of vegetation communities within the RSA in the Base Case are presented on Figure 5.6.4-1.

Distribution of vegetation communities within the LSA and SSA in the Base Case is presented on Figure 5.6.4-2. By virtue of how the LSA was derived, there are swamp and marsh-type wetlands surrounding the perimeter of the LSA on the south (Perch Lake Swamp, Perch Lake Fringe, Outlet Swamp); west (South Swamp, East Swamp); and east sides (Outlet Swamp surrounding Perch Creek). The remaining portion of the LSA is forested with poplar, red oak and eastern white pine dominated stands that are partially fragmented by 12.8% coverage of unclassified (anthropogenically cleared) areas. These altered areas are primarily made up of Plant Road and the two hydroelectric corridors, as well as a portion of the cleared area surrounding Reactor Pit 2. Plant Road and the hydroelectric corridors are linear features that bisect natural forested ecosystems across the LSA boundaries. East Mattawa Road is another linear feature on the landscape that exists, but was not captured by FRI mapping (i.e., so is not included in the calculated coverage of unclassified areas). There is also one isolated stand of Norway spruce (i.e., research plantation) within the LSA that is within a larger stand of poplar and red-oak dominated forest.

5.6.4.1.3 Ecosystem Condition

Structural stage was used as a quantitative measure of ecosystem condition. Other factors affecting ecosystem condition such as abundance and distribution of native and non-native plant species and the presence of any significant ecosystem communities (e.g., sand barrens, provincially significant wetlands) were considered qualitatively and relied upon information contained in previous studies conducted within the RSA.

Structural age class for each FRI forest unit polygon within the RSA was obtained using the *Forest Management Plan for the Ottawa Valley Forest* (Van Dyke 2011) and the *Forest Management Guide for Great Lakes-St. Lawrence Landscapes* (MNRF 2019b). In cases where the two sources had a different structural age class assigned to the same polygon, the youngest age ranges were considered "mature" to provide a conservative assessment of the potential for the NSDF Project to affect mature forest stands. The ages for each structural stage specific to each forest unit are provided in Appendix 5.6-2.

Structural age classes for each forested vegetation community are defined as follows:

- **Pre-sapling**: very young forest created by stand-replacing natural disturbance, clear-cut harvest or final removal shelterwood harvest where the remaining stand is very young (Van Dyke 2011).
- **Sapling**: general term for young trees beyond seedling but not yet at pole stage, at vigorous growth stage and consisting of trees without dead bark and only occasional dead branches (NRCan 2016).
- **Immature**: definition as it relates to forest management—in even-aged management this refers to stands of trees past regeneration stage, but not yet mature; and in uneven-aged management it refers to established trees too young for commercial harvest (NRCan 2016).
- **Mature**: definition as it relates to forest management—in even-aged management this refers to stands of trees sufficiently developed to be harvestable and that are at or near rotation age (i.e., age at which the stand can be economically and sustainably harvested) (NRCan 2016).
- **Old growth**: distinguishable from younger stands based on the structure, ecological function and species composition. There is an accumulation of woody debris and the presence of species and functional processes representative of the potential climax natural community (in the absence of disturbance; NRCan 2016). The age of onset varies based on dominant tree species. For example, poplar trees are relatively short-lived compared to other tree species. As a result, poplar-dominated forests are considered old growth at 95 years, whereas red pine-dominated forests are considered old growth at 140 years (Watkins 2011).

Older aged forest stands are ecologically important because they provide greater habitat complexity and have higher species diversity. Although wildlife trees and coarse woody debris can occur in any aged forest stand, snags, cavity trees and other types of wildlife trees and the wildlife tree users that are associated with them, are more common in mature and old growth forest stands. Older structural stages are more difficult to return on the landscape because it takes many decades for mature forests to develop. Structural stages of forested vegetation communities are summarized below in Table 5.6.4-2.

The forest type and structural age class with the largest spatial coverage within the RSA is immature mixed forest (32%). Considering all forest types combined, immature forest comprises 42% of the total RSA. Mature mixed forest is the second most common forest type and structural age class by area coverage in the RSA (17.8%), and when considering all forest types combined, mature forest is also the second largest structural stage (27.8%). Pre-sapling and sapling forest areas are relatively uncommon on the RSA landscape (combined for all forest types only comprising 2.2%). This is not surprising given the restricted activity and forest fire suppression within the CRL site. There are no old forest stands in the RSA.

Within the LSA, there is a relatively older assemblage of forest stands compared to the RSA, with 32.2% spatial coverage of all combined forest types in the mature age class. The LSA has no pre-sapling, sapling or old forest stands; all stands are either immature or mature. Compared to the RSA, the LSA has a higher proportion of mature forest stands, and therefore provides a greater proportion of high-quality habitat for mature-forest dependant species, including those that depend on cavities and other features associated with wildlife trees. Almost all of the forest in the LSA is mixed forest. Woody debris and snags are abundant in mixed forest types in the RSA.

Table 5.6.4-2: Structural Stages of Forested Vegetation Communities in the Regional and Local Study Areas by Forest Type (Base Case

Forest Type	Structural Stage Category	RSA		LSA	
		Area (ha)	Percent(a) (%)	Area (ha)	Percent (%)
Mixed	Pre-sapling	4.2	0.1	0	0.0
	Sapling	9.2	0.2	0	0.0

	Mature	86.9	2.3	0	0.0
	Old	0	0.0	0	0.0
Total – All Forest Types Combined	Pre-sapling	30.9	0.8	0	0.0
	Sapling	52.8	1.4	0	0.0
	Immature	1,618.2	42.0	13.9	6.6
	Mature	1,069.9	27.8	67.6	32.2
	Old	0	0.0	0	0.0

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

a) Percentages based on total area of the RSA and LSA, respectively, inclusive of all other land cover types, not just forest (i.e., wetlands, flooded areas, unclassified (cleared) areas and aquatic habitat).

<= less than; RSA = Regional Study Area; LSA = Local Study Area.

Although ecosystem condition is primarily focused on native plant species, planted species can offer suitable surrogate habitat for wildlife, which often respond to habitat structure more so than species composition. For example, the somewhat naturalized coniferous tree plantations in the RSA may offer habitat for wildlife, including species at risk such as eastern whip-poor-wills.

Wetlands in the RSA provide important habitat for bat foraging and maternity roosting (if mature treed swamps) and for Blanding's turtle hibernation, mating, foraging, thermoregulation, staging prior to nesting and for movement. However, as described in Section 5.7.4.5, the East Swamp Wetland, which is adjacent to the SSA, has existing radioactive contamination associated with a shallow subsurface plume from the Chemical Pit and a second plume from Reactor Pit 2, thereby reducing the condition of this wetland. The surface contamination distribution in the East Swamp has been characterized with radiation field surveys, surface surveys and vegetation contamination surveys performed in 2002, 2007 and 2012. In 2002 and 2012, these surveys included wetland soil and vegetation sampling to determine the radionuclide concentrations in these media. These results are discussed in Section 5.7.4.7 Radioactivity in Soils.

According to a spatial query of the MNRF Make-a-Map system for natural heritage areas, there are no designated provincially significant natural features within the RSA (MNRF 2019d). Their small size and lack of provincially significant species occurrence precludes the sand barrens identified in the SSA and LSA from the provincially rare vegetation community designation (MNR 2000).

Detailed vegetation inventory was not available for the RSA; however, an invasive survey was conducted along roadways and other anthropogenic disturbances identified the presence of purple loosestrife (*Lythrum salicaria*), spotted knapweed (*Centaurea maculosa)*, Phragmites (*Phragmites sp.)*, reed canary grass (*Phalaris arundinacea)* and white sweet clover (*Melilotus albus)*. Although ingress into native forested areas where the soil has not been disturbed is poorly understood, invasive species have the potential to alter ecosystem condition, particularly in smaller patches where the edge-to-interior ratio is higher (Honnay et al. 2002).

Butternut (*Juglans cinerea*) is the only SARA-listed plant species that has been recorded in the RSA (see Figure 5.6.4-1). This species does not have a high likelihood of occurrence within the SSA based on the location of the RSA, which is beyond the known northern extent of the range of butternut in Ontario, and on site conditions. Surveys to date have not indicated the presence of butternut within the SSA, and suitable habitat is not common in this location. Suitable butternut habitat consists of a range of tolerable soil types, but the highest quality conditions are rich, moist, well-drained loams typically within streamside riparian areas and also well-drained gravely sites of limestone origin (Environment Canada 2010). Butternut is shade intolerant but can be a minor component of late-successional stage forests with openings in the canopy. Butternut within the RSA (but outside of the LSA) are associated with old homesteads. Some regeneration was noted in one patch during surveys, but it was always near the parent trees that were associated with the old homestead.

5.6.4.2 Migratory Birds

5.6.4.2.1 Habitat Availability

Given the large number of species of birds from various families that are classified as migratory birds, habitat preferences among migratory bird species are highly diverse and cover the range of available habitats in the RSA. A total of 117 migratory bird species are known to be present in the RSA or have the potential to be present in the RSA based on known distribution and presence of suitable habitat in the RSA (Appendix 5.6-3). Many of these are forest landbirds, but there are also several waterfowl and waterbirds.

The vegetation community data were used to map suitable habitat for migratory birds in the LSA and RSA. Migratory birds have the potential to occupy all natural habitat available in the RSA and, therefore, suitable habitat for migratory birds was evaluated as all age classes (if applicable) for all natural cover types. The potential exists for all of the natural cover types in the RSA and LSA to be occupied by various species of migratory birds at various times of the year (i.e., breeding season, during migration, winter).

Some migratory bird species will also occupy anthropogenic structures (e.g., buildings, bridges). This potential was considered qualitatively, but only natural cover types were considered in quantitative estimates of habitat availability for migratory birds. Table 5.6.4-3 presents habitat availability for migratory birds. Approximately 3,568 ha (92.6%) of the RSA and 177 ha (84.3%) of the LSA represent available habitat for migratory birds in the Base Case. The SSA comprises mostly mature mixed forest, but wetlands and aquatic habitat (Perch Lake) are also prominent habitat types in the LSA (Section 5.6.4.1.1).

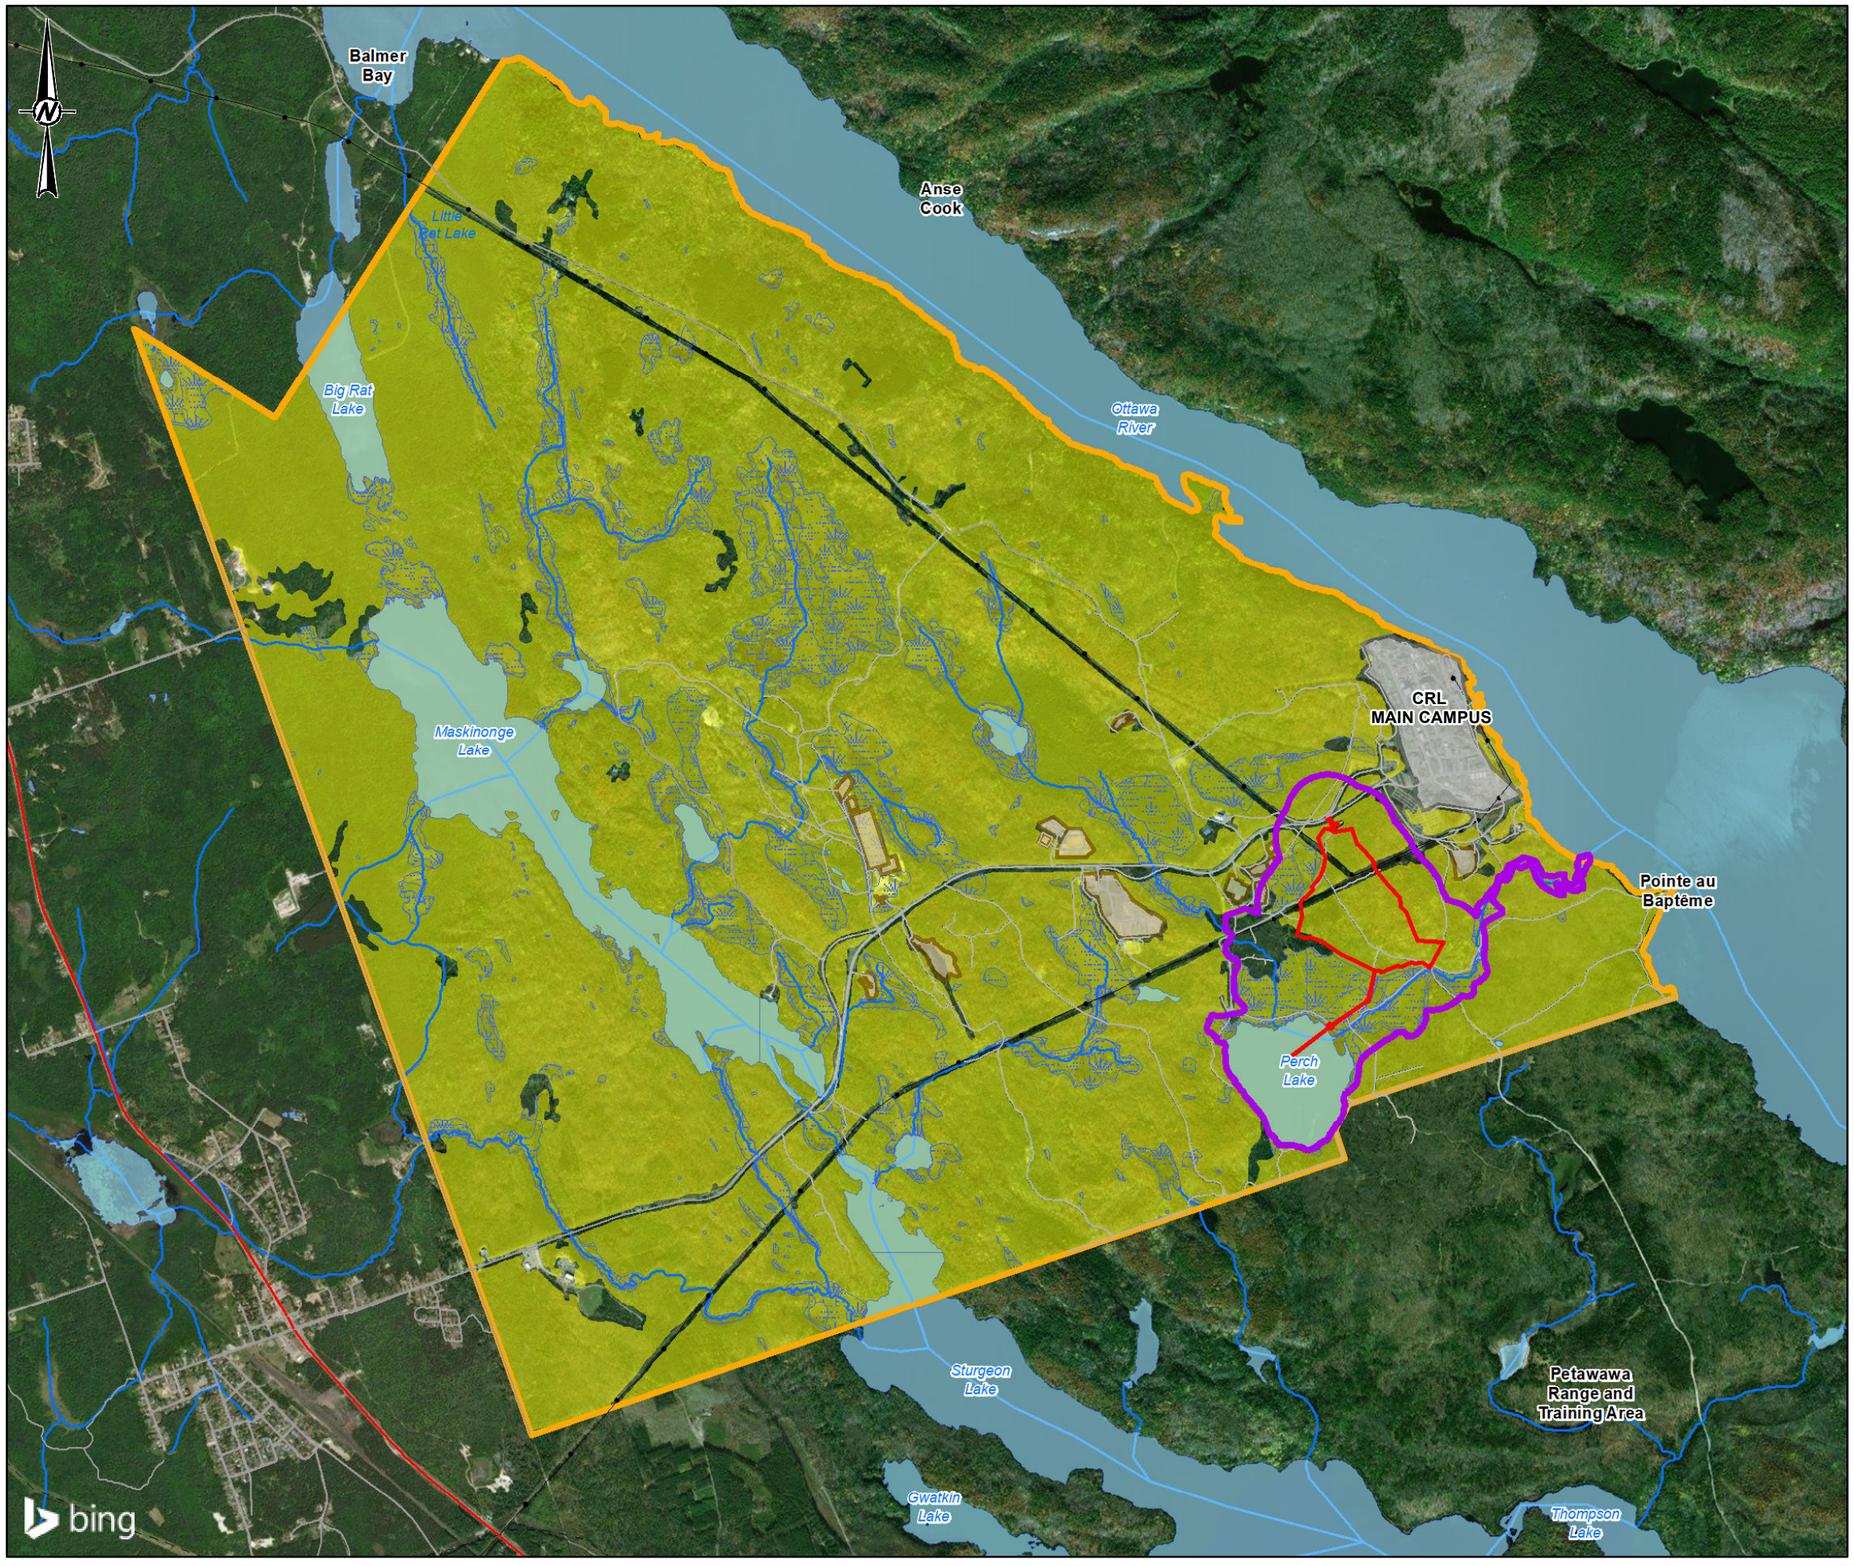
Table 5.6.4-3: Habitat Availability for Migratory Birds (Base Case)

Habitat Suitability	Regional Study Area		Local Study Area	
	Area (ha)	Percent (%)	Area (ha)	Percent (%)
Suitable	3,568	92.6	177	84.3
Unsuitable	285	7.4	33	15.7
Total	3,853	100.0	210	100.0

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

Disturbances (e.g., fire, anthropogenic) have likely had both positive and negative effects on migratory bird habitat availability in the Base Case, depending on the habitat preferences of the species. For example, forest fire or logging may represent habitat loss for a forest species but habitat gain for an edge or early-successional species. The development of industrial infrastructure in the RSA represents a loss of habitat for most species of migratory birds, but other disturbances (e.g., fire, logging, farmsteading) would have had mixed effects on habitat availability for migratory birds as a group, with some species benefiting from these disturbances while others experience habitat loss.

Several forms of significant wildlife habitat (SWH) for migratory birds may be present in the RSA (MNR 2000). Although SWH is not a recognized designation on federal lands, it is nevertheless a useful indicator of the value of habitat to species of interest. The lakes and large wetlands in the RSA qualify as candidate waterfowl stopover and staging areas (aquatic). Seven of the waterfowl species identified as indicators for this SWH type have been observed in the RSA to date. Waterfowl surveys during the migration seasons have not been completed and would be required to confirm significance based on MNRF guidelines (MNR 2000). Nevertheless, CNL considers wetlands greater than 25 ha in area to be significant waterfowl stopover and staging areas based on the definition



of a “waterfowl gathering area” in the Quebec Regulation Respecting Standards of Forest Management for Forests in the Domain of the State (chapter A-18.1, r. 7), as well as due to the proximity of the wetlands to the Ottawa River, which is a major migration corridor. The shorelines of lakes, rivers and wetlands in the RSA qualify as candidate shorebird migratory stopover areas, but surveys during the migration seasons have not been completed and would be required to confirm significance. None of the shorebird species identified as indicators for this SWH type have been observed in the RSA to date.

Great blue herons (*Ardea herodias*) have been confirmed breeding in the RSA; one nest with three young was observed in a swamp/marsh during surveys in 2012. However, only breeding colonies containing 10 or more active nests qualify as SWH in the form of colonially nesting bird breeding habitat (tree/shrub). Although suitable habitat is available in the LSA, no great blue heron colonies representing SWH have been observed during searches to date.

5.6.4.2.2 Habitat Distribution

Most of the RSA is under natural vegetative cover consisting primarily of mixed forest communities (Figure 5.6.4-3). Lakes and wetlands naturally fragment the forest cover and are themselves patchily distributed throughout the RSA. The RSA is likely less fragmented than it was in recent history because of fire suppression and cessation of logging and farmsteading, which have resulted in reforestation. Most of the current human disturbance in the RSA is concentrated in the southeastern two thirds of the RSA. Mattawa Road and a hydroelectric corridor run through the northern portion of the RSA and Plant Road runs from the CRL main campus through the western portion of the RSA to the rural village of Chalk River. The CRL main campus and WMAs are discrete, isolated disturbances that are not believed to represent major barriers to migratory bird movement since birds are highly mobile and can fly around or over these areas. Several local roads and two hydroelectric corridors cross the LSA, and a portion of the LDA is contained within the LSA, but the LSA remains mostly forested (Figure 5.6.4-4). Linear disturbances (roads, trails, hydroelectric corridors) in the LSA and RSA are generally less than 30 m wide and at most 45 m wide. Narrow linear disturbances generally do not represent barriers to bird movement (Desrochers and Hannon 1997; St. Clair et al. 1998), although they may influence territory establishment and delineation (Machtans 2006). Therefore, existing disturbances in the LSA and RSA are unlikely to function as dispersal barriers for migratory birds in the Base Case.

5.6.4.2.3 Survival and Reproduction

Fifty-five migratory bird species have been recorded in the RSA during surveys, with chestnut-sided warbler (*Setophaga pensylvanica*), veery (*Catharus fuscescens*), white-throated sparrow (*Zonotrichia albicollis*) and black-throated blue warbler (*Setophaga caerulescens*) being the most commonly observed species. An additional 62 species are known to occur in the RSA or potentially occur in the RSA based on habitat availability. Based on the Ontario Breeding Bird Atlas (OBBA) and field observations (where available), 75 species are confirmed breeders, 17 are probable breeders and 24 are possible breeders in or within the vicinity of the RSA, which overlaps primarily with OBBA survey square 18US10 and slightly with OBBA survey squares 18US00 and 18UR19 (Cadman et al. 2007; Appendix 5.6-3). The breeding status of the remaining seven species is unknown in the vicinity of the RSA.

The *State of Canada's Birds 2012* report (NABCIC 2012) concluded that bird populations in the Southern Shield and Maritimes region, which includes the RSA, had declined by 13% on average across species groups and forest birds specifically by 10% since 1970. More broadly, the *State of North America's Birds 2016* report (NABCI 2016) concluded that one third of all North American bird species, many of which are migratory birds, are in urgent need of conservation action due to declining populations and/or severe threats to their sustainability. Although the results from these reports cover broad geographic areas and include species that would not occur in the RSA, they nevertheless demonstrate that migratory birds are of conservation concern and many species are in decline. The largely contiguous forested habitats in the RSA and LSA may be of local and regional benefit to forest-dwelling migratory birds in an increasingly fragmented landscape.

Anthropogenic threats to migratory bird survival and reproduction vary among species because of their diverse ecologies. However, some universal threats that may apply in the RSA are collisions with human infrastructure and collisions with vehicles. Buildings in the CRL main campus and WMAs may pose a collision risk to migratory birds that reside in or migrate through the RSA. Vehicular traffic volume and speed limits in the RSA are low, and therefore, risk of collision with vehicles is expected to be negligible in the Base Case.

5.6.4.3 Canada Warbler

5.6.4.3.1 Habitat Availability

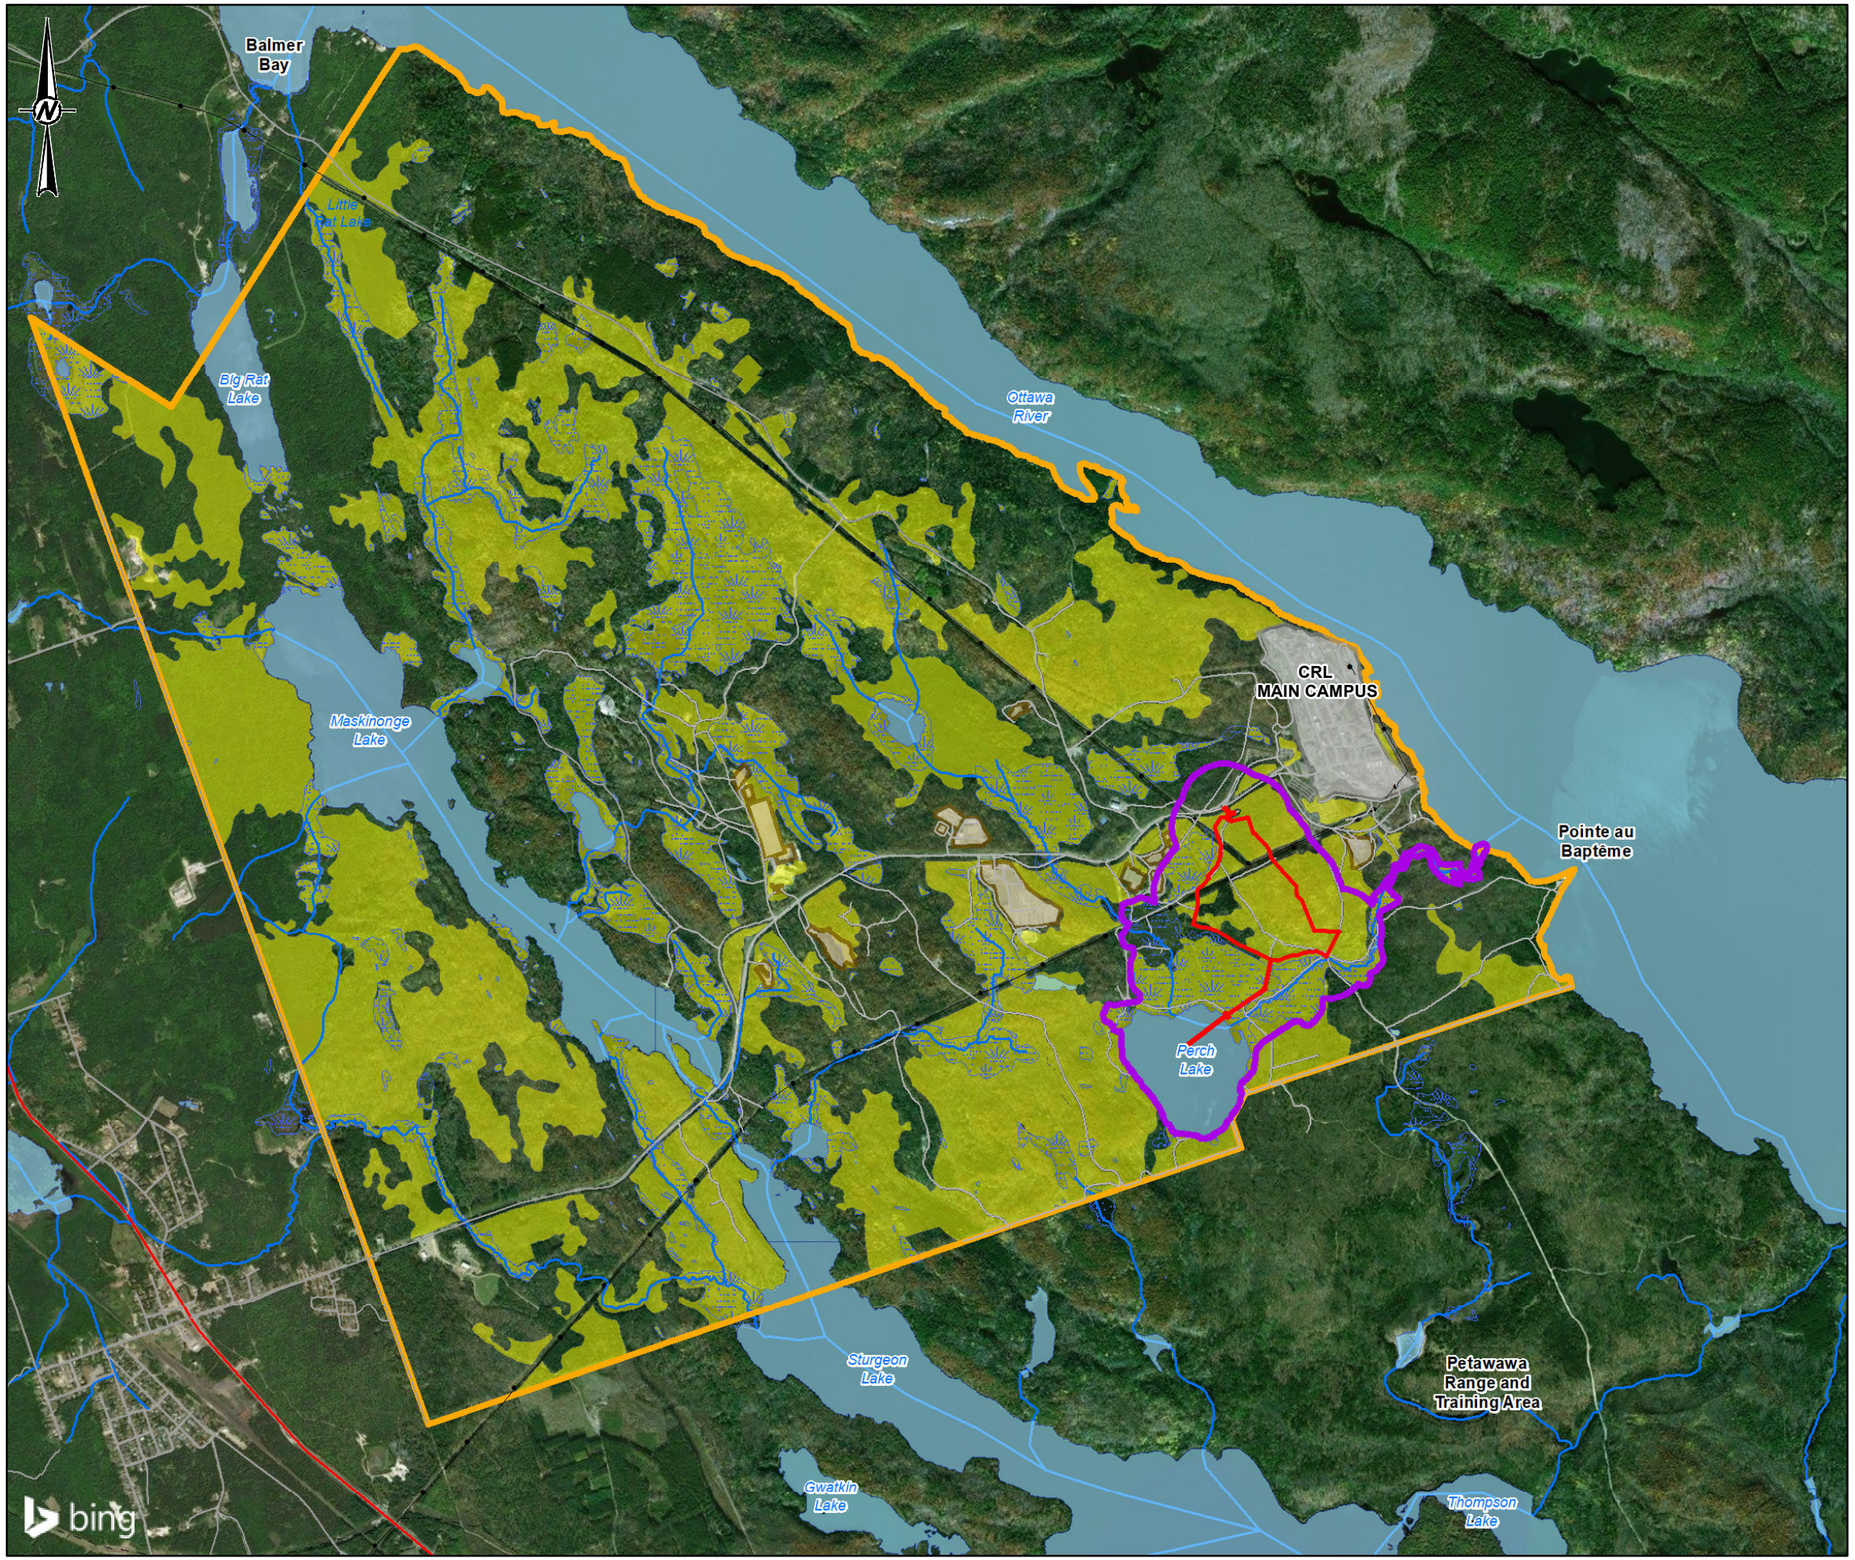
The NSDF Project is in breeding habitat for Canada warblers (*Cardellina canadensis*). Throughout their breeding range, Canada warblers nest in a range of forest types, especially wet forests with a well-developed, dense shrub layer (COSEWIC 2008; Government of Ontario 2015a). This species is commonly found in shrub marshes, red maple stands, cedar (*Thuja* spp.) stands, swamps dominated by black spruce and tamarack (*Larix laricina*) and riparian woodlands (COSEWIC 2008). In the eastern portion of their range, Canada warblers are associated with wet mixed forests and early successional forests (6 to 30 years) created by forest harvesting or natural disturbance (Ball and Bayne 2014; ECCC 2016a). Critical habitat has not yet been defined for this species (ECCC 2016a). The vegetation community data were used to map suitable habitat for Canada warbler in the LSA and RSA as follows:

- all forest stands in the pre-sapling, sapling and mature age class; and
- wetlands.

A total of 128 ha (61.0%) and 1,701 ha (44.1%) of suitable habitat for Canada warbler is estimated to be present in the LSA and RSA, respectively, in the Base Case (Table 5.6.4-4).

Table 5.6.4-4: Breeding Habitat Availability for Canada Warbler in the Base Case

Habitat Suitability	Regional Study Area		Local Study Area	
	Area (ha)	Percent (%)	Area (ha)	Percent (%)
Suitable	1,701	44.1	128	61.0
Unsuitable	2,152	55.9	82	39.0
Total	3,853	100.0	210	100.0



Disturbances can have both positive and negative effects on Canada warbler habitat availability. Disturbances result in the initial removal of habitat causing Canada warblers to be generally absent from recently disturbed areas (0 to 5 years post-disturbance; Norton et al. 2000; Schieck and Song 2006). However, vegetation clearing can improve habitat around the disturbance perimeter by creating shrubby edge habitats that are positively associated with Canada warbler abundance (Ball and Bayne 2014; Collins et al. 1982; ECCC 2016a). Firebreaks, utility corridors and road corridors may have created some suitable habitat for Canada warbler in the Base Case because forest edges generally have denser shrub layers than interior forests.

Fire suppression activities have likely had negative effects on Canada warbler habitat availability relative to what was historically available for this species in the RSA. Shrub density is highest in young regenerating (0 to 24 years) and mature forests because light levels are limited in closed-canopy stands characteristic of mid-seral stages (Alaback 1982; McKenzie et al. 2000). Most forested areas in the RSA are 60 to 80 years old and may not provide preferred habitat for Canada warbler; however, there is some uncertainty associated with the age of forests in the RSA (Section 5.6.4.1.3). Forest stands in the LSA are mostly mature (greater than 80 years old) and structurally complex (Section 5.6.4.1.1), and likely provide highly suitable habitat for Canada warbler in the Base Case.

5.6.4.3.2 Habitat Distribution

In the Base Case, suitable Canada warbler habitat is well distributed throughout the RSA (Figure 5.6.4-5) and LSA (Figure 5.6.4-6). Habitat does not appear to be a limiting factor for Canada warbler in the Base Case, as this species is highly mobile and can establish territories in new areas. Canada warblers are considered to have widespread, but clumped distribution in the Ottawa Valley Forest Management Unit (Van Dyke 2011).

Effects from habitat fragmentation on Canada warblers are unclear. Some studies suggest that fragmentation has negative effects on Canada warblers because they are an interior-forest nesting species that avoids edge habitat (Askins and Philbrick 1987; Hobson and Bayne 2000). Other studies suggest Canada warblers are resilient to habitat fragmentation because the species uses early successional and dense shrubby habitat that is often associated with habitat disturbance (Schmiegelow et al. 1997; Schmiegelow and Monkkonen 2002). Whether habitat fragmentation from linear disturbances in the LSA and RSA in the Base Case has had a positive or negative effect on the distribution of Canada warbler habitat in the RSA remains uncertain.

Linear disturbances in the RSA are generally less than 30 m wide and the RSA is composed mostly of forested habitat in patches larger than 10 ha. Similarly, several local roads and two hydroelectric corridors cross the LSA, and a portion of the LDA is contained within the LSA, but the LSA remains mostly forested. Narrow linear disturbances generally do not represent barriers to bird movement (Desrochers and Hannon 1997). St. Clair et al. (1998) found that some forest birds were reluctant to cross gaps greater than 50 m, but would cross gaps of 200 m when no other choice existed. Existing disturbances in the RSA do not likely function as dispersal barriers for this species in the Base Case.

5.6.4.3.3 Survival and Reproduction

Approximately 82% of the Canada warbler breeding range occurs in Canada (ECCC 2016a). The Canadian population of this species is estimated to be 3,000,000 individuals (ECCC 2016a). Abundance estimates of Canada warbler in Ontario suggest a population of 900,000 individuals or approximately 33% of the Canadian population (COSEWIC 2008). In Ontario, results from the OBBA indicated an annual population decline of 0.8% between the first (1981 to 1985) and second (2001 to 2005) atlas periods (Cadman et al. 2007). Long-term Breeding Bird Survey (BBS) data show a decline of Canada warbler abundance of 4.5% per year from 1968 to 2007 (overall 83% decline; ECCC 2016a). Population trends for eastern Canada (Ontario, Quebec and the Maritimes) all show long-term (1968 to 2007) and short-term (1997 to 2007) declines (COSEWIC 2008).

Because the Canada warbler population in Canada has declined by 83% from 1968 to 2007, it is considered a priority species under the Bird Conservation Strategy for the region, which has the objective of doubling current abundance (Environment Canada 2014). The Canada warbler was designated as threatened by COSEWIC in 2008 and was given the same status under Schedule 1 of SARA in 2010. Despite concerning population trend data, the federal recovery strategy concluded that “there are currently adequate numbers of individuals to sustain the species in Canada or increase its abundance with the implementation of proper conservation actions” (ECCC 2016a). The population objective for Canada warbler, as identified in the final federal recovery strategy, is to halt the national decline by 2025, with no more than a 10% decline during this time and ensure a 10-year positive population trend thereafter (ECCC 2016a).

Site-specific surveys in the RSA recorded six Canada warblers in 2007 and seven in 2013. Canada warbler was identified as a confirmed breeder in the OBBA survey square 18US00 and as a possible breeder in the OBBA survey square 18UR19 (Cadman et al. 2007). Canada warblers have been regularly reported in the areas surrounding the RSA (COSEWIC 2008; eBird 2017). The presence of Canada warbler has been confirmed during baseline surveys in the LSA and RSA and is assumed to be breeding in suitable habitat throughout the RSA.

The abundance of Canada warblers is positively related to shrub density (Norton and Hannon 1997; Hallworth et al. 2008). The primary threats to Canada warbler habitat include conversion of land for agriculture, removal of the shrub layer (e.g., from forest harvesting or silviculture), forest harvesting and accidental mortality from collisions with infrastructure (ECCC 2016a). Several theories have been suggested as to the cause of Canada warbler population decline, including habitat loss and degradation (Ball and Bayne 2014), predation on breeding grounds (Bohning-Gaese et al. 1993) and spruce budworm declines (Sleep et al. 2009). A cause-effect relationship has not been established between loss and degradation of wintering habitat and Canada warbler population decline, but loss of primary forest on the wintering grounds is still considered to be a primary potential cause of this species’ decline (ECCC 2016a). It is currently unknown whether breeding habitat is a limiting factor for this species in Canada (ECCC 2016a).

The Canada warbler primarily feeds on flying insects and spiders. Although Canada warbler will feed on various species of insects, it has been found to feed heavily on spruce budworms during outbreaks. Insect populations are declining worldwide, and spruce budworm outbreaks in eastern forests have decreased since 1970; both factors may be contributing to Canada warbler decline (ECCC 2016a). Many aerial-foraging insectivorous birds, such as Canada warbler, have experienced large declines since the 1980s (Blancher et al. 2009; NABCIC 2012). The declines suggest a single cause related to insect abundance as both forest and non-forest aerial-foraging birds are declining (Blancher et al. 2009; Nebel et al. 2010; Nocera et al. 2012; Paquette et al. 2014). Potential causes of reduced availability of insects include habitat loss, changes to timing of peak food abundance from climate change and pesticide use (Nebel et al. 2010; Nocera et al. 2012; Paquette et al. 2014). Insect and bird populations in the RSA have likely been affected by all of these factors in the Base Case. Canada warblers may be susceptible to these factors because their residency on breeding grounds is brief compared to other warblers. Canada warblers are one of the last species to arrive on breeding grounds and one of the first species to leave in the fall (COSEWIC 2008). This behaviour reduces the possibility for raising more than one clutch per year, as well as limiting adaptive capability in regard to climate change (ECCC 2016a).

5.6.4.4 Eastern Whip-poor-will

5.6.4.4.1 Habitat Availability

The NSDF Project is located in breeding habitat for this species, which is the focus of this assessment. Whip-poor-wills (*Antrostomus vociferus*) breed in semi-open or patchy forests and wide-open spaces and avoid dense forest (COSEWIC 2009). Forest structure seems to be more important that forest composition, but whip-poor-wills are most commonly found in dry deciduous or mixed forests throughout most of the species' range (Cink et al. 2017; Beaudry et al. 2010). Whip-poor-wills are also commonly found in rock or sand barrens with scattered trees, old burns, other disturbed sites with early forest succession and pine plantations (Cink et al. 2017; COSEWIC 2009). This species prefers even-aged successional habitats and is uncommon in mature forests, although individuals may use openings in mature forest areas (Bushman and Therres 1988; Government of Ontario 2015b). Nests require tree cover, shade and sparse ground cover and need to be in close proximity to open areas for foraging (MNR 2012). Utility and road corridors may provide suitable habitat for this species (COSEWIC 2009). Critical habitat has been identified in the federal recovery strategy for this species to consider a combination of habitat suitability and habitat occupancy (ECCC 2018a). Suitable habitat is divided into nesting and foraging habitat, and these must be adjacent to one another to qualify for critical habitat designation (ECCC 2018a) and includes the following:

- Suitable nesting habitat includes most forest types, with a higher preference for those at early stages of succession, or edges of forests with a dense tree cover and similar structure types at the ground level. These suitable nesting habitats may also represent rock or sand barrens, savannahs, old burns and conifer plantations (Wilson 1985; Mills 2007; Wilson and Watts 2008).
- Suitable foraging habitat is forest with low tree cover or open habitats, dense shrub cover and poorly drained soils, or agricultural land with scattered shrubs or trees. Foraging activities generally occur within 500 m of the nest.

Vegetation community data were used to map suitable habitat for eastern whip-poor-will in the LSA and RSA as follows:

- all forest stands in the pre-sapling and sapling age class;
- all forest stands (any age class) within a 50 m buffer around wetlands and aquatic habitat; and
- all forest stands (any age class) within a 50 m buffer along the Ottawa River.

Suitable breeding habitat for eastern whip-poor-will consists of forests adjacent to open habitats. Availability of breeding habitat for eastern whip-poor-will was predicted in the Base Case using the vegetation community data (Section 5.6.4.1). Suitable habitats were mixed deciduous and coniferous forests 0 to 34 years of age (i.e., pre-sapling and sapling stages) and forests of any age within 50 m of wetland and aquatic habitats. A total of 13 ha (6.0%) and 769 ha (20.0%) of suitable habitat for eastern whip-poor-will is estimated to be present in the LSA and RSA, respectively, in the Base Case (Table 5.6.4-5).

Table 5.6.4-5: Breeding Habitat Availability for Eastern Whip poor will in the Base Case

Habitat Suitability	Regional Study Area		Local Study Area	
	Area (ha)	Percent (%)	Area (ha)	Percent (%)
Suitable	769	20.0	13	6.0
Unsuitable	3,083	80.0	197	94.0
Total	3,852	100.0	210	100.0

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

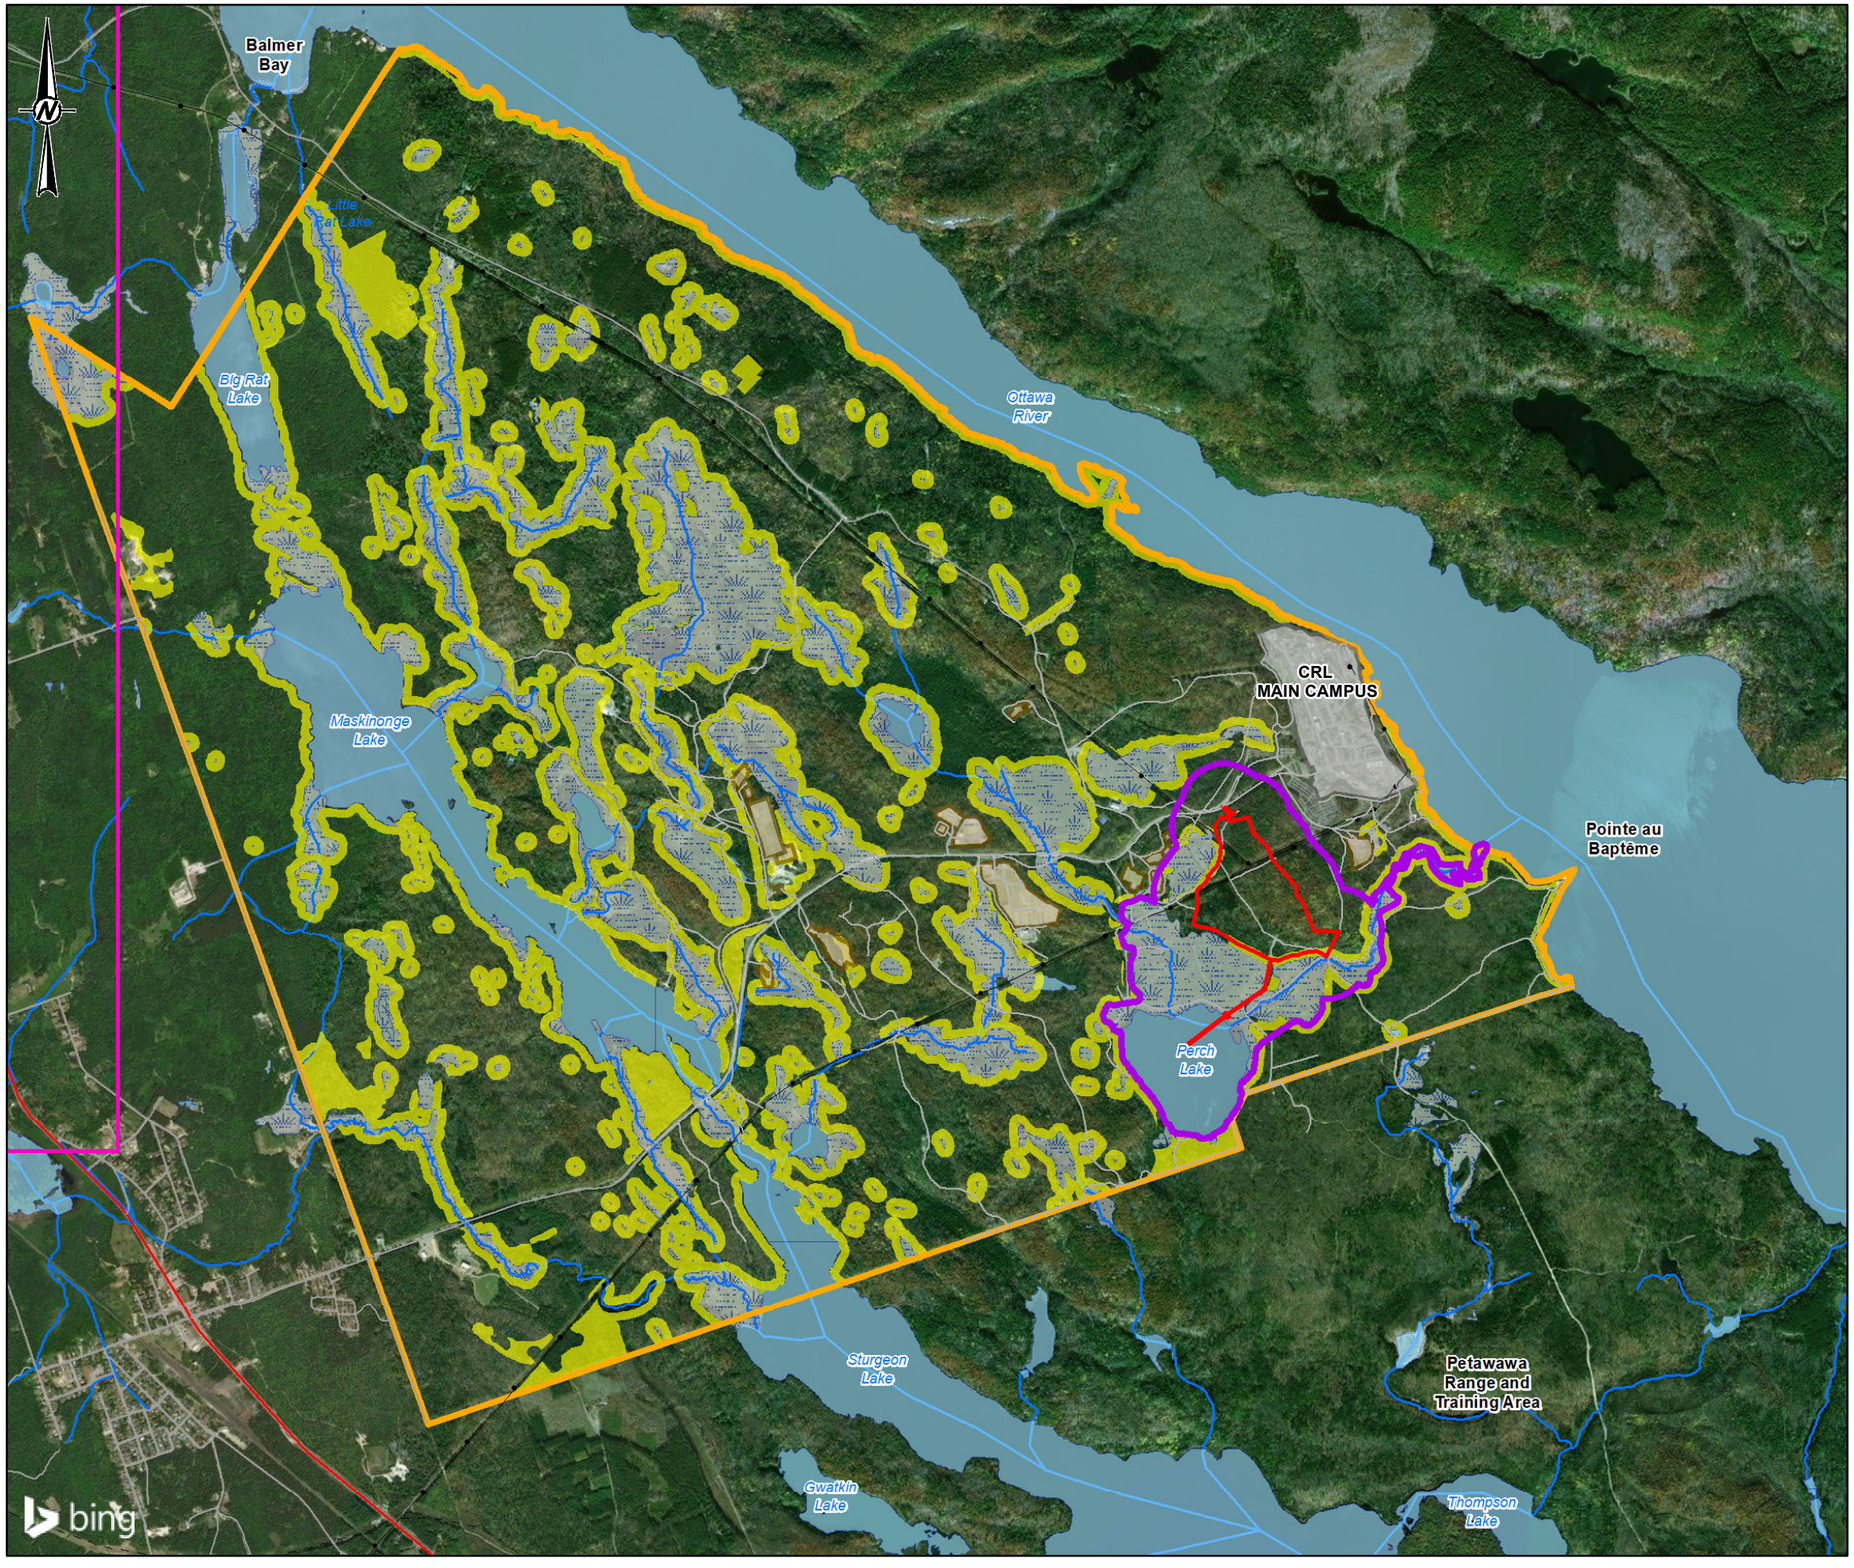
The RSA overlaps one 10 km by 10 km standardized Universal Transverse Mercator (UTM) grid square identified to contain critical habitat for this species (grid square 18TUS00; ECCC 2018a), but the area of overlap is small (28 ha). The exact location of critical habitat in grid squares is not identified in recovery strategies and, therefore, it is unknown whether critical habitat in grid square 18TUS00 overlaps with the RSA. Based on habitat mapping, approximately 3 ha of suitable habitat occurs in the grid square where it overlaps the RSA.

Rock barren habitat is uncommon in the RSA and is predominately found near the Ottawa River shoreline (AECL 2008). Sand barrens have been recorded in the Perch Lake and Maskinonge Lake basins (AECL 2008). Little development has occurred in areas with potential to contain rock and sand barren habitat.

Disturbances can have both positive and negative effects on whip-poor-will habitat availability. Fire suppression activities since the 1940s have likely increased nesting habitat availability relative to what was historically available for this species in the RSA by allowing natural forest succession. Shrub density is lowest in forests 25 to 100 years old because light levels are limited in these forest stands (Alaback 1982; McKenzie et al. 2000). Most forested areas in the RSA are 60 to 80 years old and may therefore provide suitable nesting habitat for whip-poor-will. On the contrary, fire suppression reduces the availability of open habitat and young forest used as foraging habitat by this species. Firebreaks and road and hydroelectric corridors in the RSA may provide suitable foraging habitat for whip-poor-wills (COSEWIC 2009). Larger disturbance areas, such as the WMAs, may provide suitable foraging habitat, especially areas surrounded by suitable nesting habitat (MNR 2012).

5.6.4.4.2 Habitat Distribution

In the Base Case, suitable eastern whip-poor-will habitat is well distributed throughout the RSA (Figure 5.6.4-7) and LSA (Figure 5.6.4-8). Habitat does not appear to be a limiting factor for whip-poor-will in the Base Case, and this species is highly mobile and can establish territories in new areas. The 10 km by 10 km standardized UTM grid square identified to contain critical habitat for this species (grid square 18TUS00; ECCC 2018a) overlaps the extreme northwestern tip of the RSA (Figure 5.6.4-7).



Studies suggest that habitat fragmentation may negatively affect this species because whip-poor-wills avoid small, isolated woodlands (Bushman and Therres 1988; COSEWIC 2009). Distance from large forest tract is an important factor influencing the presence of whip-poor-will (COSEWIC 2009). Fragmentation by roads and other linear disturbances is not anticipated to negatively affect whip-poor-will dispersal in the RSA because most linear disturbances are less than 30 m wide and the RSA is composed primarily of forested habitat.

5.6.4.4.3 Survival and Reproduction

Canada supports an estimated 6% of the global eastern whip-poor-will population (120,000 individuals; ECCC 2018a). Data from the BBS indicate a Canada-wide population decline of 3.19% per year from 2002 to 2012, or 75% loss of the population over this time period (ECCC 2018a). Between the first (1981 to 1985) and second (2001 to 2005) OBBA survey periods, whip-poor-wills declined by 37% (Cadman et al. 2007; ECCC 2018a).

Because the eastern whip-poor-will population in Canada has declined by 75% from 1970 to 2012, they are considered a priority species under the Bird Conservation Strategy for the region (Environment Canada 2014). The eastern whip-poor-will was designated as threatened by COSEWIC in 2009 and was listed under Schedule 1 of SARA as a threatened species in 2011. Despite the concerning population trend data, the federal recovery strategy concluded that individuals that are capable of reproduction are available to sustain the population and improve its abundance (ECCC 2018a). The population and distribution objectives for Canada as defined in the final federal recovery strategy are two-fold. In the short term, it aims to slow the decline of the species such that the population does not decrease by more than 10% (i.e., 12,000 individuals) over the 2018 to 2028 period, and maintain the area of occupancy at 3,000 km^2 or above. In the long-term, the objective is to ensure a positive 10-year population trend starting in 2028 while favouring an increase in the area of occupancy, including the gradual recolonization of areas in the southern portion of the breeding range.

Species-specific surveys for whip-poor-will were completed in the RSA in 2013. Four individuals were recorded as using habitats in the RSA. An additional three birds were recorded using habitats outside the RSA. Eastern whip-poor-will was identified as a possible breeder in the OBBA survey square 18TUS00, but was not recorded in the other OBBA survey squares that overlap the RSA (i.e., 18TUR19 and 18TUS10; Cadman et al. 2007); however, whip-poor-wills have been regularly reported using habitats in areas surrounding the RSA (eBird 2017). A nest has been confirmed in 2019 at CRL 3 km northwest of the SSA.

This page left intentionally blank

The primary threats to eastern whip-poor-wills are reduced availability of insect prey and habitat conversion for agriculture on wintering grounds (ECCC 2018a). Eastern whip-poor-wills feed on many types of flying insects (Cink et al. 2017). Insect populations are declining worldwide, and these declines may be a contributing factor to whip-poor-will population decline (COSEWIC 2009; ECCC 2018a). Many aerial-foraging insectivorous birds, such as whip-poor-will, have experienced large declines since the 1980s (Blancher et al. 2009; NABCIC 2012). Forest and non-forest aerial-foraging birds have experienced drastic population declines, which suggests the major cause of the declines is decreased insect availability (Blancher et al. 2009; Nebel et al. 2010; Nocera et al. 2012; Paquette et al. 2014). Wagner (2012) noted declines for many nocturnal moth species, which are the preferred prey for eastern whip-poor-will (Cink et al. 2017). Potential causes of reduced availability of insects include habitat loss, climate change resulting in a temporal mismatch between reproduction and peak food abundance and pesticide use, which can reduce the abundance and diversity of flying insects (ECCC 2018a; Nebel et al. 2010; Nocera et al. 2012; Paquette et al. 2014). Insect and bird populations in the RSA have likely been affected by all of these factors in the Base Case. Eastern whip-poor-will may be susceptible to these factors because they are primarily aerial insectivores and they have low annual reproductivity.

5.6.4.5 Eastern Wood-pewee

5.6.4.5.1 Habitat Availability

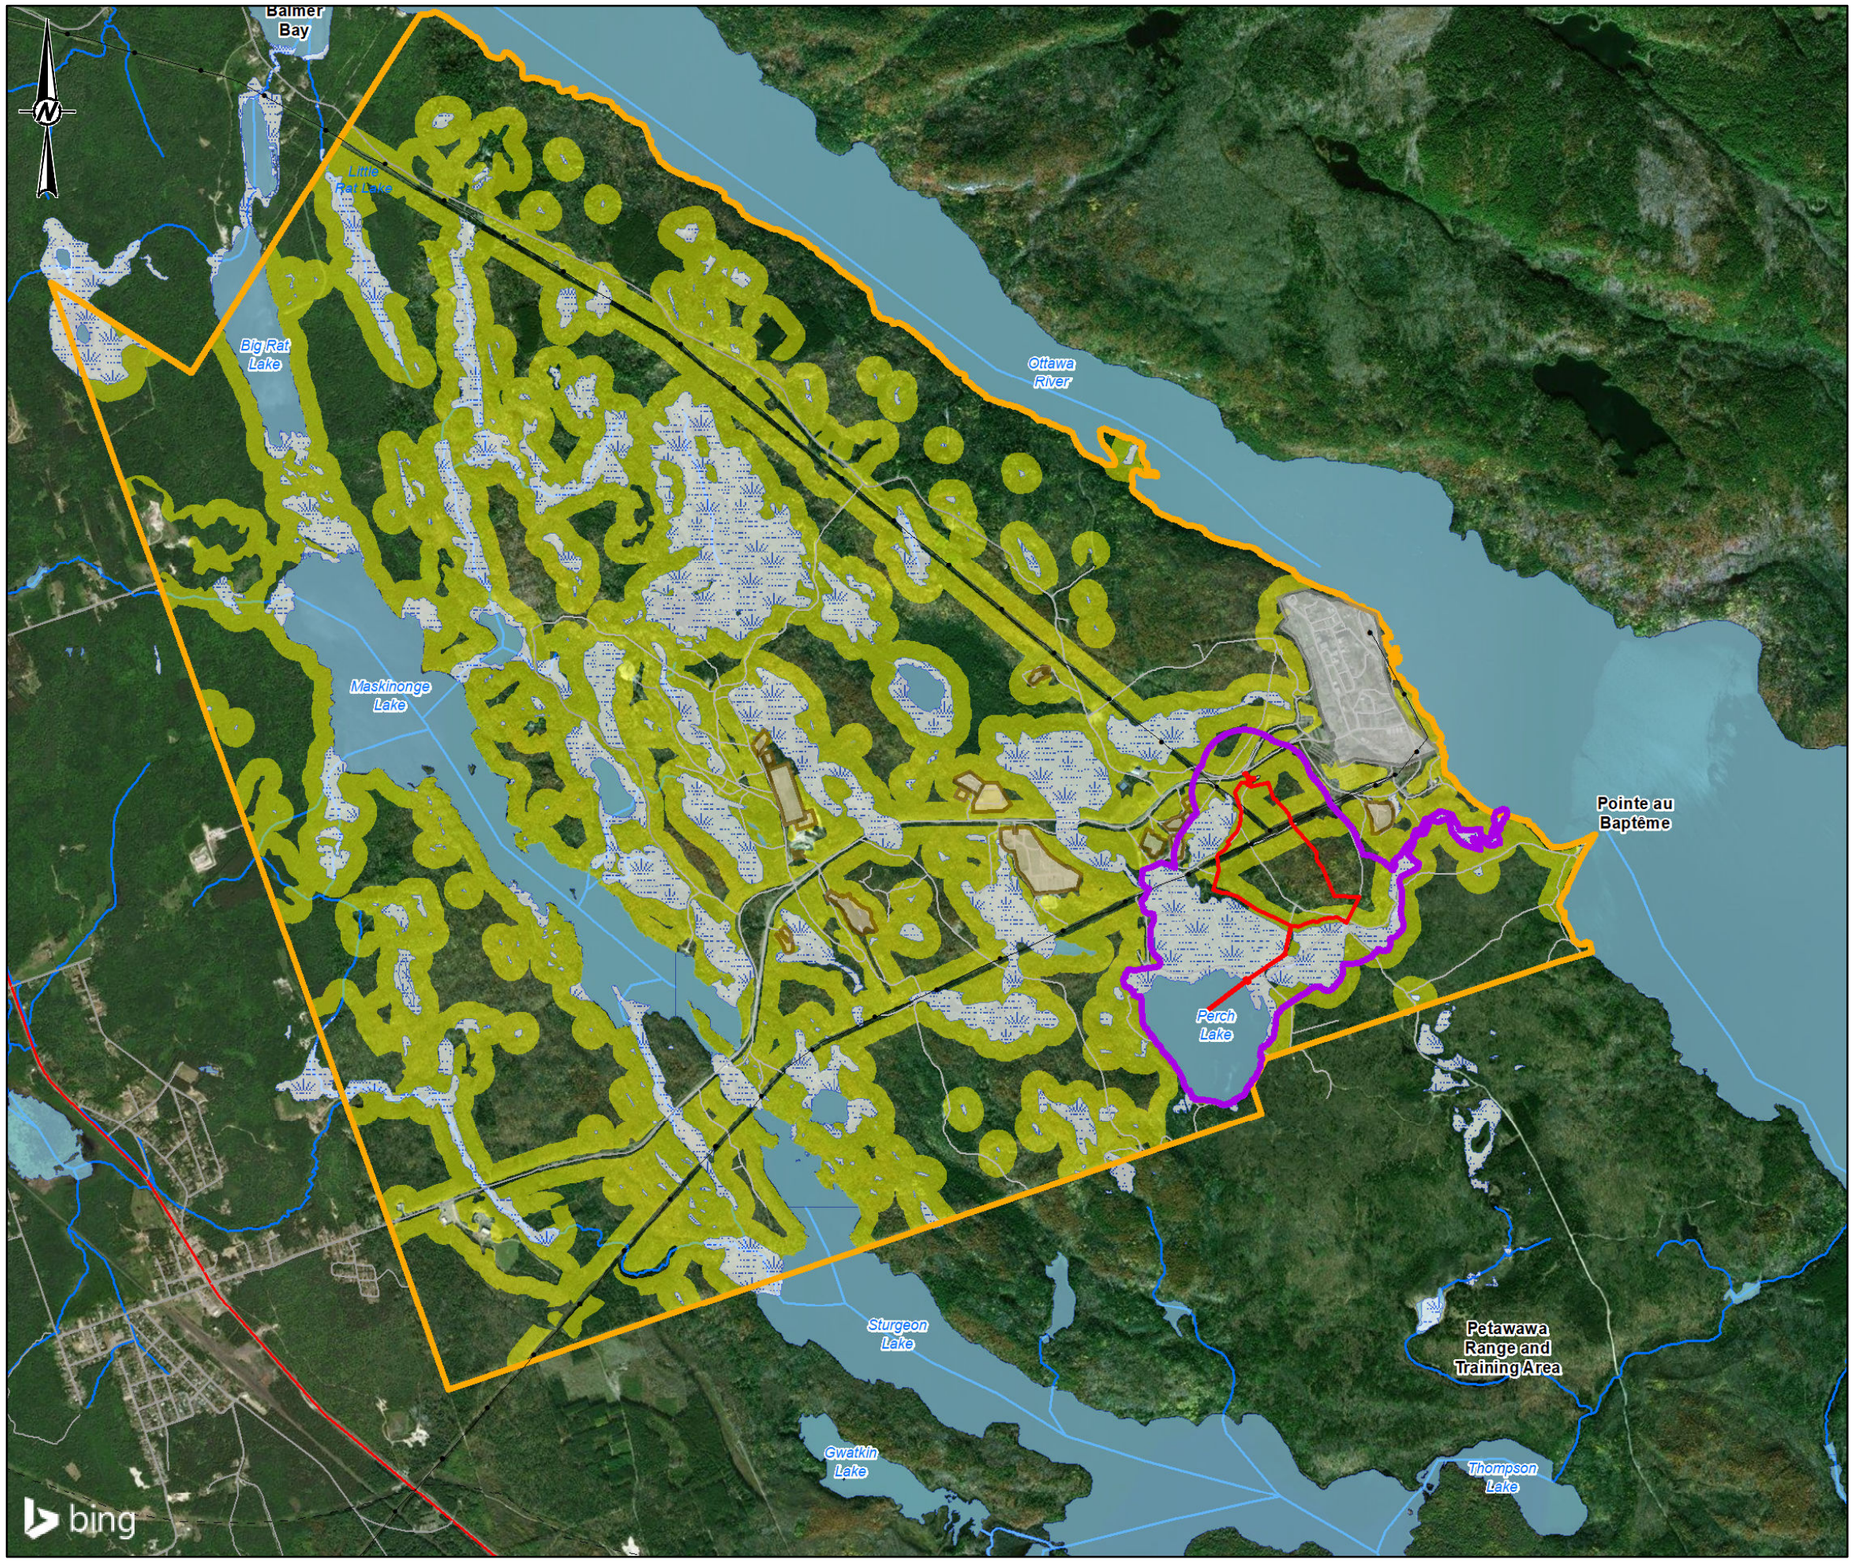
The NSDF Project is located in breeding habitat for this species and breeding habitat is the focus of the habitat availability assessment. Eastern wood-pewee (*Contopus virens*) breeds primarily in intermediate-aged to mature deciduous and mixed forests, typically near a clearing or forest edge (Peck and James 1987; COSEWIC 2012a; Watt et al. 2017). In one study, wood-pewees were most likely to be present in forest stands more than 24 years old (McDermott et al. 2011). Coniferous forests are rarely used by eastern wood-pewee in Ontario (Peck and James 1987). Distance to edge is not quantified in the literature for this species. In the absence of species-specific information, it is assumed a distance of 100 m into the forest reflects edge habitat as defined in provincial guidelines (MNR 2010) and supported by other literature and government sources (e.g., Environment Canada 2007; Terraube et al. 2016). The vegetation community data were used to map suitable habitat for eastern wood-pewee in the LSA and RSA as follows:

- Immature and mature forest stands (any forest type) within 100 m of the forest polygon edge where it abuts open habitat (wetland, aquatic habitat, flooded area, pre-sapling forest of any type, unclassified).

A total of 54 ha (25.5%) and 1,603 ha (41.6%) of suitable habitat for eastern wood-pewee is estimated to be present in the LSA and RSA, respectively, in the Base Case (Table 5.6.4-6).

Table 5.6.4-6: Breeding Habitat Availability for Eastern Wood-pewee in the Base Case

Habitat Suitability	Regional Study Area		Local Study Area	
	Area (ha)	Percent (%)	Area (ha)	Percent (%)
Suitable	1,603	41.6	54	25.5
Unsuitable	2,250	58.4	156	74.5
Total	3,853	100.0	210	100.0



Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

Disturbances can have both positive and negative effects on eastern wood-pewee habitat availability. Fire suppression activities since the 1940s have likely increased nesting habitat availability relative to what was historically available for this species in the RSA by allowing natural forest succession. Most of the forest stands in the RSA are of immature or mature structural stage and may therefore provide suitable nesting habitat for wood-pewees. However, on-going fire suppression reduces the opportunity for forest disturbance that would result in the creation of edge habitat favoured by this species. Forest edges along firebreaks, utility corridors and roads in the RSA may provide suitable habitat for eastern wood-pewee.

5.6.4.5.2 Habitat Distribution

In the Base Case, suitable eastern wood-pewee habitat is well distributed throughout the RSA (Figure 5.6.4-9) and LSA (Figure 5.6.4-10). Habitat does not appear to be a limiting factor for eastern wood-pewee in the Base Case, and this species is highly mobile and can establish territories in new areas. Fragmentation by roads and other linear disturbances is not anticipated to negatively affect wood-pewee dispersal in the RSA because most linear disturbances are less than 30 m wide and the RSA is composed primarily of forested habitat.

Eastern wood-pewees appear fairly tolerant of habitat fragmentation, given their preference for edge habitat, and forest patch size has not been found to be a strong determinant of occupancy (COSEWIC 2012a). The overall amount of forest on the landscape may be more important than local forest patch size (Perkins et al. 2003 in COSEWIC 2012a). However, large tracts of contiguous forest are likely to reduce habitat suitability for wood-pewees on the landscape due to the lack of edge habitat favoured by this species (COSEWIC 2012a). Habitat fragmentation from linear disturbances present in the LSA and RSA in the Base Case has likely had positive effects on wood-pewee habitat distribution by creating forest edge habitat.

5.6.4.5.3 Survival and Reproduction

The Canadian population of eastern wood-pewee is estimated at 435,000 individuals, with the majority (69%) of the population concentrated in southern Ontario (COSEWIC 2012a). Population data are not available for the RSA, but the RSA falls within an area where population density is believed to be high (Cadman et al. 2007). Eastern wood-pewee has been recorded in the RSA eight times during site-specific surveys, including in the LSA. Several observations were made in the RSA and vicinity between 2002 and 2013 (eBird 2017) and the species was detected during monitoring surveys in the SSA in 2017 (CNL 2017d). Eastern wood-pewee was identified as a probable breeder in the OBBA survey square 18US10, and a possible breeder in the other OBBA survey squares that overlap the RSA (i.e., 18UR19 and 18US00; Cadman et al. 2007).

BBS data identify concerning long-term and short-term declines in Canadian and Ontario populations (COSEWIC 2012a). Eastern wood-pewee is considered a priority species under the Bird Conservation Strategy, with the objective of increasing abundance in Ontario (Environment Canada 2014). Eastern wood-pewee was designated as Special Concern by COSEWIC in 2012 and was listed under Schedule 1 of SARA as a Special Concern species in November 2017. Given the recent listing, a federal management plan has not yet been developed for this species, but it is expected that the population objective for Ontario will be to increase abundance consistent with the Bird Conservation Strategy objective.

Given the species' use of a variety of forest types including secondary growth forest (which is increasing in eastern Ontario) and affinity to forest edges, habitat loss and fragmentation on breeding grounds are not likely to explain the large population declines observed for eastern wood-pewee in Canada (COSEWIC 2012a). Change in flying insect prey availability is a suspected source of population decline for this and other aerial insectivorous bird species, which as a guild have experienced substantial population declines in recent decades (Nebel et al. 2010; COSEWIC 2012a).

5.6.4.6 Golden-winged Warbler

5.6.4.6.1 Habitat Availability

The NSDF Project is located in breeding habitat for this species, which is the focus of this assessment. Golden-winged warbler (*Vermivora chrysoptera*) is a habitat specialist that relies on early successional habitat (10 to 30 years after disturbance) (COSEWIC 2006). Suitable breeding habitat for golden-winged warbler consists of early successional habitat primarily at the interface of forest and open habitat (i.e., edge habitat). Forest type appears to be less important for this species than habitat structure (Confer et al. 2011), but most individuals are found in shrubby, deciduous habitats (Beaudry et al. 2010). Golden-winged warblers prefer habitats with low to moderate canopy cover and moderate shrub and herb cover (Confer et al. 2011). Critical habitat has been identified in the federal recovery strategy for this species to be a combination of habitat suitability and habitat occupancy, where suitable habitat has been identified as the interface (shared edge) between young forest and open habitat in a forest landscape (ECCC 2016a). Nests are often located within 200 m on either side of a forest edge (ECCC 2016a). Where the open habitat contains few shrubs or scattered trees, golden-winged warblers will use the habitat less extensively, outward to about 50 m (ECCC 2016a). Edges can be along roads, trails, cutblocks and other anthropogenic disturbances in addition to natural borders (ECCC 2016a). The vegetation community data were used to map suitable habitat for golden-winged warbler in the LSA and RSA as follows:

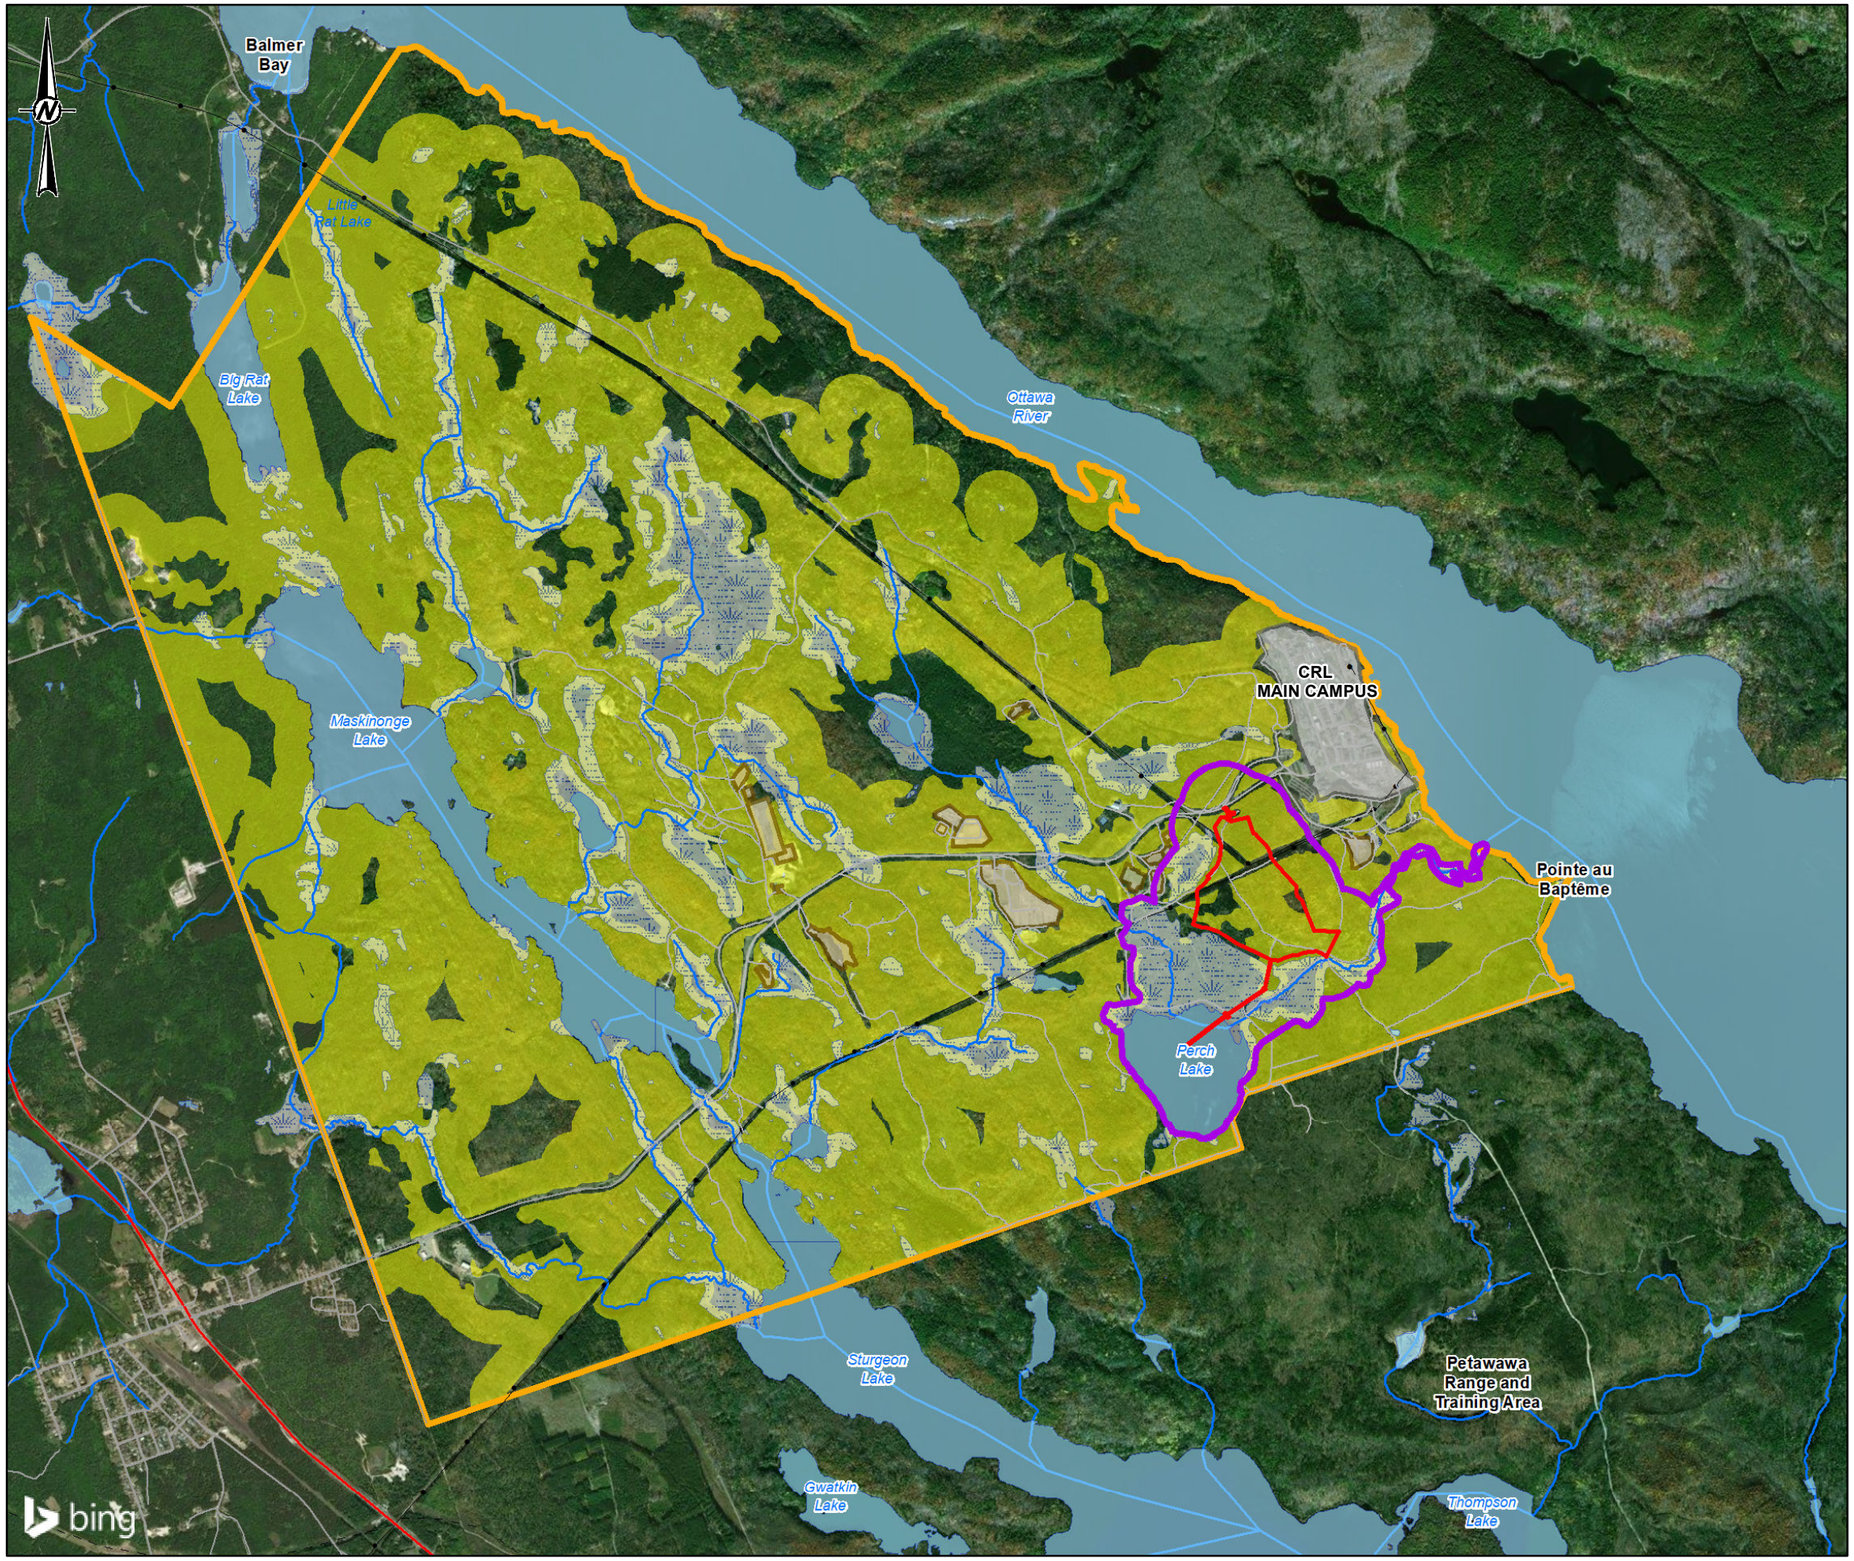
- deciduous forest stands (any age class) within 200 m of the forest polygon edge where it abuts open habitat (wetland, aquatic habitat, flooded area, pre-sapling forest of any type, unclassified);

- mixed forest stands (any age class) within 200 m of the forest polygon edge where it abuts open habitat (wetland, aquatic habitat, flooded area, pre-sapling forest of any type, unclassified); and
- 50 m buffer into the following polygon types where they abut deciduous or mixed forest stands (any age class):
  - wetland;
  - flooded area; and
  - pre-sapling forest of any type.

A total of 102 ha (48.6%) and 2,621 ha (68.0%) of suitable habitat for golden-winged warbler is estimated to be present in the LSA and RSA, respectively, in the Base Case (Table 5.6.4-7). The federal recovery strategy identified focal areas across the species' range that contain core populations that sustain the current breeding distribution and are important for expanding the population into adjacent areas (ECCC 2016a). The RSA falls within focal area GL10, but not in grid squares identified to contain critical habitat within the focal area (ECCC 2016a; Figure 5.6.4-11).

Table 5.6.4-7: Breeding Habitat Availability for Golden winged Warbler in the Base Case

Habitat Suitability	Regional Study Area		Local Study Area	
	Area (ha)	Percent (%)	Area (ha)	Percent (%)
Suitable	2,621	68.0	102	48.6
Unsuitable	1,232	32.0	108	51.4
Total	3,853	100.0	210	100.0



Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

Disturbances can have both positive and negative effects on golden-winged warbler habitat availability. Fire suppression activities since the 1940s have likely had negative effects on golden-winged warbler habitat relative to what was historically available for this species in the RSA because golden-winged warblers are reliant on early successional habitat. Maturation of young forests is considered a threat to golden-winged warbler populations in Canada (ECCC 2016a). Vegetation clearing can improve habitat around the disturbance perimeter by creating early succession habitats that are positively associated with species abundance (Askins 1994; Beaudry et al. 2010; Confer et al. 2011). However, vegetation clearing can also result in a net loss of habitat. Disturbances with higher edge-to-interior ratios are more likely to have positive effects on golden-winged warbler habitat availability. Edge habitat along firebreaks, utility corridors and roads may provide suitable habitat for golden-winged warbler.

5.6.4.6.2 Habitat Distribution

In the Base Case, suitable golden-winged warbler habitat is well distributed throughout the RSA (Figure 5.6.4-11) and LSA (Figure 5.6.4-12). Habitat does not appear to be a limiting factor for golden-winged warbler in the Base Case, and this species is highly mobile and can establish territories in new areas. Habitat fragmentation from linear disturbances present in the LSA and RSA in the Base Case has likely had positive effects on golden-winged warbler habitat distribution. Golden-winged warblers are edge habitat specialists, and edge habitat is increased with linear developments. However, extensive habitat fragmentation that results in small forest patches may negatively affect this species; one study found golden-winged warblers did not use forest patches that are smaller than 10 ha (Confer and Knapp 1981). Linear disturbances in the RSA are generally less than 30 m wide and the RSA is composed mostly of forested habitat in patches larger than 10 ha. Similarly, several local roads and two hydroelectric corridors cross the LSA and a portion of the LDA is contained within the LSA, but the LSA remains mostly forested. Narrow linear disturbances generally do not represent barriers to bird movement (Desrochers and Hannon 1997). Further, linear disturbances are less likely to be perceived as movement barriers by edge species such as golden-winged warblers than by interior-forest species. Existing disturbances in the RSA do not likely function as dispersal barriers for this species in the Base Case.

5.6.4.6.3 Survival and Reproduction

Canada is estimated to support 17% of the global population of golden-winged warblers, with most individuals occurring in Ontario (ECCC 2016a). Historical analysis of golden-winged warblers noted a dramatic population decline of 79% between 1993 and 2002; however, more recent analysis of BBS and OBBA data suggests that golden-winged warbler populations have been stable between 1970 and 2012 (ECCC 2016a).

Golden-winged warbler is considered a priority species under the Bird Conservation Strategy, with the objective of doubling current abundance (Environment Canada 2014). Golden-winged warbler was designated as threatened by COSEWIC in 2006 and was listed under Schedule 1 of SARA as a threatened species in 2007. The population objective for golden-winged warbler, as identified in the federal recovery strategy, is to maintain self-sustaining populations in the focal areas in Manitoba, Ontario and Quebec, while maintaining, at a minimum, the current abundance of approximately 35,000 pairs in Canada (ECCC 2016a).

Population data are not available for the RSA, but the RSA falls within one of the focal areas (GL10) identified in the federal recovery strategy to contain core populations that sustain the current breeding distribution and are important for expanding the population into adjacent areas (ECCC 2016a). There are occurrence records for golden-winged warbler throughout the Ottawa Valley Forest Management Unit (Van Dyke 2011). Golden-winged warblers have been recorded in the RSA two times during site-specific surveys (including in the LSA), and once during non-site-specific surveys (eBird 2017). Golden-winged warbler was identified as a confirmed breeder in the OBBA survey square 18US00, but was not recorded in the other OBBA survey squares that overlap the RSA (i.e., 18UR19 and 18US10; Cadman et al. 2007). Observations of golden-winged warbler were recorded in Chalk River in 1969 and 1970 (eBird 2017). In recent years, most observations of golden-winged warbler near the RSA have been reported south of Lac du Bois Dur (eBird 2017).

The primary threat to golden-winged warbler populations is considered to be hybridization with blue-winged warblers (*Vermivora cyanoptera*; ECCC 2016a); however, the current range of blue-winged warbler does not approach the vicinity of the RSA (Gill et al. 2001). Further, a recent study found that only six genomic regions differ between golden-winged and blue-winged warblers (Toews et al. 2016). This suggests golden-winged and blue-winged warblers are the same species, and therefore hybridization may not be a threat to the sustainability of golden-winged warbler populations.

5.6.4.7 Wood Thrush

5.6.4.7.1 Habitat Availability

The NSDF Project is located in breeding habitat for wood thrush (*Hylocichla mustelina*). In Ontario, wood thrush breeds in moist, deciduous hardwood or mixed forest stands that are often previously disturbed, with a dense deciduous understory, open forest floor with moist soil and decaying leaf litter, and tall trees for singing perches (COSEWIC 2012b). Due to its recent listing under SARA (November 2017), a federal recovery strategy has not yet been developed for wood thrush, and therefore critical habitat has not yet been defined for this species.
The vegetation community data were used to map suitable habitat for wood thrush in the LSA and RSA as follows:

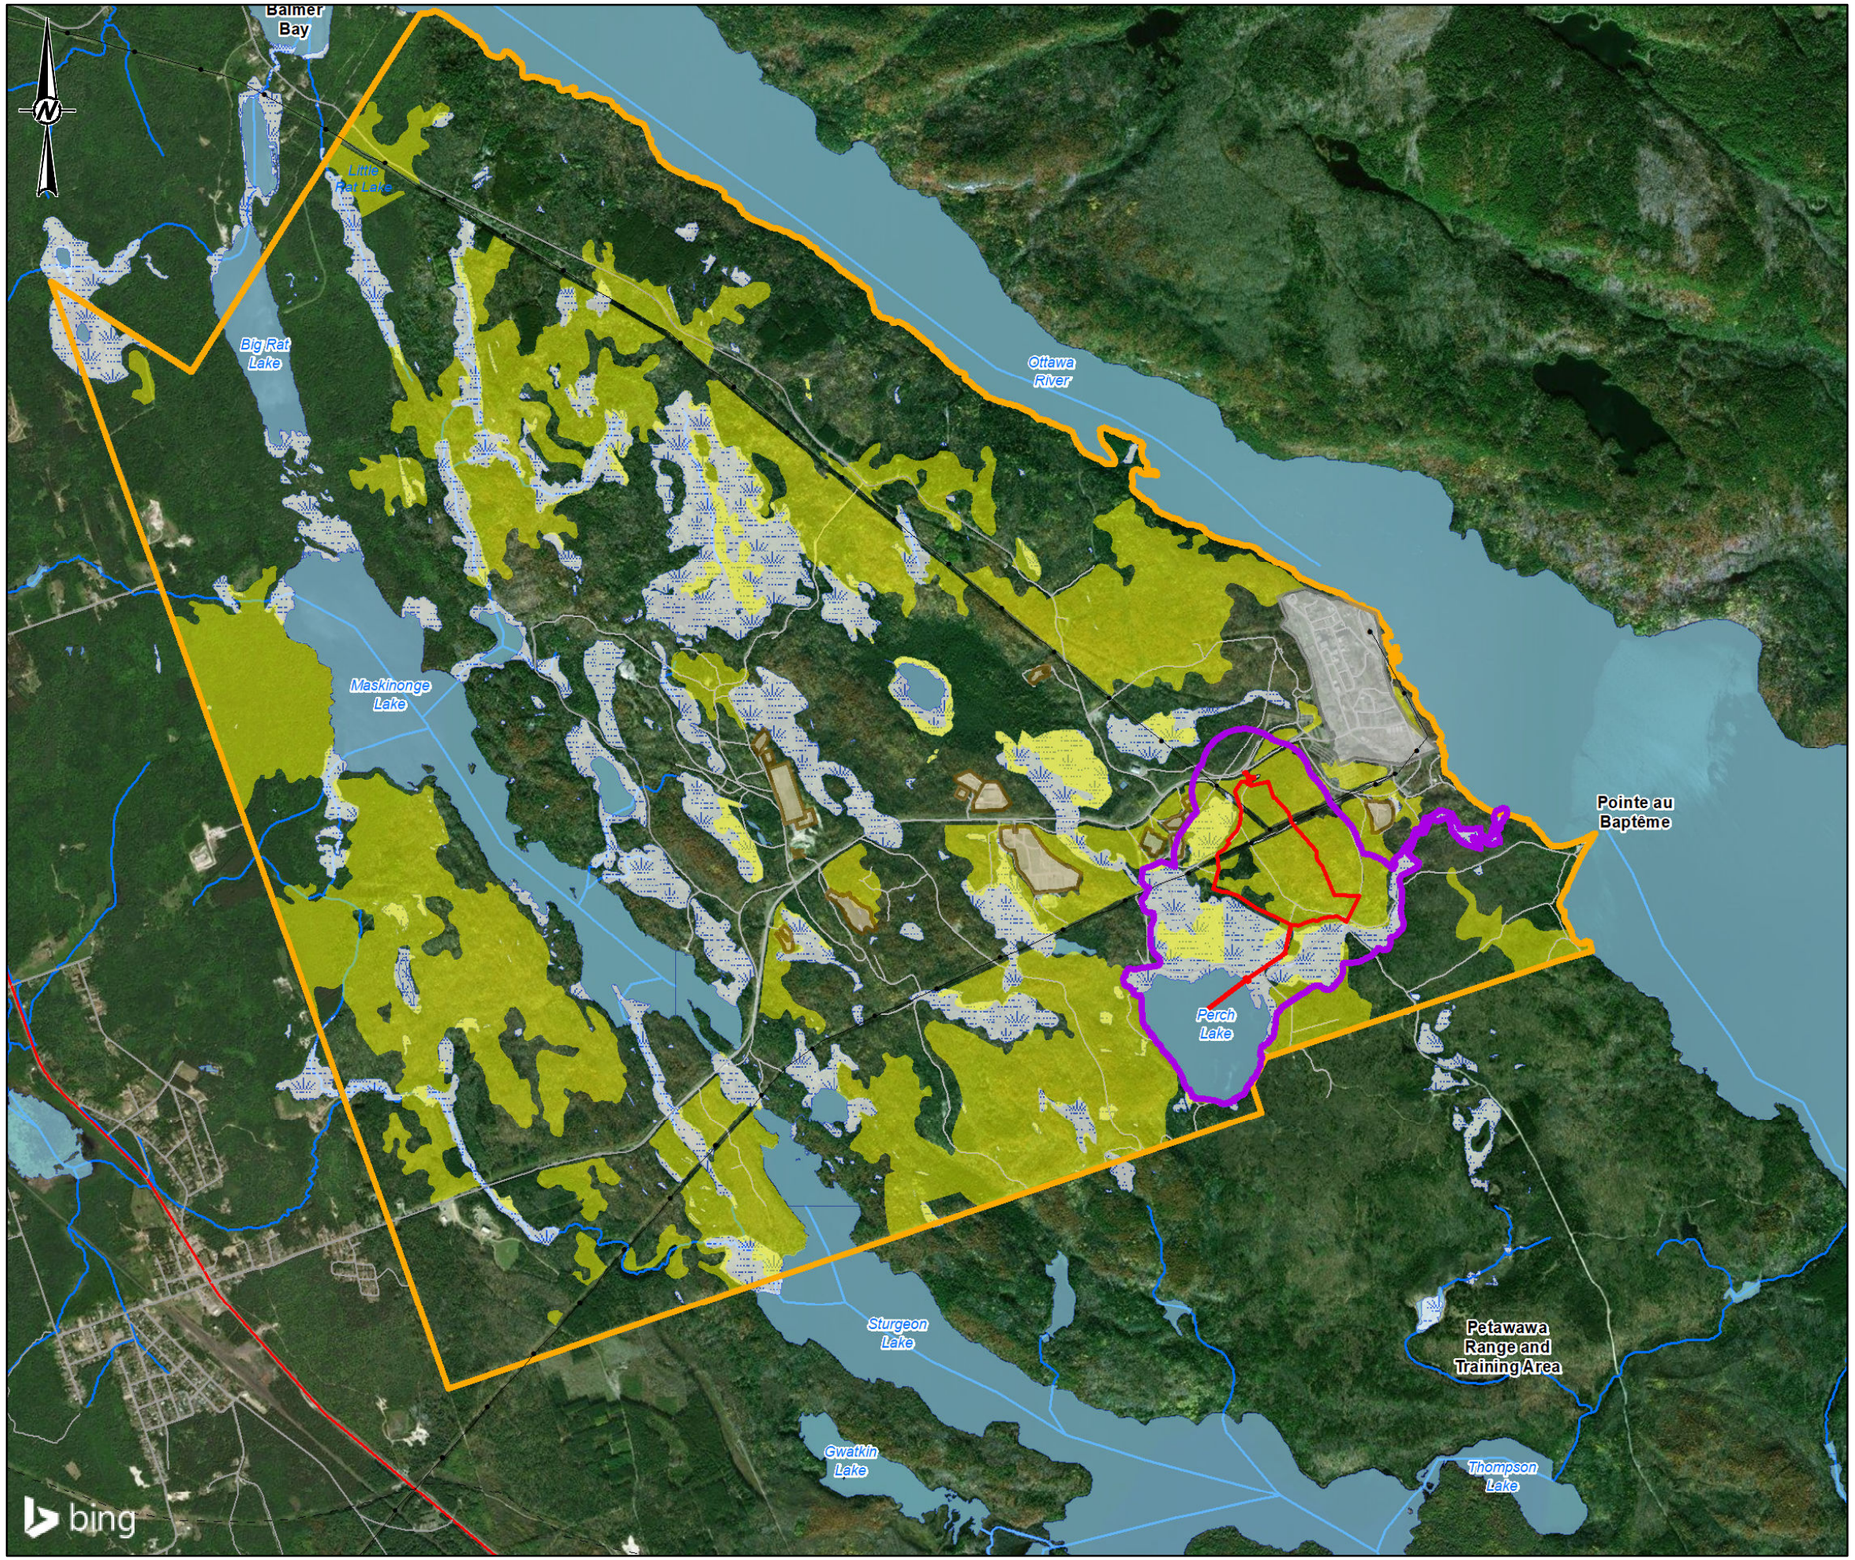
- mature deciduous and mixedwood forest stands; and
- mature treed swamps.

A total of 86 ha (41.0%) and 1,076 ha (27.9%) of suitable habitat for wood thrush is estimated to be present in the LSA and RSA, respectively, in the Base Case (Table 5.6.4-8).

Table 5.6.4-8: Breeding Habitat Availability for Wood Thrush in the Base Case

Habitat Suitability	Regional Study Area		Local Study Area	
	Area (ha)	Percent (%)	Area (ha)	Percent (%)
Suitable	1,076	27.9	86	41.0
Unsuitable	2,777	72.1	124	59.0
Total	3,853	100.0	210	100.0

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.



Wood thrushes in Ontario appear to prefer second-growth over mature forest (Peck and James 1987), suggesting that mid- to long-term effects of forestry are positive and wood thrushes in the RSA may have benefitted from historical logging, though initially this disturbance would have removed habitat. Similar observations of increased forest habitat use have been made following other disturbances, such as the major ice storm that affected much of southeastern Ontario in 1998 (COSEWIC 2012b). Periodic localized disturbances create openings in the forest that promote the development of a dense understory favoured by this species.

Most forested areas in the RSA are 60 to 80 years old and may not provide preferred habitat for wood thrush because these mid-seral stage forests typically have closed canopies that limit light penetration and development of the understory important for this species (Alaback 1982; McKenzie et al. 2000). However, there is some uncertainty associated with the age of forests in the RSA (Section 5.6.4.1.3). Forest stands in the LSA are mostly mature (greater than 80 years old) and structurally complex (Section 5.6.4.1.3), and likely provide highly suitable habitat for wood thrush in the Base Case.

5.6.4.7.2 Habitat Distribution

In the Base Case, suitable wood thrush habitat is well distributed throughout the RSA (Figure 5.6.4-13) and LSA (Figure 5.6.4-14). Habitats do not appear to be isolated from one another for wood thrush in the Base Case, and this species is highly mobile and can establish territories in new areas.

Wood thrushes appear tolerant of habitat fragmentation, nesting in woodlots as small as 0.4 ha (COSEWIC 2012b). The overall amount of forest on the landscape may be more important than local forest patch size; adverse effects of forest fragmentation on habitat use by wood thrush appear more pronounced in landscapes where overall forest cover is limited (Evans et al. 2011). Additionally, studies in forested landscapes in Ontario suggest populations in fragmented forests can be self-sustaining (COSEWIC 2012b).

5.6.4.7.3 Survival and Reproduction

The Canadian population of wood thrush is estimated at 665,000 individuals, with highest densities in southeastern Ontario and southern Quebec (COSEWIC 2012b). Population data are not available for the RSA, but information at broader spatial scales suggests that the RSA falls within an area of moderate population density (COSEWIC 2012b). Wood thrush was identified as a probable breeder in the OBBA survey square 18US10, and a possible breeder in the other OBBA survey squares that overlap the RSA (i.e., 18UR19 and 18US00; Cadman et al. 2007). Two wood thrush individuals were recorded in the SSA during breeding bird surveys conducted for the NSDF Project in 2017 (CNL 2017d). One wood thrush was recorded in the RSA in 2003 and several other observations have been made in the vicinity of the RSA between 2001 and 2014 (eBird 2017).

Nest parasitism (i.e., laying eggs in the nests of other species) by brown-headed cowbirds (*Molothrus ater*) is considered a major threat to this species, with reported parasitism rates in Ontario averaging 33% and reaching as high as 60% (COSEWIC 2012b). Parasitism rates are markedly increased in suburban areas and other highly fragmented landscapes that contain open habitat preferred by cowbirds (Lowther 1993; COSEWIC 2012b), although consequences to reproductive success are not consistently observed (Phillips et al. 2005).

Wood thrush is considered a priority species under the Bird Conservation Strategy, with the objective of maintaining current abundance (Environment Canada 2014). Wood thrush was designated as threatened by COSEWIC in 2012 and was listed under Schedule 1 of SARA as a threatened species in November 2017. Given the recent listing, a federal recovery strategy has not yet been developed for this species, but the population objective for Ontario populations will likely be to maintain self-sustaining populations. Despite declines throughout the range of the wood thrush, Ontario populations appear to be currently self-sustaining (COSEWIC 2012b).

5.6.4.8 Bats

5.6.4.8.1 Habitat Availability

All Canadian bat species have four primary habitat requirements: hibernacula, swarming sites, roosts and foraging areas. Maternity roost sites and, especially, hibernacula are considered to be the main limiting habitat features for little brown myotis (*Myotis lucifugus*), northern myotis (*Myotis septentrionalis*) and tri-colored bat (*Perimyotis subflavus*) within their ranges (COSEWIC 2013). Critical habitat for the three SARA-listed bat species has only been partially identified for hibernacula. However, the majority of locations for maternity roosts are either unknown or undocumented (ECCC 2018c). As such, maternity roosts are not identified as critical habitat under the 2018 recovery strategy (ECCC 2018c).

Within the RSA, the potential for hibernacula in exposed bedrock that typically forms caves (i.e., karst topography with limestone, dolomite and gypsum-containing minerals) was coarsely assessed at an overview-level. Figure 5.3.1-3, which describes surficial geology in the RSA, indicates the potential for bat hibernacula is low across the RSA, because these mineral types are not present. CNL biologists have not conducted surveys to date that would confirm the presence or absence of hibernacula or potential hibernacula features within the RSA; however, the potential for hibernacula to be present within the RSA is considered to be low. Foraging habitat requirements are varied between the three species representing this VC and not likely limiting in the environment. As a result, the focus of this assessment is on potential maternity roost habitat.

Based on research conducted to date on maternity roosting behaviour in natural habitats, older forests are generally preferred by bats, including the three SARA-listed species represented by this VC, likely because of higher snag availability (in the case of little brown myotis and northern myotis; COSEWIC 2013). Snags contain cavities and loose bark required for sheltering roosting females and pups (ECCC 2018c). Two of the three species (little brown bat and northern myotis) show a preference for large-diameter (i.e., older) trees and little brown myotis and tri-colored bat females show evidence of philopatry in roost selection (the tendency to return to the same home area following hibernation; COSEWIC 2013; ECCC 2018c).

There is considerable variation in preferred roost tree species. Lacki et al. (2007) determined that little brown myotis most often roost in large trembling aspen (*Populus tremuloides*), but also in white spruce and red spruce (*Picea rubens*). Olson and Barclay (2013) found the majority of roosts to be located in trembling aspen or balsam poplar (*Populus balsamifera*). In Alberta's boreal forest, females are known to locate maternity roosts in tall trees of the genus *Populus* (i.e., balsam poplar, trembling aspen and cottonwood) with early stages of decay, located in old forest stands with moderate canopy cover (Crampton and Barclay 1998). Mature poplar-leading forest stands are common within the RSA. However, preferred roost tree species may vary by region and availability in the forest community.

As a conservative, coarse-scale estimation of potential maternity roost habitat within the RSA that applies to all three bat species, all of the oldest forest stands (i.e., mature age class) of all forest types within the RSA were included. The vegetation community data were used to determine the availability of forests or swamp wetland types with the following characteristics representing recorded maternity roost habitat preferences for little brown myotis and northern myotis:

- mature forest stands (all types; age of trees depending on tree species composition); and
- mature treed swamps (age of trees depending on tree species composition).

Anthropogenic structures such as buildings, bridges and bat boxes are used for maternity roosts by little brown myotis and less commonly by northern myotis (Whitaker et al. 2006). There are no such anthropogenic structures in the SSA.

A total of 1,149 ha (30.0%) and 86 ha (41.0%) of suitable maternity roost habitat for bats is estimated to occur in the RSA and LSA respectively, in the Base Case (Table 5.6.4-9). Within the SSA, most of the forested area is suitable, with the exception of the two coniferous forest stands, East Mattawa Road and two hydroelectric corridors.

Table 5.6.4-9: Maternity Roosting Habitat Availability for Bats in the Base Case

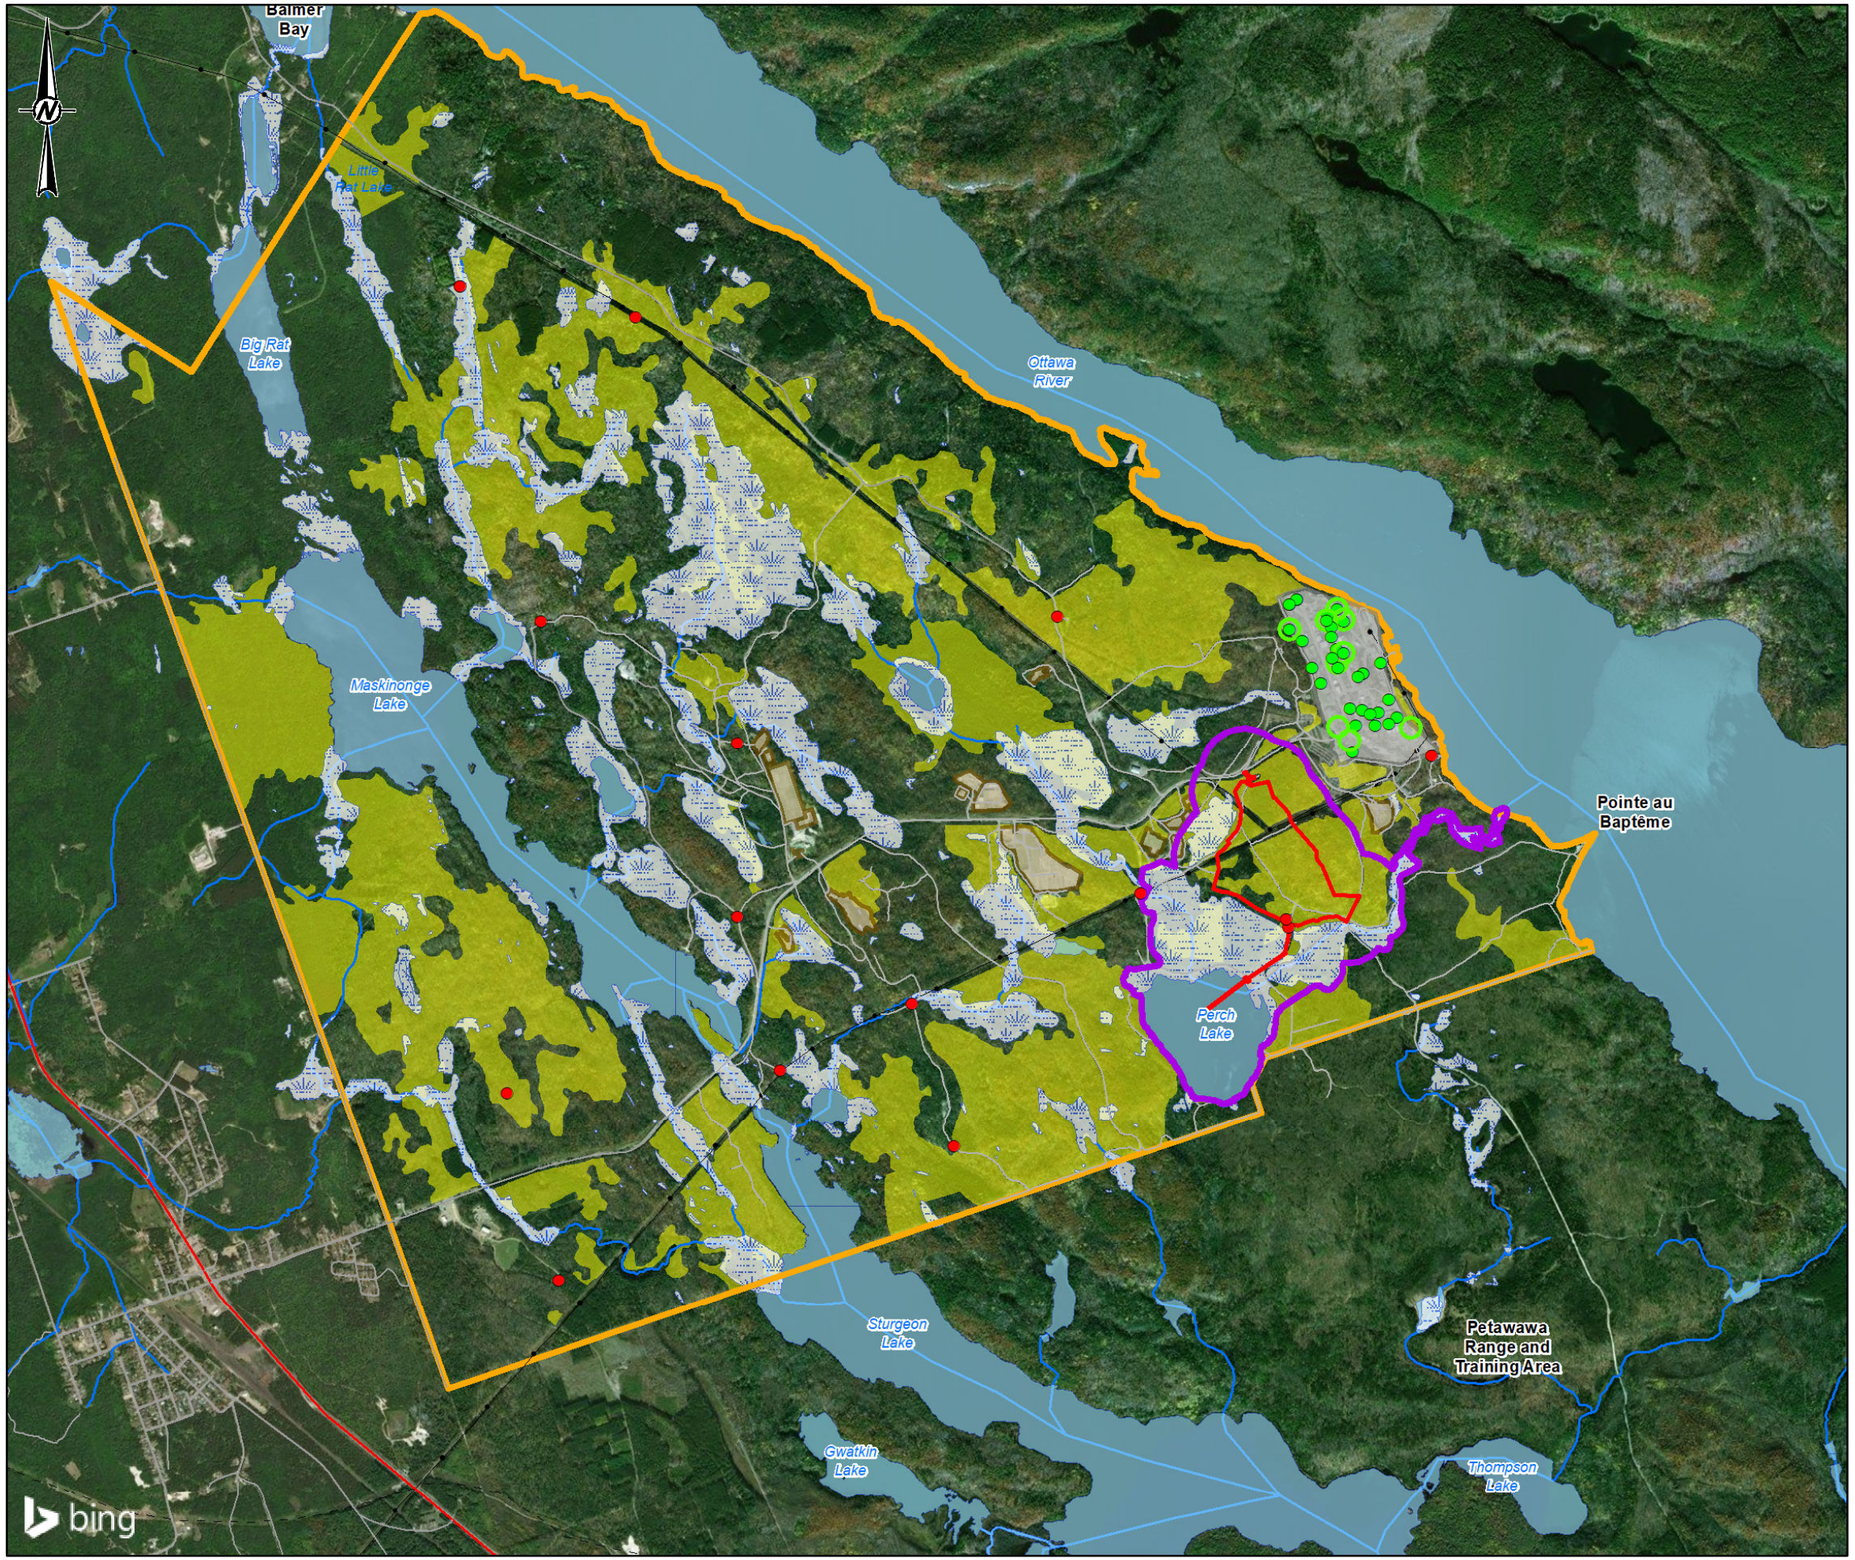
Habitat Suitability	Regional Study Area		Local Study Area	
	Area (ha)	Percent (%)	Area (ha)	Percent (%)
Suitable	1,149	30.0	86	41.0
Unsuitable	2,704	70.0	124	59.0
Total	3,853	100.0	210	100.0

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

CNL biologists have conducted acoustic monitoring surveys to determine the composition of the bat community at specific areas within the CRL site since 2014. The 2015 surveys focused on the CRL main campus, and 2016 to 2018 surveys covered a broader area, including the SSA and LSA. These surveys have determined the presence of all three SARA-listed species, little brown myotis, northern myotis and tri-colored bat, using habitats within the LSA.

Acoustic monitoring is not sufficient to determine the location of roosts or to confirm that habitat within the LSA is used for roosting by bats, because the bats recorded by acoustic monitors could fly several kilometres per night and roost in other areas. In order to provide appropriate protection it is necessary to understand where roosts are, the number of individuals using these roosts as well as specific habitat requirements. To address this issue, CNL has begun a research project in 2019 and will continue the project in 2020, which will involve netting for all three federally-listed bat species and affixing radio transmitters to select individuals. These individuals will be tracked to their maternity roosts and these roosts will be monitored for activity levels to determine the size and importance of each roost. In addition to determining the location of maternity roosts, the type of habitat being used for each roost will be assessed. The field work began in 2019 and resulted in 20 bats being captured and fitted with radio-transmitters. Those bats led to the identification of 15 different tree roosts composed mainly of large-tooth aspen (*Populus grandidendata*).

Information collected during the 2019-2020 telemetry study will allow for increased protection of maternity roosts on the CRL site, as well as aiding in protecting the species at a larger landscape level as the research conducted will increase the knowledge of local habitat requirements. With a greater understanding of important biophysical attributes for maternity roosts these elements can be protected. This information will be used for the development of a Sustainable Forest Management Plan at CRL. Currently, CRL is collaborating with Natural Resources Canada (NRCan) - Petawawa Research Forest (PRF) to develop a Sustainable Forest Management Plan for the CRL site and the PRF due to common elements for both organizations. The process will include establishing objectives (e.g., maintaining bat habitat and managing fuel load) as well as an advisory committee. Input will be solicited from stakeholders and Indigenous communities and organizations.



Because the forest types present in the LSA are consistent with roosting habitat preferences and because SARA-listed bats have been confirmed using this habitat, this assessment applies the precautionary principle and assumes that the habitat is used for maternity roosts. In both the RSA and LSA, stands of high-quality potential maternity roosting habitat for bats are relatively abundant. The majority of the RSA has been undisturbed for the last 75 years as a result of CNL activities. Fire suppression within the RSA has likely had a generally positive effect on the availability of maternity roost tree habitat for little brown myotis and northern myotis, because both species are more commonly found roosting in large diameter trees and snags that are present in mature forest stands. Maternity roost characteristics of tri-colored bats are less well known, but are also associated with forested stands (COSEWIC 2013). In addition, suitable foraging habitat in the form of wetlands and riparian areas around the numerous small lakes is also abundant in close proximity to potential roosting habitats.

The CRL main campus, roads and associated infrastructure have likely reduced maternity roosting habitat availability in the RSA in some locations. However, even these changes do not represent a complete loss of potential roosting habitat. Little brown myotis are considered to be habitat generalists and are well adapted to human disturbance and will use buildings, bat houses and bridges for maternity roosts. CNL installed eight bat boxes at CRL in 2017 and surveys conducted in 2018 confirmed that little brown myotis used five of these eight boxes (CNL 2018c). Availability of maternity roosting habitat is not likely a limiting factor for bats in the Base Case, within the boundaries of the RSA. Additionally, information collected during the 2019-2020 telemetry

study will allow for increased protection of maternity roosts on the CRL site. The development of a Sustainable Forest Management Plan at CRL is expected to increase suitable bat maternity habitat over time.

5.6.4.8.2 Habitat Distribution

In the Base Case, potential maternity roost habitat is common and well distributed across the RSA (Figure 5.6.4-15) and LSA (Figure 5.6.4-16). Required foraging habitat features (wetlands, open water features such as Perch Lake) are also well distributed and commonly intersperse the potential maternity roosting habitat at both spatial scales. At the regional scale, highest-quality habitat distribution is roughly in a north–south gradient, with the least-disturbed areas at the north end of the RSA and most-disturbed areas in the south end of the RSA, closest to the CRL main campus. Throughout the RSA and LSA, linear features in the form of roads, two hydroelectric corridors and other gaps in forest cover create gaps and potential commuting corridors, if they are not too wide. All three species generally avoid large clear cuts in forested areas, as well as open areas (COSEWIC 2013; ECCC 2018c). Studies in Alberta found the centre of clear cuts greater than 30 m from the forest edge were completely avoided by northern myotis and that little brown myotis travelled 2 to 2.5 times less in the centre than through the forest edges or along retained stands of trees within the clear cut block (COSEWIC 2013). Tri-colored bats and northern myotis are generally forest associated and negatively affected by forest clearing activities (ECCC 2018c), but there is less information available about thresholds for maximum gap sizes.

The effects of habitat edges and corridors around mature forest stands on little brown myotis, northern myotis and tri-colored bats are not well known, and there are inter-specific differences among them. A number of studies suggest that some degree of forest fragmentation may be beneficial for little brown myotis (Broders and Forbes 2004; Broders et al. 2006; Ethier and Fahrig 2011; Jantzen and Fenton 2013; Segers and Broders 2014). Other studies have found that little brown myotis prefer closed and cluttered canopy areas and avoid edges (Kalcounis and Brigham 1995; Jung et al. 1999; Morris et al. 2010). The forest structure preferred by northern myotis is not well characterized; however, edge habitat around the outer limits of mature forest stands, riparian and cleared corridors (from roads and hydroelectric lines) represent potential foraging and commuting corridors (COSEWIC 2013). Consequently, not only are maternity roost and foraging habitats common in the RSA and LSA in the Base Case, they are also well connected. Within the SSA, potential maternity roosting habitat covers most of the area, with travel corridors in the form of East Mattawa Road and the two hydroelectric corridors interspersed throughout.

CNL has initiated a research project in collaboration with Dr. Jeff Bowmann, adjunct professor with Trent University, to help CNL understand the habitat preference of bat species at risk using the CRL site. This will help to understand habitat quality, distribution and availability at CRL. This project is of a duration of two years.

5.6.4.8.3 Survival and Reproduction

Little brown myotis and northern myotis occur in every province and territory in Canada (except Nunavut) and approximately 50% and 40%, respectively, of their global range is within Canada. Tri-colored bat occur in Ontario, Quebec, New Brunswick and Nova Scotia, and 10% of their global range is within Canada (ECCC 2018c). These three bat species were listed as endangered on Schedule 1 of SARA through an emergency listing order in 2014. The urgency of this listing was due to dramatic population declines caused by white nose syndrome (WNS), which is a fungal disease caused by *Pseudogymnoascus destructans* that affects bats while they are hibernating.

WNS causes physical damage (erosion of the skin, as well as damage to sweat glands, muscles, hair follicles and other tissue) and results in white-grey blotches on the surface of wings and ears, and fuzzy white growth on the muzzle (ECCC 2018c). The physical damage causes bats to arouse from their state of torpor (i.e., sleep) and expend energy that is typically reserved until spring emergence. The change in activity levels and physical damage combined are what eventually causes death (ECCC 2018c). Canada is currently divided into WNS-affected and non WNS-affected areas. The province of Ontario, as well as Quebec, New Brunswick, Nova Scotia and Prince Edward Island are considered WNS affected, and all other provinces and territories are currently non-WNS-affected areas.

In general, the total population sizes of bats in Canada are not clearly known based on limitations in survey effort. However, prior to the introduction of WNS, little brown myotis was likely the most common bat species in Canada, with northern myotis also common, and populations of both species might have exceeded one million individuals (COSEWIC 2013). Canadian populations of tri-colored bats were likely less abundant, estimated to be under 20,000 individuals (ECCC 2018c). Since detection of WNS in 2010, the recorded population of myotis bats (which includes little brown and northern myotis) has been reduced by 94% in Nova Scotia, New Brunswick, Ontario and Quebec. For tri-colored bat, the estimated reduction in eastern Ontario, Quebec and Nova Scotia populations is also 94% (ECCC 2018c).

WNS has been estimated to travel at an average rate of 200 to 400 km per year (COSEWIC 2013). It is anticipated that the entire Canadian population of little brown myotis will be affected by WNS within 11 to 22 years, or possibly sooner based on the recent confirmation of WNS in Washington State (USGS 2016). Based on modelling, little brown myotis is predicted to be functionally extirpated (i.e., less than 1% of existing population or 65,000 individuals) in Canada and the United States by 2026 (COSEWIC 2013; ECCC 2018c); however, this modeling did not consider higher rates of WNS survival in the north portion of the species' range than originally expected. The northern myotis population is expected to have similar declines based on the similarity of their life history characteristics (ECCC 2018c). There is less information available about tri-colored bats; however, most of the Canadian range overlaps with the current WNS infection range, and further population declines are anticipated (ECCC 2018c).

Little brown myotis, northern myotis and tri-colored bat populations that overlap the RSA are within the WNS-affected area of Canada. Consequently, these populations are particularly susceptible to any additional sources of changes to survival or reproduction because the resilience and adaptability limits of these populations may have been exceeded in the Base Case. Declines of little brown myotis average 73% within two years of infection with WNS and 91% with more than two years of exposure (MECP 2018). In Ontario, little brown myotis populations are assumed to have declined by at least 30% (MECP 2018).

Beyond the devastating effects of WNS, other threats to the three species of bat comprising this VC have been recognized as habitat loss and degradation (at hibernacula, maternity roosts and foraging areas), disturbance or harm (through collision with or barotrauma from wind turbines, intentional harm from extermination, or unintentional harm from recreational [e.g., spelunking] or scientific disturbances and industrial disturbance), pollution and climate change (ECCC 2018c). Little brown myotis in particular are vulnerable to persecution and extermination efforts because of their tendency to roost in anthropogenic structures such as attics (ECCC 2018c). Extermination of large colonies can affect local populations, particularly in WNS-affected areas such as Ontario.

Regarding reproduction and lifespan, all three bat species are relatively long-lived and have low reproductive rates, making their populations sensitive to increases in adult mortality and slow to recover when the population size is already small. Individuals of little brown myotis have been recorded to live to over 30 years of age (Fenton and Barclay 1980), although the average lifespan is thought to be shorter (COSEWIC 2013). The lifespans of northern myotis and tri-colored bat are at least 15 years (COSEWIC 2013).

Survivorship of all three species is not well understood, and there is uncertainty based on deficiencies in study design and analysis used in studies that have reported survival rates. The mean annual survival of little brown myotis in Ontario was 0.82 for males and 0.71 for females (Keen and Hitchcock 1980). Survival rates are lowest in the first year of life because juveniles often lack sufficient fat reserves needed for hibernation (Fenton and Barclay 1980). Females of all three species start breeding after their first year and continue breeding annually (COSEWIC 2013). Females give birth to one pup per year (possibly two for tri-colored bat) after 44 to 60 days of gestation (COSEWIC 2013). For little brown myotis, which are more widely studied, reproductive rates seem to decline with increasing latitude; a reproductive rate of greater than 96% was recorded in the eastern United States, with lower rates of 33% to 74% in the Yukon (COSEWIC 2013).

In summary, because the RSA is within a WNS-affected area, survival and reproduction of bat populations overlapping the RSA is likely impaired in the Base Case (COSEWIC 2013).

5.6.4.9 Blanding's Turtle

5.6.4.9.1 Habitat Availability

Blanding's turtles (*Emydoidea blandingii*) are semi-aquatic reptiles that inhabit a variety of aquatic and wetland habitats such as marshes, ponds, swamps, bogs, fens, coastal wetlands, slow-flowing rivers and creeks, pools, lakes, bays, sloughs, marshy meadows, and artificial channels. They may also occupy wetlands maintained by beaver dams. They prefer aquatic habitats with soft, muddy bottoms and abundant aquatic vegetation. They use these habitats for hibernating, mating, foraging, thermoregulation, summer inactivity (i.e., prolonged dormancy during hot or dry periods) and movement (ECCC 2018b).

Blanding's turtles hibernate from approximately October to April and partially bury themselves in soft substrates underwater. The typically overwinter in permanent wetlands such as bogs, fens, and marshes (ECCC 2018b). They emerge from the water to warm themselves or "bask" on available structures close to the water, such as logs, rocks, vegetation hummocks, sedge/grass tussocks, floating mats of aquatic vegetation, muskrat mounds and lodges, or up to 1 m from the water's edge on shorelines and channel banks. Fidelity to overwintering areas has been observed in this species (ECCC 2018b).

Although they spend most of their time in aquatic habitats and wetlands, Blanding's turtles also travel seasonally through upland terrestrial habitats to meet important life history requirements such as nesting (COSEWIC 2005). Terrestrial habitats also support thermoregulation, summer inactivity and movement functions (ECCC 2018b). In Ontario, Blanding's turtles typically nest from late May through to the second week of July, with a peak of nesting activity in June (ECCC 2018b). Nests are typically constructed in open areas such as beaches, shorelines, meadows, rocky outcrops and forest clearings, as well as in areas modified by human activity such as gardens, power line ROWs, fields, gravel roads and road shoulders, sand/gravel quarries, railway ROWs, cycling paths, hiking trails and all-terrain vehicle trails (ECCC 2018b). They require loose sandy substrates or organic soils to create nests. Nesting in open areas raises the mean temperature in the nest, resulting in an increased likelihood of nest success (COSEWIC 2005; ECCC 2018b). Females generally show high nest site fidelity (ECCC 2018b).

Blanding's turtles inhabit the RSA and have been the subject of field studies on the CRL site since 2009. Critical habitat for Blanding's turtles was partially defined in the draft recovery strategy (ECCC 2018b), and this definition was applied to the CNL baseline data for this VC. ECCC (2018b) identifies critical habitat based on two criteria: habitat occupancy and habitat suitability.

The following steps were undertaken to develop habitat mapping for Blanding's Turtle in the study areas:

1) Map all CNL observation records of Blanding's turtles in the study areas.

2) Within a 2 km radial distance from all observation records, identify and include all the permanent and seasonal wetlands and watercourses as critical habitat (based on average home range length observed in Ontario and Quebec; ECCC 2018b).

3) Apply a 240 m buffer to all those aquatic and wetland features to incorporate suitable terrestrial habitat into the critical habitat mapping (based on the average distance individuals moved between required resources within the home range; ECCC 2018b).

4) Remove all unsuitable habitats that fit the description in the recovery strategy (man-made structures, active sand and gravel pits, active agricultural fields and active roadways and shoulders) from the critical habitat mapping. Other anthropogenic features, such as powerlines that have low human activity may be used as nesting sites and were considered part of critical habitat. Additionally, large fast flowing rivers act as a barrier to the Blanding's turtle population connectivity, and thus critical habitat also is limited by the Ottawa River.

Overall, CNL's 2009 to 2018 field surveys were restricted to the southern portion of the RSA. Consequently, only using known observation records to map Blanding's turtle habitat in the RSA would underestimate the extent of critical habitat. Therefore, potential critical habitat was mapped as all remaining permanent and seasonal wetlands and watercourses in the RSA, plus a 240 m buffer around each aquatic or wetland feature.

A total of 179 ha (85.2%) and 2,788 ha (72.4%) of critical habitat for Blanding's turtle is estimated to be present in the LSA and RSA, respectively, in the Base Case (Table 5.6.4-10). An additional 571 ha (14.8%) of potential critical habitat is estimated to be present in the RSA (Table 5.6.4-10).

Table 5.6.4-10 Critical Habitat and Potential Habitat Availability for Blanding's Turtle in the Base Case

Habitat Suitability	Regional Study Area		Local Study Area	
	Area ha]	Percent (%)	Area (ha)	Percent (%)
Critical Habitat	2,788	72.4	179	85.2
Potential Critical Habitat	571	14.8	0	0.0
Unsuitable	493	12.8	31	14.8
Total	3,852	100.0	210	100.0

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

The RSA contains 521.4 ha and the LSA contains 61 ha of wetlands. The SSA is bordered by wetlands to the north, west and south. A large wetland complex consisting of South Swamp and East Swamp abuts the northwest and southwest sides of the SSA. A riparian wetland associated with Perch Creek is located to the southeast of the SSA.

There are Blanding's turtle observation records congregated within various waterbodies and wetlands throughout the RSA and LSA. CNL baseline studies indicate that Blanding's turtles use the wetland habitats that surround the SSA. The closest observation records for Blanding's turtles are within the riparian corridor of Perch Creek, as well as a roadkill individual on Plant Road at the intersection with East Mattawa Road. CNL confirmed hibernation habitat at various location throughout the RSA, including the wetlands approximately 1 km east-southeast of the SSA and various wetlands northeast of the SSA (north of Plant Road; CNL 2015).

Perch Lake has the potential to be used as overwintering habitat for Blanding's turtles. This is a eutrophic lake of approximately 45 ha with a drainage area of 730 ha. The maximum depth of the lake is 3.5 m and the mean depth is 2 m (Robertson and Barry 1985). The majority of Perch Lake is open water except for the littoral zones, which are shallow wetlands composed of floating, emergent and submerged vegetation that amount to about 30% of the lake's surface (Yankovich et al. 2000). The outer fringe of this zone is known as Perch Lake Marsh.
This open marsh may be considered part of the lake, within which it is physically continuous. To the north, there are extensive wetlands, notably Perch Lake Swamp, South Swamp, East Swamp and West Swamp. The lake is confined in part by sand outcrops along the northern and southern shores, and by bedrock along the western

shores. These sandy areas around Perch Lake have potential as suitable nesting areas for Blanding's turtle; however, CNL's monitoring program did not include nesting surveys and this potential has not been confirmed.

Although the SSA is dominated by forest cover, the roads and hydroelectric corridors provide openings within which suitable turtle nesting habitat may be found. The surficial geology at the SSA consists primarily of sands, underlain by dense sandy silt till containing cobbles and boulders. Consequently, the SSA contains a suitable substrate for nest building. On steep slopes where there is bare ground and sparse vegetation cover, there are patches of exposed sand that have potential for Blanding's turtle nesting habitat. There are sand barrens identified through the SSA and LSA near WMA A (CH2M Gore and Storrie 1998). These sand barrens are near where a Blanding's turtle was found dead on the road in July 2013. These findings suggest there is the possibility of the sand barrens in this area being used during nesting (found in nesting period and in suitable habitat); however, this is an incidental sighting, and nesting locations for the local populations are undefined. Therefore, there has been no nesting habitat confirmed in the SSA to date.

CNL is committed to developing nesting habitat on the CRL site by building nesting mounds at five Priority 1 culverts (nesting mounds constructed in 2019/2020), and three Priority 3 culverts (nesting mounds to be created after culvert replacement, which will occur when culverts fail); Priority 2 culverts will be replaced when the NSDF Project is approved (see Section 5.6.7.8 for more details). Artificial nest mounds will be constructed on both sides of the culverts following guidelines developed by the Northeast Blanding's Turtle Working Group (NBTWG, no date). These artificial nesting mounds will be monitored for use by turtles during the nesting period using methods adapted from provincial protocols (MNR 2013b). Specifically, nesting surveys will be conducted at least once per week during the nesting period (May 15 to June 30); additional surveys will be completed after periods of rain to capture potential increases in nesting behaviour associated with even light rainfall (MNR 2013b; Golder 2019a). During nest mound inspections, maintenance of the nest mounds (e.g., vegetation removal) will occur if females are not present (Golder 2019a). More details on the locations of nesting mounds are presented in Section 5.6.4.9.3, below.

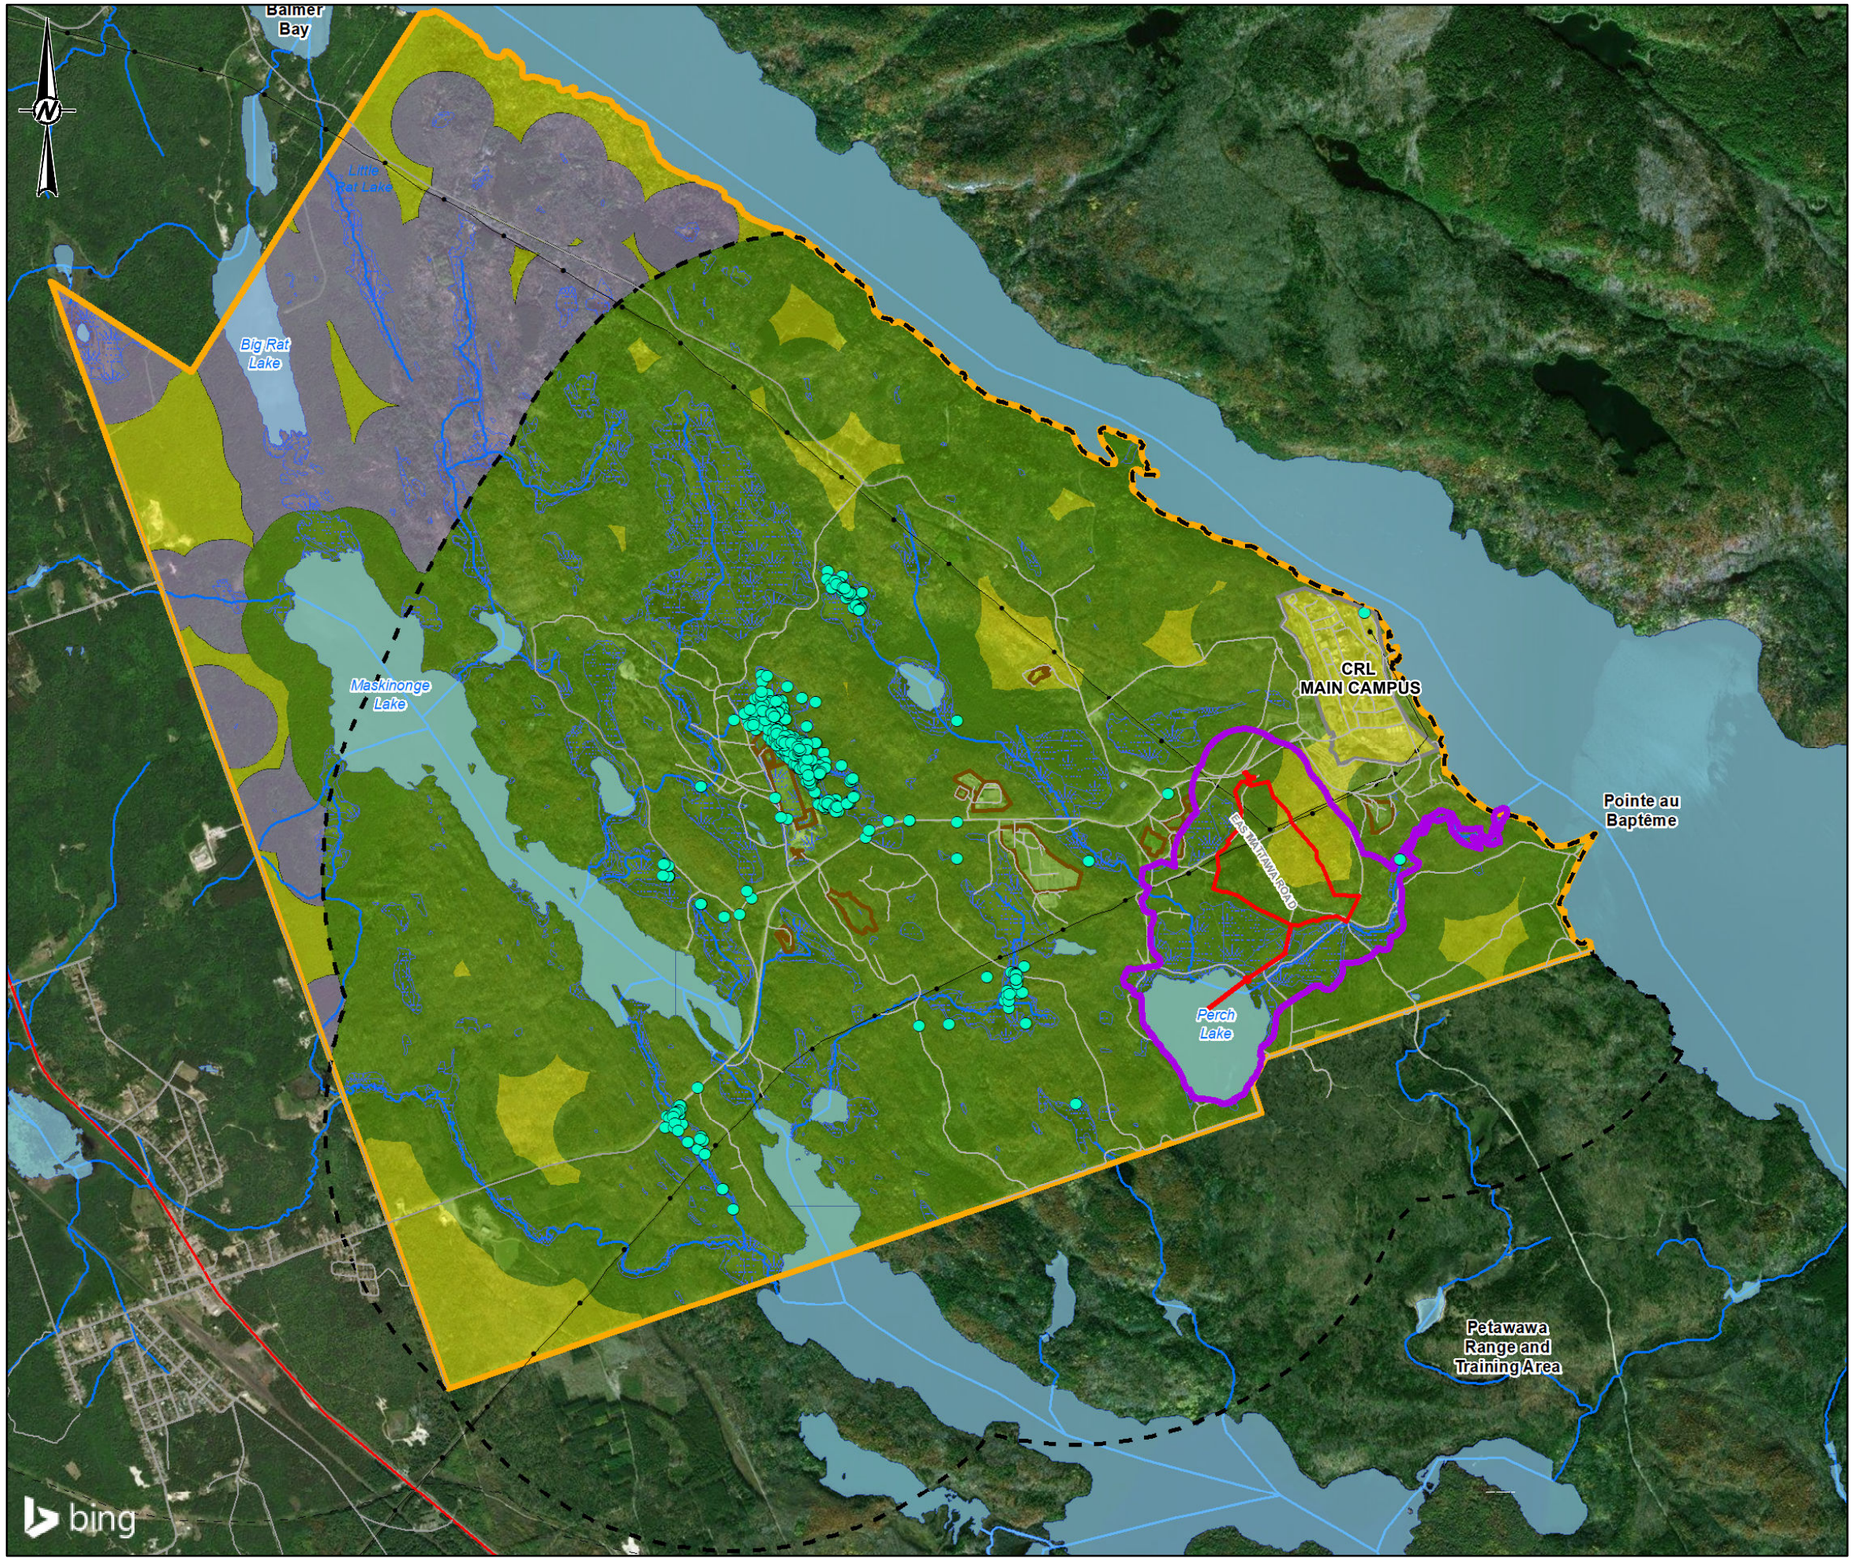
There are two cleared and maintained hydroelectric corridors for the 115 kV transmission lines through the RSA, one spanning most of the north–south length of the CRL site and the other spanning the southern east–west length of the RSA. These lines intersect in the SSA and thus, also span the width and length of the LSA. These open areas provide good opportunities for Blanding's turtle nesting because they are areas where eggs would incubate well, increasing the chance of successful hatchling development (COSEWIC 2016). Although these habitats could be suitable for nesting, they also represent ecological traps for the species because they are "active rights-of-way" maintained by Hydro One and CNL regularly to prevent a loss of Class IV power.

5.6.4.9.2 Habitat Distribution

Critical habitat for Blanding's turtles is well distributed throughout the RSA, and where observations of Blanding's turtles have precluded critical habitat mapping, potential critical habitat (wetlands and adjacent 240 m buffer) is well distributed (Figure 5.6.4-17). Shallow wetlands and waterbodies are distributed throughout the LSA and RSA and occupy 102 ha of the LSA and 797 ha of the RSA. Hydrologically connected wetlands in the RSA either drain to Maskinonge Lake or Perch Lake and eventually to the Ottawa River. The main wetland complex in proximity to the SSA is the Perch Lake Swamp complex. Perch Lake drains to the Ottawa River through Perch Creek, which contains a riparian wetland conducive to Blanding's turtle movement. Little, if anything, is known about the nesting habitat of Blanding's turtle in the study areas; however, based on the general nesting habitat requirements, there are likely nesting areas throughout the SSA, LSA and RSA.

CNL studies have provided some insights into Blanding's turtle movement in the three study areas. Wetlands are natural movement corridors for this species. It is likely that individuals move from the Perch Lake area, north through the wetlands that cross Plant Road, or east through the wetlands that extend along Perch Creek, which flows under ER-3 (Emergency Road), but the two-year telemetry study (2014 and 2015) did not record any Blanding's Turtle individuals crossing Plant Road. CNL has observation records that indicate the use of wetlands throughout the RSA and LSA during the active season. One particular observation of note is within the Perch Creek riparian corridor in the LSA. This riparian corridor connects Perch Lake to the Ottawa River (Figure 5.6-18) and outlets near a sand covered point of the Ottawa River known as Pointe au Baptême. Pointe au Baptême contains sand dunes and has the potential to be suitable nesting habitat for Blanding's turtles.

From 2009 to 2018, a total of 1,339 days have been surveyed in the RSA for Blanding's turtle using live traps and 113 live trap survey days have been completed in the LSA (Table 5.6.4-11). During the same time period, a total of 2,034 person-hours have been spent completing road searches in the RSA and LSA (Table 5.6.4-11). There were 32 individuals that were surveyed using telemetry in 2014 and 2015 (Table 5.6.4-11). There are no Blanding's turtle observation records within the SSA to date; search efforts by CNL did not incidentally locate Blanding's turtle nests. Based on CNL's extensive knowledge of the CRL site, there are numerous sandy outcrops throughout the LSA and RSA which have the potential to be nesting areas for Blanding's turtle (Figure 5.6.4-18). To highlight a few potential nesting areas within or in proximity to the SSA, the hydroelectric corridors that run through the study areas, particularly within the upland areas containing sandy soils and the sandy outcrop adjacent to Perch Lake both have the potential to be used as nesting habitat. Hibernation habitat has been confirmed in several wetlands/waterbodies in the RSA to the north, northeast and east of the SSA. Within the LSA, hibernation habitat for Blanding's turtle is likely in Perch Lake Swamp.



During the active season, many of CNL's observations of individuals were on roads and trails and along roadside shoulders. This is likely due to the intensive road surveys that CNL undertook (e.g., CNL 2017d, 2018b); however, this also may indicate that Blanding's turtles are using roads as travel corridors and as potential nesting areas. One Blanding's turtle nest was confirmed in 2019 on Plant Road over 2 km away from the SSA.

One new culvert is being installed in 2019 and five Priority 1 culverts are scheduled to be replaced in 2019/2020. Three additional Priority 3 culverts will be replaced during the Base Case; replacement will occur as the culverts fail. Priority 2 culverts will be replaced when the NSDF Project is approved (see Section 5.6.7.8 for more details). New and replaced culverts will be enhanced by having nesting mounds created nearby on both sides of the culvert, as well as by planting native vegetation around the culvert entrances, while maintaining a clear line of site through the culvert (Golder 2019a). The new culvert and Priority 1, Priority 2, and Priority 3 culverts are inspected weekly during the active turtle season (May to September) and after heavy rainfall events (≥7 millimetres per hour [mm/hr]) (Golder 2019a). During the inspections, barriers that can impede the passage of turtles through the culverts are removed or modified (Golder 2019a). These mitigations are anticipated to increase habitat connectivity for turtles at Base Case. More details on the new culvert and the replacement of Priority 1 and Priority 3 culverts are presented in Section 5.6.4.9.3, below.

Table 5.6.4-11: Survey Effort for Blanding's Turtles in the Local and Regional Study Areas, 2009 to 2018

Year	Regional Study Area			Local Study Area	
	Live Traps (Number of Survey Days)	Searches (Person-Hours)	Telemetry (Number of Individuals)	Live Traps (Number of Survey Days)	Searches (Person-Hours)
2009	150	0	0	20	Unknown
2010	484	360	0	93	Unknown
2011	194	270	0	0	Unknown

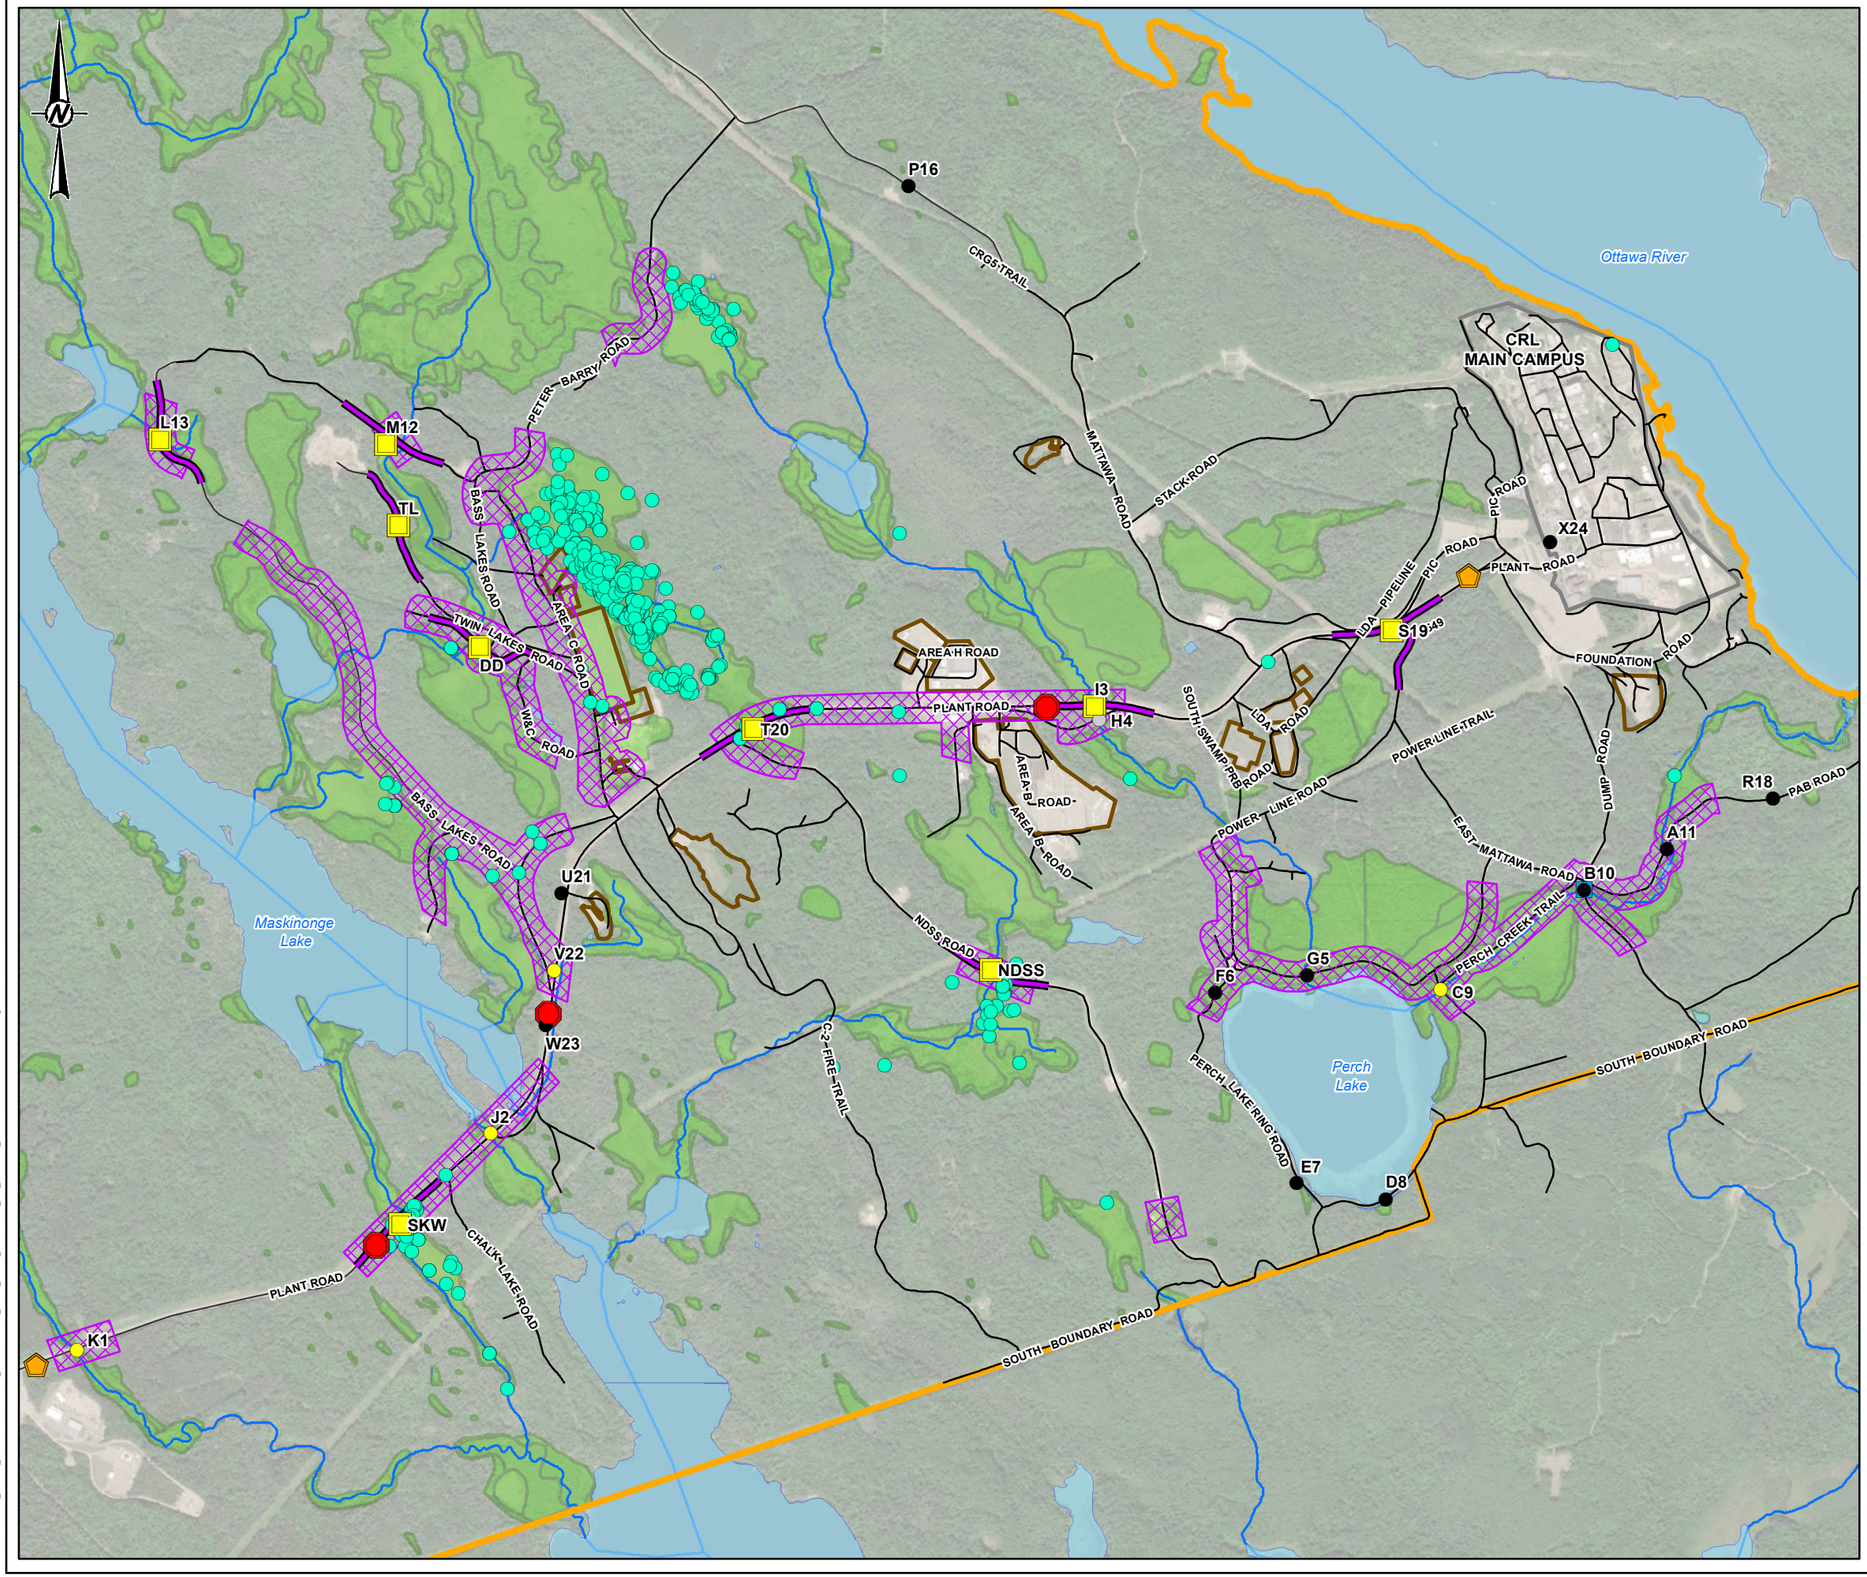
5.6.4.9.3 Survival and Reproduction

The Blanding's turtles in the RSA belong to the Great Lakes/St. Lawrence population, which is listed as threatened on Schedule 1 of SARA and under the Ontario *Endangered Species Act, 2007*. COSEWIC (2016) assessed the population as endangered. The Great Lakes / St. Lawrence population occurs in Ontario and Quebec and its size is roughly estimated at between 25,000 and 45,000 individuals (COSEWIC 2016).

Mean estimates of Blanding's turtle densities in Ontario were 0.78, 0.29 and 0.12 adults per hectare in the Lake Erie/Lake Ontario ecoregion, Lake Simcoe/Rideau ecoregion and Georgian Bay ecoregion, respectively (COSEWIC 2016). Based on CNL's mark-recapture studies in 2014 and 2015, an adult/sub-adult population of 25 ± 4 adults was determined to be within the portion of the RSA that was studied. In 2018, a total of seven Blanding's turtles were captured at five netting sites; two individuals were captured twice (SARA permit SARA-OR-2018-0434). No hibernating sites were observed and one nesting site was observed after it had been predated. Most (six) individuals were captured at Lake 233 N (313664 E 5102590 N).

According to the Ottawa Valley Forest Management Plan, the Ottawa Valley Forest, which encompasses the RSA, is one of the last remaining "strong holds" for Blanding's turtle in Ontario and Canada (Van Dyke 2011). There are occurrence records for this species throughout the Ottawa Valley Forest Management Unit. Available data suggest that Blanding's turtles survive and reproduce successfully in the RSA and that the RSA likely is important for the conservation of this species.

Habitats used by female Blanding's turtles for nesting within the RSA are likely present, including one confirmed nesting site on the Plant Road in 2019, but nest site records are uncommon. CNL's mark-recapture study did not include the capture or observation of any hatchlings; however, it should be noted that capture efforts were not expended in the hatchling emergence period (September and October), as trapping was not authorized by ECCC after August 31, and the mesh size of the hoop net may be larger than the hatchlings. CNL also noted that there was a relatively low number of juvenile/immature individuals captured during its studies. It is unknown whether this is an indication that juveniles are rare and reflects a low-level of recruitment in the population or whether juveniles eluded capture. It has been reported that high annual survivorship of juveniles is required to maintain a stable population of Blanding's turtles on the E. S. George Reserve in Michigan (Congdon et al. 1993).



Mortality along roadways and railways has been identified as the most important threat to the Great Lakes / St. Lawrence Blanding's turtle population (ECCC 2018b). The risk of roadkill is a concern in the RSA. According to CNL's annual species at risk reports, two adult Blanding's turtle mortality events have been identified on the roads within the RSA in the last six years. One roadkill occurred on July 7, 2013, on Plant Road and the other occurred on Twin Lakes Road on June 6, 2014. Detection of roadkill events is unlikely to be 100% and other instances may have occurred, but were not recorded. CNL's observation records and road surveys, particularly during June and July, note a considerable number of turtles travelling on roadways (gravel roads) and near roadsides. This may indicate females in search of nesting sites, which makes them susceptible to roadkill. Late maturity, low reproductive output and an extremely long life make this turtle highly vulnerable to adult mortality (Congdon et al. 1993; ECCC 2018b). Low reproductive success and low recruitment make this species especially vulnerable to extinction even with a very small increase of the annual mortality rate (less than 5%) from anthropogenic activities (Gibbs and Shriver 2002).

Because the RSA may act as a refuge for Blanding's turtles, road mortality on the CRL Site is a primary concern for the sustainability of the regional Blanding's turtle population. That is, there is concern that the RSA could function as a population sink because turtles are attracted to the abundant habitat on the CRL Site but may suffer high rates of road mortality. For this reason, CNL started implementing a detailed *Blanding's Turtle Road Mortality Mitigation Plan* (Golder 2019a) in 2019, and will continue to implement the plan moving forward. The *Blanding's Turtle Road Mortality Mitigation Plan* is designed to reduce or eliminate turtle road mortality at CRL and increase connectivity among habitats. This plan includes mitigation implemented in four key areas: driver awareness; installation of permanent exclusion fencing; creation of nesting mounds; and replacement of culverts in key areas. A key component of the *Blanding's Turtle Road Mortality Mitigation Plan* is the use of monitoring and adaptive management to determine the efficacy of mitigation and to develop and implement improvements to mitigation, as required (Golder 2019a).

Currently, temporary exclusion fencing is installed at Culvert J2 and Culvert SKW on both sides of Plant Road (Figure 5.6.4-19). Inspection of this temporary fencing is completed weekly during the active turtle season (May to September) and after heavy rainfall events (≥7 mm/hr) (Golder 2019a). Culverts in hotspots are also inspected during the exclusion fence inspections and barriers that can impede passage through the culverts are removed or modified (Golder 2019a).

One new culvert will be installed in November 2019 along the Twin Lakes Road at Dew Drop Lake (Culvert DD; Figure 5.6.4-19). Culvert H4 will be removed in November 2019 as the road that the culvert is located is will be closed. The remaining existing culverts that have identified for replacement are prioritized based on their proximity to a wetland, turtle observations, and potential for road mortality at the location (i.e., traffic levels). In the short-term (2019/2020), efforts are focused on Plant Road, as this is the road with the highest amount of traffic on the CRL Site. Five Priority 1 culverts will be replaced in November 2019 (Culverts T20, I3, S19, M12, and TL) and one Priority 1 culvert will be replaced in April 2020 (Culvert SKW) (Figure 5.6.4-19). Priority 2 culverts will be replaced after the NSDF Project has been approved and will mitigate effects from the NSDF Project (see Section 5.6.7.8.3 for more details). Remaining Priority 3 culverts (L13, M12, and NDSS) will be replaced as they fail (Figure 5.6.4-19). Not all culverts that are located in reptile hotspots are Priority 1, 2, or 3 because of barriers (e.g., a weir) that prevents turtles from accessing the culvert (see Appendix A in the *Blanding's Turtle Road Mortality Mitigation Plan* for more details). All new and replaced culverts will have appropriate permanent fencing for 200 m on either side of the culvert to guide turtles through the tunnel. Inspection of permanent fencing and culverts in hotspots will be undertaken similar to current inspections of temporary fencing at CRL. That is, inspections will occur weekly during the active turtle season (May to September) and after heavy rainfall events (≥7 mm/hr) (Golder 2019a).

Once culverts are installed or replaced, they will be enhanced by planting native vegetation around the culvert entrances, while maintaining a clear line of site through the culvert (Golder 2019a). Additionally, to help limit movement requirements for females to reach nesting areas, nesting mounds will be created in late 2019/early 2020 on both sides of culverts S19, I3, T20, and SKW (Figure 5.6.4-19). To improve the chance of successful nesting, starting in 2020, five wire-screen cages will be deployed over areas were eggs have been laid. An additional 25 cages will be constructed and deployed in 2021 and beyond. These nest cages will be designed according to guidelines adapted from Gillingwater (2008) and Ratnaswamy et al. (1997) (Golder 2019a). Nest cages will be deployed during the nesting season (May 15 to June 30) and weekly inspections of the cages will be completed from the end of the nesting period through to the end of the hatchling emergence period (July 1 to October 15). Cages will be retrieved prior to May 15 of the following year.

To increase employee, contractor, and visitor awareness about the presence of turtles on the CRL site, the following mitigations have already been, and will continue to be, implemented at the site:

- Three permanent turtle crossing signs have been installed along Plant Road (Figure 5.6.4-19);
- Two electronic turtle crossing signs have been installed along Plant Road and are in use during the turtle terrestrial season (May 15 to September 30) (Figure 5.6.4-19);
- Detailed species at risk training (1-hour session) is provided to employees familiar with species at risk; and
- The presence of turtles on the CRL site is communicated using the following methods:
  - Information is included as a bulletin on the “My CNL” webpage;
  - Email notifications are regularly sent out to all employees;
  - Information is presented in the Contractor Safety Orientation training and specific contractor training; and
  - Employees are asked to fill out questionnaires each autumn to evaluate how familiar employees are with the mitigation program and objectives and to provide opportunities for employee feedback and suggestions.

Additionally, to avoid negative interactions with nesting turtles, road grading and levelling activities were not completed during the turtle terrestrial season (May 15 to September 30) in 2019 and these restrictions will remain in place during future years. Restrictions on vegetation removal during the terrestrial season will be in place in 2020 and beyond.

Formal turtle road mortality surveys were implemented at the CRL Site in 2019 (no Blanding’s turtle mortality was detected). These road mortality surveys will continue throughout the life of the CRL Site. Road mortality surveys are completed weekly along Plant Road and along hotspots on secondary roads during the active turtle terrestrial season (May 15 to September 30) (Figure 5.6.4-19; Golder 2019a). As part of the adaptive management component of the *Blanding’s Turtle Road Mortality Mitigation Plan*, results from the road mortality surveys will be used to consider the implementation of additional mitigation. For example, if there are road mortality hotspots, permanent exclusion fencing, crossing structures, and/or reduced speed limits during the nesting period may be implemented at these locations.

Adaptive management is an important part of the *Blanding’s Turtle Road Mortality Mitigation Plan*. Depending on results of monitoring, CNL is committed to taking additional actions, as required, to achieve a neutral or positive contribution to Blanding’s turtles. Potential additional actions would be developed as needed, but could include activities such as incubating Blanding’s turtle eggs in facilities that would be located on the CRL Site, which would result in improved recruitment into the population. Eggs that are incubated would be those rescued from the CRL site and more broadly from Renfrew County and hatchlings would be released in the RSA or other areas where eggs were collected to support the local Blanding’s turtle population.

With the implementation of the comprehensive mitigation outlined above, CNL’s activities in the RSA are predicted to have a net neutral or positive effect on the local Blanding’s turtle population during the Base Case. That is, the mitigation that is or will be implemented on the CRL Site is considered sufficient to limit and offset mortality from previous and existing anthropogenic activities in the RSA. There is uncertainty regarding the effectiveness of mitigation, but monitoring and adaptive management will be implemented so that CNL achieves a net neutral or positive effect on the Blanding’s turtle population at CRL.

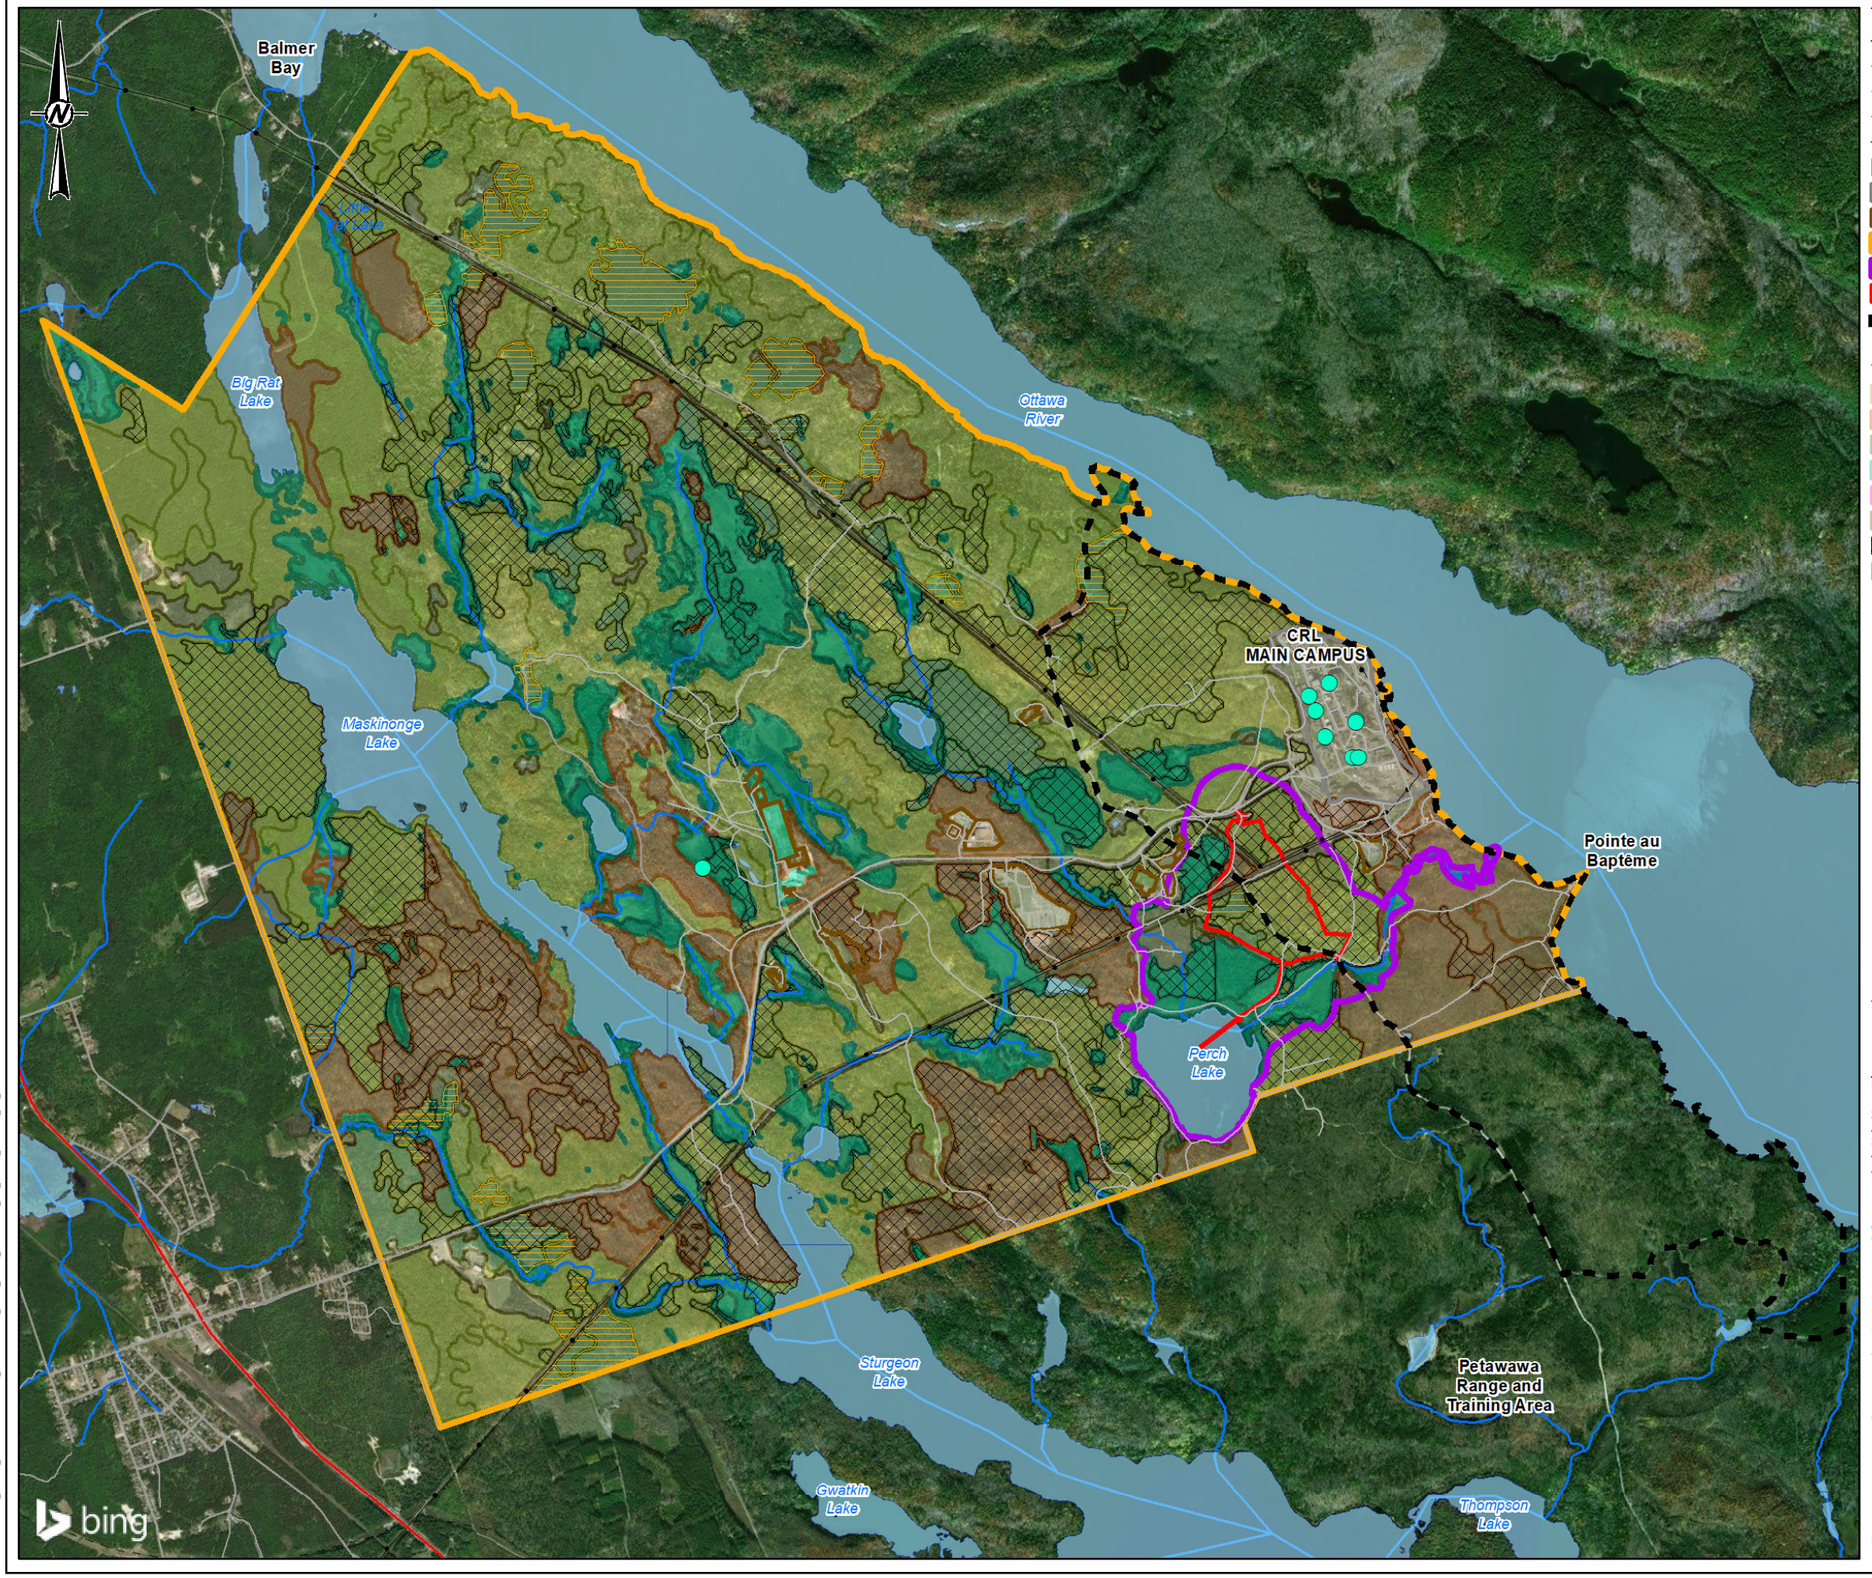
5.6.4.10 Eastern Milksnake

5.6.4.10.1 Habitat Availability

Eastern milksnakes (*Lampropeltis triangulum*) use a wide range of habitats including prairies, pastures, hayfields, wetlands and various forest types, and they occur regularly in rural areas where they frequent older buildings. Row and Blouin-Demers (2006a) report a strong preference for open habitats during their active period; however, eastern milksnakes require microhabitats for their critical life history stages of egg laying, hibernation and thermoregulation (COSEWIC 2014). This species lays eggs in late June / early July in rotting logs or under other suitable cover, and hibernation can take place in mammal burrows, hollow logs, gravel or soil banks, and old building foundations (COSEWIC 2014). Their hibernation sites can vary from well-drained sites at a distance from water or in areas close to water (COSEWIC 2014). They are known to display fidelity to their hibernation sites (Environment Canada 2015). Closed canopy forests may be less suitable for this species because the lack of available sunlight may limit their ability to thermoregulate (COSEWIC 2014). This is supported by a study from eastern Ontario (south of Ottawa) that found that milksnakes avoid forested habitat at both the home range and microhabitat scale (Row and Blouin-Demers 2006b).

The milksnake has adapted to rural areas in southern Ontario, suggesting it is resilient to low levels of anthropogenic disturbance. However, extensive changes in land use such as urbanization and intensive agriculture are reducing habitat availability across its range (COSEWIC 2014).

Because milksnakes are considered habitat generalists and microhabitat preferences cannot be determined from vegetation community mapping, a qualitative assessment of habitat availability was conducted for this species. The availability of natural habitat in the RSA and LSA, and its proximity to the Ottawa River and other wetlands, suggests that portions of the RSA and LSA may be suitable for eastern milksnake. The SSA is forested, with dense canopy in many places, and likely does not contain basking habitat that would be preferred by eastern milksnakes for thermoregulation. However, some microhabitats used for egg-laying by the species (e.g., rotting logs) may be present. These microhabitats are predicted to be of lower quality than similar features in areas with higher thermal quality than the SSA (i.e., open canopy or unforested habitats).



5.6.4.10.2 Habitat Distribution

The SSA is located within the known range of eastern milksnakes and the presence of individuals in the RSA has been confirmed (Figure 5.6.4-20). There are 11 occurrence records for this species in the RSA, most of which are located on the CRL main campus. The supporting information with the occurrence records note that individuals were often found inside buildings. This is typical for eastern milksnakes, which will often use buildings for hibernation. The timing of observation on the CRL main campus spanned from the late summer through to early winter period (late August through December) which generally corresponds with the hibernation period from October/November to April. A few of the observations were of individuals in the basements of buildings, which also might indicate hibernation sites.

No sightings of milksnakes have been recorded in the LSA or SSA. In addition, no road mortalities have been documented within the CRL site. However, given the secretive nature of this species and the use of microhabitats and cover objects, there is a strong likelihood that they may be using habitats within the LSA and SSA but have gone undetected. The CRL main campus, where the majority of observation records occur, borders the LSA to the north. Because home ranges of milksnakes in Ontario are typically between 5 and 29 ha (Row and Blouin-Demers 2006a), the home ranges of milksnakes using the CRL main campus could encompass the LSA and perhaps the SSA. Because eastern milksnakes prefer open habitats, the wetlands within the LSA may be used in the spring, summer and fall.

The road network within the RSA may limit movement and dispersal of this species in the Base Case if snakes are basking on roads in order to thermoregulate and being exposed to road mortality; however, no road mortalities have been documented within the RSA.

5.6.4.10.3 Survival and Reproduction

In Canada eastern milksnakes are mainly found in the Great Lakes / St. Lawrence region. These snakes are a species of Special Concern on Schedule 1 of the federal SARA. The main threats to the persistence of this species in Canada are road-related mortality, predation (from pets and other predators) and habitat loss (COSEWIC 2014). Other threats include intentional killing and collection for the pet trade. Because eastern milksnakes are a long-lived species with delayed maturity, this species is likely sensitive to changes in adult survival (Environment Canada 2015). Females are known to lay eggs only once every two years, which may make this species less resilient than more productive species (Environment Canada 2015).

Little is known about the abundance of this species nationally or provincially; however, the total adult population likely exceeds 10,000 and there are recent occurrence records in every jurisdiction (county or regional municipality) within their known range in Ontario (COSEWIC 2014). Consequently, this species was recently downlisted from Special Concern to Not at Risk by the Committee on the Status of Species at Risk in Ontario. The justification for downlisting is that while the species has exhibited declines in highly developed parts of Ontario (i.e., Toronto area), these areas represent a limited portion of the habitat available to this species in other parts of Ontario (i.e., eastern Ontario). The Committee on the Status of Species at Risk in Ontario also noted that the threats to this species are less severe in the part of its range on and near the Canadian Shield, where the CRL site is located.

Population estimates for eastern milksnakes are not available and density estimates are difficult to obtain due to their cryptic, fossorial (i.e., burrowing), behaviour and preference for hunting at night. A low detection rate for this species compared to other Ontario snakes suggests that eastern milksnakes occur at low density across the species' range (COSEWIC 2014). This is further supported by statistics on road mortality because the absolute numbers of milksnakes killed on roads and railroads is low compared to other species of snakes (COSEWIC 2014).

Most of the identified threats to milksnake populations are absent from the RSA. There have been no reported road mortalities on the CRL site, about 87% of the RSA consists of natural habitat (mostly forested) and predation from pets or intentional killing are highly unlikely given the CNL Employee Education Program, which prohibits pets and includes environmental awareness training. Predation during all life stages is likely the main factor affecting milksnake survival and reproduction in the RSA. Predators of milksnakes that may be present in the RSA include bullfrogs (*Rana catesbeiana*), brown thrashers (*Toxostoma rufum*), raccoons (*Procyon lotor*), hawks, owls, foxes, skunks, other snakes (Environment Canada 2015). Weasels and shrews may pose a threat to eggs and young hibernating milksnakes. With the exception of predation, other factors affecting milksnake survival and reproduction appear to be absent from the RSA, suggesting that the milksnake population that overlaps with the RSA may be more resilient to additional sources of mortality as compared to other populations within its range that are exposed to road-related mortality, habitat loss, intentional killing/collection and/or predation by domestic animals.

5.6.4.11 Monarch Butterfly

5.6.4.11.1 Habitat Availability

Monarch butterflies (*Danaus plexippus*) require milkweed (*Asclepius* spp.) for caterpillars and wildflowers that supply a nectar source for adults. Because the caterpillars feed solely on milkweed, breeding habitat suitability is defined by availability of milkweed, which grows in open habitats (ECCC 2016b). Consequently, monarch butterflies are often found on abandoned farmland, meadows, open wetlands, prairies and roadsides, but also in

city gardens and parks where milkweed is planted (COSEWIC 2010). Monarch butterflies that breed in Ontario migrate south to overwinter in Mexico. Summer breeding habitat, which overlaps with the RSA, is the focus of this assessment.

Vegetation community data were used to map suitable summer breeding habitat for monarch butterflies in the LSA and RSA based on the likelihood of each vegetation community type to support milkweed plants. The following vegetation community types were identified as suitable monarch butterfly habitat:

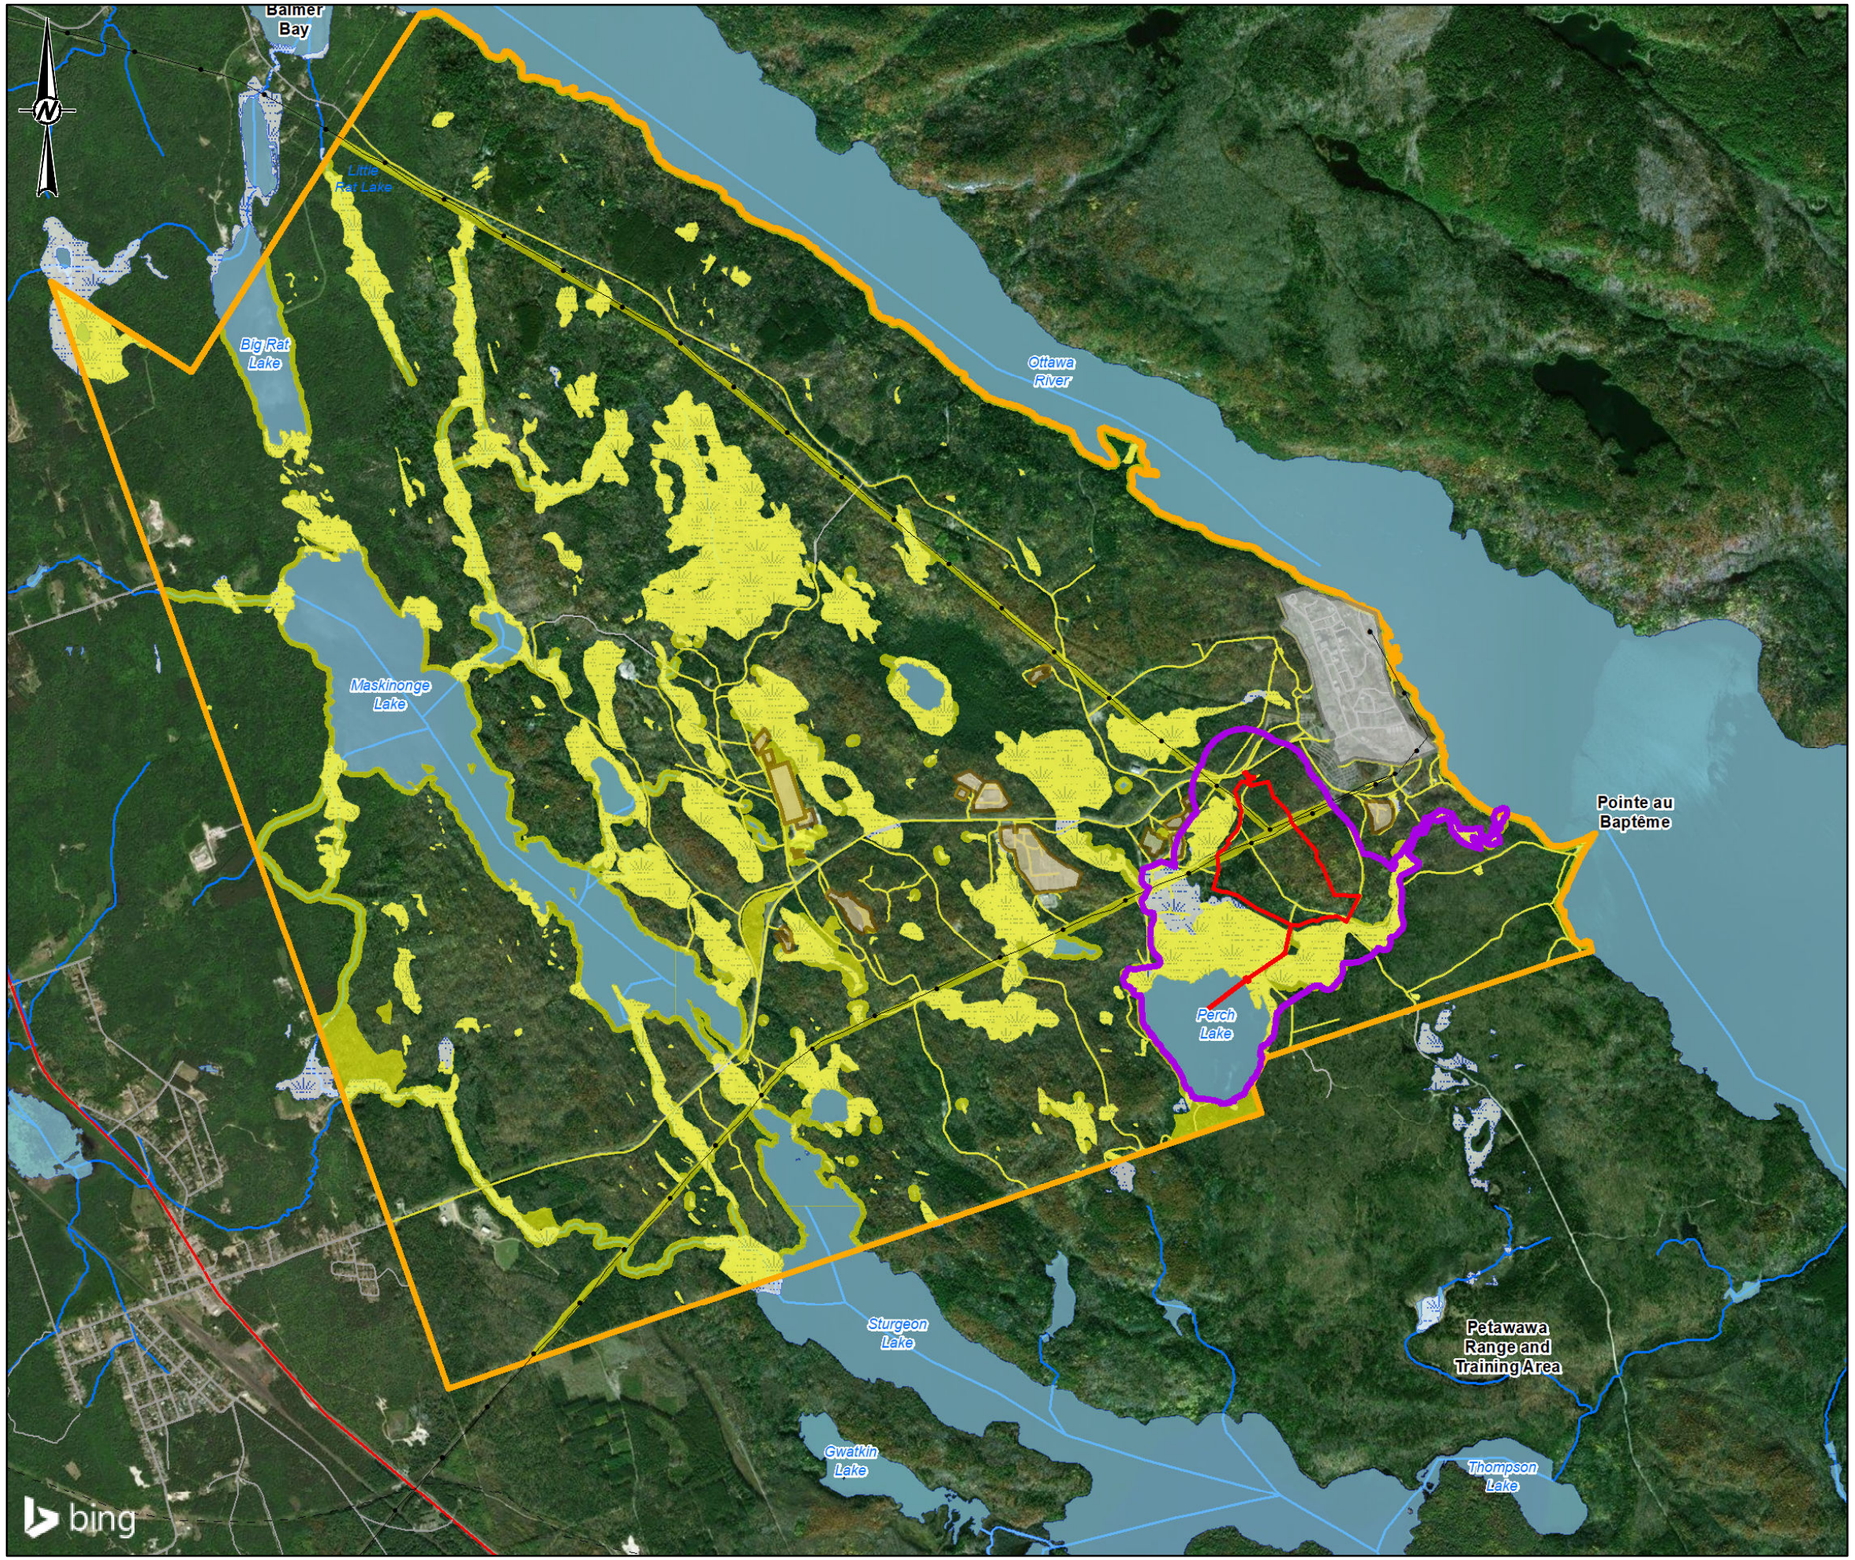
- pre-sapling forest of any type;
- wetland;
- flooded area;
- 30 m buffer on aquatic habitat (i.e., each side of a river or around the perimeter of a lake);
- transmission line ROW; and
- 5 m buffer on roads (i.e., each side of a road).

A total of 80 ha (38.1%) and 805 ha (20.9%) of suitable habitat for monarch butterflies is estimated to be present in the LSA and RSA, respectively, in the Base Case (Table 5.6.4-12). Most of the suitable habitat (over 80%) in both the LSA and RSA is in the form of wetlands and shorelines. Road verges and transmission line ROWs represent about 15% of the suitable habitat in both the LSA and RSA. Flooded areas and pre-sapling forest represent a minor component (3%) of suitable habitat in the RSA only. The wetland community type includes swamps in addition to marsh and minor fen and bog elements. Swamps, other than thicket swamps or sunny openings in treed swamps, are generally not suitable habitats for monarch butterflies, so habitat availability in the study areas may be overestimated.

Table 5.6.4-12: Summer Habitat Availability for Monarch Butterfly in the Base Case

Habitat Suitability	Regional Study Area		Local Study Area	
	Area (ha)	Percent (%)	Area (ha)	Percent (%)
Suitable	805	20.9	80	38.1
Unsuitable	3,047	79.1	130	61.9
Total	3,852	100.0	210	100.0

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.



Disturbance can have a positive effect on monarch butterfly habitat, particularly in predominantly forested landscapes such as the RSA. Fire suppression activities since the 1940s have likely had negative effects on monarch butterfly habitat relative to what was historically available for this species in the RSA because monarch butterflies occupy early successional habitat. Loss of breeding habitat in part due to reforestation of previously cleared land cover has been identified as a moderate threat to this species (ECCC 2016b). Regular vegetation maintenance in utility corridors and along roadsides maintains open land cover that provides suitable habitat for monarch butterflies due to the ability of milkweed to establish in these disturbed areas. However, excessive vegetation maintenance and herbicide use in road verges can be detrimental to milkweed establishment and growth (COSEWIC 2010). It is CNL's policy to minimize the use of all pesticides, including insecticides, herbicides

and fungicides, on all its sites (CNL 2018c). The extent to which the quality of potential monarch butterfly habitat is reduced through the use of pesticides in the RSA and LSA in the Base Case is not known, but is presumably low given that approximately 15% of their suitable habitat is in areas that may require pesticide management by CNL (i.e., road verges and transmission line ROWs).

5.6.4.11.2 Habitat Distribution

In the Base Case, suitable monarch butterfly habitat is well distributed throughout the RSA (Figure 5.6.4-21) and LSA (Figure 5.6.4-22). Linear disturbances present in the LSA and RSA in the Base Case have likely had positive effects on monarch butterfly habitat distribution because these disturbances maintain open habitat suitable for the establishment and growth of milkweed and also provide movement corridors connecting patches of open habitat in a largely forested landscape. Adult monarch butterflies are highly mobile and not likely to be limited by habitat distribution in the study areas.

5.6.4.11.3 Survival and Reproduction

Population estimates for monarch butterflies in Ontario and more broadly in Canada are unavailable. Individuals numbering in the hundreds of thousands have been reported passing through Long Point and Point Pelee during fall migration, but what proportion of the Ontario population these numbers represent is unknown (COSEWIC 2010). The estimated population of monarch butterflies overwintering in Mexico is between 66 million to 200 million individuals; however, this includes American breeding populations, as well as those that breed in eastern Canada. Despite the large estimated overwintering population and year-to-year fluctuations, there is an annual declining trend in the overwintering population due to forest habitat loss in Mexico. Similar declining trends have not been consistently observed among breeding populations (COSEWIC 2010).

Overall, Canada supports about 10% of the global breeding range of the species, and southern Ontario and Quebec contain the most important breeding areas with highest concentrations of individuals in the country (COSEWIC 2010; ECCC 2016b). However, the RSA is unlikely to be an important breeding area for monarch butterflies given that it is mostly forested and approaching the northern limit of milkweed distribution in Ontario.

Road verges represent about 8.5% of the available habitat for monarch butterflies in both the LSA and RSA. These linear strips of vegetation maintained in early successional stages have been identified as important habitat for monarch butterflies as agricultural landscapes that formerly provided habitat continue to be lost due to agricultural intensification, urban development and reforestation, and it has been estimated that road verges support about 10% of the milkweed population (all species) in North America (Flockhart et al. 2014). However, mowing as part of roadside vegetation maintenance can cause direct mortality of eggs and caterpillars, and the use of herbicides in roadside vegetation maintenance can kill milkweed, reducing carrying capacity for monarch butterflies. Additionally, milkweed exposed to road salt runoff has been found to contain elevated concentrations of sodium, which have been linked to reduced monarch caterpillar survival rates and altered physiology in survivors with unknown implications for fitness (reviewed in COSEWIC 2010). CNL is committed to reducing the use of road salt in the RSA; however, more than 500 tonnes per year are required to maintain safety of operations and personnel (CNL 2018c).

Vehicle collisions have been identified as a threat to monarch butterflies given their tendency to occupy road verges (COSEWIC 2010). Risk of collision increases with road width and traffic speed (Skórkaa et al. 2013). Most of the roads in the RSA are secondary roads. Plant Road is the widest and most heavily used road in the RSA, posing the largest collision risk. However, due to existing traffic control measures enforced by CNL and the likelihood that monarch butterfly abundance in the RSA is relatively low, risk of collision is expected to be negligible.

5.6.5 Project Interactions and Mitigation

5.6.5.1 Methods

This section describes the process by which interactions between NSDF Project components and activities and terrestrial biodiversity VCs were identified and evaluated. Potential effects pathways are identified, and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation measures are

further characterized in subsequent subsections of the assessment, as required. As such, the “Project Interactions and Mitigation” section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all phases of the NSDF Project. The next step in the analysis was the development of environmental design features and mitigation practices that could be incorporated into the NSDF Project to eliminate and/or reduce effects to terrestrial biodiversity VCs. Environmental design features included design elements, environmental best practices and management policies and procedures. These steps are widely recognized as the most important components of the mitigation hierarchy for biodiversity conservation (BBOP 2015). Environmental design features and mitigation were developed through an iterative process between the Project’s engineering and environmental teams, combined with input from Project-specific or regional engagement with other interested parties. The environmental design features and/or mitigation were selected considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effects pathways.

Remediation was not incorporated into the pathway analysis as a means to eliminate interactions between the NSDF Project and the environment because the duration between the effect and remediation is long and because diverse vegetation communities supporting a range of terrestrial biodiversity features equivalent to that present in the Base Case are not expected on the reclaimed landscape. Upon completion of the installation of the final cover over the ECM, turf-grass will be established. The final cover will be maintained to deter wildlife and avoid the disruption of roots to the final cover. Consequently, the post-remediation state of the SSA will be highly modified and unlikely to support terrestrial biodiversity.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience of the professionals conducting the assessment with similar developments and the demonstrated or expected effectiveness of mitigation:

- **No linkage**: The pathway is removed by environmental design features or mitigation so that the NSDF Project would not be expected to result in a measurable environmental change relative to Base Case values, and therefore would have no residual effect on terrestrial biodiversity.
- **Secondary pathway**: The pathway could result in a minor measurable change in the environment relative to the Base Case, but this change would have a negligible residual effect on terrestrial biodiversity and is not expected to contribute cumulatively to other NSDF Project effects or other previous, existing and reasonably foreseeable developments to cause a significant effect.
- **Primary pathway**: The pathway is likely to result in a measurable environmental change relative to the Base Case that could contribute to residual adverse effects on terrestrial biodiversity.

Environmental design features and mitigation that have been or could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects to terrestrial biodiversity were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to terrestrial biodiversity through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways were carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the NSDF Project on terrestrial biodiversity. In some cases, there was uncertainty associated with the success of proposed mitigation, which contributes to uncertainty for the

pathway analysis process. Where uncertainty about potential effect size after mitigation was high, pathways were considered primary.

5.6.5.2 Results

Potential interactions between the NSDF Project and terrestrial biodiversity are presented in Table 5.6.5-1. Mitigations identified to address and, if possible, remove potential interactions between the NSDF Project and terrestrial biodiversity are also integrated into the pathway analysis presented in Table 5.6.5-1. Following the table, assessments for each pathway considered secondary or having no linkage to terrestrial biodiversity are presented and primary pathways are summarized.

This page left intentionally blank

Table 5.6.5-1: Pathways Analysis for the Terrestrial Biodiversity Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Project activities during the construction phase: ▪ Site preparation ▪ Construction of the ECM, ▪ Blasting ▪ Development of surface water management structures	Vegetation clearing and grubbing will result in the loss or alteration of existing vegetation and topographical features. This will cause losses of some vegetation communities and potentially change wildlife habitat availability, use and connectivity, and could influence wildlife abundance and distribution.	▪ The SSA has been designed to avoid wetlands, where possible, and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. ▪ A 30 m buffer will be established along identified wetlands near the SSA; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion ▪ A 5 m treeline buffer is established from all property lines on the SSA to limit disturbance to vegetation and large tree roots at the treeline. ▪ Critical Blanding's turtle habitat will be assessed annually to ensure no significant loss at CRL and to determine compensation measures initiated at CRL or elsewhere.	Primary
	Vegetation clearing and grubbing will result in an increase in edge habitat, which could increase predation risk and nest parasitism risk for bird VCs.		Secondary

Table 5.6.5-1: Pathways Analysis for the Terrestrial Biodiversity Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
▪ Construction of the WWTP and other support facilities ▪ On-site road and access development ▪ Haulage of construction materials ▪ Installation of security and fencing around perimeter of ECM	Vegetation clearing and grubbing for the two temporary laydown and staging areas required for the installation of the transfer line to Perch Lake will result in the temporary loss or alteration of wetland habitat in the Perch Lake Swamp. This will cause temporary losses of a wetland vegetation community and potentially have a temporary effect on wildlife habitat availability, use and connectivity.	▪ Artificial nest mounds will be constructed on both sides of new and replaced culverts ▪ New and replaced culverts will be enhanced by planting native vegetation around the culvert entrances, while maintaining a clear line of site through the culvert ▪ The transfer line to Perch Lake will be installed using high-pressure horizontal directional drilling methods. This will limit surface disturbance within the wetland area of Perch Lake Swamp to two areas required for laydown and staging: one 400 m^2 area on the shoreline of Perch Lake, and one 100 m^2 area midway along Perch Lake Ring Road approach to the ECM. ▪ The mitigation described in the DFO Ontario Operational Statement – High-Pressure Directional Drilling (DFO 2007) will be followed, including siting of the transfer line and access to temporary laydown and staging areas largely within a previously established access road ROW (Perch Lake Ring Road), minimization of vegetation removal beyond previously disturbed areas, creation of, and adherence to an emergency Frac-out Response Plan and Spill Contingency Plan during installation, and full-time environmental monitoring during all phases of transfer line works within the Perch Lake Swamp to evaluate adherence to environmental protection measures and make observations on signs of surface frac-out of drilling mud (i.e., release through fractured bedrock drilling mud that travels toward the surface). Evidence of frac-out will trigger implementation of the Frac-out Response Plan. ▪ All in-water work will target the timing window of July 16 to October 1 to avoid critical fish spawning and egg/larval development periods for spring spawning fish species (DFO 2013, MNR 2013) while being protective of turtle overwintering habitats in and around Perch Lake. The construction duration is anticipated to be short term (i.e., <30 days). ▪ The Blanding's Turtle Road Mortality Mitigation Plan (Golder 2019a) includes provisions which will compensate for the removal of a portion of critical Blanding's turtles habitat near Perch Lake. The installation of nesting mounds as well as culverts are proposed to increase habitat connectivity and providing adequate nesting areas in close proximity to current habitat to limit movement requirements for nesting females. ▪ The disturbed portions of the two temporary laydown and staging areas beyond the edge of the Perch Lake Ring Road ROW (which will remain in place) will be restored to the natural wetland vegetation communities that were present prior to construction. ▪ Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site will be used during construction around disturbed areas, where appropriate. ▪ Bat boxes are relatively inexpensive and can be highly effective at providing habitat for roosting little brown myotis and possibly northern myotis. Tri colored bats are less likely to use bat boxes, but may use other forms of artificial roosting habitat; these options may be considered. Installation of bat boxes in suitable locations in the RSA is recommended to offset the incremental contribution of the NSDF Project to cumulative effects on SARA listed bats. ▪ In consultation with CNL biologists and in consideration of future losses of anthropogenic structures that may provide roosting habitat, offsetting in the form of 16 bat boxes was recommended. Bat boxes were installed in May 2017. Each two chambered box (Bat Conservation International approved design) was installed back to back on wooden poles in eight different locations around the proposed NSDF location. Occupancy was confirmed in July 2018 and has been increasing since then. This box design is suggested to have capacity for 350–400 individual bats per box, providing roosting habitat for a potential maximum of 6,400 individual bats (with 16 boxes). ▪ Criteria for appropriate siting included accessibility of box locations for installation and future monitoring of utilization/effectiveness, avoidance of areas with radiological contamination in surface water features and appropriate distance to anthropogenic disturbances to avoid sensory effects (i.e., noise). Immature forested areas adjacent to larger uncontaminated waterbodies and wetlands are high priority locations because these forest types do not currently provide high quality roosting habitat and would be most benefited by installation of bat roost boxes to expand the spatial coverage of potential roosting habitat within the RSA. Final site selection will be at the discretion of CNL biologists. ▪ Monitoring is being conducted at least weekly to determine if boxes are being used. Boxes not being used may be moved to an alternate location. ▪ A project in collaboration with Trent University is currently underway, where bats are being trapped and tracked back to the roost site (natural tree or bat box). Guano collection is being performed as well. This work has a duration of two years and will provide CNL with a better understanding of habitat occupancy by the bat species at risk, including bat boxes, and habitat preference. This work will support the objective of addressing knowledge gaps on the three bat species at risk ▪ A comprehensive Sustainable Forest Management Plan will be implemented to ensure the long-term retention of trees serving as maternity roosts for the bat species	Secondary

Table 5.6.5-1: Pathways Analysis for the Terrestrial Biodiversity Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Project activities during the construction phase (continued)	Vegetation clearing and grubbing may remove active migratory bird nests, bat maternity roosts and monarch butterflies (various life stages), which may influence reproduction and survival (incidental take).	■ Vegetation clearing and grubbing in the majority of the SSA, and particularly in complex forested habitat, will occur before April 8 or after August 31 to avoid effects on nesting birds and bat maternity roosts. ■ CNL has a risk assessment checklist to determine if an area qualifies as a simple habitat, qualifying for nest searches and clearing in the absence of nests during the breeding season. The checklist has a series of risk factors and the total score provides whether the area qualifies. Examples of risk factors are: ▪ knowledge of time periods of which migratory bird species are present; ▪ ability to perform searches for evidence of nesting using non-intrusive search methods to prevent disturbance; ▪ known breeding evidence of species at risk birds within 200 m (that reside in a similar habitat composition); ▪ habitat size and complexity; ▪ level of difficulty to locate and avoid the present nest types; ▪ frequency of disturbance; ▪ duration of disturbance; ▪ intensity of disturbance; ▪ extent of disturbance; ▪ level of noise emissions generated from disturbances; and ▪ birds' tolerance to disturbance. ■ If vegetation clearing in small areas with simple habitat (i.e., that can be effectively searched for nests) cannot be conducted outside the breeding bird nesting period (April 8 to August 28), or bat maternity roosting period (May 1 to August 31), pre-clearing bird and bat surveys will be completed to confirm no active nests/roosts are present in trees to be felled. Pre-clearing bird and bat surveys will be completed by CNL's Environmental Protection team to confirm no active nests/roosts are present in trees to be felled. This work must be approved by Environmental Protection prior to execution and can be denied if the risk to birds or bats is considered high. ■ Species-specific buffers will be put in place around active nests/roosts to avoid disturbance to wildlife caused by noise and other sensory disturbance caused by site preparation activities. ■ Implementation of a comprehensive Sustainable Forest Management Plan to ensure the long-term retention of trees serving as maternity roosts for the bat species. At CRL, harvesting has not been conducted in a consistent manner since CNL operations started back in the 1940s. In absence of natural disturbances such as forest fire, the CRL forest does not represent what the forest should look like under a natural disturbance regime. For this reason, the CRL site consists of more old forest stands than would exist in a natural environment offering more habitat to bat species than it would under natural regimes. Many bat species preferentially roost in older forest stands, compared to young forests. If the forest is not actively managed, the old trees will disappear from natural decay and will be replaced with species that do not represent a natural forest structure for this area and would not be suitable habitat for bats. For this reason, CNL is committing to implement a Sustainable Forest Management Plan to ensure a representative presence of roost trees in the landscape and through time. ■ Trees will not be felled until the nests/roosts are confirmed inactive and no longer occupied. ■ A 5 m treeline buffer is established from all property lines on the SSA to limit disturbance to vegetation and large tree roots at the treeline. ■ If vegetation clearing is scheduled in open habitat between late May and October, the habitat will be searched in advance of construction for the presence of milkweed. Areas of the footprint that contain milkweed will be cleared outside of late May to October to avoid effects on monarch butterflies.	No Linkage
	Vegetation clearing and grubbing may remove active milksnake hibernacula, which may influence reproduction and survival (incidental take of hibernating snakes).	■ None	Primary

Table 5.6.5-1: Pathways Analysis for the Terrestrial Biodiversity Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Project activities during the construction phase (continued)	The high-pressure horizontal directional drilling installation of the transfer line to Perch Lake may result in a release of drilling mud (i.e., frac-out), which may cause changes to surface water quality, which can cause changes to soils and vegetation communities (including wetlands), which in turn can affect wildlife survival and reproduction.	▪ The transfer line to Perch Lake will be installed using high-pressure horizontal directional drilling methods. The mitigation described in the DFO Ontario Operational Statement – High-Pressure Directional Drilling (DFO 2007) will be followed, including creation of, and adherence to a Frac-out Response Plan and Spill Contingency Plan during installation, and full-time environmental monitoring during all phases of transfer line works within the Perch Lake Swamp to evaluate adherence to environmental protection measures and make observations on signs of surface frac-out of drilling mud. Evidence of frac-out will trigger implementation of the Frac-out Response Plan.	Secondary
	Fly rock from blasting may result in injury or mortality to wildlife.	▪ A blasting plan, as part of the EPP, will be developed by the Contractor and implemented for the NSDF Project Blasting activities will follow industry standard best management practices and applicable federal regulations. ▪ Additional guidance for the NSDF Project blasting limits will be obtained from the Ontario Provincial Standard Specification (OPSS) in the document OPSS 120 – General Specification for the Use of Explosives (OPSS 2014). ▪ Set-back distances required for blasting will be identified in the Blasting Plan. ▪ Blasting activities will be temporarily suspended if wildlife are observed in the blasting area.	No Linkage
	Blasting residuals and metals may be released during construction of the ECM and surface water drainage features through the SSA may transport them directly into downstream waterbodies or adjacent wetlands, affecting surface water and sediment quality and causing changes to wetlands and riparian vegetation communities, which in turn can affect wildlife habitat availability and distribution.		No Linkage
	The construction of the NSDF Project may change downstream discharge, water levels and channel/bank stability in streams, which can cause changes to soils and vegetation communities (including adjacent wetlands), which in turn can affect wildlife habitat availability and distribution.	▪ Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site will be used during construction around disturbed areas, where appropriate. ▪ Where practical, natural drainage patterns will be used to reduce the use of ditches and diversion berms. ▪ Culverts will be installed or upgraded along site access roads, as necessary, to maintain drainage; all drainage features will be designed to safely convey the flows associated with the probable maximum precipitation event. ▪ The surface water pond designs will promote infiltration and suspended particulate settling, and will control discharge to the downstream receiving natural systems.	No Linkage

Table 5.6.5-1: Pathways Analysis for the Terrestrial Biodiversity Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Project activities during the construction phase: ▪ Site preparation ▪ Construction of the ECM ▪ Blasting (as required) ▪ Development of surface water management structures ▪ Construction of the WWTP and other support facilities ▪ On-site road and access development ▪ Construction of transfer line and Perch Lake diffuser ▪ Domestic waste (solid and liquid) management ▪ Soil spoils haulage to a soil storage area ▪ Installation of security and fencing around perimeter of ECM Project activities during the operations phase: ▪ Phased development of disposal cells in the ECM ▪ On-site transportation of waste and placement in the ECM ▪ Progressive closure of disposal cells and installation of final cover ▪ Operation of the WWTP ▪ Existing presence of fencing around perimeter of ECM ▪ Surface water management ▪ Domestic waste (solid and liquid) management; and, ▪ Routine operational management and monitoring activities.	Sensory disturbance (i.e., lights, smells, noise, human activity, alteration of viewscape) can change wildlife habitat availability, use and connectivity (movement and behaviour), which can lead to changes in wildlife abundance and distribution.	▪ Activities with highest levels of noise and habitat disturbance will be avoided during most sensitive life history phase (i.e., breeding and nesting for birds, maternity roosting for bats) by conducting vegetation clearing and grubbing before April 8, or after August 31 to avoid effects on nesting birds, bat maternity roosts and the active Blanding's turtle season, and to minimize effects on monarch butterfly and milksnake. ▪ Activities with a high noise level (e.g., rock crushing) will be completed during day light conditions. ▪ Work inside closed buildings may take place during non-daylight conditions.	Primary

	Potential introduction and spread of noxious weed species from trucks and other equipment can affect vegetation community species composition, which can affect wildlife habitat availability and distribution.	▪ An Invasive Species Management Plan in keeping with best management practices such as the MNR Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNRF 2019a) will be implemented to limit effects of noxious and invasive plants on natural vegetation, which includes:
		  ▪ cleaning and inspection of vehicles and equipment prior to SSA entry;
		  ▪ re-cleaning vehicles and equipment if an area of weed infestation is encountered, prior to advancing to a weed free area; and
		  ▪ locating and managing cleaning locations on the SSA.
			Secondary

	Attraction of wildlife to the NSDF Project (e.g., food waste, petroleum-based products) may increase human-wildlife interactions and change predator-prey relationships, which can affect wildlife survival and reproduction.	▪ All wastes that arise as a result of the construction, operations and closure phases will be safely managed and in accordance with CNL's Waste Management Program. ▪ Attractants (e.g., collection and storage in appropriate wildlife-resistant containers) will be managed to limit interactions between people and wildlife. ▪ As per CNL's Management of Land, Habitat and Wildlife procedure, (CNL 2018c) feeding of wildlife is prohibited to minimize habituation. ▪ Staff and contractors will be provided with training to reinforce the importance of not feeding wildlife and carrying out proper waste management practices.	Secondary
	Movement of heavy equipment and other vehicles on roads and through previously undeveloped / forested areas may cause injury or mortality to Blanding's turtle, milksnake and monarch butterfly.	▪ Reptile exclusion fencing will be installed around the perimeter of the SSA prior to initiating activities during the construction phase and prior to the active Blanding's turtle season (i.e., prior to April). This mitigation will also benefit milksnakes. ▪ Damaged or ineffective fencing and signage will be repaired. ▪ Road grading and levelling activities will not be completed during the turtle terrestrial season (May 15 to September 30).	Primary
	Installation and maintenance of perimeter fencing will potentially modify movement corridors for Blanding's turtle and milksnake in the LSA, which may increase their travel distances and thus increase the risk of injury/mortality on roads.	▪ Temporary exclusion fencing will be installed around the NSDF EMR footprint during construction of the NSDF Project. This temporary exclusion fencing will be replaced by permanent fencing by the end of construction of the NSDF Project. Exclusion fencing will benefit both Blanding's turtles and milksnakes. ▪ A road mortality survey will be completed for turtles and milksnake in the species' active seasons of April 15 to September 30 ▪ After replacement, culverts will have appropriate permanent fencing installed for 200 m on either side of the culvert to guide turtles through the tunnel. ▪ Following approval of the NSDF Project, additional permanent exclusion fencing will be installed in reptile hotspots along Plant Road ▪ Drivers have standard safety training and are provided with environmental awareness training. ▪ Existing CRL site speed limits on access roads will be enforced. ▪ Signs warning drivers of high use wildlife areas will be posted and speed limits in these areas reduced. ▪ Employees in vehicles encountering wildlife of concern (e.g., Blanding's turtle, milksnake) on roads are required to communicate the presence of wildlife on the roads to other employees working in the area and to CNL's Environmental Protection team. ▪ The existing CNL Employee Education Program will be adapted to the NSDF Project prior to construction. All employees and contractors will be trained on the identification and safe handling of Blanding's turtle to help the turtles across the road. ▪ Per CNL's Management of Land, Habitat and Wildlife procedure (CNL 2018c), dead or wounded animals on roads must be reported to the environmental department. ▪ Wildlife collisions with vehicles will be monitored, which provides feedback for adaptive management.	Primary

Table 5.6.5-1: Pathways Analysis for the Terrestrial Biodiversity Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Project activities during the construction phase (continued) Project activities during the operations phase (continued):	Attraction of wildlife to surface water management ponds may influence wildlife survival and reproduction.	▪ Reptile exclusion fencing will prevent Blanding's turtles and other reptiles (e.g., milksnake) and amphibians from entering the surface water management ponds. ▪ Migratory bird exclusion measures will be implemented at the surface water management ponds.	No Linkage

	Vegetation clearing and grubbing activities and hauling activities during operations use vehicles and equipment that combust fuel and emit criteria air contaminants. These activities involve material handling, vehicles travelling on paved and unpaved roads, and wind erosion of stockpiles that will result in fugitive dust emissions. Air and dust emissions and subsequent deposition may cause a change in soil quality and (directly affecting vegetation communities), which could in turn lead to indirect changes in wildlife habitat availability.	▪ CNL's procedure for Management and Monitoring of Emissions, (CNL 2018d) which includes operational control monitoring, verification monitoring and environmental monitoring, will be implemented.
		▪ The Dust Management Plan (AECOM 2018) for the NSDF Project will include:
		  ▪ restricting or suspending activities if unacceptable amounts of dust are generated due to winds or other site conditions;
		  ▪ use of water spraying or misting techniques (e.g., water trucks) as the primary dust control method;
		  ▪ use of fixatives (e.g., chemical suppressant) for dust control and for use as daily ECM cover;
		  ▪ suspension of excavating, loading, hauling and disposal operations when wind speeds exceed the specified criterion; and
		  ▪ vehicles that have come into contact with contamination will be required to pass through the vehicle decontamination facility.
		▪ On-site vehicles and equipment engines will meet Tier 2 emission standards and be maintained in good working order.
		▪ Idling of vehicles on site will be limited.
			Secondary

	Surface water runoff from the SSA (i.e., non-contact water) can contain contaminants and suspended solids, which can affect soil, water and vegetation quality, ultimately leading to changes to wildlife habitat availability, survival and reproduction.	▪ Procedures for surface water management will be developed and implemented for the NSDF Project. ▪ The target surface water quality objective for non-contact surface water is provided in the Stormwater Management Planning and Design Manual (MOE 2003). ▪ Non-contact surface water from all external areas will be conveyed by ditches, swales and culverts to surface water management ponds that will address water quality and water quantity criteria established for the wetland receiving waters and, ultimately, Perch Creek. ▪ The surface water management ponds are designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during the operations, closure and post-closure phases. ▪ The current surface water management pond footprints reflect the overall storage required to control post-closure flows to predevelopment levels for the 2-year through to 100-year rainfall events at the site. This volume also contains the storage required for sediment control during construction and water quality control during the operations phase. ▪ Where drainage crosses roadways, culverts are sized to convey the 25-year design event without road overtopping.	No Linkage

Table 5.6.5-1: Pathways Analysis for the Terrestrial Biodiversity Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment

Project activities during the operations and closure phases:
▪ Surface water management
▪ Operation of the WWTP
▪ Discharge of treated effluent from the WWTP
	Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) can cause changes to groundwater and surface water quality in the wetland and Perch Lake, as well as downstream surface water quality, which can affect wildlife survival and reproduction.	▪ The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses best available technology that is economically achievable and capable of meeting regulatory requirements.
		▪ Effluent discharge targets for wastewater discharges are protective of the environment and human health.
		  ▪ Discharge targets for non-radiological contaminants are sourced from federal and provincial guidelines for protection of aquatic biota.
		  ▪ Discharge targets for radionuclides are the Canadian Drinking Water Guidelines with the exception of tritium for which a site-specific target is developed (Section 3.4.2.5.1).
		▪ Treated effluent will be monitored and confirmed to meet the effluent discharge targets before release to the environment.
		▪ An exfiltration gallery is proposed at the discharge outlet to promote the exfiltration of treated effluent into the local groundwater regime.
		▪ The transfer line will release treated effluent via a diffuser to limit mobilization of sediment in Perch Lake.
		▪ Appropriate procedures to identify emergency spill occurrences and response, as well as appropriate response to non-contact surface water or leachate contamination, will also be implemented as described in the Operations and Maintenance Plan.
			Secondary

	Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch lake (via a transfer line) and the discharge of non-contact water to adjacent wetlands can cause changes to hydrology, resulting in scouring of the wetlands, which can affect wildlife habitat availability and distribution.	▪ Discharge of treated effluent to the exfiltration gallery area will help to reduce water loss from the hydrogeological system. ▪ Design consideration was given during the selection of the discharge location of treated effluent for environmental effects of scour on the receiving waterbodies. As such, the preferred design (i.e., discharge to the exfiltration gallery and Perch Lake diffuser) was chosen as the favourable alternative as they resulted in negligible scour potential. ▪ Outlet flows from all three SWMPs will be dispersed by level spreaders that will provide an even flow distribution to the adjacent wetlands with an appropriately wide dispersal pattern. ▪ The WWTP system's outlet utilizes a headwall which discharges to a level spreader for the purposes of preventing erosion and sedimentation at the outlet for the exfiltration gallery. ▪ The outlet locations of the SWMPs are limited by the site boundary (greater than 5 m separation required) so that there is no discharge from the spreader directly to a waterbody. ▪ Annual inspection and maintenance activities will identify any erosion problems. ▪ Inspections will be undertaken and maintenance activities completed, as required, after major storm events and after the annual spring melt to confirm there are no major erosion issues.	No Linkage
Project activities during the operations and closure phases: ▪ Surface water management ▪ Operation of the WWTP ▪ Discharge of treated effluent from the WWTP	Leakage of leachate from the ECM during the operations and closure phases may cause changes to groundwater quality in the wetland and downstream surface water quality, which can affect wildlife survival and reproduction.	▪ Design of the ECM includes base contours that have been developed using a herringbone pattern with ridges and valleys to promote leachate transport to the leachate collection system for removal. ▪ The base liner design include both primary and secondary liner systems that are designed to have redundancy in case of premature degradation and are a combination of natural and synthetic barrier systems. These include a compacted clay liner (CCL), two geosynthetic clay liners (GCL) and an HDPE geomembrane. ▪ Clay materials were selected for the CCL and GCL components of the liner system as these materials are anticipated to maintain their function as hydraulic barriers throughout and beyond the design life of the disposal facility (i.e., 550 years). ▪ The high-density polyethylene (HDPE) geomembrane for the liner was selected as it is compatible with the leachate generated by the waste and will achieve a long service life. ▪ The base liner system will include an underlying compacted clay liner to supplement the primary and secondary liner system. ▪ The leachate collection and monitoring system design will provide accessible access points for monitoring, inspections, maintenance, repairs and replacements. ▪ Appropriate responses to leachate leakage and contamination will be implemented as described in the Operations and Maintenance Plan and Contingency Plan	No Linkage

Table 5.6.5-1: Pathways Analysis for the Terrestrial Biodiversity Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Project activities during the closure and post-closure phases: ▪ Maintenance of fencing around perimeter of ECM ▪ Installation of final cover, remediation and grading of SSA ▪ On-going long-term performance monitoring, transfer of NSDF Project into institutional control	The installation of the final cover of the ECM and decommissioning of NSDF Project infrastructure may change downstream discharge, water levels and channel/bank stability in streams, which can cause changes to soils and vegetation communities (including adjacent wetlands), which in turn can affect wildlife habitat availability and distribution.	▪ The final cover will be designed to promote positive drainage from the SSA and reduce erosion or abrasion of the final cover. ▪ Environmental monitoring will be completed as required during the institutional control period for the NSDF Project to confirm that the final cover is functioning as intended	No Linkage
	Leakage of leachate from the ECM during the post-closure phase (i.e., after year 2400) from liner and final cover degradation as a result of normal evolution can cause changes to groundwater quality in the wetland and downstream surface water quality, which can affect wildlife survival and reproduction.	▪ The final cover is designed to promote positive drainage from the SSA and reduce erosion or abrasion of the final cover. ▪ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound and minimize leachate generation. ▪ The final cover system design incorporates a series of shallow, trapezoidal, riprap-lined drainage channels that are designed to convey water at low velocity. ▪ The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the final cover and underlying waste materials, destabilization of the ECM structure and damage to access roads. ▪ The ECM Final Grading and Drainage Plan includes collection ditches along the top of the ECM berm road to collect side slope drainage. ▪ Environmental monitoring will be completed as required during the institutional control period for the NSDF Project to confirm that the final cover is functioning as intended	Secondary
	Potential introduction and spread of noxious weed species during closure and remediation can affect vegetation community species composition, which can affect wildlife habitat availability and distribution.	▪ Locally appropriate grass seed mixtures that are certified weed-free will be applied to any cleared and reclaimed areas as soon as practical following construction. ▪ Upon completion of the installation of the final cover over the ECM, turf grass will be established and maintained. Maintenance of the final cover includes restricting weed establishment and preventing surface erosion and abrasion.	Secondary

ECM = engineered containment mound; WWTP = Wastewater Treatment Plant; VC = Valued Component; SSA = Site Study Area; DFO = Fisheries and Oceans Canada; ROW = right-of-way; OPSS = Ontario Provincial Standard Specification; MNR = Ministry of Natural Resources; LSA = Local Study Area; MECP = Ministry of Environment, Conservation and Parks; MOECC = Ontario Ministry of the Environment and Climate Change.

5.6.5.2.1 No Linkage Pathways

The following pathways were assessed as having no measurable environmental change and hence, no linkage to residual effects on terrestrial biodiversity VCs.

- **Vegetation clearing and grubbing may remove active migratory bird nests, bat maternity roosts and monarch butterflies (various life stages), which may influence survival and reproduction.**

The MBCA prohibits the destruction of migratory bird nests during the breeding season. In the RSA, the migratory bird breeding season extends from April 8 to August 28. Little brown myotis, northern myotis and tri-colored bat are listed as endangered on the Ontario *Endangered Species Act, 2007,* and federal SARA. As such, there are prohibitions against killing or harming individuals or destroying a residence, including maternity roosting habitat. Female bats form maternity roost colonies to give birth and raise their young; most young are born in late-June or early-July and are weaned at 26 days of age (COSEWIC 2013). Roosts are also used during the pre-maternity roosting period and swarming period. Therefore, bat roosting period is assumed to be from May 1 to August 31.

Vegetation clearing in the majority of the SSA and particularly in complex forested habitat will be scheduled to occur outside of the migratory bird nesting period (April 8 to August 28) and out of the bat maternity roosting period (May 1 to August 31). Upland areas attractive to migratory birds carry a particularly high risk of disturbing or destroying migratory bird nests or eggs. Because the SSA contains upland areas known to support a diversity of migratory birds, the general use of nest searches as a form of mitigation is not recommended because it is unlikely that all nests would be successfully located. Furthermore, nest sweeps in complex forested habitat in the SSA would likely identify many active nests with overlapping setbacks where clearing could not take place until young have fledged, resulting in schedule delays and additional costs associated with monitoring nest activity. Therefore, every effort will be made to remove vegetation and topsoil prior to the nesting and roosting period to minimize nesting attempts and preclude bat roosting.

Pre-clearing bird and bat surveys will be completed by CNL's Environmental Protection team to confirm no active nests/roosts are present in trees to be felled. This work must be approved by Environmental Protection prior to execution and can be denied if the risk to birds or bats is considered high. If vegetation clearing activities must be completed during the migratory bird nesting period or bat maternity roosting period, they will only occur in small areas and/or areas of simple habitat, where an active search for nests may be carried out successfully if undertaken by experienced observers using widely accepted protocols and including behaviour indicative of nesting (e.g., aggressive, territorial, defensive, distractive behaviour; carrying of faecal sacs, food or nesting material). CNL has a risk assessment checklist to determine if an area qualifies as a simple habitat, qualifying for nest searches and clearing in the absence of nests during the breeding season. The checklist has a series of risk factors and the total score provides whether the area qualifies. Examples of risk factors include the ability to perform searches for evidence of nesting using non-intrusive search methods to prevent disturbance and known breeding evidence of species at risk birds within 200 m (that reside in a similar habitat composition).

In addition, a 5 m treeline buffer is established from all property lines on the SSA to limit disturbance to vegetation and large tree roots at the treeline. Nest searches will be completed prior to any clearing or construction activities during the migratory bird nesting period, including in areas that were pre-cleared to account for ground nesting birds.

If vegetation clearing is scheduled in open habitat between late May and October, the habitat will be searched in advance of construction for the presence of milkweed. Areas of the footprint that contain milkweed will be cleared outside of late May to October to avoid effects on monarch butterflies.

These mitigation practices are anticipated to avoid any changes to the survival or reproductive success of birds, bats and monarch butterflies from the NSDF Project relative to baseline conditions. Therefore, this pathway was determined to have no linkage to effects on survival and reproduction of these species and is not predicted to affect the maintenance of self-sustaining and ecologically effective populations that overlap the RSA.

- **Blasting residuals and metals may be released during construction of the ECM and surface water drainage features through the SSA may transport them directly into downstream waterbodies adjacent wetlands, affecting surface water and sediment quality and causing changes to wetlands and riparian vegetation communities, which in turn can affect wildlife habitat availability and distribution.**
- **Fly rock from blasting may result in injury or mortality to wildlife.**

Use of explosives during the construction phase of the NSDF Project could cause changes in surface water and soil quality, which has potential to affect wildlife habitat. Explosives have the potential to release nitrogen residual substances (e.g., ammonium nitrate/fuel oil). Blasting activities and the removal of waste rock could increase dust deposition and could increase trace metal (e.g., aluminum, cadmium, chromium, copper, iron, mercury and silver) concentrations and nitrogen residual substances.

A Blasting Plan will be developed and implemented for the NSDF Project. The Blasting Plan will comply with Fisheries and Oceans Canada (DFO) *Guidelines for the Use of Explosives in or Near Canadian Waters* (Wright and Hopky 1998) to limit the potential for residual blasting interactions with downstream water quality. The Blasting Plan will also provide mitigation to limit the potential for effects on surface water quality from fugitive dust generation through excavation and material transport. Additional guidance will be obtained from *OPSS 120 – General Specification for the Use of Explosives* (OPSS 2014).

The anticipated quantities of blasted rock are approximately 170,000 m^3. There will also be an allowance made for additional trench blasting that may be required to facilitate utility runs. It is anticipated that the majority of blasted rock will be recycled for use within the construction of the ECM. Rock that cannot be recycled for reuse will either be stored at the CRL site or cleared for off-site use. Set-back distances required for blasting will be identified in the Blasting Plan. Any runoff in contact with blasting residues at the SSA will be managed according to the Surface Water Management Plan (e.g., directed to surface water management ponds and associated systems) during the construction phase. In addition, the potential for transporting blasting residuals into downstream waterbodies is minimized as blasting operations will be limited to a relatively short period of time during the construction phase. Blasting activities can also cause physical injury or mortality to wildlife. Surface blasting will be temporarily suspended if animals are observed within the danger zone identified by the blast supervisor.

The use of explosives for the development of the ECM in the proposed NSDF Project is considered to potentially influence runoff quality with respect to minor increases in nitrate and ammonia concentrations for a short period in the construction phase. As such, blasting activities are not predicted to affect the maintenance of self-sustaining and ecologically effective vegetation communities and wildlife populations that overlap the RSA.

- **The construction of the NSDF Project may change downstream discharge, water levels and channel/bank stability in streams, which can cause changes to soils and vegetation communities, which in turn can affect wildlife habitat availability and distribution, including sensitive species such as Blanding's turtle.**

- **The installation of the final cover of the ECM and decommissioning of NSDF Project infrastructure may change downstream discharge, water levels and channel/bank stability in streams, which can cause changes to soils and vegetation communities (including adjacent wetlands), which in turn can affect wildlife habitat availability and distribnarchmoution.**

Changes to surface flows, water levels and water quality from NSDF Project construction and decommissioning are expected to be limited using environmental design features and mitigation. The NSDF Project was designed to limit disturbance to the natural environment to the extent feasible and will avoid stream and wetland habitats. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. In addition, a 30 m buffer is established along all identified wetlands near the SSA. In addition to the wetlands buffer, a 5 m treeline buffer is established from all property lines on the SSA to limit disturbance to vegetation and large tree roots at the treeline. Buildings or structures will not be situated within 5 m of this buffer zone (i.e., 10 m from property line) to provide access for equipment around structures. A buffer zone will also be maintained between the waste and the boundary of the disposal site. This zone provides sufficient area surrounding the facility operations to allow environmental monitoring to be performed, facilitate maintenance and to allow implementation of contingency measure during an emergency.

All proposed physical works are located within the SSA, affecting a relatively small area (5.1%) of the total contributing basin area for Perch Creek (720 ha; Robertson and Barry 1985). Any changes to existing drainage patterns will largely be restricted to the Perch Creek and Perch Lake Watershed. The total annual volume of contact surface water to be treated is 11,000 m^3. The volume represents approximately 0.6% of the average total outflow from Perch Lake (1,700,000 m^3/yr), or 0.5% of the average total outflow from Perch Creek (2,200,000 m^3/yr). Operational treated effluent discharge is expected to be less than 11 m^3/hr. Flow rates within Perch Creek are approximately 252 m^3/hr; the effluent discharge rate is roughly 0.4% of the average Perch Creek flows and approximately 11.5% of East Swamp weir flows. Furthermore, the receiving wetlands are expected to buffer the discharge, further reducing flow rates into Perch Creek. Effects to the wetlands, including the East Swamp wetland, are expected to be minimal based on the NSDF Project's anticipated change to flows in Perch Creek and East Swamp weir flows.

All non-contact and contact surface water will be managed within the SSA according to the Surface Water Management Plan that will be developed, reducing the potential for the NSDF Project to affect downstream discharge, water levels and channel/bank stability. Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site will be used during construction and decommissioning around disturbed areas, where appropriate.

Closure activities include the installation of a final cover over the ECM to limit ponding and water infiltration into the waste. Modification to the drainage ditches and conveyance channels will be made to promote positive drainage from the site and limit erosion or abrasion of the final cover. Runoff control for the final cover is designed to limit ponding and infiltration of water into the ECM, erosion of the final cover and waste material, and destabilization of the structure. The ECM design approach is to control the direction and velocity of the runoff to prevent erosion and abrasion of the final cover. Any surface water infiltrating the final cover will be collected by the leachate collection system and sent to the WWTP. The three surface water management ponds will remain to promote infiltration and settlement of suspended solids and restrict discharge rates to the nearby wetland. Decommissioning of the WWTP and all associated surface water management structures will be completed after

the leachate quantity and quality no longer requires treatment. In the event that the WWTP is required beyond its design life, the unit would be refurbished to enable continued treatment of leachate or other treatment options investigated. Environmental monitoring will be completed throughout the post-closure phase for the NSDF Project to confirm that the final cover is functioning as intended.

Based on this information, effects to hydrology from changes in the Perch Creek and Perch Lake Watershed were determined to be negligible (Section 5.4.2.5.2.2). Consequently, these pathways were determined to have a no linkage to effects on vegetation and wildlife habitat availability and distribution. Changes to hydrology are not predicted to affect the maintenance of self-sustaining and ecologically effective vegetation communities and wildlife populations that overlap the RSA.

- **Attraction of wildlife to surface water management ponds may influence wildlife survival and reproduction.**

Surface water is categorized as contact or non-contact runoff. Contact runoff is considered to be contaminated and must be treated by the WWTP. Non-contact (i.e., non-contaminated) runoff is conveyed by ditches and culverts to the three surface water management ponds. All surface water management ponds are designed to address erosion and sediment control during construction (i.e., acting as interim sediment control ponds), and water quality/quantity concerns during the operations phase.

The surface water management ponds will be within the six-foot high chain link perimeter fence surrounding the NSDF Project, and therefore not accessible to ground-based wildlife species (e.g., most mammals, herpetofauna [i.e., reptiles and amphibians]). Birds and bats may be attracted to the surface water management ponds, especially during the spring if these ponds are the only open sources of water in the area (i.e., they are ice-free). These open surface water pond features are not predicted to contain any levels of contaminants that would be of concern to wildlife. In addition, the ponds will be small, and it is expected that the Ottawa River and other larger natural waterbodies in the RSA and LSA (Perch Lake, specifically) will be more attractive to wildlife than the ponds within the SSA. As such, this pathway was determined to have no linkage to effects on the survival and reproduction of wildlife and is not anticipated to affect the maintenance of self-sustaining and ecologically effective wildlife populations that overlap the RSA.

- **Surface water runoff from the NSDF Project can contain contaminants and suspended solids, which can affect soil, water and vegetation quality, ultimately leading to changes to wildlife habitat availability, survival and reproduction.**

The surface water management ponds are designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during the operations, closure and post-closure phases. The current surface water management pond footprints reflect the overall storage required to control post-closure flows to predevelopment levels for the 2-year through to 100-year rainfall events at the site. This volume also contains the storage required for sediment control during construction and water quality control during the operations phase. The target surface water quality objective is provided in the *Stormwater Management Planning and Design Manual* (MOE 2003), which reports a 60% total suspended solids removal that provides basic water quality treatment for discharge to the receiving wetland. The surface water management ponds 1 will meet 80% total suspended solids removal which will provide enhanced water quality treatment. surface water management ponds 2 will provide 76% TSS removal and surface water management ponds 3 will meet 60% total suspended solids removal during operations which will be sufficient because the

receiving waterbody is a wetland and not a watercourse. The wetland functions as a sediment trap that will provide additional treatment prior to stormwater reaching any watercourses in wetlands.

During the construction phase, erosion and sediment control measures will be in place to mitigate the effects of soil erosion and sediment transport. The measures include the use of erosion control blankets, as needed, to control erosion on steep slopes, check dams in ditches and swales, and the three proposed surface water management ponds that will be constructed to serve as interim sediment control facilities during construction, and then as stormwater management facilities during the operations and post-closure phases. Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site (i.e., CNL's *Management of Land, Habitat and Wildlife* procedure; CNL 2018c) will be used around disturbed areas, where appropriate. Furthermore, an Environmental Management Plan has been developed as part of the design plan for the site outlining the erosion and sediment control measures and surface water management pond construction schedule discussed. It additionally outlines administrative protocols such as training, contractor document submissions and staffing required for effective surface water management throughout all phases of the NSDF Project.

Site operations include surface water management for the ECM and all external areas. Surface water from all external areas will be conveyed by ditches, swales and culverts to surface water management ponds that will address water quality and water quantity criteria established for the wetland receiving waters and, ultimately, Perch Creek. Contact water, which is exposed to waste within the ECM, will drain from the active cells of the ECM and be conveyed to the WWTP. Non-contact water drainage from completed cells and yet-to-be completed cells will be directed either by gravity to the external surface water management system or to temporary holding ponds within the ECM, then pumped to the three surface water management ponds.

Facility inspections will be completed on a defined schedule to confirm that inlets and outlets are clear of debris and to confirm that there are no major erosion issues at the inlet or outlet. As well, the integrity of berms and outlet structures will be confirmed by visual inspections (e.g., to identify any animal burrowing activity or active soil erosion). The transfer line will release treated effluent via a diffuser to limit mobilization of sediment in Perch Lake. Inspections will also include an annual sediment level monitoring component within each pond to identify sediment accumulation rates that may require clean-out. If necessary, pond sediment will be extracted by excavation equipment and will be disposed of based on sediment sampling, testing and classification according to MECP standards, or stockpiled, dewatered and reused on site for daily ECM cover operations. Sediment removal will follow procedures identified in the *Stormwater Management Planning and Design Manual* (MOE 2003).

Roadway, sidewalk and parking lot winter maintenance activities that may release road salt to the environment include snow plowing/shoveling and de-icing practices, salt and sand storage, and snow stockpiling, removal and disposal. The current winter maintenance practices outlined in the CRL Salt Management Plan provide for effective management of salt use, and will be applied to the NSDF Project, as necessary. Per the plan, the application of road salt on the SSA will be to be limited as salt residual within contact water and/or leachate may compromise the treatment effectiveness of the WWTP systems. Instead, alternative products in winter road management, such as a sand-stone mixtures, are currently being considered.

The implementation of this mitigation will reduce the potential for changes to soil, water and vegetation quality from surface water runoff from the SSA. As such, this pathway was determined to have no linkage to effects on the abundance of wildlife habitat, and survival and reproduction of wildlife and is not anticipated to affect the maintenance of self-sustaining and ecologically effective wildlife populations that overlap the RSA.

- **Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) and the discharge of non-contact water to adjacent wetlands can cause changes to hydrology, resulting in scouring of the wetlands, which can affect wildlife habitat availability and distribution.**

The NSDF Project will generate two water streams which will have the potential to impact water flows and levels in wetlands including:

- treated effluent from the WWTP which will be routed to the exfiltration gallery or Perch Lake; and
- non-contact water (i.e., water that has not been contaminated through contact with the ECM) which will be managed through a series of SWMPs.

A Surface Water Management Plan will be implemented to mitigate effects from wastewater discharges. Most of the wastewater flow will be generated from non-contact water produced during active filling of the ECM; contributions by leachate and decontamination activities represent a small fraction of the overall wastewater that will be treated by the WWTP. The total annual volume of water to be treated is 11,000 m^3. The volume represents approximately 0.6% of the average total outflow from Perch Lake (1,700,000 m^3/yr), or 0.5% of the average total outflow from Perch Creek (2,200,000 m^3/yr). Operational treated effluent discharge is expected to be a maximum of approximately 11 m^3/hr with an average effluent discharge rate below 1 m^3/hr. Flow rates within Perch Creek are approximately 252 m^3/hr; the maximum effluent discharge rate is roughly 0.4% of the average Perch Creek flows and approximately 11.5% of East Swamp weir flows. During the operations phase, the additional infiltration applied at the exfiltration gallery results in a localized increase in water table elevation of up to 1 m compared to the current conditions (see Section 5.3.2.6).

An exfiltration gallery is proposed at the discharge outlet for the treated effluent to promote the exfiltration of treated water into the local groundwater regime. Treated effluent will also be discharged directly to Perch Lake via a transfer line. The transfer line to Perch Lake has been designed to manage the full annual volume of treated effluent, if required, which will prevent the potential for overland flow at the exfiltration gallery.

The major flow system for all three SWMPs, which manage non-contact water, will outlet to adjacent wetlands and will be dispersed by level spreaders that will provide an even flow distribution to the wetlands with an appropriately wide dispersal pattern. Current SWMPs outlet locations are limited by the site boundary (greater than 5 m separation required) so that there is no discharge from the spreader directly to the wetlands. Local topography between the level spreader and the wetlands, as well as any setbacks, has influenced the location of the on-site level spreader.

Annual maintenance activities will identify any erosion problems. Facility inspections will be completed twice annually to confirm that inlets and outlets are clear of debris and to confirm that there are no major erosion issues at the inlet or outlet. In addition, a maintenance review will be completed after major storm events and after the annual spring melt to confirm there are no major erosion issues at the dispersion outlets. As a result of the design of the surface water management pond outlets and the proposed low discharge rates (i.e., 1 m^3/hr), the discharge of treated effluent and non-contact water to receiving wetlands is not predicted to result in changes to water levels, flows, and channel and bank stability, that would affect water quality at downstream locations. As a result, this pathway is not predicted to affect the maintenance of self-sustaining and ecologically effective vegetation communities and wildlife populations that overlap the RSA.

- **Leakage of leachate from the ECM during the operations and closure phases may cause changes to groundwater quality in the wetland and downstream surface water quality, which can affect wildlife survival and reproduction.**

Design of the ECM includes base contours that have been developed using a herringbone pattern with ridges and valleys to promote leachate transport to the leachate collection system for removal. The base liner design includes both primary and secondary liner systems that are designed to have redundancy in case of premature degradation and are a combination of natural and synthetic barrier systems. The primary liner will include a leachate collection system with the secondary liner housing a leak detection system. The composite base liner will contain perforated high-density polyethylene (HDPE) collection and monitoring pipes. The HDPE geomembrane was selected as it is compatible with the leachate generated by the waste and will achieve a long service life. The HDPE geomembrane was selected as it is compatible with the leachate generated by the waste and is expected to perform as an effective hydraulic and diffusion barrier over the 550-year design life (see Section 3.4.1.4). The base liner system will include an underlying compacted clay liner to supplement the primary and secondary liner system. The leachate collection and monitoring system design will provide accessible access points for monitoring, inspections, maintenance, repairs and replacements.

The primary liner system will contain the leachate collection system and will convey leachate to a single collection point for removal from the mound, and ultimately to the WWTP for treatment. The primary liner system will also protect the natural environment below the mound from leachate migration and will maintain a maximum depth of leachate on the geomembrane liner of less than or equal to 300 mm. The secondary liner system will contain the leak detection system, which will be used to detect leaks in the unlikely event that the primary liner system fails. The secondary liner will also protect the natural environment from leachate migration if the primary liner system fails. Leachate collected by the leachate collection system will be pumped to the on-site WWTP for treatment.

Perimeter berms consist of three main geotechnical elements, or layers, each contributing to the soundness and integrity of the berm itself and the whole ECM. A slope stability analysis was completed to provide the information needed to support the design of the base slopes, sidewalls and side slopes of the ECM. The slope stability analysis addresses the range of anticipated loading conditions, under both short-term and long-term scenarios, to confirm that the slope designs will satisfy minimum factor-of-safety requirements for stability. Size and shape of the berms and each of the elements and layers were determined using a seismic design basis.

The implementation of this mitigation will reduce the potential for changes to groundwater and surface water quality from the NSDF Project. As such, this pathway was determined to have no linkage to effects on the abundance of wildlife habitat, and survival and reproduction of wildlife and is not anticipated to affect the maintenance of self-sustaining and ecologically effective wildlife populations that overlap the RSA.

5.6.5.2.2 Secondary Pathways

The following pathways were assessed as potentially having a measurable minor environmental change, but negligible residual effect on the terrestrial biodiversity VCs relative to Base Case.

- **Vegetation clearing and grubbing will result in an increase in edge habitat, which could increase predation risk and nest parasitism risk for bird VCs.**

The NSDF Project may increase predation risk by increasing the amount of edge habitat in the LSA. Ground-nesting bird species are particularly vulnerable to nest predation (Cink et al. 2017) and many predators will use habitat edges as movement corridors (Chalfoun et al. 2002). An increase in edge habitat may also

increase the risk of nest parasitism. Fragmentation of forests has increased accessibility for brown-headed cowbirds, which prefer more open habitats (Lowther 1993). However, cowbirds are generally more dispersed and have lower densities in forested areas in the Canadian Shield than south of the Canadian Shield where agricultural land is more common (Lowther 1993). Therefore, nest parasitism risk to bird VCs is not anticipated to increase with construction of the NSDF Project. Increases in edge habitat are not predicted to affect the maintenance of self-sustaining and ecologically effective bird populations that overlap the RSA.

- **Vegetation clearing and grubbing for the two temporary laydown and staging areas required for the installation of the transfer line to Perch Lake will result in the temporary loss or alteration of wetland habitat in the Perch Lake Swamp. This will cause temporary losses of a wetland vegetation community and potentially have a temporary effect on wildlife habitat availability, use and connectivity.**

The construction phase of the NSDF Project has the potential to affect wetland habitat in the Perch Lake Swamp as a result of the installation of a transfer line from the WWTP to Perch Lake. The method of installation of this transfer line is mitigation in itself, as high-pressure directional drilling reduces the extent of surface disturbance within the alignment of the line route to the entry and exit points of the line. The DFO *Ontario Operational Statement – High-Pressure Directional Drilling* (DFO 2007) was created to provide a standard set of regionally appropriate mitigation that, if followed, avoid effects on fish habitat, and more broadly, any habitat potentially affected by these works. The use of horizontal directional drilling will limit surface disturbance within the Perch Lake Swamp wetland to two areas required for laydown and staging: one 300 m^2 area on the shoreline of Perch Lake, and one 100 m^2 area midway along the Perch Lake Ring Road approach to the ECM. An additional shallow trench (2 m deep and 30 m long) will be excavated within the riparian area of Perch Lake for the installation of the discharge transfer line (effects described in the Section 5.5.5.2.2). The disturbed portions of the two laydown and staging areas beyond the edge of the Perch Lake Ring Road ROW (which will remain in place) and the trenched area will be restored to the natural vegetation communities that were present prior to construction. Disturbed areas should be re-vegetated immediately upon completion of the NSDF Project to prevent erosion or colonization of noxious weed species (mitigation described below).

The construction of the transfer line may result in minor, temporary changes to the abundance and distribution of plant populations and communities relative to baseline conditions. Therefore, this interaction was determined to have a negligible residual effect on vegetation and wildlife habitat availability and distribution. The clearing of small areas required for construction of the transfer line is not predicted to affect the maintenance of self-sustaining and ecologically effective vegetation communities and wildlife populations in the RSA.

- **The high-pressure horizontal directional drilling installation of the transfer line to Perch Lake may result in a release of drilling mud (i.e., frac-out), which may cause changes to surface water quality, which can cause changes to soils and vegetation communities (including wetlands), which in turn can affect wildlife survival and reproduction.**

With high pressure drilling operations, there is a risk of the drilling mud entering the environment through tunnel collapse, spills or frac-out (the rupture of mud to the ground surface). On-going environmental monitoring during drilling works can limit the effects of a frac-out, and having an appropriate response plan in place can reduce the environmental effects of frac-out. Drilling mud is considered a deleterious substance that can adversely affect aquatic organisms and habitat. Specifically, introductions of this substance to aquatic habitat can result in adverse effects such as fish egg suffocation and reduction of plant and insect productivity (Falk and Lawrence 1973; Land 1974; Ferrante 1981).

The mitigation described in the DFO *Ontario Operational Statement – High-Pressure Directional Drilling* (DFO 2007) will be followed, including siting of the transfer line and access to temporary laydown and staging areas largely within a previously established access road ROW (Perch Lake Ring Road); minimization of vegetation removal beyond previously disturbed areas; creation of, and adherence to an emergency Frac-out Response Plan and Spill Contingency Plan during installation; and full-time environmental monitoring during all phases of transfer line works within the Perch Lake Swamp to evaluate adherence to environmental protection measures and make observations on signs of surface frac-out of drilling mud. Evidence of frac-out will trigger implementation of the Frac-out Response Plan. The following measures will be enacted to allow the NSDF Project to meet relevant provincial and federal legislation (particularly the *Fisheries Act*):

- Machine operation will take place on land above the high water mark of Perch Lake. Drilling machinery will kept be clean and leak free. Service, washing or refuel and storage of these substances for the machinery will be away from surface water features. Emergency spill kits will be kept on site in the event of a fluid leak or spill. Potential pathways for spilled products (e.g., storm drains) will be mapped and plans put in place to prevent entry of deleterious products into the storm drain system.
- Where possible, drilling will occur during daylight hours, which will increase the probability of visually identifying a frac-out (i.e., a condition where drilling mud from a directional drilling operation is released through fractured bedrock and travels to the surface through surrounding porous materials).
- Drilling mud, cuttings and all waste will be disposed of at appropriate disposal facility. All waste materials will be contained in a dugout or holding basin away from wetlands or other surface water features, or storm drains, to avoid entering natural surface water features, until the waste can be transported for disposal.
- Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site will be used during construction of the transfer line to Perch Lake as the exit point for drilling will be within the Perch Lake riparian area.
- On-going monitoring will be in effect during all phases of drilling works to assess fluid pressure (by drillers) and changes in turbidity in local surface water features (by environmental monitors) that would indicate surface migration (frac-out) of drilling mud.
- All material and equipment required to contain and clean up a frac-out event will be available on site.
- In the event of frac-out:
  - Work will be stopped and drilling mud will be contained. Care will be taken that cleanup effort does not result in damage to Perch Lake Swamp or Perch Lake.
  - Containment booms, silt fences and other appropriate erosion control measures will be deployed to prevent further migration to surrounding areas. Erosion control equipment will be on site and ready for deployment.
  - The CNL facilities representative on site will be notified.
  - Drillers are to evaluate data and circumstances leading to the loss of circulation and, if possible, implement methods to seal the fracture.

- All spills will be evaluated and work will cease if frac-out cannot be stopped and/or thresholds of environmental regulations are exceeded (i.e., relevant water quality guidelines). A Directional Drilling Contingency Plan will be implemented if drilling is unsuccessful along the designated corridor. Enactment of this contingency plan will require review by the responsible parties with CNL prior to initiation.

The implementation of mitigation will reduce the potential for a frac-out to occur during drilling of the transfer line. Some localized effects may occur, but the mitigation to address these identified above would result in small and temporary changes to surface water, soils and vegetation community quality. Therefore, this interaction was determined to have a negligible residual effect on terrestrial biodiversity. The accidental release of drilling mud during installation of the transfer line to Perch Lake is not predicted to affect the maintenance of self-sustaining and ecologically effective vegetation communities and wildlife populations in the RSA.

- **Potential introduction and spread of noxious weed species from trucks and other equipment can affect vegetation community species composition, which can affect wildlife habitat availability and distribution.**
- **Potential introduction and spread of noxious weed species during closure and remediation can affect vegetation community species composition, which can affect wildlife habitat availability and distribution.**

The construction, operations and closure phases of the NSDF Project have potential to introduce noxious weed species listed under the provincial *Weed Control Act*. There is also potential to introduce invasive plant species into new areas, which can disrupt plant communities and decrease habitat quality (Mack et al. 2000; Carlson and Shephard 2007; Truscott et al. 2008). Weed species introduced into natural areas have the potential to affect plant community structure and species diversity directly through competition and indirectly through alterations to soil microorganisms, nutrients and soil moisture (Mack et al. 2000; Truscott et al. 2008).

The majority of weed species introductions arise from human transport (Mack et al. 2000; Reichard and White 2001), and roads also act as dispersal route and habitat for weed establishment (Parendes and Jones 2000). Transportation corridors to and from construction areas provide a means of ingress for noxious weed species through direct dispersion of plant propagules (seeds and/or vegetative parts) from vehicles and machinery, and indirectly through the formation of suitable sites for weeds, in the form of disturbed road edges. Many weed species are able to spread more easily in landscapes that have been fragmented, often becoming established along edge habitats such as disturbed road edges associated with transportation corridors (Lafortezza et al. 2010).

Preventing weed species from entering an area is often more efficient and cost effective than dealing with their removal once established (Clark 2003; Polster 2005; Carlson and Shephard 2007). An Invasive Species Management Plan, in keeping with best management practices outlined in the MNR *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNRF 2019a), will be developed and implemented to limit effects of noxious and invasive plants on natural vegetation. For example, to mitigate the transport and introduction of prohibited, noxious, nuisance and invasive plant species into new areas, construction equipment will be regularly cleaned on site.

Locally appropriate grass seed mixtures that are certified weed-free will be applied to any cleared and reclaimed areas as soon as practical following construction. This will reduce the potential for the establishment and spread of invasive plant and weed species. Upon completion of the installation of the final cover over the ECM, turf-grass will be established and maintained. Maintenance of the final cover includes restricting weed establishment and preventing surface erosion and abrasion.

The implementation of this mitigation will reduce the potential for introduction of weed species during activities of the construction and operations phases. Some localized introduction of weed and invasive species may occur, but the mitigation to address these identified in Table 5.6.5-1 would result in minor changes to the abundance and distribution of plant populations and communities relative to Base Case conditions. Therefore, this interaction was determined to have a negligible residual effect on vegetation and wildlife habitat availability and distribution. Introduction of weed species is not predicted to affect the maintenance of self-sustaining and ecologically effective vegetation communities and wildlife populations in the RSA.

- **Attraction of wildlife to the NSDF Project (e.g., food waste, petroleum based products) may increase human-wildlife interactions and change predator-prey relationships, which can affect wildlife survival and reproduction.**

Food smells and other aromatic compounds such as petroleum-based chemicals can attract carnivores to human developments (Benn and Herrero 2002; Peirce and Van Daele 2006; CWS 2007; Beckmann and Lackey 2008). In addition, infrastructure such as buildings (e.g., the administration office building, which will be installed and used during the construction phase and remain through the operations phase) may also attract carnivores as it can serve as a refuge to escape extreme heat or cold (CWS 2007). Corvids (e.g., crows and ravens) and raptors (e.g., hawks, eagles, and owls) may also be attracted to infrastructure and anthropogenic food sources (Restani et al. 2001; Marzluff and Neatherlin 2006; CWS 2007; Kristan and Boarman 2007; Baxter and Allan 2008). Attraction of carnivores and predatory birds (e.g., ravens and gulls) to the NSDF Project can increase predation pressure on VC prey species (e.g., passerines [sparrows, warblers] and waterfowl [ducks, geese, grebes]), and may cause local declines in abundance in these prey species (Monda et al. 1994; CWS 2007; Liebezeit et al. 2009).

The attraction of wildlife to the NSDF Project also has the potential to increase human-wildlife interactions, which may result in the removal of wildlife by mortality or relocation. The implementation of the mitigation summarized in Table 5.6.5-1 and in the CNL's Waste Management Program and Management of Land, Habitat and Wildlife Procedure is anticipated to limit the attraction of wildlife to the site and result in minor changes in survival and reproduction from problem wildlife and altered predator-prey relationships relative to Base Case conditions. Subsequently, this pathway is expected to have a negligible net effect on wildlife abundance, and is not predicted to affect the maintenance of self-sustaining and ecologically effective populations that overlap the RSA.

- **Movement of heavy equipment and other vehicles on roads and through previously undeveloped/ forested areas may cause injury or mortality to bird VCs and monarch butterfly.**

The NSDF Project will increase vehicle traffic during construction, which could result in increased injury and mortality to bird VCs and monarch butterfly. The risk of vehicle-wildlife collisions is not uniform among species; highly mobile species such as birds and butterflies have a lower mortality risk from crossing roads than slower species such as amphibians and reptiles because they are more capable of avoiding collision (Hels and Buchwald 2001; Fahrig and Rytwinksi 2009).

Traffic speed and volume are the primary factors that contribute to road-related wildlife mortality. Speed limits will be clearly posted on access roads and enforced to mitigate against potential wildlife mortalities during the construction, operations and closure phases. In addition, drivers will have standard safety training and are provided with environmental awareness training. Because of the mitigation that will be applied, increases in vehicle traffic during NSDF Project construction, operations and closure are expected to result in minor changes to avian and monarch butterfly populations as compared to Base Case conditions. Therefore, collisions with NSDF Project vehicles are expected to have negligible residual effects on avian and monarch butterfly populations and are not predicted to affect the maintenance of self-sustaining and ecologically effective avian or monarch butterfly populations that overlap the RSA.

- **Vegetation clearing and grubbing activities and hauling activities during operations use vehicles and equipment that combust fuel and emit Criteria Air Contaminants. These activities involve material handling, vehicles travelling on paved and unpaved roads, and wind erosion of stockpiles that will result in fugitive dust emissions. Air and dust emissions and subsequent deposition may cause a change in soil quality and (directly affecting vegetation communities), which could in turn lead to indirect changes in wildlife habitat availability.**

The construction and operations phases of the NSDF Project will generate air and dust emissions such as carbon monoxide (CO), oxides of sulphur (SOx includes sulphur dioxide [SO_2]), oxides of nitrogen (NOx includes nitrogen dioxide NO_2), particulate matter ($PM_{2.5}$ [particulate matter with a diameter less than 2.5 microns]) and suspended particulate matter (SPM). Air emissions such as SOx and NOx can result from the use of fossil fuels in generators, vehicles and machinery. Vehicle exhaust and fugitive dust from unpaved and paved roads is the largest contributor to particulate matter (SPM, PM_{10} and $PM_{2.5}$) during both the construction and operations phases (Section 5.2.1.6.2).

Air and dust emissions and subsequent deposition can change soil quality and alter vegetation and wetlands, which can adversely influence wildlife habitat availability and distribution. SO_2 and NO_x from combustion of fossil fuels and dust deposition can affect soil pH and nutrient content, and soil fauna composition (Rusek and Marshall 2000). Changes in soil quality (physical, chemical and biological properties) can affect plant community composition, structure and diversity (Grantz et al. 2003; Peachey et al. 2009). Dust that falls directly on plants also can have a physical effect by smothering plant leaves or blocking stomata openings (Farmer 1993; Grantz et al. 2003). Plant species have different levels of tolerance to dust deposition, which can result in changes to above-ground biomass and species composition. For example, bryophytes (e.g., mosses) and lichens can be sensitive to the chemical effects of dust because they obtain moisture and nutrients from the atmosphere and immediate surroundings, including substances that are trapped or deposited directly on the surface of the bryophyte leaf or lichen thalli (Farmer 1993). Bryophytes and lichens may experience the largest effects close to roads where the greatest amount of deposition frequently occurs (Auerbach et al. 1997). Rates of dust deposition and accumulation are dependent on the rate of supply from the source, wind speed, precipitation events, topography and vegetation cover. Mitigation to be implemented to limit predicted residual effects from NSDF Project emissions to air quality (and subsequently to aquatic biodiversity VCs) includes: meeting Tier 2 emission standards for on-site vehicles and equipment engines, use of vehicles that are maintained in good working order and idling of vehicles on site will be limited.

Dust control will be conducted to support waste placement operations in accordance with the *Dust Management Plan* (AECOM 2018) during loading, transportation, placement, and compaction operations. Work areas that have the potential for generating dust will require implementation of dust suppression applications. The primary dust control method will include water spraying or misting techniques (e.g., water trucks). Fixatives (e.g., chemical suppressant) may also be used for dust control and for use as daily ECM cover. Water application and the use of fixatives will be controlled to limit potential effects on leachate and surface water runoff generated by the ECM.

Predicted concentrations for the Application Case during both construction and operations phases are below applicable air quality guidelines and/or standards with the exception of nitrogen dioxide, that will not meet the 2020 1-hour Canadian Ambient Air Quality Standards (Section 5.2.1.6.2, Table 5.2.1-14). The contributing factor to the high magnitude nitrogen dioxide emissions is the heavy-duty construction equipment and the conservative assumption that all equipment will run simultaneously and continuously during working hours. In reality, individual equipment will be idling or off for varying parts of the workday that can not be predicted but will result in lower emissions than currently estimated. The likelihood that all equipment operates simultaneously for an hour or more along with unfavourable weather conditions to produce the maximum concentrations modelled is very low.
The World Health Organization (WHO) has established annual critical levels at which vegetation growth and community composition characteristics may be altered due to SO_2 and NO_x emissions (WHO 2000).
The maximum modelled annual SO_2 (1.05 micrograms per cubic metre [µg/m^3]) and NO_2 (15.48 µg/m^3) concentrations at the LSA boundary are also below the WHO critical levels of 20 µg/m^3 and 30 µg/m^3, respectively (WHO 2000).

With the implementation of the mitigation summarized in Table 5.6.5-1 and in CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018d) and through the implementation of the *Dust Management Plan* (AECOM 2018) for the NSDF Project, air and dust emissions and subsequent deposition are expected to result in minor and local changes to soil quality and vegetation communities relative to Base Case conditions. Therefore, this pathway was determined to have a negligible net effect on wildlife habitat availability and distribution. Air and dust emissions are not predicted to affect the maintenance of self-sustaining and ecologically effective vegetation communities and wildlife populations that overlap the RSA.

- **Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) can cause changes to groundwater quality in the wetland and Perch Lake as well as downstream surface water quality, which can affect wildlife survival and reproduction.**

The WWTP for the NSDF Project will be a new, standalone facility with a new discharge point. The WWTP will treat leachate generated in the ECM during the operations and closure phases. The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses best available technology that is economically achievable and capable of meeting regulatory requirements.

The radionuclide concentrations in wastewater will be a combination of the leachate concentrations and the leachate volume, combined with the contact water and decontamination volumes. The contact water is assumed to have very low radionuclide concentrations because of the effects of daily ECM cover and water management practices within the disposal cell. Decontamination water is assumed to have the same radiological and chemical characteristics as the wastewater from the ECM. In the absence of quantitative information, non-radiological waste constituents were developed from information gathered from other sites and the expected characteristics of wastes to be disposed of in the NSDF. These values present a reasonable and conservative estimate of

concentrations in wastewater such that the WWTP design is capable of treating wastewater to meet effluent discharge targets (as described in Section 3.4.2.2, Tables 3.5.3-2 and 3.5.3-3).

Treated effluent will be sampled and confirmed that it meets effluent discharge targets before release to the environment. A portion of the treated effluent from the WWTP will be released to an exfiltration gallery to promote the exfiltration of treated water into the local groundwater regime; from here, small quantities of residual contaminants will migrate from the East Swamp Wetland to East Swamp Stream. The remaining treated effluent will be released into Perch Lake using a submerged diffuser. It is anticipated that the diffuser placement will result in a ten-fold dilution of any treated effluent discharge to Perch Lake within 100 m of the discharge (Golder 2019b). The East Swamp Stream flows into Main Stream and then Perch Lake, which is connected to the Ottawa River through Perch Creek.

Both aquatic and terrestrial species will be exposed to contaminated surface water and sediment in the East Swamp Stream, Perch Lake, Perch Creek, and possibly the Ottawa River. Doses to non-human biota were calculated based on water concentrations from East Swamp Stream. Although dilution will occur in Perch Lake, Perch Creek and the Ottawa River, the exposure limits within the aquatic environment was conservatively assessed to match that of East Swamp Stream during the period of leachate management system and WWTP operations. Doses to non-human biota were calculated based on the waterborne and airborne emissions from the ECM and assessed against the most conservative criteria available such as Environmental Quality Guidelines (CCME 2019) for non-radiological contaminants, No-Effect Concentrations for non-human biota derived for the boreal Canadian Shield forest ecosystem (SENES 2010) for radiological contaminants. The NSDF Project is confident that there will be no adverse effects to biota during operations phase by ensuring that releases and subsequent environmental concentrations are below the relevant guidelines or are below levels that would result in potential adverse effects on aquatic life as summarized in Section 5.7.6.2.1.

Many of the site's existing WMAs, including WMAs A and B and the Liquid Dispersal Area (which includes Reactor Pit 1, Reactor Pit 2 and the Chemical Pit) may also affect the Perch Creek and Perch Lake Watershed. Contaminants are transported by groundwater to nearby wetlands, including East Swamp and via the transfer discharge line directly into Perch Lake, which will be the recipient waterbodies for the NSDF Project wastewater. Contaminants released into the Perch Lake then migrate to Perch Creek from where they reach the Ottawa River, which is the ultimate receptor for all CRL discharges. The NSDF Project's contribution to potential effects on populations of non-human biota in the Perch Creek and Perch Lake Watershed does not result in unacceptable cumulative effects. Estimated doses resulting from historic contamination, due to releases from WMAs and Liquid Dispersal Areas, fall below benchmark values for Perch Lake and Perch Creek. Potential contribution from the NSDF to exposure of aquatic species in East Swamp is less than 1% of the current levels of exposures.

For non-radiological and radiological constituents, two surface water model scenarios were completed for a select group of constituents of potential concern (COPCs) as defined in Section 5.4.2.6.1.4 and Section 5.7.6.2.1. Key elements of the COPCs selection process included identifying those COPCs that were expected to change as a result of the NSDF Project, those with available guidelines, treatment requirements, high existing environmental conditions, potential for nutrient effects, water properties and those that were expected to be toxic to aquatic organisms. The selected non-radiological COPCs included: aluminum, ammonia, antimony, boron, barium, calcium, cadmium, chloride, chromium, cobalt, copper, fluoride, iron, lead, manganese, magnesium, mercury, molybdenum, nickel, phosphorus, potassium, selenium, silver, sodium, strontium, sulfate, thallium, tin, uranium, vanadium and zinc. Radiological COPCs included: carbon-14, caesium-137, cobalt-60, gross beta and tritium.

The predicted radiological and non-radiological concentrations for the COPCs were compared to effluent discharge targets[1] and to local background at the six water quality nodes (i.e., East Swamp weir, Perch Lake Inlet 2, Perch Lake, Perch Creek weir, Perch Creek Outlet and the Ottawa River; Section 5.4.2.6.2 and Tables 5.4.2-9 to 5.4.2-18). The predicted concentrations for most COPCs met the effluent targets at all sampling nodes, with the exception of aluminum, barium, copper, iron, lead, manganese, phosphorus, selenium and silver. However, predicted concentrations were generally similar to local background concentrations at these nodes with the exception of selenium concentrations that were predicted to exceed local ambient concentrations. Predicted selenium concentrations were less than the United States Environmental Protection Agency guidelines for protection of aquatic life and therefore are predicted to not result in adverse effects on aquatic life.

For most COPCs, the incremental changes in concentration as a result of the NSDF Project are expected not to be measurable in the Ottawa River. COPCs that increase above background in the Ottawa River included only Tritium. However, results of the radiological dose assessment for the operations phase and post-closure phase also indicates that doses to ecological health VCs are below their respective No Effect Concentrations (see Section 5.7.8). As such, changes to surface water quality (and habitat quality) from the discharge of treated effluent are expected to have negligible residual effects on wildlife VCs.

- **Leakage of leachate from the ECM during the post-closure phase (i.e., after year 2400) from liner and final cover degradation as a result of normal evolution can cause changes to groundwater quality in the wetland and downstream surface water quality, which can affect wildlife survival and reproduction.**

Potential impacts on terrestrial biota from failure of cover and liner as a result of normal evolution are assessed in Section 5.7.6.3.2.1. No adverse effects are predicted to terrestrial biodiversity VCs.

5.6.5.2.3 Primary Pathways

Primary pathways advanced for further residual effects assessment and determination of significance are summarized by VC in Table 5.6.5-2. As a result of mitigation, the migratory bird VC will not be affected by any mortality-related pathways. Because several other VCs are migratory birds and changes in habitat availability and distribution will be addressed for these VCs, migratory birds as a group were not carried forward for further assessment.

[1] Effluent discharge targets for radiological COPCs were composed of No Effect Concentrations for the protection of aquatic biota (See Section 5.4.2.6.1).

Table 5.6.5-2: Interaction between Primary Pathways and Terrestrial Biodiversity Valued Components

Primary Pathway	Vegetation Communities	Migratory Birds	Canada Warbler	Eastern Whip-poor-will	Eastern Wood-pewee	Golden-winged Warbler	Wood Thrush	Bats	Blanding's Turtle	Eastern Milksnake	Monarch Butterfly
Vegetation clearing and grubbing during construction will result in the loss or alteration of existing vegetation and topographical features. This will cause losses of some vegetation communities, and potentially change wildlife habitat availability, use and connectivity, and could influence wildlife abundance and distribution.	+	+	+	+	+	+	+	+	+	+	+
Vegetation clearing and grubbing may remove active milksnake hibernacula, which may influence survival and reproduction.	-	-	-	-	-	-	-	-	-	+	-
Sensory disturbance (i.e., lights, smells, noise, human activity, alteration of viewscape) can change wildlife habitat availability, use and connectivity (movement and behaviour), which can lead to changes in wildlife abundance and distribution.	-	+	+	+	+	+	+	+	+	+	+

Table 5.6.5-2: Interaction between Primary Pathways and Terrestrial Biodiversity Valued Components

Primary Pathway	Vegetation Communities	Migratory Birds	Canada Warbler	Eastern Whip-poor-will	Eastern Wood-pewee	Golden-winged Warbler	Wood Thrush	Bats	Blanding's Turtle	Eastern Milksnake	Monarch Butterfly
Movement of heavy equipment and other vehicles on roads and through previously undeveloped / forested areas may cause injury or mortality to Blanding's turtle and milksnake.	-	-	-	-	-	-	-	-	+	+	-
Installation and maintenance of perimeter fencing will potentially modify movement corridors for Blanding's turtle and milksnake in the LSA which may increase their travel distances and thus increase the risk of injury/mortality on roads.	-	-	-	-	-	-	-	-	+	+	-

+ = primary pathway for this valued component; **-** = no interaction or secondary pathway for this valued component; LSA = Local Study Area

5.6.6 Residual Effects Assessment Methods

5.6.6.1 Residual Effects Analysis

The residual effects analysis for the Application Case describes the incremental changes caused by the NSDF Project from existing conditions. Residual effects are described for each of the measurement indicators identified in Section 5.6.2 for the primary pathways identified for each terrestrial biodiversity VC (Section 5.6.6.3), as follows:

- Changes in ecosystem availability were estimated quantitatively by calculating differences in the amount of different types of vegetation communities. For wildlife VCs, changes in habitat availability were estimated quantitatively by calculating differences in the amount of suitably habitat and qualitatively by considering potential changes in habitat use by wildlife (e.g., avoidance due to sensory disturbance).
- Changes in ecosystem distribution were estimated for the vegetation community VC by qualitatively examining changes to the size and distribution of vegetation communities within the RSA and LSA. For wildlife VCs, changes in habitat distribution in the RSA and LSA were estimated by qualitatively evaluating the distribution of suitable wildlife habitat and considering wildlife VC movement, habitat connectivity and potential barriers to their dispersal.
- Changes in ecosystem condition (vegetation community VC) or survival and reproduction (wildlife VCs) were identified qualitatively and quantitatively using the results from changes in vegetation communities and knowledge of potential changes in abundance from other NSDF Project components and activities (e.g., wildlife strikes with vehicles). Predictions of change were made using data collected in the RSA and the LSA, where possible, and supported by scientific literature.

The residual effects analysis uses a logical reasoning to describe anticipated changes to each measurement indicator caused by the NSDF Project. This narrative description of anticipated effects is the foundation for the residual effects classification presented in Section 5.6.6.3.

5.6.6.2 Prediction Confidence

The predicted residual effects are based on scientific inference and logical reasoning, which are associated with uncertainty. Consequently, a description of the level of confidence that can be assigned to the residual effect analysis was presented for each terrestrial biodiversity VC.

Primary factors affecting confidence in the predictions made in the terrestrial biodiversity assessment include:

- availability and accuracy of baseline data;
- efficacy of mitigation applied at CNL during the Base Case;
- accuracy of vegetation spatial data and inferences on habitat associations;
- level of understanding of the strength of primary pathways (i.e., mechanisms) in terms of the effects they are likely to have on each VC;
- level of certainty associated with the effectiveness of proposed mitigation specific to the NSDF Project, where applicable; and
- level of understanding of the cumulative drivers of change in measurement indicators and associated effects on assessment endpoints.

Uncertainty in the assessment was managed by:

- reviewing historical and current data and relevant studies conducted in the study areas;
- conducting desktop studies to understand potential interactions between the proposed NSDF Project and terrestrial biodiversity, and supplementing with local and regional data to the extent possible; and
- comparing assessment results with relevant published literature to make inferences about ecological interactions and mechanisms of change.

Remaining uncertainty was primarily addressed by making assumptions that overestimated rather than underestimated potential effects of the NSDF Project (i.e., a precautionary assessment). This approach meant that when uncertainty was identified, the assessment was likely to overestimate predicted residual effects. For example, East Mattawa Road is an existing road that will be used as the main access road for the NSDF Project. The north and south ends of East Mattawa Road require upgrading, but no or little additional clearing to widen and have sufficient clearance for operational needs is needed. East Mattawa Road was not mapped as "unclassified" in the FRI dataset; it was considered to be part of the forested polygon. Consequently, the amount of physical disturbance to vegetation communities from the NSDF Project was overestimated in these areas (as the FRI dataset used for calculating changes to vegetation communities would make it appear that the entire segment of East Mattawa Road within the SSA is a "new" disturbance to the forested land cover), providing a precautionary assessment.

5.6.6.3 Residual Effects Classification

Residual effects from the NSDF Project on each measurement indicator for each VC were classified according to the standard effects criteria described by Canadian Environmental Assessment Agency (The Agency 2015) and presented in Table 5.6.6-1.

Magnitude was not classified categorically because narrative or numeric quantification is more useful for unambiguously describing the effects of the NSDF Project for these VCs. Integrating context to understand the point at which an effect size is large enough to be important for a VC is directly linked to the self-sustaining and ecologically effective status of the population, and is therefore considered as part of the significance evaluation.

Table 5.6.6-1: Definitions of Effects Categories Used to Classify Predicted Residual Effects Terrestrial Biodiversity Valued Components

Criteria	Definition	Description
Direction	Direction relates to the "value" of the effect in relation to the environment.	▪ Positive – net gain or benefit; effect is desirable ▪ Neutral – no change compared with baseline conditions and trends ▪ Negative – net loss or adverse effect; effect is undesirable
Magnitude	Magnitude is the intensity of the effect or a measure of the degree of change from existing (baseline) conditions expected to occur in the criterion.	▪ Magnitude will be defined for each measurement indicator to reflect VC-specific characteristics

Table 5.6.6-1: Definitions of Effects Categories Used to Classify Predicted Residual Effects Terrestrial Biodiversity Valued Components

Criteria	Definition	Description
Geographic extent	Geographic extent refers to the spatial area over which an effect will occur/can be detected (distance covered or range).	▪ SSA – effect is limited to the direct physical disturbance from the NSDF Project ▪ Local – the effect is confined to the LSA ▪ Regional – the effect extends beyond the LSA boundary, but is confined within the RSA ▪ Beyond regional – the effect extends beyond the RSA boundary
Duration/ reversibility	▪ Duration is the period of time over which the environmental effect will be present—the amount of time between the start and end of an activity or stressor (which relates to project development phases), plus the time required for the effect to be reversed. Duration and reversibility are functions of the length of time a criterion is exposed to activities. ▪ Reversibility is an indicator of the potential for recovery of the criterion from an effect. Reversible implies that the effect will not influence the criterion at a future predicted period in time. For effects that are permanent, the effect is determined to be irreversible.	▪ Short-term – the effect is reversible before the end of construction ▪ Medium-term – the effect occurs during the construction and/or operations phase and is reversible soon after the operations phase begins ▪ Long-term – the effect occurs during the construction and/or operations phase and persists into the closure phase, but is reversible ▪ Permanent – the effect occurs during construction and/or operations phases and is irreversible
Frequency	Frequency refers to the occurrence of the environmental effect over the duration of the assessment. Discussions on seasonal considerations are made when they are important in the evaluation of the effect.	▪ Infrequent – the effect is expected to occur rarely ▪ Frequent – the effect is expected to occur intermittently ▪ Continuous – the effect is expected to occur continually
Likelihood	Likelihood is a measure of the probability that an activity will result in an environmental effect.	▪ Unlikely – the effect is not likely to occur ▪ Possible – the effect may occur, but is not likely ▪ Probable – the effect is likely to occur ▪ Certain – the effect will occur

VC = valued component; SSA = Site Study Area; LSA = Local Study Area; RSA = Regional Study Area.

5.6.6.4 Determination of Significance

For each terrestrial biodiversity VC, a determination of significance was made based on an assessment of existing cumulative effects of previous and existing developments described in the Base Case. This classification provides context from the Base Case to which incremental changes in the Application Case are added.
The addition of the incremental effects of the NSDF Project are described and classified according to the methods outlined in Sections 5.6.6.1 and 5.6.6.3, respectively.

Future beyond regional disturbance factors such as climate change have the potential to adversely affect vegetation communities and populations of wildlife VCs that overlap with the RSA. Therefore, a determination of significance was also made based on the cumulative effects of previous and existing developments, the incremental effect of the NSDF Project, and a qualitative consideration of future, beyond regional disturbance factors.

Overall significance determination based on cumulative effects provides important context because the effects of a single project infrequently cause an ecologically significant effect on their own (McCold and Saulsbury 1996) and many environmental effects of primary concern are cumulative (Canter and Ross 2010). Therefore, whether vegetation communities or populations of wildlife VCs would remain self-sustaining and ecologically effective was assessed considering the cumulative effects of previous and existing developments in combination with the NSDF Project (i.e., Application Case). If a significant effect was identified for the Application Case, the incremental contribution of the NSDF Project to the significant effect is clearly described.

Significance of cumulative effects was predicted as a binary response, with effects classified as significant or not significant. Residual effects were determined to be significant if a VC is expected to no longer be 1) self-sustaining, or 2) ecologically effective. Specifically:

- A vegetation community or wildlife VC population was considered to be no longer self-sustaining where residual effects were expected to place the vegetation community or abundance of a wildlife VC, whether an open or closed population, on a declining trajectory that is not predicted to recover or stabilize. Part of being self-sustaining, in this context, was that a vegetation community or wildlife VC population that stabilizes at a lower abundance is not expected to be extirpated because of unrelated stochastic events (e.g., wildfires). Another part of being considered self-sustaining was the assumption that no additional mitigation or management actions beyond the proposed NSDF Project mitigation strategies and existing management strategies in the region would be required. Residual effects that are considered to be not significant could result in either no change, stabilization at lower abundance, stabilization at higher abundance, or a temporary decline followed by recovery. Where vegetation communities or wildlife populations remain stable, fragmentation effects that cause vegetation communities or wildlife populations to become isolated or substantially disconnected (e.g., severely reducing or eliminating gene flow and/or immigration within one regional or local populations) may also be considered significant.
- A vegetation community or wildlife VC population that has lost important ecological function would also result in determination of a significant adverse effect, regardless of its self-sustaining status. Ecological function can be lost, even when a vegetation community remains abundant, if the composition of that community is altered. For wildlife VCs, loss of ecological function occurs when a population can no longer perform its ecological role, such that it might trigger ecological changes that result in degraded or simplified ecosystems (Soulé et al. 2003). The potential to lose ecological function is more common for highly interactive wildlife VCs that have important ecological effects on other species, such as predators or ecosystem engineers (i.e., organism that creates, considerably modifies, maintains or destroys a habitat; Soulé et al. 2003).

The approach to determining the significance of residual effects for each VC incorporated the concepts of resilience and adaptability using the reasoned narrative provided in the residual effects assessment. Although the determination of significance was informed by the VC for characterizing residual effects, the interaction between ecological context from the Base Case and the magnitude, duration and geographic extent of the interacting residual effects were the most important factors. Provincial and federal standards, guidelines and objectives were considered, where available, and integrated into the reasoned narrative.

If uncertainty was high about where a threshold for a significant cumulative effect would occur in the range of cumulative change for the Application Case, and if the residual effect could be assessed as either significant or not significant, a precautionary approach was applied and the effect was identified as significant. The greater the uncertainty, the earlier a significant effect would be identified on the continuum of cumulative change. Effects determined significant because of high uncertainty around undefined true thresholds were clearly identified as such, and additional follow-up actions to reduce uncertainty were proposed (Section 5.6.8).

Adding to the challenges of understanding complex systems is the difficulty of forecasting a future that may be outside the range of observable baseline environmental conditions (Walther et al. 2002). For example, climate change models predict an increase in average global temperatures (Huff and Thomas 2014); however, the effect of these changes on ecosystem processes is uncertain (Deser et al. 2010; Walther 2010). Predicting how an ecosystem or an individual species will cope with climate change is difficult and many scenarios are possible (Dawson et al. 2011).

Climate change was addressed in this assessment using a precautionary approach. For example, climate change may have different effects on plant species abundance and distribution through shifts in temperature, precipitation, fire and insects, which can alter wildlife populations (Huff and Thomas 2014). If one scenario was much more likely than another, the assessment considered the most likely scenario. However, if uncertainty was high, the assessment considered a precautionary outcome for each VC.

Effects of the NSDF Project were considered significant if they contributed in a meaningful way to a significant adverse cumulative effect (i.e., a change that would contribute to jeopardizing the survival of the regional population).

5.6.7 Residual Effects Assessment Results

5.6.7.1 Vegetation Communities

5.6.7.1.1 Residual Effects Analysis

Ecosystem Availability

The incremental effect of the NSDF Project on ecosystem availability is summarized in Table 5.6.7-1. At the RSA scale, the changes to ecosystem availability represents a total permanent loss of 0.8% of forested ecosystems, primarily of second-growth, mature, mixed forest with high poplar content and snag presence. A somewhat greater proportional loss of the total coniferous forest coverage in the RSA (at 2%) is predicted. Coniferous forest stands are relatively rare in the RSA and the effects of the NSDF Project on coniferous forests is due to the predicted loss of one Norway spruce plantation stand and a portion of another coniferous forest stand.

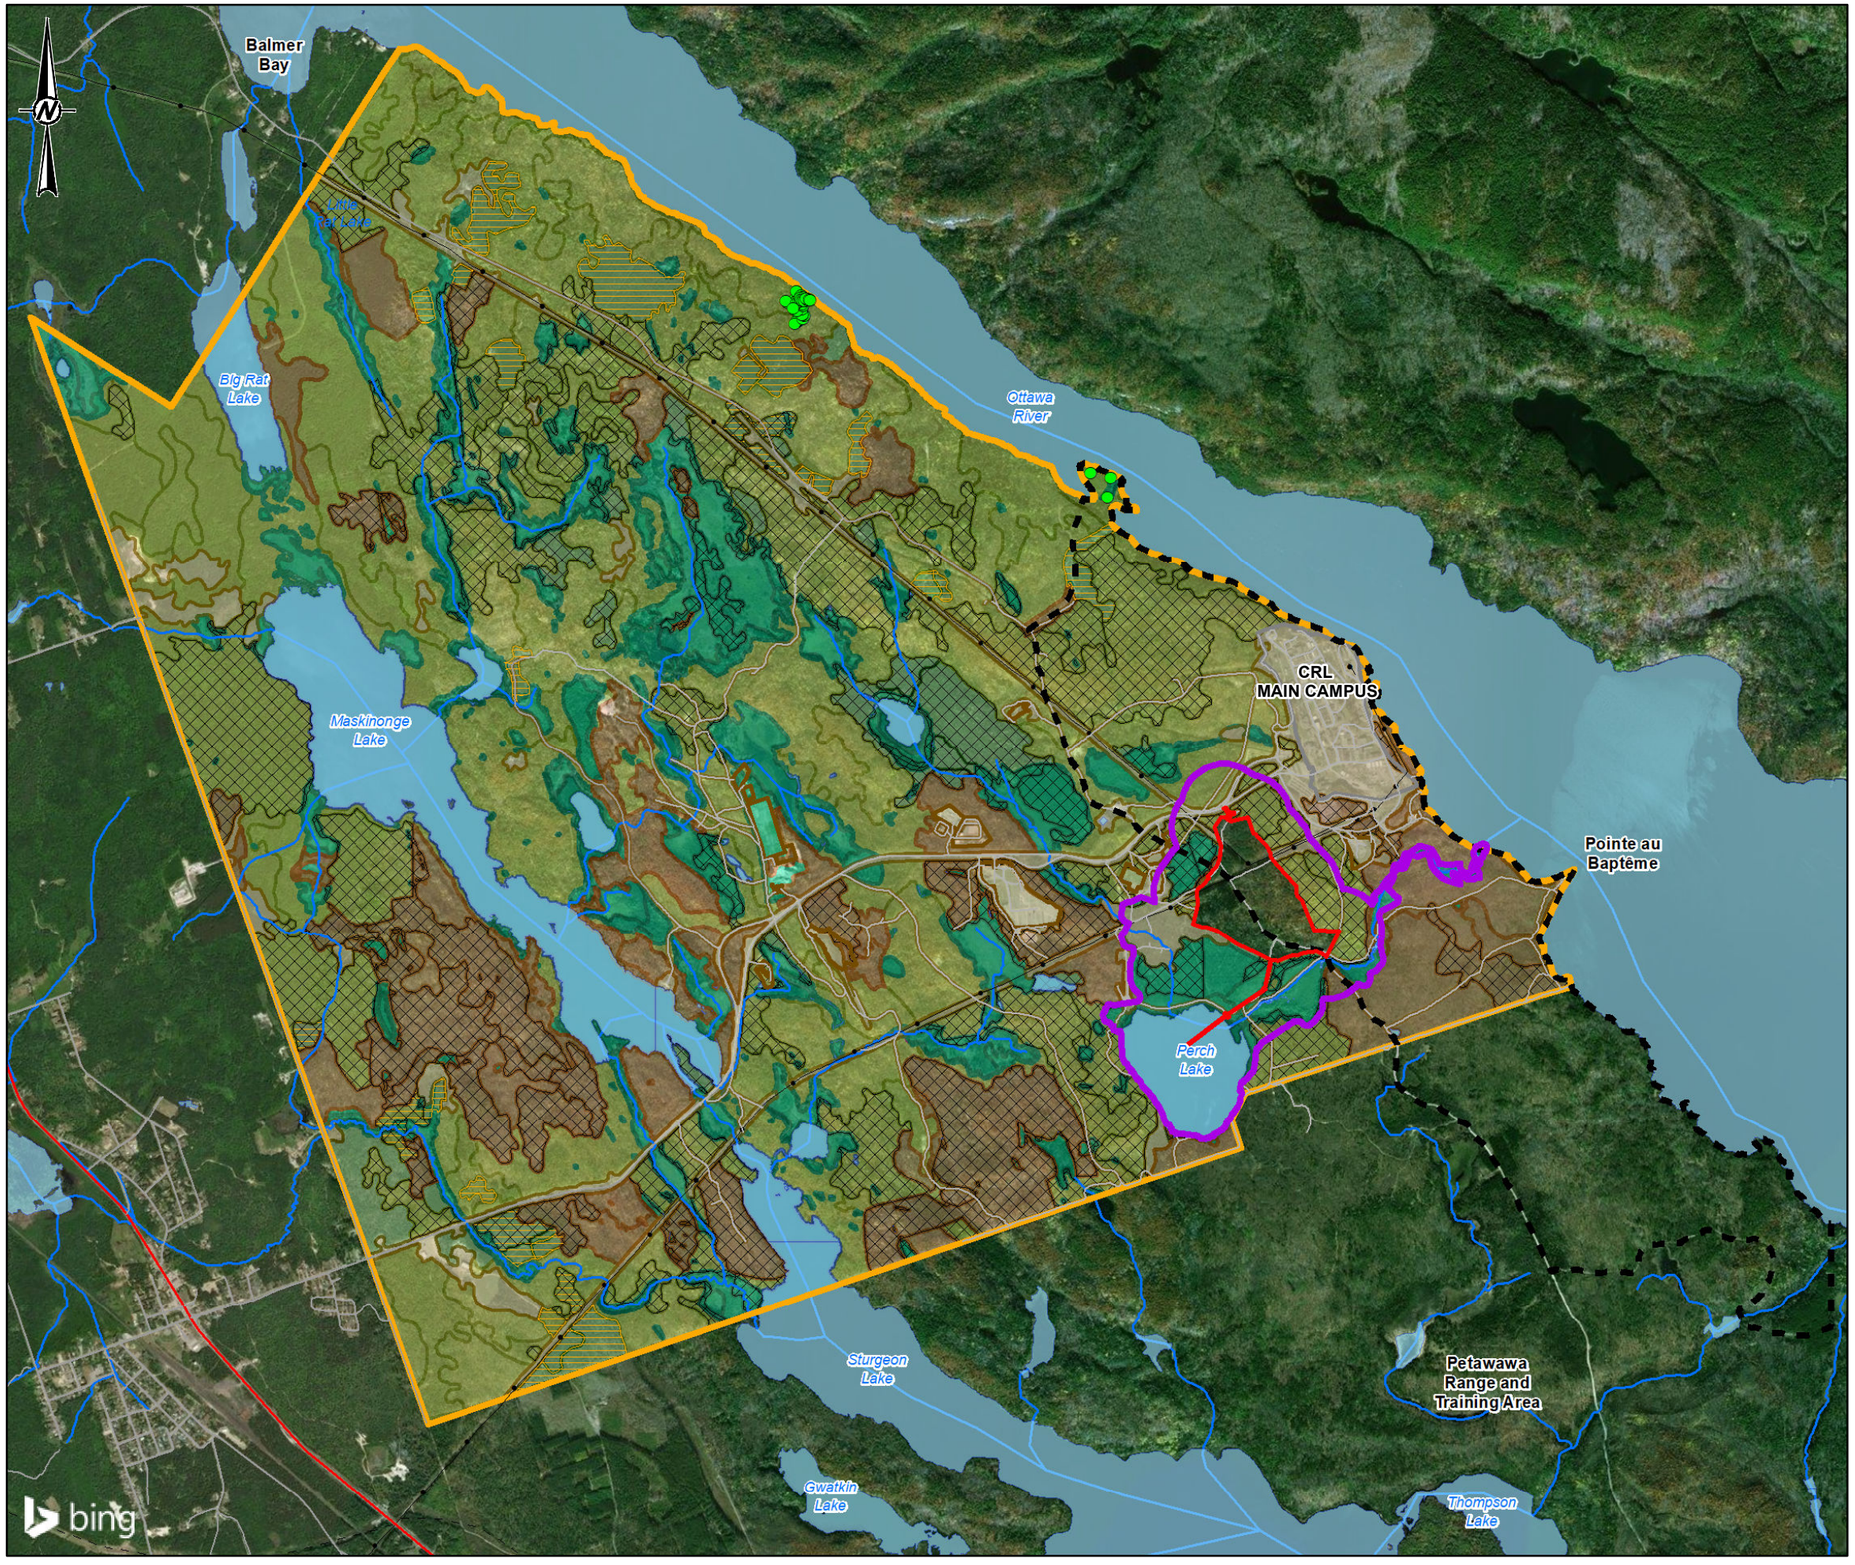
There will be a total loss of 33 ha of forested ecosystems as a result of the NSDF Project (i.e., in the SSA), which will be converted to unclassified (cleared) land cover. A minor amount of wetland habitat (less than 1 ha) will be affected temporarily by the laydown and staging areas required for the installation of the Perch Lake transfer line (assessed as a secondary pathway). The remaining 4 ha within the SSA is unclassified / already anthropogenically altered land cover that will permanently retain the same classification once the NSDF Project has been constructed. Avoidance undertaken during the NSDF Project design means that wetland ecosystems availability is largely unchanged, with the exception of the wetland area to be temporarily affected by the laydown and staging areas required for the installation of the Perch Lake transfer line. At the LSA scale, the permanent conversion of 33 ha of forest to cleared land cover translates to a loss of 53.0% of forested ecosystems.

Table 5.6.7-1: Changes to Availability of Vegetation Communities in the Application Case

Vegetation Community	Regional Study Area				Local Study Area			
	Base Case (ha)	Application Case (ha)	Change in Area[a] (ha)	Percent Change[a] (%)	Base Case (ha)	Application Case (ha)	Change in Area[a] (ha)	Percent Change[b] (%)
Mixed Forest	1,930	1,903	-27	-1.4	70	42	-27	-39.1
Deciduous Forest	643	641	-2	-0.3	6	4	-2	-33.3
Coniferous Forest	199	195	-4	-2.0	5	1	-4	-80.0
Wetland	522	522	<1	<1.0	61	61	<1	<1.0
Flooded	1	1	0	0	0	0	0	0
Unclassified (cleared)	268	301	33(a)	12.3	27	60	33[a]	126.2
Total Aquatic Habitat:	274	274	0	0	41	41	0	0
Gaps/Slivers:	16	16	0	0	0	0	0	0
Total	3,853	3,853	0	0	210	210	0	0

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

a) A total of 3.81 ha of the SSA is “Unclassified (cleared)” in the Base Case and will remain in this vegetation community in the Application Case. Therefore, the change in area in the RSA and LSA in the Application Case does not equal the total SSA of 38 ha.



b) The total percent change is calculated relative to the total area and therefore this value will not equal the sum of the individual values.

SSA = Site Study Area; RSA = Regional Study Area; LSA = Local Study Area.

Ecosystem Distribution

At the RSA scale, the NSDF Project creates a relatively minor gap in existing forest coverage (0.8% change in coverage with a corresponding small degree of change to distribution). This disturbance is primarily associated with the distribution of vegetation communities within the RSA in the Application Case are presented on Figure 5.6.7-1. The location of the NSDF Project is within the southeast corner of the RSA, which already contains the highest level of anthropogenic disturbance and activity, leaving the northern two-thirds of the RSA still largely undisturbed.

Distribution of vegetation communities within the LSA and SSA in the Application Case are presented on Figure 5.6.7-2. At a local level, the SSA represents a relatively larger gap in forested ecosystems, a span of approximately 1,021 m north–south and 645 m east–west (53.0% change in coverage). Ecosystem processes, and in particular, the use of ecosystems by the wildlife VCs considered, are at a broader scale and are less likely to be disturbed as a whole, at this local scale. The range of these species is beyond the LSA boundary—which does not have an ecologically functional basis and is primarily defined by the footprint of the NSDF Project. Fragmentation of forested ecosystems is a concern if it reaches a threshold beyond what interior and area-sensitive species can tolerate. With the high degree of forest cover remaining on the CRL site, it is highly unlikely the forest clearing associated with the NSDF Project will represent a level of fragmentation that goes beyond this threshold. The forested ecosystems within the SSA were already fragmented by East Mattawa Road, which bisects the forested area, and two transmission corridors that criss-cross the northern portion of the forested area; therefore, the actual “new” edge creation is limited, but the size of the gap between the edges is increased.

This page left intentionally blank

Ecosystem Condition

The SSA is approximately 38 ha and consists primarily of mature forest, dominated by poplar species, red oak, eastern white pine and spruce species. It also contains a 1.2 km long segment of East Mattawa Road and two linear areas cleared as 30 to 45 m wide ROW for overhead hydroelectric lines. The area of the SSA associated with the Perch Lake transfer line is within Perch Lake Swamp and largely within the previously disturbed area of the wetland feature along the Perch Lake Ring Road right of way. Although the entire length of the transfer line is mapped, the surface disturbance in Perch Lake Swamp associated with this project component will be limited to two temporary laydown and staging areas, one 300 m^2 area (on the Perch Lake shoreline) and one 100 m^2 area (along the Perch Lake Ring Road segment that approaches the ECM). The East Mattawa Road corridor and Perch Lake Ring Road corridor were not captured in the FRI data, but the hydroelectric corridors were. Inclusion of the true extent of East Mattawa Road and Perch Lake Ring Road would result in a minor decrease to the mixed forest total coverage of the SSA and the wetland total coverage of the SSA, respectively, because the East Mattawa Road bisects a mixed forest stand and Perch Lake Ring Road bisects the Perch Lake Swamp wetland feature.

There are two areas of immature coniferous forest stands in the SSA: one is a tree research plantation containing 100% Norway spruce and the other is a portion of a stand of spruce, balsam fir and larch species. The Norway spruce research plantation is within the western portion of the SSA and was planted in the 1950s. Personnel with the Petawawa Research Forest have confirmed this plantation is no longer required for research purposes. There is also a portion of one deciduous forest stand, within the northwest end of the SSA, which contains poplar species, yellow birch and red oak.

There are no flooded areas within the SSA. The surficial geology around the SSA consists primarily of sands underlain by dense sandy silt till containing cobbles and boulders. Organic soils (e.g., peat) have deposited in the low-lying areas. The overburden thickness at the site typically ranges from approximately 0 to 10 m, depending on bedrock topography. The vegetation communities present within the SSA reflect these soil conditions.

At the regional scale, the NSDF Project will create a minor change in ecosystem condition with regard to mature forest cover (a loss of 3%; Table 5.6.7-2) but negligible change to ecosystem condition with regard to wetland cover (temporary loss of two areas for laydown and staging within Perch Lake Swamp, totalling 400 m^2, addressed as a secondary pathway above, with the assumption that all mitigation is followed). At the local scale, the NSDF Project will have a larger relative effect (reduction in 43% of available mature forest cover) and result in a permanent conversion of primarily mature forest to road and/or turf-grass. The temporary loss, for the duration of the construction period, of 400 m^2 wetland cover will also be negligible at the local scale (addressed as a secondary pathway above). The NSDF Project will create a permanent change to ecosystem condition from forested habitat to turf-grass habitat, with low value for terrestrial biodiversity. Moreover, terrestrial wildlife will be excluded from the SSA by a six foot high chain link perimeter fence that will remain through post-closure.

Table 5.6.7-2: Changes to Ecosystem Condition (as measured by Mature Forest Cover) in the Application Case

Ecosystem Condition Measures	Regional Study Area				Local Study Area			
	Base Case (ha)	NSDF Project Case (ha)	Change in Area (ha)	Percent Change (%)	Base Case (ha)	NSDF Project Case (ha)	Change in Area (ha)	Percent Change (%)
Mature Forest Cover	1,070	1,041	-29	-2.7	68	39	-29	-42.6

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

5.6.7.1.2 Prediction Confidence

Confidence in description of Base Case ecosystem availability, distribution and condition is tempered by reliance on primarily air-photo interpreted mapping—this potential for error is highlighted by the discrepancy in classification of a stand of one forest ecosystem type from the North-South (2002) survey work in one portion of the SSA. The North-South survey classified the forested area within the north portion of the SSA, north of the east–west transmission line ROW, and straddling the north–south transmission line ROW, as white pine / red pine forest. The FRI data for the site have this area mapped as a poplar / yellow birch / red oak deciduous forest stand on the west side of the north–south transmission line ROW (which is inconsistent with the North-South 2002 report) but white pine / poplar / red pine on the east side of that ROW (which is consistent; Figure 5.6.7-2).

In addition, the FRI dataset did not contain some common attributes that are used to assign ecosystem condition, including the year of origin for forest stands. The dataset used only provided the attribute of “age,” and no date for the GIS spatial dataset was available, meaning there may be some discrepancy in true forest stand ages relative to what was used in the assessment—with the degree of discrepancy widening depending on the age of the FRI dataset used.

Because of the lack of recent, ground-based surveys, the presence or absence of regionally or provincially rare vegetation species within areas to be disturbed cannot be determined. There is only one SARA-listed plant species that has been recorded in the RSA and could occur within the SSA: butternut (see Figure 5.6.4-1). However, this species does not have a high likelihood of occurrence within the SSA due to the lack of suitable habitat and location of the RSA, which is north of the current northern range extent (Appendix 5.6-1). Butternut located at CRL are associated with an old homestead. Some regeneration was noted in one patch during surveys, but it was always near the parent trees that were associated with the old homestead.

In all cases where there was the opportunity to be more conservative/precautionary in the assessment of effects on vegetation communities, decisions were made to achieve conservatism (e.g., use of modified age categories for forest unit structural age class definition so that stands that should be identified as mature or old based on leading tree species, specifically poplar, were identified as such).

Despite acknowledged deficiencies in reliance on desktop-derived data, the vegetation communities to be removed as a result of the NSDF Project are not unique on the regional landscape. The FRI data for the SSA also generally aligns with the observations of the reconnaissance-level site visit in 2016. Overview level review of Google Earth imagery has also confirmed general agreement with existing levels of forest cover and general composition.

Regardless of some level of uncertainty on exact stand composition, particularly in other areas of the RSA that were not visited during the site reconnaissance, the prediction of effects on the physical losses of vegetation communities has high confidence as the significance determination is primarily based on accurately quantifiable spatial changes to the landscape.

5.6.7.1.3 Residual Effects Classification

Vegetation communities in the RSA in the Base Case are considered to be within the limits of resilience and adaptive capacity to changes in availability, distribution and composition. After calculating changes from the NSDF Project, the composition of vegetation communities remain common and well distributed in the RSA. An estimated 99% of non-disturbed vegetation communities (i.e., the forested stands and wetlands) present in the Base Case will remain intact in the Application Case. Moreover, the implementation of appropriate invasive species control in keeping with best management practices such as the MNR *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNRF 2019a) will reduce the potential for invasive species to colonize vegetation communities adjacent to the NSDF Project. The most sensitive vegetation communities in the RSA (wetlands) will be largely avoided by the NSDF Project. With the implementation of mitigation described and adherence to the DFO *Ontario Operational Statement – High-Pressure Directional Drilling* (DFO 2007), there will be a temporary and minor effect on a small portion of Perch Lake Swamp, and no permanent loss of wetland habitat will occur within the SSA.

A summary of the classification of incremental adverse effects of the NSDF Project on vegetation communities in the Application Case is provided for each measurement indicator in Table 5.6.7-3. Residual effects after the implementation of effective mitigation are described, and are summarized according to direction, magnitude, geographic extent, duration/reversibility, frequency/timing and likelihood of the effect occurring following the methods described in Section 5.6.6.1. Effective implementation of mitigation summarized in Section 5.6.5.1 is expected to reduce the magnitude and duration of residual effects on vegetation communities.

Residual effects on the availability and distribution of vegetation communities resulting from the NSDF Project are predicted to be negative, resulting in a loss of 0.8% of forested communities in the RSA and 15.9% in the LSA. Construction of the NSDF Project will permanently remove forested vegetation communities and the direct effects of the changes will be confined to the SSA. Effects on vegetation community condition (e.g., species abundance and richness) are certain with regard to the permanent change in composition from largely undisturbed mature forest to heavily maintained turf-grass, but less certain due to the effectiveness of mitigation to avoid intrusion into adjacent forest and wetland edges by invasive species. For the purposes of this assessment, changes to all three indicators are assumed to be irreversible for vegetation communities affected by the SSA. Although remediation of the SSA will be completed, for the purposes of terrestrial biodiversity and vegetation communities specifically, conversion of a largely undisturbed, mature forested area to a permanently fenced, turf-grass habitat that is highly modified (i.e., mown, fertilized and maintained as tree-free to avoid the disruption of roots to the cover structure) eliminates the applicability of remediation as a means to reduce the level of residual effects.

Table 5.6.7-3: Classification of Residual Effects on Vegetation Community Indicators in the Application Case

Indicator	Characteristic	Rating/Effect Size
Ecosystem Availability	Direction	Negative
	Magnitude	Loss of 33 ha of ecosystems (0.8% of the RSA Base Case; 15.9% of the LSA Base Case). All ecosystem losses that would be caused by the NSDF Project are forested ecosystems.
	Geographic Extent	SSA
	Duration/Reversibility	Permanent/Irreversible
	Frequency/Timing	Continuous
	Likelihood	Certain
Ecosystem Distribution	Direction	Negative
	Magnitude	Changes to the distribution of vegetation communities primarily affects mixed forests and creates a localized fragmentation and distribution of this community type. However, East Mattawa Road and the two hydroelectric corridors already create three linear breaks in the distribution of forested communities in the SSA. The existing Perch Lake Ring Road through the Perch Lake Swamp is another existing linear break in the distribution of wetland habitat in the SSA. These mixed forest communities and wetlands remain well connected in the majority of the RSA; this change in distribution only occurs within the southeast corner of the RSA that is already affected by anthropogenic activity and disturbance, and the remaining largely undisturbed areas are left unmodified by the NSDF Project. Permanent fragmentation of wetlands, which are the most sensitive vegetation community, will not occur as a result of the NSDF Project, following implementation of mitigation during installation of the Perch Lake transfer line.
	Geographic Extent	SSA
	Duration/Reversibility	Permanent/Irreversible
	Frequency/Timing	Continuous
	Likelihood	Certain
Ecosystem Condition	Direction	Negative
	Magnitude	Conversion of the Base Case vegetation community composition from largely forested to turf-grass or unvegetated. Permanently affects the condition of a 38 ha SSA area that is comprised primarily of mature forest under existing conditions. Edge effects during the operations phase may alter adjacent vegetation community richness.
	Geographic Extent	Local
	Duration/Reversibility	Permanent /Irreversible
	Frequency/Timing	Continuous
	Likelihood	Certain (change to ecosystem condition) / Possible (introduction of invasive species)

RSA = Regional Study Area; SSA = Site Study Area.

5.6.7.1.4 Determination of Significance

The combined effects of past and present activity have altered vegetation communities in the RSA. Historically, forest composition and structure in the Georgian Bay Ecoregion was primarily driven by wildfire, insect outbreaks and disease. Within the RSA, active fire suppression combined with a lack of timber harvest since the 1940s has resulted in a high concentration of forested habitats, including mature forests (Section 5.6.4.1). The forest age class with highest coverage in the RSA in the Base Case is the immature seral stage at 1,618 ha (42%), with mature forest having second highest coverage, at 1,070 ha (28%). The LSA has the reverse, with mature forest at higher coverage (66 ha and 31.6% total area coverage) than immature forest (14 ha or 6.7%).

The relatively high coverage of older seral stages of forest cover within the RSA, as well as relatively high spatial coverage of wetlands and other aquatic habitat types, combines to create an area of high value for terrestrial biodiversity. This is especially true relative to areas surrounding the RSA that are more affected by forestry, farming and industrial disturbance. These forested ecosystems are interspersed and relatively abundant, and wetlands and natural vegetation communities are well distributed and connected in the RSA in the Base Case. Therefore, the combined evidence considered for ecosystem availability, distribution and condition indicates vegetation communities are currently self-sustaining and ecologically effective in the Base Case.

Because vegetation communities in the RSA are abundant, well connected and in good condition, they are expected to have the capacity to adapt and be resilient to existing natural and human-related disturbances. The NSDF Project will result in a permanent loss of 33 ha of forest, most of which is mature (3.0% of the Base Case RSA; 43% of the Base Case LSA). This is predicted to create small, negative changes to vegetation community availability, distribution and condition. However, although the loss of forest is permanent, these forest types are abundant in the RSA. The permanent incremental loss of forested vegetation communities and temporary, but replaced, loss of 400 m^2 of wetland habitat, from the NSDF Project is predicted to have little influence on ecological structure and function; 99% of undisturbed forested and wetland ecosystems present in the Base Case are predicted to remain in the Application Case. The NSDF Project will not permanently alter or fragment wetlands, which are the most sensitive vegetation community.

With effective implementation of the mitigation summarized in Table 5.6.5-1, the incremental contribution of the NSDF Project to combined effects from previous and existing development on vegetation communities in the RSA is not expected to change the self-sustaining and ecologically effective status of this VC. Consequently, effects on vegetation communities in the Application Case are predicted to be not significant.

On-going fire suppression in the RSA is anticipated to continue to promote succession of open habitat to forested habitat and young forest to old forest. However, climate change is predicted to increase the frequency and intensity of extreme weather events, including droughts, forest fires and heavy precipitation (Huff and Thomas 2014).

Overall, the weight of evidence from the analysis of the primary pathways predicts that changes to vegetation community ecosystem availability, ecosystem distribution and ecosystem condition in the RSA as a result of the NSDF Project are within the resilience and adaptability limits of this ecosystem. Continued fire suppression in the RSA and climate change are expected to affect vegetation community ecosystem availability, ecosystem distribution and ecosystem condition in the RSA. However, vegetation communities are expected to have the capacity to adapt and be resilient to natural and human-related disturbance, and fire suppression and effects of climate change are predicted to act together to continue to maintain a heterogeneous vegetative landscape in the RSA that provides habitat for a diversity of terrestrial flora and fauna. Therefore, effects from continued fire

suppression and climate change in conjunction with the effects of the NSDF Project and past and present activities and developments in the RSA are not predicted to exceed the resilience and adaptability limits of vegetation communities in the RSA. Consequently, cumulative effects of previous and existing developments, the incremental effect of the NSDF Project and future, beyond regional disturbance factors (e.g., climate change) on vegetation communities in the RSA, are predicted to be not significant. The contributions of the NSDF Project are therefore also considered not significant.

5.6.7.2 Canada Warbler

5.6.7.2.1 Residual Effects Analysis

Habitat Availability

The NSDF Project is estimated to remove 28 ha of suitable breeding habitat for Canada warbler, which is 21.9% of suitable habitat in the LSA and 1.6% of suitable habitat in the RSA (Table 5.6.7-4). Sensory disturbance during the construction, operations and closure phases may indirectly reduce Canada warbler habitat availability in the LSA through avoidance. Noise levels greater than 50 dB can negatively affect birds (ECCC 2019). Canada warblers may avoid otherwise suitable habitat in areas where NSDF Project activities create noise levels greater than 50 dB.

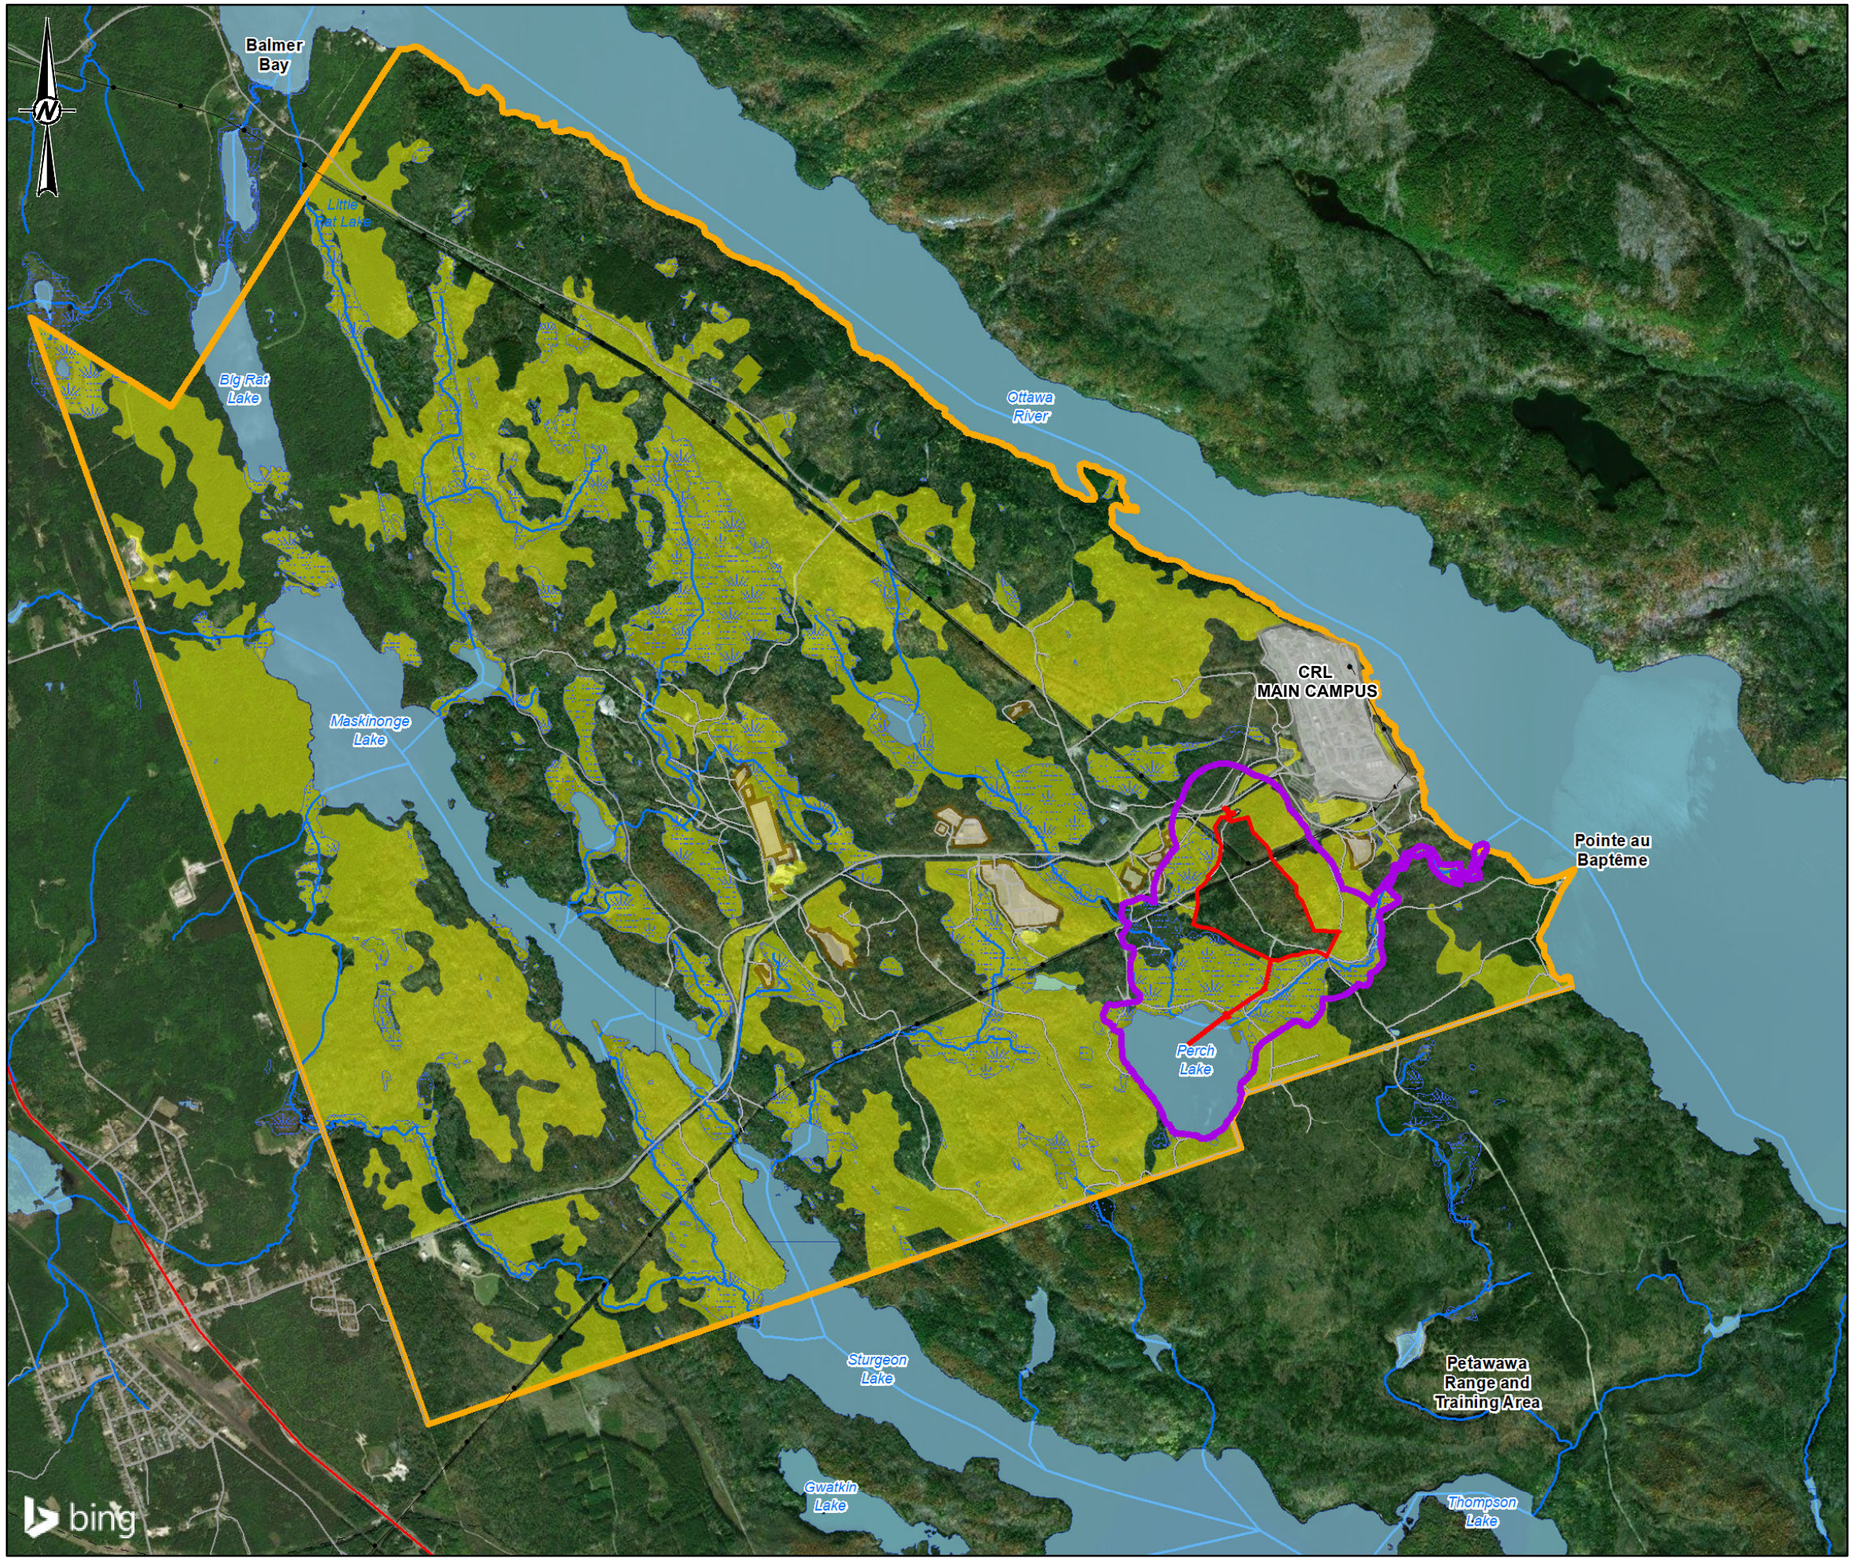

Table 5.6.7-4: Changes to Canada Warbler Breeding Habitat Availability in the Application Case

Habitat Suitability	Regional Study Area				Local Study Area			
	Base Case (ha)	Application Case (ha)	Change in Area (ha)	Percent Change (%)	Base Case (ha)	Application Case (ha)	Change in Area (ha)	Percent Change (%)
Suitable	1,701	1,673	-28	-1.6	128	100	-28	-21.9
Unsuitable	2,152	2,180	28	1.3	82	110	28	34.1

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

Habitat Distribution

The development of the NSDF Project is unlikely to have a measurable effect on Canada warbler habitat distribution and movement in the RSA given the small size of the SSA and its location in the southeastern portion of the RSA where most existing human disturbance is concentrated (Figure 5.6.7-3). Canada warblers are highly mobile and capable of moving around or over the NSDF Project infrastructure. Forest clearing in the SSA is approximately 33 ha. Canada warblers may perceive this area of forest clearing as a barrier to movement (Desrochers and Hannon 1997; St. Clair et al. 1998); however, the land around the SSA will remain in natural cover, which is primarily forest, allowing individuals to move around the NSDF Project during transit. The SSA represents a large portion of the LSA (17.9%) and is expected to affect Canada warbler movement, with individuals travelling along the perimeter of the LSA more frequently in the Application Case than in the Base Case, as a result of the SSA being located in the centre of the LSA (Figure 5.6.7-4).

Survival and Reproduction

Site clearing for the NSDF Project is not predicted to cause Canada warbler mortality. Adult Canada warblers are mobile and can avoid interactions with activities that could result in direct mortality, and mitigation will be implemented to avoid nest loss (Section 5.6.5.2.1).

The loss of breeding habitat may affect reproductive success if individuals are displaced or return to breeding grounds to find habitat removed, and subsequently are unable to establish a new territory or establish a territory in lower quality habitat. However, potentially suitable nesting habitat is broadly available in the RSA.

Sensory disturbance, such as noise from construction of the NSDF Project, may potentially reduce reproductive success and survival in the LSA by raising stress levels and interfering with communications (e.g., reducing ability to hear approaching predators or vocalizations by others of the same species; Ortega 2012). Thus, the carrying capacity of the LSA and RSA during the Application Case may be reduced relative to conditions in the Base Case.

5.6.7.2.2 Prediction Confidence

The residual effects assessment for Canada warbler is based on a good understanding of this species' ecology and tolerance to anthropogenic activities and a moderate understanding of threats to the persistence of the species.

There is some uncertainty concerning the Canada warbler population in the RSA because few quantitative data are available. Some uncertainty also exists in the accuracy of the mapping layer used to predict habitat availability, which was defined by relatively coarse vegetation community categories that did not always capture detailed habitat preferences. Moreover, the mapping could not be validated due to the limited amount of ground-truthing data available. This assessment dealt with uncertainty in map accuracy by making precautionary assumptions about habitat availability and occupancy in the study areas, and most likely overestimated the amount of habitat loss and reduction in carrying capacity.

There is a high level of uncertainty associated with the future population status of Canada warbler in Canada. Evidence suggests that populations are declining across the species' range, including in Ontario. If the declining population trend is not reversed or accelerates over the next decade, then Canada warbler may be up-listed from Threatened to Endangered. Critical habitat for Canada warbler is anticipated to be identified and one or more action plans will be developed for this species by 2021 (ECCC 2016a).

5.6.7.2.3 Residual Effects Classification

A summary of the classification of incremental adverse residual effects of the NSDF Project on Canada warbler in the Application Case is provided for each measurement indicator in Table 5.6.7-5. Residual effects after the implementation of effective mitigation are described, and are summarized according to direction, magnitude, geographic extent, duration/reversibility, frequency/timing and likelihood of the effect occurring following the methods described in Section 5.6.6.3 and the definitions provided in Table 5.6.6-1.

Table 5.6.7-5: Classification of Residual Effects on Canada Warbler in the Application Case

Indicator	Characteristic	Rating/Effect Size
Habitat Availability	Direction	Negative
	Magnitude	Direct loss of 28 ha of suitable habitat; reduced quality of nesting habitat and possible avoidance in the LSA from sensory disturbance during the construction and operations phases
	Geographic Extent	SSA (direct habitat loss); Local (sensory disturbance)
	Duration/Reversibility	Permanent/Irreversible (direct habitat loss); Long-term (sensory disturbance)
	Frequency/Timing	Continuous
	Likelihood	Certain (direct habitat loss); Probable (sensory disturbance)
Habitat Distribution	Direction	Negative
	Magnitude	Small change in movement in the LSA, with individuals travelling along the perimeter of the LSA more frequently as a result of the NSDF Project
	Geographic Extent	Local
	Duration/Reversibility	Permanent/Irreversible
	Frequency/Timing	Continuous
	Likelihood	Probable
Survival and Reproduction	Direction	Negative
	Magnitude	Small reduction in carrying capacity from habitat loss and sensory disturbance
	Geographic Extent	Local
	Duration/Reversibility	Long-term (sensory disturbance)
	Frequency/Timing	Continuous
	Likelihood	Probable

LSA = Local Study Area; SSA = Site Study Area.

5.6.7.2.4 Determination of Significance

The loss/degradation of overwintering habitat may be the most important factor affecting the Canada warbler population that overlaps the RSA in the Base Case (ECCC 2016a). The loss/degradation of breeding habitat is also considered a primary threat, but its relative importance varies across the species' geographic range (ECCC 2016a). Ontario may support 50% of Canada's breeding population of this VC and 44.1% of the RSA comprises suitable habitat for this species. Habitat availability for the population of Canada warbler that overlaps with the RSA is not considered a limiting factor in the Base Case and changes to this indicator have not exceeded its resilience or adaptability limits. Existing disturbance in the RSA and LSA do not likely function as dispersal barriers for this species in the Base Case because it is highly mobile.

Other threats affecting this VC in the Base Case include accidental mortality (e.g., collision with anthropogenic structures) and changes in the availability of insect prey (ECCC 2016a). Canada warblers may have a low ability to adapt to changes because they are a single-brooded species that arrives late on the breeding grounds and leaves early. However, Canada warblers also have the ability to produce many young, which increases the species' resilience to changes in survival and reproduction. The federal recovery strategy states that "there are currently adequate numbers of individuals to sustain the species in Canada or increase its abundance with the implementation of proper conservation actions" (ECCC 2016a). Therefore, changes to Canada warbler survival and reproduction in the Base Case are considered to be within the resilience and adaptability limits of this species.

For the primary pathways influencing habitat availability, habitat distribution, and survival and reproduction, the residual effects of the NSDF Project are predicted to be negative in direction and restricted to the SSA or LSA in geographic extent, which implies that at least a portion of the population is affected during any given year, but likely not the entire population every year. In the Application Case, the SSA is predicted to remove 28 ha of suitable Canada warbler habitat in the RSA. In addition, there may be changes to Canada warbler movement in the LSA as Canada warblers may not be willing to cross the gap in the forest created by the SSA. Suitable habitat in the LSA may be avoided by Canada warbler due to sensory disturbance during the construction and operations phases. Effects from habitat loss are expected to be permanent because the development of the NSDF Project will result in the permanent reconfiguration of habitat on the landscape. Conversely, effects from sensory disturbance during the construction and operations phases of the NSDF Project are expected to be continuous, but reversible at the end of the operations phase (long-term), although some individuals may adapt to sensory disturbance during construction and operations. Although these changes are negative, they are relatively small in a population context. After implementation of mitigation, the incremental changes due to the NSDF Project are not predicted to adversely affect populations of Canada warbler that overlap with the RSA. Consequently, cumulative effects from the NSDF Project and previous and existing activities and developments in the RSA on the Canada warbler population that overlaps with the RSA are predicted to be not significant in the Application Case.

On-going fire suppression in the RSA may reduce Canada warbler habitat availability as fire creates natural forest gaps with complex and dense shrubby cover required by this species (ECCC 2016a). Climate change is also likely to affect the Canada warbler population for the foreseeable future, although the direction and magnitude of changes are uncertain because predictions are based on simulations that can be highly variable and many scenarios are possible. Warmer and drier conditions in Ontario due to climate change may alter the onset of spring and summer and the timing of insect hatches (Nituch and Bowman 2013). Insectivorous long-distance migrants, such as Canada warblers, often exhibit a strong synchronization between breeding and peak food abundance, and climate change may affect this timing by creating a temporal mismatch between reproduction and optimal foraging conditions for prey (Both et al. 2009). A longer growing season may allow for Canada warblers to

raise more than one brood per year, which is currently not possible with the timing of this species migration patterns (COSEWIC 2008). Climate change is also predicted to increase the frequency and intensity of extreme weather events, including droughts, forest fires and heavy precipitation (Huff and Thomas 2014). Extreme weather events during the breeding season can result in reduced fecundity and nest success. Forest fires may increase habitat availability by creating nesting habitat through the creation of gaps in the forest that contain a dense shrub layer. Individuals may also be susceptible to extreme weather events outside of the breeding season. The frequency and intensity of hurricanes are predicted to increase as a result of climate change, which may negatively affect individuals during fall migration and on wintering grounds.

Overall, the weight of evidence from the analysis of the primary pathways predicts that changes to Canada warbler habitat availability, habitat distribution, and survival and reproduction in the RSA as a result of the NSDF Project are within the resilience and adaptability limits of the species. Continued fire suppression in the RSA and climate change are expected to also affect Canada warbler habitat availability, habitat distribution, and survival and reproduction in the RSA. However, neither of these threats has been identified as being of high concern to the persistence of the species (ECCC 2016a). Therefore, effects from continued fire suppression and climate change in conjunction with the effects of the NSDF Project and past and present activities and developments in the RSA are not predicted to exceed the resilience and adaptability limits of the Canada warbler population that overlaps with the RSA. Consequently, cumulative effects of previous and existing developments, the incremental effect of the NSDF Project and consideration of future, beyond regional disturbance factors (e.g., climate change) on the Canada warbler population that overlaps with the RSA, are predicted to be not significant.
The contributions of the NSDF Project are therefore also considered not significant.
