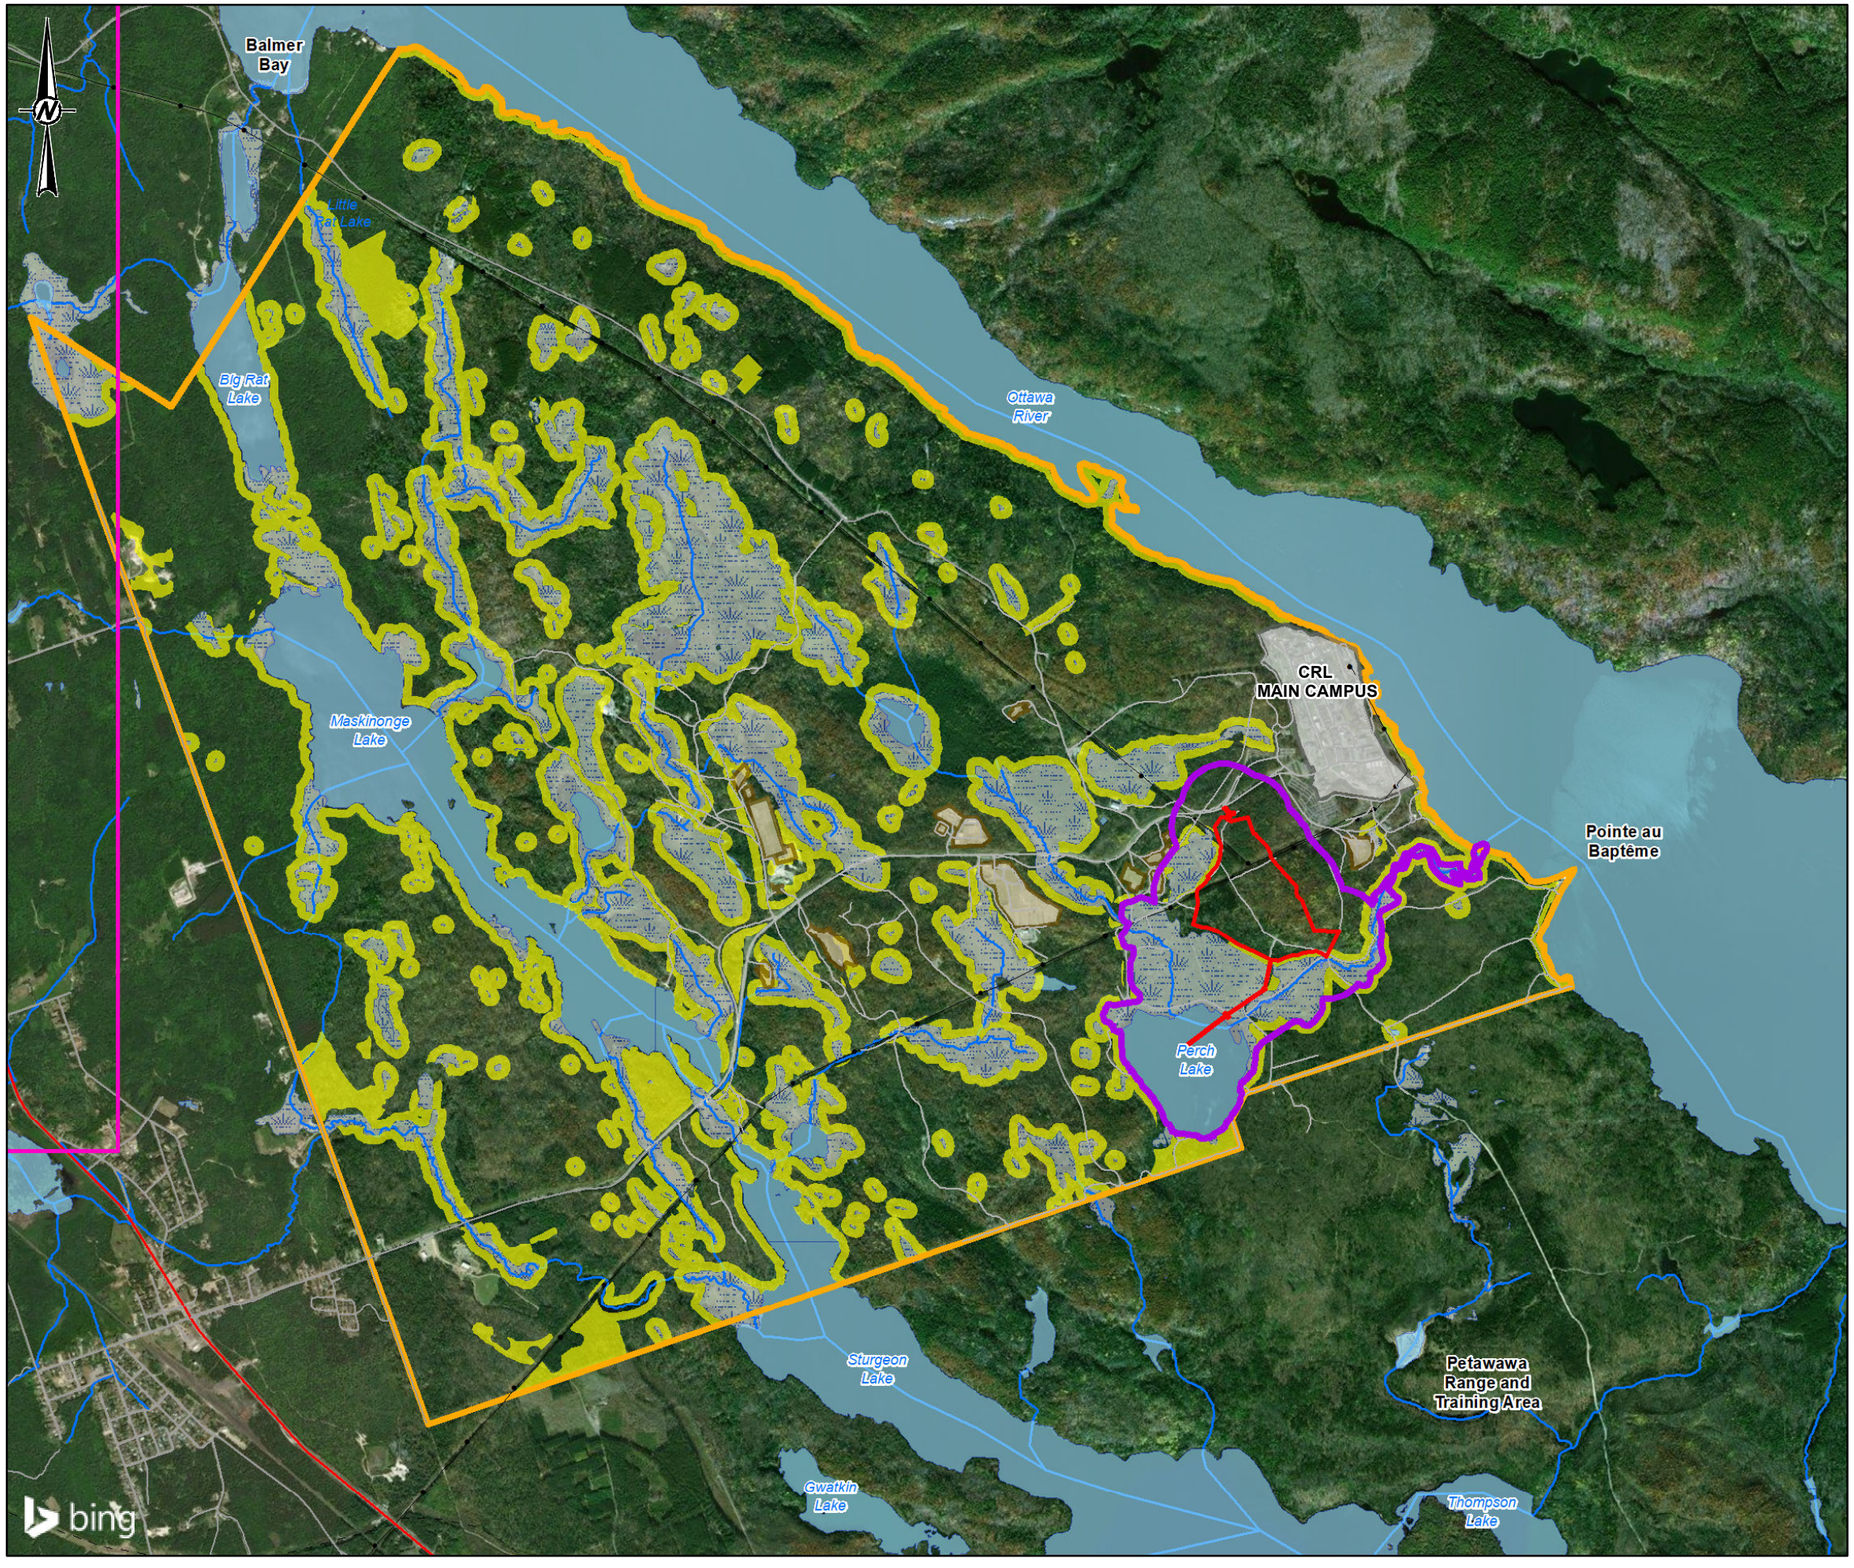
The NSDF Project is estimated to remove approximately 2 ha of suitable breeding habitat for eastern whip-poor-will, which is 15.4% of suitable habitat in the LSA and 0.3% of suitable habitat in the RSA (Table 5.6.7-6). Sensory disturbance during the construction, operations and closure phases may indirectly reduce eastern whip-poor-will habitat availability in the LSA through avoidance. Noise levels greater than 50 dB can negatively affect birds (ECCC 2019). Eastern whip-poor-will may avoid otherwise suitable habitat in areas where NSDF Project activities create noise levels greater than 50 dB.

Table 5.6.7-6: Changes to Eastern Whip poor will Breeding Habitat Availability in the Application Case

Habitat Suitability	Regional Study Area				Local Study Area			
	Base Case (ha)	Application Case (ha)	Change in Area (ha)	Percent Change (%)	Base Case (ha)	Application Case (ha)	Change in Area (ha)	Percent Change (%)
Suitable	769	767	-2	-0.3	13	11	-2	-15.4
Unsuitable	3,083	3,085	2	<0.1	197	199	2	1.0

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

Effects on whip-poor-will from changes to habitat availability are expected because there is anticipated to be a direct loss of suitable breeding habitat; indirect habitat loss from avoidance due to sensory disturbance is also probable. Although effects are assumed to cease after the completion of closure activities, some individuals may adapt to sensory disturbance and may use suitable habitat within one to three years after NSDF Project construction is complete.



Habitat Distribution

The development of the NSDF Project is unlikely to have a measurable effect on eastern whip-poor-will habitat distribution and movement in the RSA given the small size of the SSA and its location in the southeastern portion of the RSA, where most existing human disturbance is concentrated (Figure 5.6.7-5). Whip-poor-wills are highly mobile and capable of moving around or over the NSDF Project infrastructure. Forest clearing in the SSA is approximately 33 ha. Whip-poor-wills may perceive this area of forest clearing as a barrier to movement (Desrochers and Hannon 1997; St. Clair et al. 1998); however, the land around the SSA will remain in natural cover, which is primarily forest, allowing individuals to move around the NSDF Project during transit. The SSA represents a large portion of the LSA (17.9%) and is expected to affect whip-poor-will movement locally, with individuals travelling along the perimeter of the LSA more frequently in the Application Case than in the Base Case, as a result of the SSA being located in the centre of the LSA (Figure 5.6.7-6). However, the SSA is less likely to be perceived as a movement barrier by species that use earlier successional habitats, such as eastern whip-poor-wills, than by interior-forest species.

Survival and Reproduction

Site clearing for the NSDF Project is not predicted to cause whip-poor-will mortality. Adult whip-poor-wills are mobile and can avoid interactions with activities that could result in direct mortality, and mitigation will be implemented to avoid nest loss (Section 5.6.5.2.1). The loss of breeding habitat may affect reproductive success if individuals are displaced or return to breeding grounds to find habitat removed, and subsequently are unable to establish a new territory or establish a territory in lower quality habitat. The loss of suitable breeding habitat due to the NSDF Project is predicted to result in a small reduction in the carrying capacity of the LSA and RSA. However, this is unlikely to have a measurable effect on the eastern whip-poor-will population in the RSA given the small area of predicted habitat loss (0.3% of suitable habitat in the RSA) and good representation of suitable habitat in the RSA (19.9% of RSA). Sensory disturbance may affect reproductive success and survival in the LSA by raising stress levels and interfering with communications (e.g., reducing ability to hear approaching predators or vocalizations by others of the same species; Ortega 2012). Thus, the carrying capacity of the LSA and RSA may be reduced in the Application Case relative to conditions in the Base Case.

5.6.7.3.2 Prediction Confidence

The residual effects assessment for eastern whip-poor-will is based on a good understanding of whip-poor-will ecology and the species' tolerance to anthropogenic activities and a moderate understanding of threats to the persistence of the species.

There is moderate uncertainty concerning the whip-poor-will population in the RSA because few quantitative datasets are available. There is moderate confidence in the habitat mapping. Some uncertainty exists in the accuracy of the mapping layer used to predict habitat availability, which was defined by relatively coarse vegetation community categories that did not always capture detailed habitat preferences. Moreover, the mapping could not be validated due to the limited amount of ground-truthing data available. This assessment dealt with uncertainty in map accuracy by making precautionary assumptions about habitat availability and occupancy in the study areas and most likely overestimating the amount of habitat loss and reduction in carrying capacity.

There is a high level of uncertainty associated with the future population status of whip-poor-will in Canada. Evidence suggests that populations are declining across the species' range, including in Ontario. If the declining population trend is not reversed or accelerates over the next decade, then whip-poor-will may be up-listed from Threatened to Endangered. The federal recovery strategy has partially identified critical habitat for the species and outlines a schedule to further identify critical habitat by 2035; and one or more action plans will be developed for this species by 2020 (ECCC 2018a).

5.6.7.3.3 Residual Effects Classification

A summary of the classification of incremental adverse residual effects of the NSDF Project on eastern whip-poor-will in the Application Case is provided for each measurement indicator in Table 5.6.7-7. Residual effects after the implementation of effective mitigation are described, and are summarized according to direction, magnitude, geographic extent, duration/reversibility, frequency/timing and likelihood of the effect occurring following the methods described in Section 5.6.6.3 and the definitions provided in Table 5.6.6-1.

Table 5.6.7-7: Description of Residual Effects on Eastern Whip poor will in the Application Case

Indicator	Characteristic	Rating/Effect Size
Habitat Availability	Direction	Negative
	Magnitude	Direct loss of 2 ha of suitable habitat (15.4% in LSA; 0.3% in RSA); reduced quality of nesting habitat and possible avoidance in the LSA from sensory disturbance during the construction and operations phases
	Geographic Extent	SSA (direct habitat loss); Local (sensory disturbance)
	Duration/Reversibility	Permanent /Irreversible (direct habitat loss); Long-term (sensory disturbance)
	Frequency/Timing	Continuous
	Likelihood	Certain (direct habitat loss); Probable (sensory disturbance)
Habitat Distribution	Direction	Negative
	Magnitude	Small change in movement in the LSA, with individuals travelling along the perimeter of the LSA more frequently as a result of the NSDF Project
	Geographic Extent	Local
	Duration/Reversibility	Permanent/Irreversible
	Frequency/Timing	Continuous
	Likelihood	Probable

Table 5.6.7-7: Description of Residual Effects on Eastern Whip poor will in the Application Case

Indicator	Characteristic	Rating/Effect Size
Survival and Reproduction	Direction	Negative
	Magnitude	Small reduction in reproductivity from habitat loss and sensory disturbance
	Geographic Extent	Local
	Duration/Reversibility	Permanent/Irreversible (direct habitat loss); Long-term (sensory disturbance)
	Frequency/Timing	Continuous
	Likelihood	Probable

LSA = Local Study Area; RSA = Regional Study Area.

5.6.7.3.4 Determination of Significance

The population of eastern whip-poor-will that overlaps with the RSA is not considered sensitive to changes in habitat availability or distribution because breeding habitat is not considered a limiting factor for this VC in the RSA, and suitable habitat is well represented (19.9% of RSA) and well distributed in the RSA. The RSA overlaps one 10 km by 10 km standardized UTM grid square identified to contain critical habitat for this species (grid square 18US00; ECCC 2018a). However, the area of overlap is small (28 ha) and is located in the extreme northwestern tip of the RSA (Figure 5.6.7-5). The exact location of critical habitat in grid squares is not identified in recovery strategies. Based on habitat mapping, approximately 3 ha of suitable habitat occurs in the grid square where it overlaps with the RSA. Whip-poor-wills are highly mobile and they demonstrate flexibility in habitat selection, including use of human disturbance, such as clear cuts and utility corridors. These characteristics suggest resilience and adaptability to changes in habitat availability and distribution. Whip-poor-wills have been regularly reported using habitats in areas surrounding the RSA (eBird 2017), and seven individuals were observed in and around the RSA during species-specific surveys. Despite concerning population trend data, the federal recovery strategy concluded that individuals that are capable of reproduction are available to sustain the population and improve its abundance (ECCC 2018a). Therefore, changes to whip-poor-will survival and reproduction in the Base Case are considered to be within the resilience and adaptability limits of this species. Overall, there is no evidence to suggest the population that overlaps the RSA is not self-sustaining and ecologically effective in the Base Case.

In the Application Case, the SSA would permanently remove approximately 2 ha of suitable breeding habitat during construction. Additional suitable breeding habitat in the LSA may be avoided due to sensory disturbance. The NSDF Project would result in a change in movement patterns at the local scale, but this change is not expected to alter the extent of occurrence of the population that overlaps with the RSA because the area of disturbance is small and localized, and whip-poor-wills are highly mobile and capable of using anthropogenic disturbances for breeding. With effective implementation of mitigation, the incremental changes due to the NSDF Project are not predicted to adversely affect the population of whip-poor-wills that overlaps with the RSA because habitat is unlikely to be a limiting factor in the RSA and direct mortality of individuals will be avoided by implementing appropriate mitigation. Therefore, effects from the NSDF Project are not predicted to exceed the resilience and adaptability limits of the whip-poor-will population that overlaps with the RSA. Consequently, cumulative effects from the NSDF Project and previous and existing activities and developments in the RSA on the eastern whip-poor-will population that overlaps with the RSA are predicted to be not significant in the Application Case.

On-going fire suppression in the RSA may reduce whip-poor-will habitat availability as forests progress towards old growth age and lose preferred attributes of nesting and foraging habitat (ECCC 2018a). Climate change is also likely to affect the whip-poor-will population for the foreseeable future, although the direction and magnitude of changes are uncertain because predictions are based on simulations that can be highly variable and many scenarios are possible. Warmer and drier conditions in Ontario due to climate change may alter the onset of spring and summer and the timing of insect hatches (Nituch and Bowman 2013). Insectivorous, long-distance migrants such as eastern whip-poor-wills often exhibit a strong synchronization between breeding and peak food abundance, and climate change may affect this timing by creating a temporal mismatch between reproduction and optimal foraging conditions for prey (Both et al. 2009; COSEWIC 2009). On the contrary, an anticipated longer growing season may have a positive effect on eastern whip-poor-will by allowing for this species to increasingly raise more than one brood per year. However, climate change is also predicted to increase the frequency and intensity of extreme weather events, including droughts, forest fires and heavy precipitation (ECCC 2018a; Huff and Thomas 2014). Extreme weather events during the breeding season can result in reduced fecundity and nest success. Forest fires may increase habitat availability by creating foraging habitat and eventually nesting habitat through succession. Individuals may also be susceptible to extreme weather events outside of the breeding season. The frequency and intensity of hurricanes are predicted to increase as a result of climate change, which may negatively affect individuals during fall migration and on wintering grounds.

Overall, the weight of evidence from the analysis of the primary pathways predicts that changes to eastern whip-poor-will habitat availability, habitat distribution, and survival and reproduction in the RSA as a result of the NSDF Project are within the resilience and adaptability limits of the species. Continued fire suppression in the RSA and climate change are expected to also affect whip-poor-will habitat availability, habitat distribution, and survival and reproduction in the RSA. However, neither of these threats has been identified as being of high concern to the persistence of the species (ECCC 2018a). Therefore, effects from continued fire suppression and climate change in conjunction with the effects of the NSDF Project and past and present activities and developments in the RSA are not predicted to exceed the resilience and adaptability limits of the whip-poor-will population that overlaps with the RSA. Consequently, cumulative effects of previous and existing developments, the incremental effect of the NSDF Project, and consideration of future, beyond regional disturbance factors (e.g., climate change) on the eastern whip-poor-will population that overlaps the RSA are predicted to be not significant. The contributions of the NSDF Project are therefore also considered not significant.

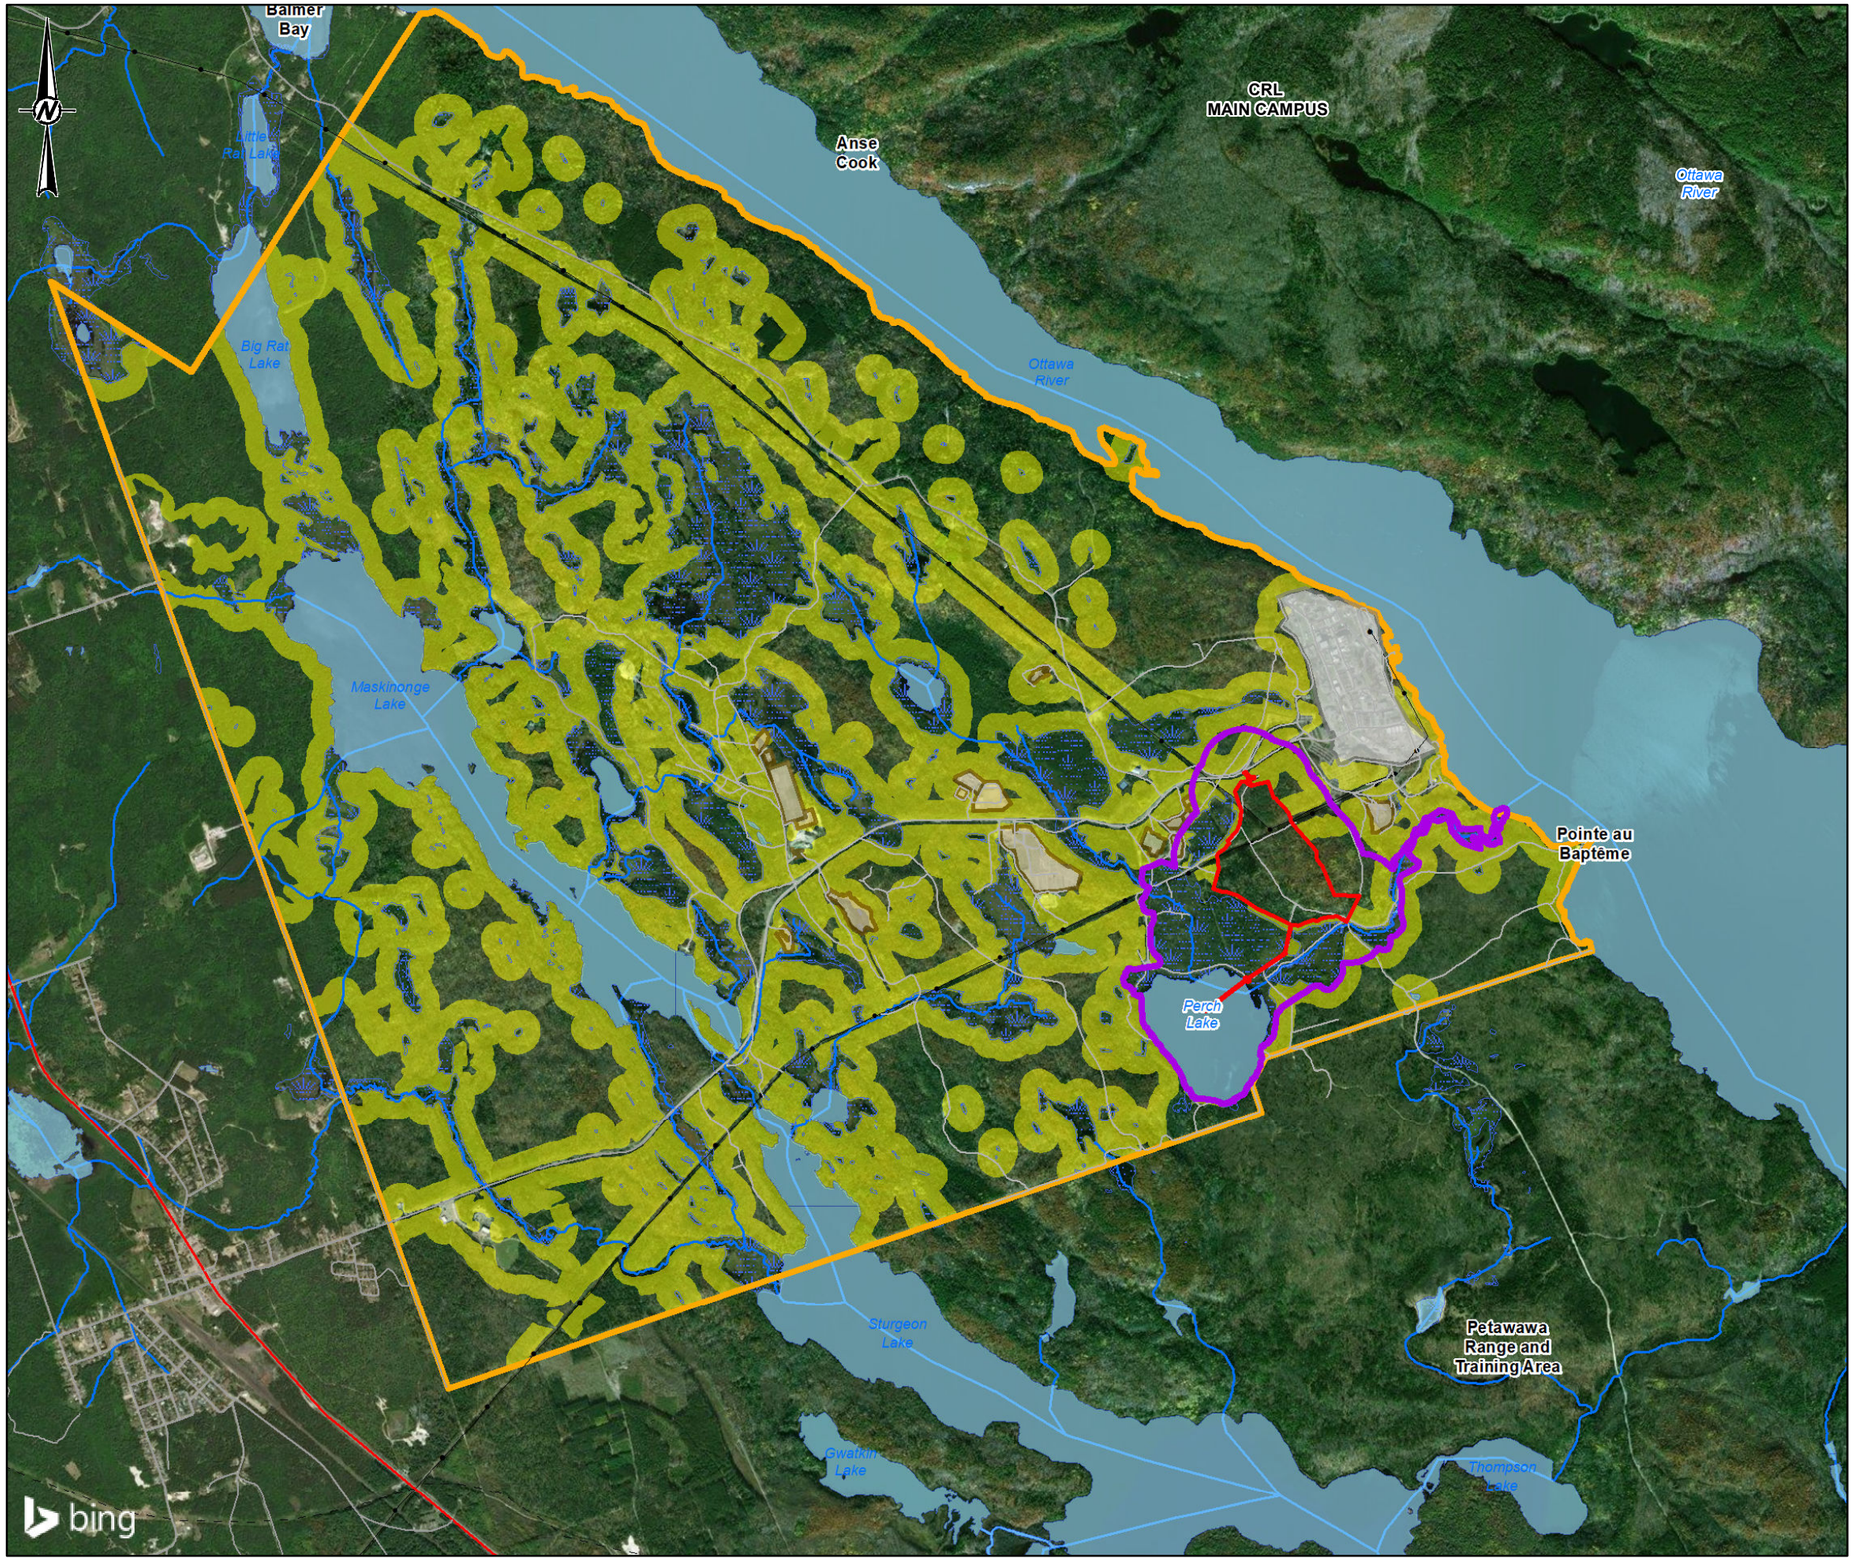
5.6.7.4 Eastern Wood-pewee

5.6.7.4.1 Residual Effects Analysis

Habitat Availability

The NSDF Project is estimated to remove 18 ha of suitable breeding habitat for eastern wood-pewee, which is 33.3% of suitable habitat in the LSA and 1.1% of suitable habitat in the RSA (Table 5.6.7-8). Sensory disturbance during the construction, operations and closure phases may reduce eastern wood-pewee habitat availability in the LSA through avoidance. Noise levels greater than 50 dB can negatively affect birds (ECCC 2019). Eastern wood-pewee may avoid otherwise suitable habitat in areas where NSDF Project activities create noise levels greater than 50 dB.

Table 5.6.7-8: Changes to Eastern Wood-pewee Breeding Habitat Availability in the Application Case



Habitat Suitability	Regional Study Area				Local Study Area			
	Base Case (ha)	Application Case (ha)	Change in Area (ha)	Percent Change (%)	Base Case (ha)	Application Case (ha)	Change in Area (ha)	Percent Change (%)
Suitable	1,603	1,584	-18	-1.1	54	36	-18	-33.3
Unsuitable	2,250	2,268	18	0.8	156	174	18	11.5

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

Effects on eastern wood-pewee from changes to habitat availability are expected because there will be a direct loss of suitable breeding habitat, and indirect habitat loss from avoidance due to sensory disturbance is also probable. Changes to habitat availability from habitat loss are permanent because the ECM will remain deforested in perpetuity. Effects from sensory disturbance are conservatively assumed to cease after completion of closure activities; however, some individuals may adapt to sensory disturbance and may use suitable habitat within one to three years after construction is complete.

Habitat Distribution

The development of the NSDF Project is unlikely to have a measurable effect on eastern wood-pewee habitat distribution and movement in the RSA given the small size of the SSA and its location in the southeastern portion of the RSA where most existing human disturbance is concentrated (Figure 5.6.7-7). Eastern wood-pewees are highly mobile and capable of moving around or over the NSDF Project infrastructure. Forest clearing in the SSA is approximately 33 ha. Eastern wood-pewees may perceive this area of forest clearing as a barrier to movement (Desrochers and Hannon 1997; St. Clair et al. 1998); however, the land around the SSA will remain in natural cover, which is primarily forest, allowing individuals to move around the NSDF Project during transit. The SSA represents a large portion of the LSA (17.9%) and is expected to affect eastern wood-pewee movement, with individuals travelling along the perimeter of the LSA more frequently in the Application Case than in the Base Case, as a result of the SSA being located in the centre of the LSA (Figure 5.6.7-8).

Survival and Reproduction

Site clearing for the NSDF Project is not predicted to cause eastern wood-pewee mortality. Adult wood-pewees are mobile and can avoid interactions with activities that could result in direct mortality, and mitigation will be implemented to avoid nest loss (Section 5.6.5.2.1). The loss of breeding habitat may affect reproductive success if individuals are displaced or return to breeding grounds to find habitat removed, and subsequently are unable to establish a new territory or establish a territory in lower quality habitat. The loss of suitable breeding habitat due to the NSDF Project is predicted to result in a small reduction in the carrying capacity of the LSA and RSA. However, this is unlikely to have a measurable effect on the eastern wood-pewee population in the RSA since suitable nesting habitat is broadly available in the RSA.

Sensory disturbance, such as noise from construction of the NSDF Project, may potentially reduce reproductive success and survival in the LSA by raising stress levels and interfering with communications (e.g., reducing ability to hear approaching predators or vocalizations by others of the same species; Ortega 2012). Thus, the carrying capacity of the LSA and RSA during the Application Case may be reduced relative to conditions in the Base Case.

5.6.7.4.2 Prediction Confidence

The residual effects assessment for eastern wood-pewee is based on a good understanding of this species ecology and tolerance to anthropogenic activities and a moderate understanding of threats to the persistence of the species.

There is some uncertainty concerning the eastern wood-pewee population in the RSA because few quantitative data are available. There is moderate confidence in the habitat mapping. Some uncertainty exists in the accuracy of the mapping layer used to predict habitat availability, which was defined by relatively coarse vegetation community categories that did not always capture detailed habitat preferences. Moreover, the mapping could not be validated due to the limited amount of ground-truthing data available. This assessment dealt with uncertainty in map accuracy by making precautionary assumptions about habitat availability and occupancy in the study areas and most likely overestimating the amount of habitat loss and reduction in carrying capacity.

There is some uncertainty about the future population status of eastern wood-pewee in Canada. Discrepancies exist among population trend estimates from different bird population monitoring programs, although it was determined through expert panel review that BBS results were most reliable and demonstrate consistent long- and short-term declines in Canada and Ontario (COSEWIC 2012a).

5.6.7.4.3 Residual Effects Classification

A summary of the classification of incremental adverse residual effects of the NSDF Project on eastern wood-pewee in the Application Case is provided for each measurement indicator in Table 5.6.7-9. Residual effects after the implementation of effective mitigation are described, and are summarized according to direction, magnitude, geographic extent, duration/reversibility, frequency/timing and likelihood of the effect occurring following the methods described in Section 5.6.6.3 and the definitions provided in Table 5.6.6-1.

Table 5.6.7-9: Classification of Residual Effects on Eastern Wood-pewee in the Application Case

Indicator	Characteristic	Rating/Effect Size
Habitat Availability	Direction	Negative
	Magnitude	Direct loss of 18 ha of suitable habitat; reduced quality of nesting habitat and possible avoidance in the LSA from sensory disturbance during the construction and operations phases
	Geographic Extent	SSA (direct habitat loss); Local (sensory disturbance)

	Geographic Extent	Local
	Duration/Reversibility	Permanent (direct habitat loss); Long-term (sensory disturbance)
	Frequency/Timing	Continuous
	Characteristic	Rating/Effect Size

LSA = Local Study Area; SSA = Site Study Area.

5.6.7.4.4 Determination of Significance

The population of eastern wood-pewee that overlaps with the RSA is not considered sensitive to changes in habitat availability or distribution because breeding habitat is not considered a limiting factor for this VC in the RSA, and suitable habitat is well represented (41.6% of RSA) and well distributed in the RSA. Wood-pewees are highly mobile, use a wide variety of forest types and appear relatively insensitive to habitat fragmentation (COSEWIC 2012a). These characteristics suggest resilience and adaptability to changes in habitat availability and distribution. Eastern wood-pewees have been observed using habitats in the RSA and surrounding areas in recent years (eBird 2017). Although population trends indicate short- and long-term declines in Canada and Ontario, Ontario supports the greatest densities of the species in the country and individuals that are capable of reproduction are available to sustain the population and improve its abundance. Therefore, changes to wood-pewee survival and reproduction in the Base Case are considered to be within the resilience and adaptability limits of this species. Overall, there is no evidence to suggest the population that overlaps the RSA is not self-sustaining and ecologically effective in the Base Case.

In the Application Case, the SSA is predicted to remove 18 ha of suitable eastern wood-pewee habitat in the RSA. In addition, there may be changes to wood-pewee movement in the LSA as wood-pewees may not be willing to cross the gap in the forest created by the SSA. Suitable habitat in the LSA may be avoided by wood-pewees due to sensory disturbance during the construction and operations phases. Effects from habitat loss are expected to be permanent because the development of the NSDF Project will result in the permanent reconfiguration of habitat on the landscape. Conversely, effects from sensory disturbance during the construction and operations phases of the NSDF Project are expected to be continuous, but reversible at the end of the operations phase (long-term), although some individuals may adapt to sensory disturbance over the medium-term. Although these changes are negative, they are relatively small in a population context. After implementation of mitigation, the incremental changes due to the NSDF Project are not predicted to adversely affect the population of wood-pewee that overlaps with the RSA. Consequently, cumulative effects from the NSDF Project and previous and existing activities and developments in the RSA on the eastern wood-pewee population that overlaps with the RSA are predicted to be not significant in the Application Case.

On-going fire suppression in the RSA may reduce wood-pewee habitat availability as forests progress towards old growth age and habitat edge attributes preferred by this species are lost. Climate change is also likely to affect the wood-pewee population for the foreseeable future, although the direction and magnitude of changes are uncertain because predictions are based on simulations that can be highly variable and many scenarios are possible. Warmer and drier conditions in Ontario due to climate change may alter the onset of spring and summer and the timing of insect hatches (Nituch and Bowman 2013). Insectivorous, long-distance migrants such as eastern wood-pewees often exhibit a strong synchronization between breeding and peak food abundance, and climate change may affect this timing by creating a temporal mismatch between reproduction and optimal foraging conditions for prey (Both et al. 2009; COSEWIC 2012a). On the contrary, an anticipated longer growing season may have a positive effect on eastern wood-pewee by allowing this species to increasingly raise more than one brood per year. Climate change is also predicted to increase the frequency and intensity of extreme weather events, including droughts, forest fires and heavy precipitation (ECCC 2018a; Huff and Thomas 2014). Forest fires and other extreme weather events that cause forest disturbance may increase habitat availability by creating edge habitat. However, extreme weather events during the breeding season can result in reduced fecundity and nest success. Individuals may also be susceptible to extreme weather events outside of the breeding season. The frequency and intensity of hurricanes are predicted to increase as a result of climate change, which may negatively affect individuals during fall migration and on wintering grounds.

Overall, the weight of evidence from the analysis of the primary pathways predicts that changes to eastern wood-pewee habitat availability, habitat distribution, and survival and reproduction in the RSA as a result of the NSDF Project are within the resilience and adaptability limits of the species. Continued fire suppression in the RSA and climate change are expected to also affect wood-pewee habitat availability, habitat distribution, and survival and reproduction in the RSA. Neither has been identified as a major threat to the persistence of the species, though climate change may factor in changes to prey availability, which itself has been identified as a potential serious threat requiring more study (COSEWIC 2012a). Therefore, effects from continued fire suppression and climate change in conjunction with the effects of the NSDF Project and past and present activities and developments in the RSA are not predicted to exceed the resilience and adaptability limits of the wood-pewee population that overlaps with the RSA. Consequently, cumulative effects of previous and existing developments, the incremental effect of the NSDF Project, and consideration of future, beyond regional disturbance factors (e.g., climate change) on the wood-pewee population that overlaps the RSA are predicted to be not significant. The contributions of the NSDF Project are therefore also considered not significant.

5.6.7.5 Golden-winged Warbler

5.6.7.5.1 Residual Effects Analysis

Habitat Availability

The NSDF Project is estimated to remove 27 ha of suitable breeding habitat for golden-winged warbler, which is 26.5% of suitable habitat in the LSA and 1.0% of suitable habitat in the RSA (Table 5.6.7-10). Sensory disturbance during the construction, operations and closure phases may reduce golden-winged warbler habitat availability in the LSA through avoidance. Noise levels greater than 50 dB can negatively affect birds (ECCC 2019). Golden-winged warbler may avoid otherwise suitable habitat in areas where NSDF Project activities create noise levels greater than 50 dB.

Table 5.6.7-10: Changes to Golden winged Warbler Breeding Habitat Availability in the Application Case

Habitat Suitability	Regional Study Area				Local Study Area			
	Base Case (ha)	Application Case (ha)	Change in Area (ha)	Percent Change (%)	Base Case (ha)	Application Case (ha)	Change in Area (ha)	Percent Change (%)
Suitable	2,621	2,594	-27	-1.0	102	75	-27	-26.5
Unsuitable	1,232	1,259	27	2.2	108	135	27	25.0

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

Effects on golden-winged warbler from changes to habitat availability are expected because there will be a direct loss of suitable breeding habitat, and indirect habitat loss from avoidance due to sensory disturbance is also probable. Effects from sensory disturbance are conservatively assumed to cease after completion of closure activities; however, some individuals may adapt to sensory disturbance and may use suitable habitat within one to three years after construction is complete.

Habitat Distribution

The development of the NSDF Project is unlikely to have a measurable effect on golden-winged warbler habitat distribution and movement in the RSA given the small size of the SSA and its location in the southeastern portion of the RSA, where most existing human disturbance is concentrated (Figure 5.6.7-9). Golden-winged warblers are highly mobile and capable of moving around or over the NSDF Project infrastructure. Forest clearing in the SSA is approximately 33 ha. Golden-winged warblers may perceive this area of forest clearing as a barrier to movement (Desrochers and Hannon 1997); however, the land around the SSA will remain in natural cover, which is primarily forest, allowing individuals to move around the NSDF Project during transit (Figure 5.6.7-10). The SSA represents a large portion of the LSA (17.9%) and may affect golden-winged warbler movement, with individuals travelling along the perimeter of the LSA more frequently in the Application Case than in the Base Case as a result of the SSA being located in the centre of the LSA. However, the SSA is less likely to be perceived as a movement barrier by edge species, such as golden-winged warblers, than by interior-forest species.

Survival and Reproduction

Site clearing for the NSDF Project is not predicted to cause golden-winged warbler mortality. Adult golden-winged warblers are mobile and can avoid interactions with activities that could result in direct mortality, and mitigation will be implemented to avoid nest loss (Section 5.6.5.2.1). The loss of breeding habitat may affect reproductive success if individuals are displaced or return to breeding grounds to find habitat removed, and subsequently are unable to establish a new territory or establish a territory in lower quality habitat. The loss of suitable breeding habitat due to the NSDF Project is predicted to result in a small reduction in the carrying capacity of the LSA and RSA. However, this is unlikely to have a measurable effect on the golden-winged warbler population in the RSA given the small area of predicted habitat loss (1.0% of suitable habitat in the RSA) and overall abundance of suitable habitat in the RSA (68.0% of RSA).

Sensory disturbance, such as noise from construction of the NSDF Project may affect reproductive success and survival in the LSA by raising stress levels and interfering with communications (e.g., reducing ability to hear approaching predators or vocalizations by others of the same species; Ortega 2012). Thus, the carrying capacity of the LSA and RSA may be further reduced relative to that predicted based on habitat loss alone.

5.6.7.5.2 Prediction Confidence

The residual effects assessment for golden-winged warbler is based on a good understanding of golden-winged warbler ecology, threats to the persistence of the species and the species' tolerance to anthropogenic activities.

There is moderate uncertainty concerning the golden-winged warbler population in the RSA because few quantitative data are available. Some uncertainty exists in the accuracy of the mapping layer used to predict habitat availability, which was defined by relatively coarse vegetation community categories that did not always capture detailed habitat preferences. Moreover, the mapping could not be validated due to the limited amount of ground-truthing data available. This assessment dealt with uncertainty in map accuracy by making precautionary assumptions about habitat availability and occupancy in the study areas and most likely overestimating the amount of habitat loss and reduction in carrying capacity.

There is a moderate level of uncertainty associated with the future population status of golden-winged warbler in Canada. There are discrepancies among population trend estimates, with some suggesting steep declines across the species' range, and others suggesting stable population trends (ECCC 2016a). The federal recovery strategy has partially identified critical habitat for the species and outlines a schedule to further identify critical habitat by 2023, and one or more action plans will be developed for this species by 2022 (ECCC 2016a).

5.6.7.5.3 Residual Effects Classification

A summary of the classification of incremental adverse residual effects of the NSDF Project on golden-winged warbler in the Application Case is provided for each measurement indicator in Table 5.6.7-11. Residual effects after the implementation of effective mitigation are described, and are summarized according to direction, magnitude, geographic extent, duration/reversibility, frequency/timing and likelihood of the effect occurring following the methods described in Section 5.6.6.3 and the definitions provided in Table 5.6.6-1.

Table 5.6.7-11: Description of Residual Effects on Golden winged Warbler in the Application Case

Indicator	Characteristic	Rating/Effect Size
Habitat Availability	Direction	Negative
	Magnitude	Direct loss of 27 ha of suitable habitat (26.5% in LSA; 1.0% in RSA); reduced quality of nesting habitat and possible avoidance in the LSA from sensory disturbance during the construction and operations phases
	Geographic Extent	SSA (direct habitat loss); Local (sensory disturbance)
	Duration/Reversibility	Permanent /Irreversible (direct habitat loss); Long-term (sensory disturbance)
	Frequency/Timing	Continuous
	Likelihood	Certain (direct habitat loss); Probable (sensory disturbance)
Habitat Distribution	Direction	Negative
	Magnitude	Small change in movement in the LSA, with individuals travelling along the perimeter of the LSA more frequently as a result of the NSDF Project
	Geographic Extent	Local
	Duration/Reversibility	Permanent/Irreversible
	Frequency/Timing	Continuous
	Likelihood	Probable
Survival and Reproduction	Direction	Negative
	Magnitude	Small reduction in reproductivity from habitat loss and sensory disturbance
	Geographic Extent	Local
	Duration/Reversibility	Permanent/Irreversible (direct habitat loss); Long-term (sensory disturbance)
	Frequency/Timing	Continuous
	Likelihood	Probable

LSA = Local Study Area; RSA = Regional Study Area; SSA = Site Study Area.

5.6.7.5.4 Determination of Significance

The population of golden-winged warbler that overlaps with the RSA is not considered sensitive to changes in habitat availability or distribution because breeding habitat is not considered a limiting factor for this VC in the RSA, and suitable habitat is abundant (68.0% of RSA) and well distributed in the RSA. The RSA falls within one of the focal areas (GL10) identified to contain core populations that sustain the current breeding distribution and are important for expanding the population into adjacent areas; however, the RSA does not overlap grid squares identified to contain critical habitat within the focal area (ECCC 2016a). Golden-winged warblers are highly mobile and they demonstrate flexibility in habitat selection, including use of human disturbance such as roadsides and utility corridors, which create edge habitat preferred by this species. These characteristics suggest resilience and adaptability to changes in habitat availability and distribution. The population objective for golden-winged warbler, as identified in the federal recovery strategy, is to maintain self-sustaining populations in the focal areas, which indicates the population overlapping the RSA is considered to be relatively stable. Therefore, changes to golden-winged warbler survival and reproduction in the Base Case are considered to be within the resilience and adaptability limits of this species. Overall, there is no evidence to suggest the population that overlaps the RSA is not self-sustaining and ecologically effective in the Base Case.

In the Application Case, the SSA would permanently remove 27 ha of suitable breeding habitat during construction. Additional suitable breeding habitat in the LSA may be avoided due to sensory disturbance. The NSDF Project may result in a change in movement patterns at the local scale, but this change is not expected to alter the extent of occurrence of the population that overlaps with the RSA because the area of disturbance is small and localized, and golden-winged warblers are highly mobile and capable of using anthropogenic disturbances for breeding. With effective implementation of mitigation, the incremental changes due to the NSDF Project are not predicted to adversely affect the population of golden-winged warblers that overlaps with the RSA because habitat is unlikely to be a limiting factor in the RSA and direct mortality of individuals will be avoided by implementing appropriate mitigation. Therefore, effects from the NSDF Project are not predicted to exceed the resilience and adaptability limits of the golden-winged warbler population that overlaps with the RSA. Consequently, cumulative effects from the NSDF Project and previous and existing activities and developments in the RSA on the golden-winged warbler population that overlaps with the RSA are predicted to be not significant in the Application Case.

On-going fire suppression in the RSA may reduce golden-winged warbler habitat availability as forests progress towards old growth age and habitat edge attributes preferred by this species are lost. Climate change is also likely to affect the golden-winged warbler population for the foreseeable future, although the direction and magnitude of changes are uncertain because predictions are based on simulations that can be highly variable and many scenarios are possible. An anticipated longer growing season may have a positive effect on golden-winged warbler by allowing for this species to raise more than one brood per year. However, climate change is also predicted to increase the frequency and intensity of extreme weather events, including droughts, forest fires and heavy precipitation (ECCC 2016a; Huff and Thomas 2014). Extreme weather events during the breeding season can result in reduced fecundity and nest success. Forest fires may increase habitat availability by creating habitat edges preferred by this species. Individuals may also be susceptible to extreme weather events outside of the breeding season. The frequency and intensity of hurricanes are predicted to increase as a result of climate change, which may negatively affect individuals during fall migration and on wintering grounds.

Blue-winged warblers continue to expand northward, and this may be exacerbated by climate change and fire suppression (ECCC 2016a). Although both warbler species are considered early- to mid-successional habitat specialists, blue-winged warblers will start nesting at a later stage of succession and continue to nest further into succession than golden-winged warblers (Gill et al. 2001). An expansion of the blue-winged warbler range into the RSA would increase the likelihood of hybridization and competition with the golden-winged warbler population overlapping with the RSA (ECCC 2016a). However, further research is required to determine the taxonomic relationship between these species given that recent research suggests they are one species (Toews et al. 2016).

Overall, the weight of evidence from the analysis of the primary pathways predicts that changes to golden-winged warbler habitat availability, habitat distribution, and survival and reproduction in the RSA as a result of the NSDF Project are within the resilience and adaptability limits of the species. Continued fire suppression in the RSA, climate change and potential northward range expansion of the blue-winged warbler into the RSA are expected to also affect golden-winged warbler habitat availability, habitat distribution, and survival and reproduction in the RSA. However, only hybridization with blue-winged warbler has been identified as being of high concern to the persistence of the species among these threats (ECCC 2016a), and it is uncertain if this is a threat. Therefore, effects from continued fire suppression, climate change and potential northward range expansion of the blue-winged warbler into the RSA in conjunction with the effects of the NSDF Project and past and present activities and developments in the RSA are not predicted to exceed the resilience and adaptability limits of the golden-winged warbler population that overlaps with the RSA. Consequently, cumulative effects of previous and

existing developments, the incremental effect of the NSDF Project, and consideration of future, beyond regional disturbance factors (e.g., climate change) on the golden-winged warbler population that overlaps the RSA are predicted to be not significant. The contributions of the NSDF Project are therefore also considered not significant.

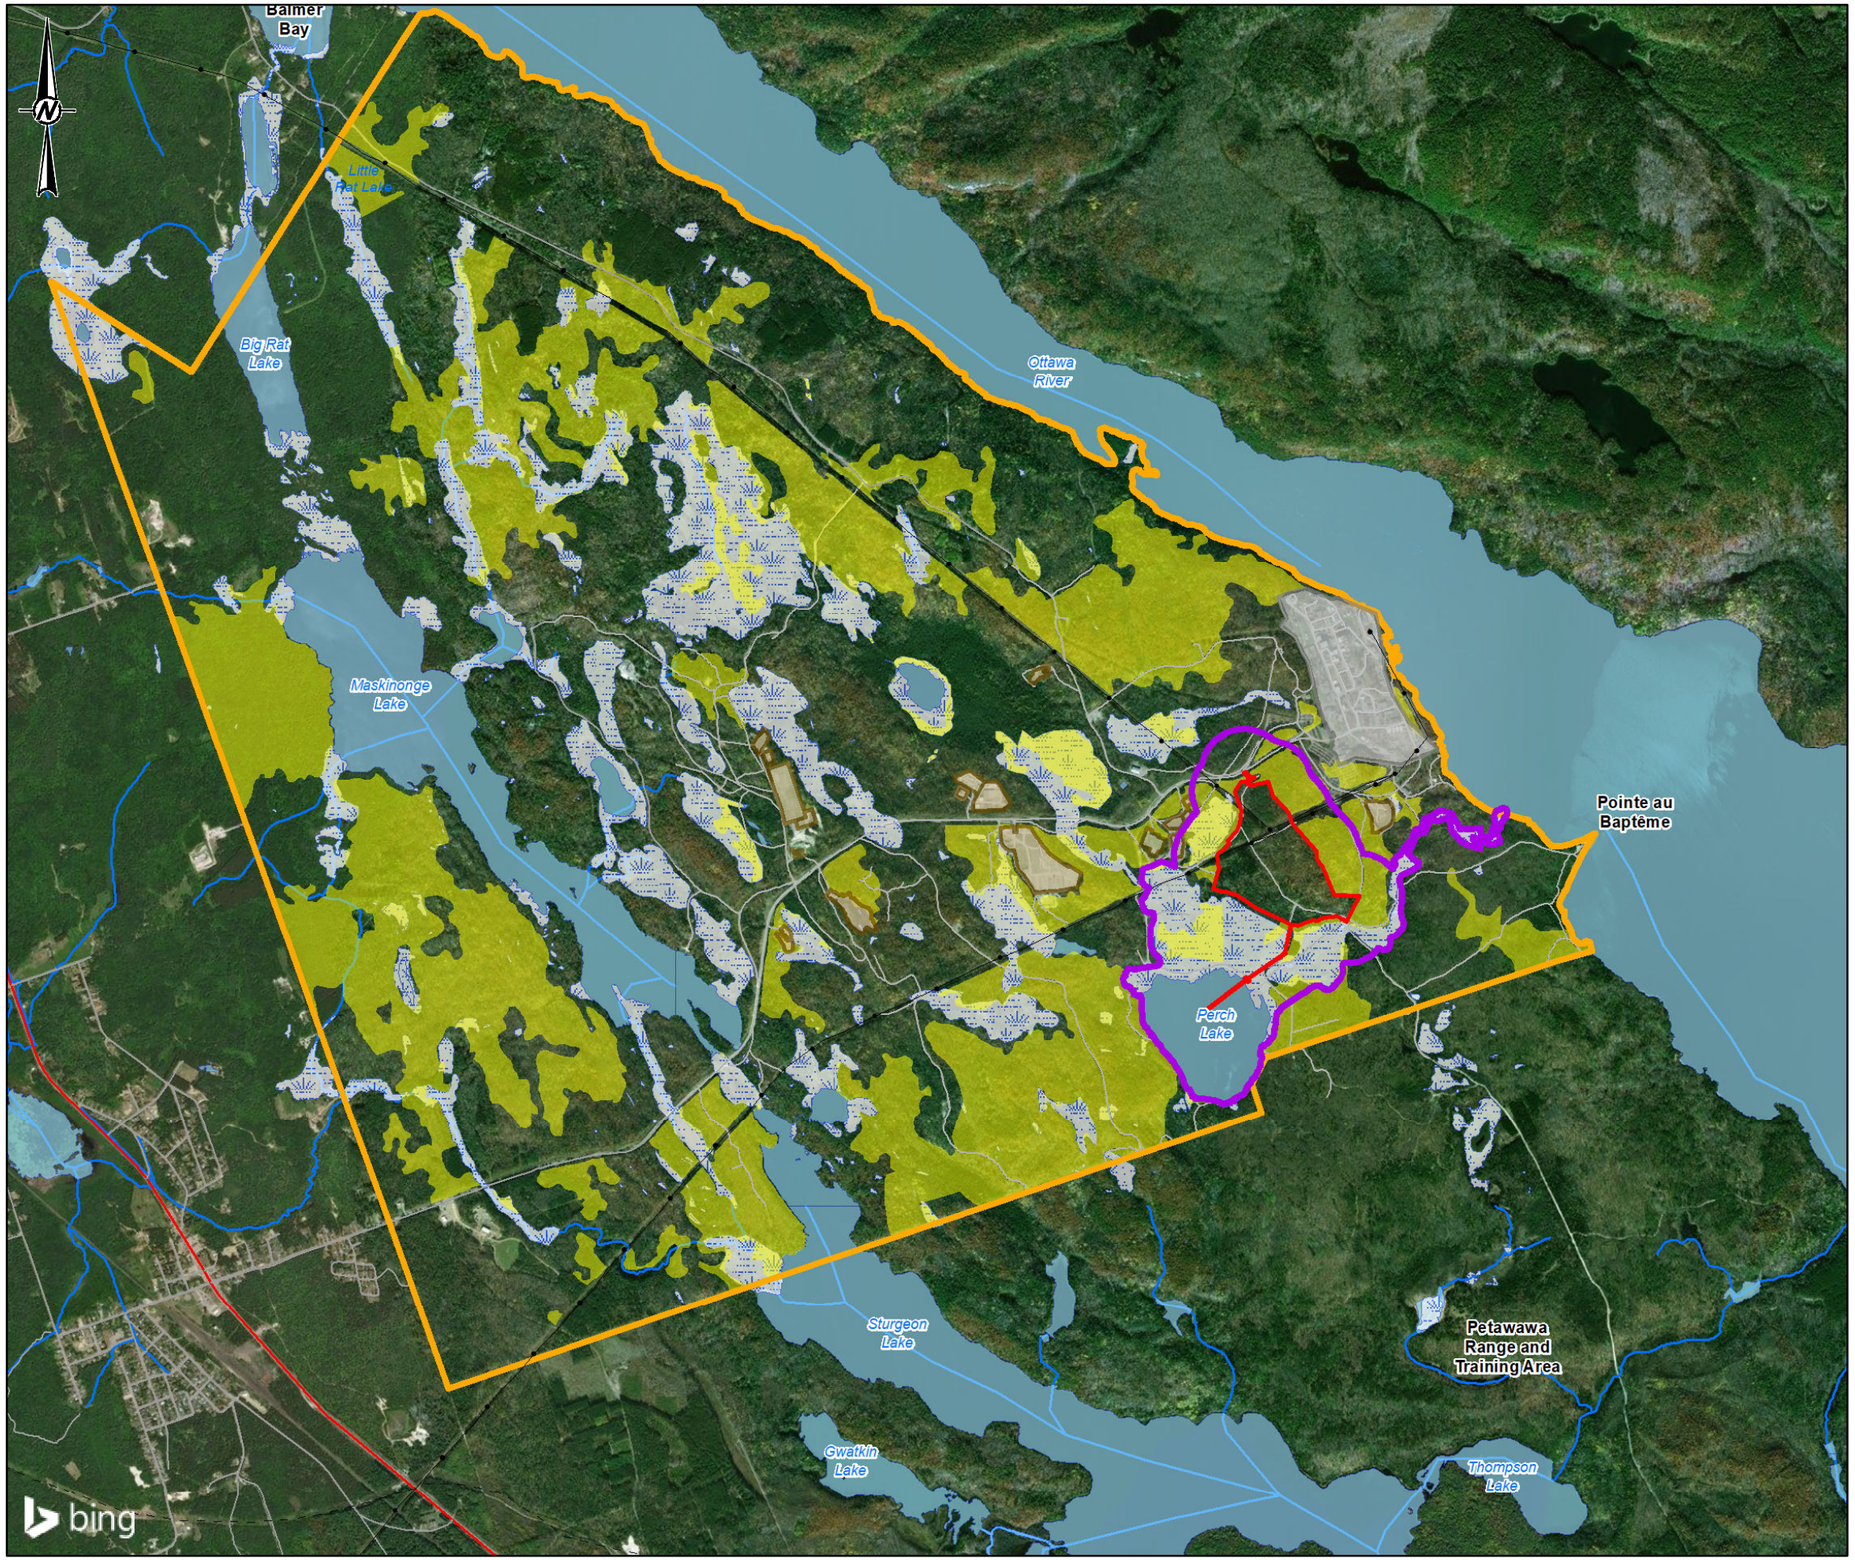
5.6.7.6 Wood Thrush

5.6.7.6.1 Residual Effects Analysis

Habitat Availability

The NSDF Project is estimated to remove 28 ha of suitable breeding habitat for wood thrush, which is 32.6% of suitable habitat in the LSA and 2.6% of suitable habitat in the RSA (Table 5.6.7-12). Sensory disturbance during the construction, operations and closure phases may reduce wood thrush habitat availability in the LSA through avoidance. Noise levels greater than 50 dB can negatively affect birds (ECCC 2019). Wood thrush may avoid otherwise suitable habitat in areas where NSDF Project activities create noise levels greater than 50 dB.

Table 5.6.7-12: Changes to Wood Thrush Breeding Habitat Availability in the Application Case



Habitat Suitability	Regional Study Area				Local Study Area			
	Base Case (ha)	Application Case (ha)	Change in Area (ha)	Percent Change (%)	Base Case (ha)	Application Case (ha)	Change in Area (ha)	Percent Change (%)
Suitable	1,076	1,047	-28	-2.6	86	58	-28	-32.6
Unsuitable	2,777	2,805	28	1.0	124	152	28	22.6

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

Effects on wood thrush from changes to habitat availability are expected because there will be a direct loss of suitable breeding habitat, and indirect habitat loss from avoidance due to sensory disturbance is also probable. Changes to habitat availability from habitat loss are permanent because the ECM will remain deforested in perpetuity. Effects from sensory disturbance are conservatively assumed to cease after completion of closure activities; however, some individuals may adapt to sensory disturbance and may use suitable habitat within one to three years after construction is complete.

Habitat Distribution

The development of the NSDF Project is unlikely to have a measurable effect on wood thrush habitat distribution and movement in the RSA given the small size of the SSA and its location in the southeastern portion of the RSA where most existing human disturbance is concentrated (Figure 5.6.7-11). Wood thrushes are highly mobile and capable of moving around or over the NSDF Project infrastructure. Forest clearing in the SSA is approximately 33 ha. Wood thrushes may be reluctant to move through the open habitat created by the SSA (Desrochers and Hannon 1997; St. Clair et al. 1998); however, the land around the SSA will remain in natural cover, which is primarily forest, allowing individuals to move around the NSDF Project during transit. The SSA represents a large portion of the LSA (17.9%) and is expected to affect wood thrush movement, with individuals travelling along the perimeter of the LSA more frequently in the Application Case than in the Base Case, as a result of the SSA being located in the centre of the LSA (Figure 5.6.7-12).

Survival and Reproduction

Site clearing for the NSDF Project is not predicted to cause wood thrush mortality. Adult wood thrushes are mobile and can avoid interactions with activities that could result in direct mortality, and mitigation will be implemented to avoid nest loss (Section 5.6.5.2.1). The loss of breeding habitat may affect reproductive success if individuals are displaced or return to breeding grounds to find habitat removed, and subsequently are unable to establish a new territory or establish a territory in lower quality habitat. The loss of suitable breeding habitat due to the NSDF Project is predicted to result in a small reduction in the carrying capacity of the LSA and RSA. However, this is unlikely to have a measurable effect on the wood thrush population in the RSA since suitable nesting habitat is broadly available in the RSA.

Sensory disturbance, such as noise from construction of the NSDF Project, may potentially reduce reproductive success and survival in the LSA by raising stress levels and interfering with communications (e.g., reducing ability to hear approaching predators or vocalizations by others of the same species; Ortega 2012). Thus, the carrying capacity of the RSA during the Application Case may be reduced relative to conditions in the Base Case.

5.6.7.6.2 Prediction Confidence

The residual effects assessment for wood thrush is based on a good understanding of this species' ecology and a moderate understanding of threats to the persistence of the species.

There is uncertainty concerning the status of the wood thrush population in the RSA because few quantitative data are available. Uncertainty also exists in the accuracy of the mapping layer used to predict habitat availability, which was defined by relatively coarse vegetation community categories that did not always capture detailed habitat preferences. Habitat selection is strongly based on microhabitat characteristics (Evans et al. 2011), which could not be determined from the vegetation community data. Finally, the mapping could not be validated due to the limited amount of ground-truthing data available. This assessment dealt with uncertainty in map accuracy by making precautionary assumptions about habitat availability and occupancy in the study areas, and most likely overestimated the amount of habitat loss and reduction in carrying capacity.

There is a moderate level of uncertainty associated with the future population status of wood thrush in Canada. Population trend estimates are generally consistent in showing short- and long-term population declines across the range of the species; however, declines are not universally severe and some populations, including in Ontario, appear to be relatively stable and self-sustaining (COSEWIC 2012b).

5.6.7.6.3 Residual Effects Classification

A summary of the classification of incremental adverse residual effects of the NSDF Project on wood thrush in the Application Case is provided for each measurement indicator in Table 5.6.7-13. Residual effects after the implementation of effective mitigation are described, and are summarized according to direction, magnitude, geographic extent, duration/reversibility, frequency/timing and likelihood of the effect occurring following the methods described in Section 5.6.6.3 and the definitions provided in Table 5.6.6-1.

Table 5.6.7-13: Classification of Residual Effects on Wood Thrush in the Application Case

Indicator	Characteristic	Rating/Effect Size
Habitat Availability	Direction	Negative
	Magnitude	Direct loss of 28 ha of suitable habitat; reduced quality of nesting habitat and possible avoidance in the LSA from sensory disturbance during the construction and operations phases
	Geographic Extent	SSA (direct habitat loss); Local (sensory disturbance)
	Duration/Reversibility	Permanent /Irreversible (direct habitat loss); Long-term (sensory disturbance)
	Frequency/Timing	Continuous
	Likelihood	Certain (direct habitat loss); Probable (sensory disturbance)
Habitat Distribution	Direction	Negative
	Magnitude	Small change in movement in the LSA, with individuals travelling along the perimeter of the LSA more frequently as a result of the NSDF Project
	Geographic Extent	Local
	Duration/Reversibility	Permanent/Irreversible
	Frequency/Timing	Continuous
	Likelihood	Probable
Survival and Reproduction Indicator	Direction	Negative
	Magnitude	Small reduction in carrying capacity from habitat loss and sensory disturbance
	Geographic Extent	Local
	Duration/Reversibility	Permanent/Irreversible (direct habitat loss); Long-term (sensory disturbance)
	Frequency/Timing	Continuous
	Characteristic	Rating/Effect Size

LSA = Local Study Area; SSA = Site Study Area.

5.6.7.6.4 Determination of Significance

The population of wood thrush that overlaps with the RSA is not considered sensitive to changes in habitat availability or distribution because breeding habitat is not considered a limiting factor for this VC in the RSA, and suitable habitat is well represented (27.9% of RSA) and well distributed in the RSA. Wood thrushes are highly mobile and they demonstrate flexibility in habitat selection, including use of anthropogenic habitats such as suburban residential areas and parks where suitable forest attributes are present (Evans et al. 2011). These characteristics suggest resilience and adaptability to changes in habitat availability and distribution. Wood thrushes have been observed using habitats in the RSA and surrounding areas in recent years (eBird 2017). Despite concerning population trend data indicating declines across the species' range, declines in Ontario are not significant (COSEWIC 2012b) and are more likely to be in more urbanized areas where habitat has been more heavily fragmented. Studies of Ontario populations suggest these populations are self-sustaining despite often extensive forest fragmentation (COSEWIC 2012b). Because Ontario populations are doing relatively well, changes to wood thrush survival and reproduction from previous developments in the province are considered to be within the resilience and adaptability limits of this species. Overall, there is no evidence to suggest the population that overlaps the RSA is not self-sustaining and ecologically effective in the Base Case.

In the Application Case, the SSA is predicted to remove 28 ha of suitable wood thrush habitat in the RSA. These habitat changes may also alter wood thrush movement in the LSA because wood thrushes may not be willing to cross the gap in the forest created by the SSA. Moreover, suitable habitat in the LSA may be avoided by wood thrushes due to sensory disturbance during the construction and operations phases. Effects from habitat loss are expected to be permanent because the development of the NSDF Project will result in the permanent reconfiguration of habitat on the landscape. Conversely, effects from sensory disturbance during the construction and operations phases of the NSDF Project are expected to be continuous, but reversible at the end of the operations phase (long-term), although some individuals may adapt to sensory disturbance over the medium term. Although the NSDF Project is likely to cause adverse effects to wood thrush, the effects are relatively small in a population context. After implementation of mitigation, the incremental changes due to the NSDF Project are not predicted to adversely affect the population of wood thrush that overlaps with the RSA. Consequently, cumulative effects from the NSDF Project and previous and existing activities and developments in the RSA on the wood thrush population that overlaps with the RSA are predicted to be not significant in the Application Case.

On-going fire suppression may reduce wood thrush habitat availability as increasingly aging forests lose habitat attributes preferred by this species (e.g., dense understory; COSEWIC 2012b). Climate change is also likely to affect the wood thrush population for the foreseeable future, although the direction and magnitude of changes are uncertain because predictions are based on simulations that can be highly variable and many scenarios are possible. Warmer and drier conditions in Ontario due to climate change may alter the onset of spring and summer and the timing of insect hatches (Nituch and Bowman 2013). Insectivorous, long-distance migrants such as wood thrushes often exhibit a strong synchronization between breeding and peak food abundance, and climate change may affect this timing by creating a temporal mismatch between reproduction and optimal foraging conditions for prey (Both et al. 2009). On the contrary, an anticipated longer growing season may have a positive effect on wood thrush by allowing for this species to increasingly raise two broods per year. Climate change is also predicted to increase the frequency and intensity of extreme weather events, including droughts, forest fires and heavy precipitation (Huff and Thomas 2014). Forest fires may increase habitat availability in the medium term as the forest understory regenerates. Other extreme weather events that result in forest disturbances (e.g., winter ice storms) may similarly increase habitat availability (COSEWIC 2012b). However, extreme weather events during the breeding season can result in reduced fecundity and nest success. Individuals may also be susceptible to extreme weather events outside of the breeding season. The frequency and intensity of hurricanes are predicted to increase as a result of climate change, which may negatively affect individuals during fall migration and on wintering grounds.

Overall, the weight of evidence from the analysis of the primary pathways predicts that changes to wood thrush habitat availability, habitat distribution, and survival and reproduction in the RSA because of the NSDF Project are within the resilience and adaptability limits of the species. Continued fire suppression in the RSA and climate change are expected to also affect wood thrush habitat availability, habitat distribution, and survival and reproduction in the RSA. However, neither has been identified as a major threat to the persistence of the species (COSEWIC 2012b). Therefore, effects from continued fire suppression and climate change in conjunction with the effects of the NSDF Project and past and present activities and developments in the RSA are not predicted to exceed the resilience and adaptability limits of the wood thrush population that overlaps with the RSA. Consequently, cumulative effects of previous and existing developments, the incremental effect of the NSDF Project and consideration of future, beyond regional disturbance factors (e.g., climate change) on the wood thrush population that overlaps the RSA are predicted to be not significant. The contributions of the NSDF Project are therefore also considered not significant.

5.6.7.7 Bats

5.6.7.7.1 Residual Effects Analysis

Habitat Availability

The RSA contains extensive spatial coverage of potential maternity roost habitat (Table 5.6.7-14). The reduction in habitat availability caused by the NSDF Project at the RSA scale is relatively minor (i.e., 1%). At the LSA scale, there will be a larger relative decrease in the availability of potential maternity roost habitat (reduction of 32.6%).

Table 5.6.7-14: Changes to Availability of Potential Bat Maternity Roost Tree Habitat in the Application Case

Habitat Suitability	Regional Study Area				Local Study Area			
	Base Case (ha)	Application Case (ha)	Change in Area (ha)	Percent Change (%)	Base Case (ha)	Application Case (ha)	Change in Area (ha)	Percent Change (%)
Suitable	2,943	2,915	-28	-1	86	58	-28	-32.6
Unsuitable	910	938	28	3.1	124	152	28	22.6

Note: Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

Site clearing and sensory disturbance during the construction and operations phases of the NSDF Project could also result in adverse changes to the availability of potential bat maternity roosting habitat in the LSA adjacent to the SSA if the level of disturbance causes avoidance and abandonment of occupied maternity roosts. Detailed information on how bats respond to anthropogenic noise is limited and varies among species; however, it is known that female bats may abandon their maternity roosts and young if noise is at a sufficient level. Bats have been found to abandon roosts when they are directly disturbed by human activity, especially those causing loud and sudden noises (California Department of Transportation 2016). Information on how noise (decibel) levels effect roosting bats is not currently available. Noise frequencies that overlap with echolocation frequency ranges (i.e., approximately 10 to 70 kHz) are expected to have the greatest effect on bats (Heffner et al. 2003, 2013; Koay et al. 2002, 2003). Harrison (1965) found that little brown myotis did not respond to frequencies above 40 kHz when in torpor (i.e., while roosting). A study by Luo et al. (2014) found bats were more sensitive to noise when it occurred closer to sunset as opposed to earlier in the daily roosting period and responded least to traffic noise and most to vegetation noise (e.g., rustling of leaves), possibly because traffic noise was at a lower frequency than their hearing range. Noise produced by vehicles, construction equipment and industrial and commercial facilities is usually below 10 kHz (Berglund et al. 1996; Nemeth and Brumm 2009). Bats may rapidly become habituated to repeated and prolonged noise exposure (e.g., bats roosting under bridges) (Luo et al. 2014). Potential maternity roosting habitat is predicted to be affected in the immediate perimeter of the tree stands surrounding the SSA.

Maternity roosts are only seasonally occupied. Because vegetation clearing for the NSDF Project will be conducted outside of the bat maternity roosting period (May 1 to August 31) when potential roost trees are not occupied, the NSDF Project will not result in a loss of actively used habitat. The RSA is dominated by forested ecosystems and the estimated number of suitable roost trees for the entire property, including suitable roost trees in sapling stands, exceeds 116,000 (Table 5.6.7-15). The number of suitable roost trees varies across the RSA, but is substantially higher in stand 216, which encompasses most of the area to be affected in the SSA, compared to elsewhere in the RSA (Table 5.6.7-15). This difference may be an artifact of sampling intensity, which was much higher in stand 216 than in other forested stands in the RSA.

Table 5.6.7-15: Estimated Number of Suitable Roost Trees in the Site and Regional Study Areas

Study Area	Number of Suitable Roost Trees[a]	Area (ha)	Average Roost Tree Density (#/ha)
RSA outside of SSA	110,405	3,514	31
SSA	6,485	37	175
Total (CRL site)	116,890	3,551[b]	33

a) Includes sapling stands.

b) The total area considers the total area within the CRL site covered by the FRI dataset and excludes aquatic habitat and minor gaps and slivers in GIS. For that reason, there is a discrepancy between this value and the total RSA area (if total of suitable + unsuitable habitat is added, the total is 3,853 ha).

RSA = Regional Study Area; SSA = Site Study Area; FRI = Forest Resource Inventory; GIS = geographic information system.

Acoustic monitoring for bats was carried out by CNL across the RSA during June to August 2017 to confirm activity of the three SARA-listed bat species within the stands undergoing assessment of roost tree habitat potential and within the area to be cleared for the NSDF Project (i.e., the SSA). This acoustic monitoring was undertaken using detectors set in a grid pattern within the SSA and randomly in the rest of the RSA (Appendix 5.6-4: Figures 1 and 2). Acoustic monitoring was also conducted at eight bat boxes installed as compensatory habitat to offset losses of maternity roost habitat associated with the NSDF Project. Acoustic monitoring in the SSA during the roost emergence window indicates that SARA-listed bats are roosting in suitable roost trees in the SSA, although estimated occupancy per suitable roost tree is lower than in most other stands in the RSA (Table 5.6.7-16; Appendix 5.6-4). A telemetry study was started in 2019 and will continue through 2020. This study has so far identified 15 different tree roosts on the CRL site. As such, although suitable roost trees are very abundant in stand 216, the available data indicate that many of them remain unoccupied. The intensity of roost use by SARA-listed bats estimated from acoustic detectors deployed in the SSA is consistent with individual roosting bats or small groups. The acoustic data yielded no evidence of large maternal roosting colonies of little brown myotis or northern myotis in the SSA. Little brown myotis were also confirmed to use the five of the eight bat boxes that were installed at the CRL site. A total of eight little brown myotis were observed in the bat boxes during weekly checks of the bat boxes from May 10 to July 18, 2018. In 2019, preliminary results demonstrate that half of the bat boxes are being used since the beginning of May and occupied by a few individuals. On July 16, 2019, one of the bat boxes was confirmed to be functioning as a maternity roost for little brown myotis, and four pregnant females, two juvenile males and two juvenile females were captured.

Overall, the data strongly support a conclusion that some roosts used by SARA-listed bats will be damaged or destroyed by the NSDF Project, but that potential roost tree occupancy is low (Appendix 5.6-4). Data collected during the roost emergence window in the SSA did not identify intensity of roost occupancy values consistent with maternal roosts used by large numbers of little brown myotis (Appendix 5.6-4). Spatial coverage for data collection within the SSA was high, but lack of detection of large maternal roosting colonies of little brown myotis

does not guarantee that none are present. A precautionary conclusion given the amount of available habitat would be that some larger maternal roosting colonies of little brown myotis could be present in the SSA. The data collected by CNL during the summer of 2017 and 2019 indicate that suitable maternity roost trees that are currently unoccupied are present in the RSA outside of the SSA in sufficient abundance to accommodate the three SARA-listed bat species that will be displaced as a result of the NSDF Project (Appendix 5.6-4).
The availability of additional maternity roosting habitat for displaced bats is high because maternity roosts are not likely a limiting factor within the RSA. Instead, bat populations overlapping with the RSA are limited by WNS and occur at densities that are likely to be well below the carrying capacity of the available habitat.

The 2019 telemetry study identified that large-tooth aspen are the preferred roost tree for the three bat species at risk located at the CRL site. Mitigation to protect and enhance preferred areas at the CRL site as part of a comprehensive Sustainable Forest Management Plan has the potential to offset impacts from the NSDF Project. Additionally, little brown myotis were found to occupy the bat boxes that were installed at the NSDF Project, including using these boxes as maternity roosts.

Table 5.6.7-16: Bat Species at Risk Stand Occupancy and Suitable Maternity Roost Data from the Site Study Area

Stand ID	Age Class	# SARA-Listed Species Calls/Detector Night (primary emergence window)	# All Species Calls/Detector Night (primary emergence window)	Density of Suitable Roost Trees (trees/ha)	Area of Stand within SSA (ha)	Calculated # Suitable Roost Trees (within SSA)
215	Mature	Predicted – 0.7	Predicted – 6.6	Predicted – 48.5	<0.1	1
216	Mature	0.6	3.1	262.6	22.7	5,952
218	Mature	0	0	50	0.9	44

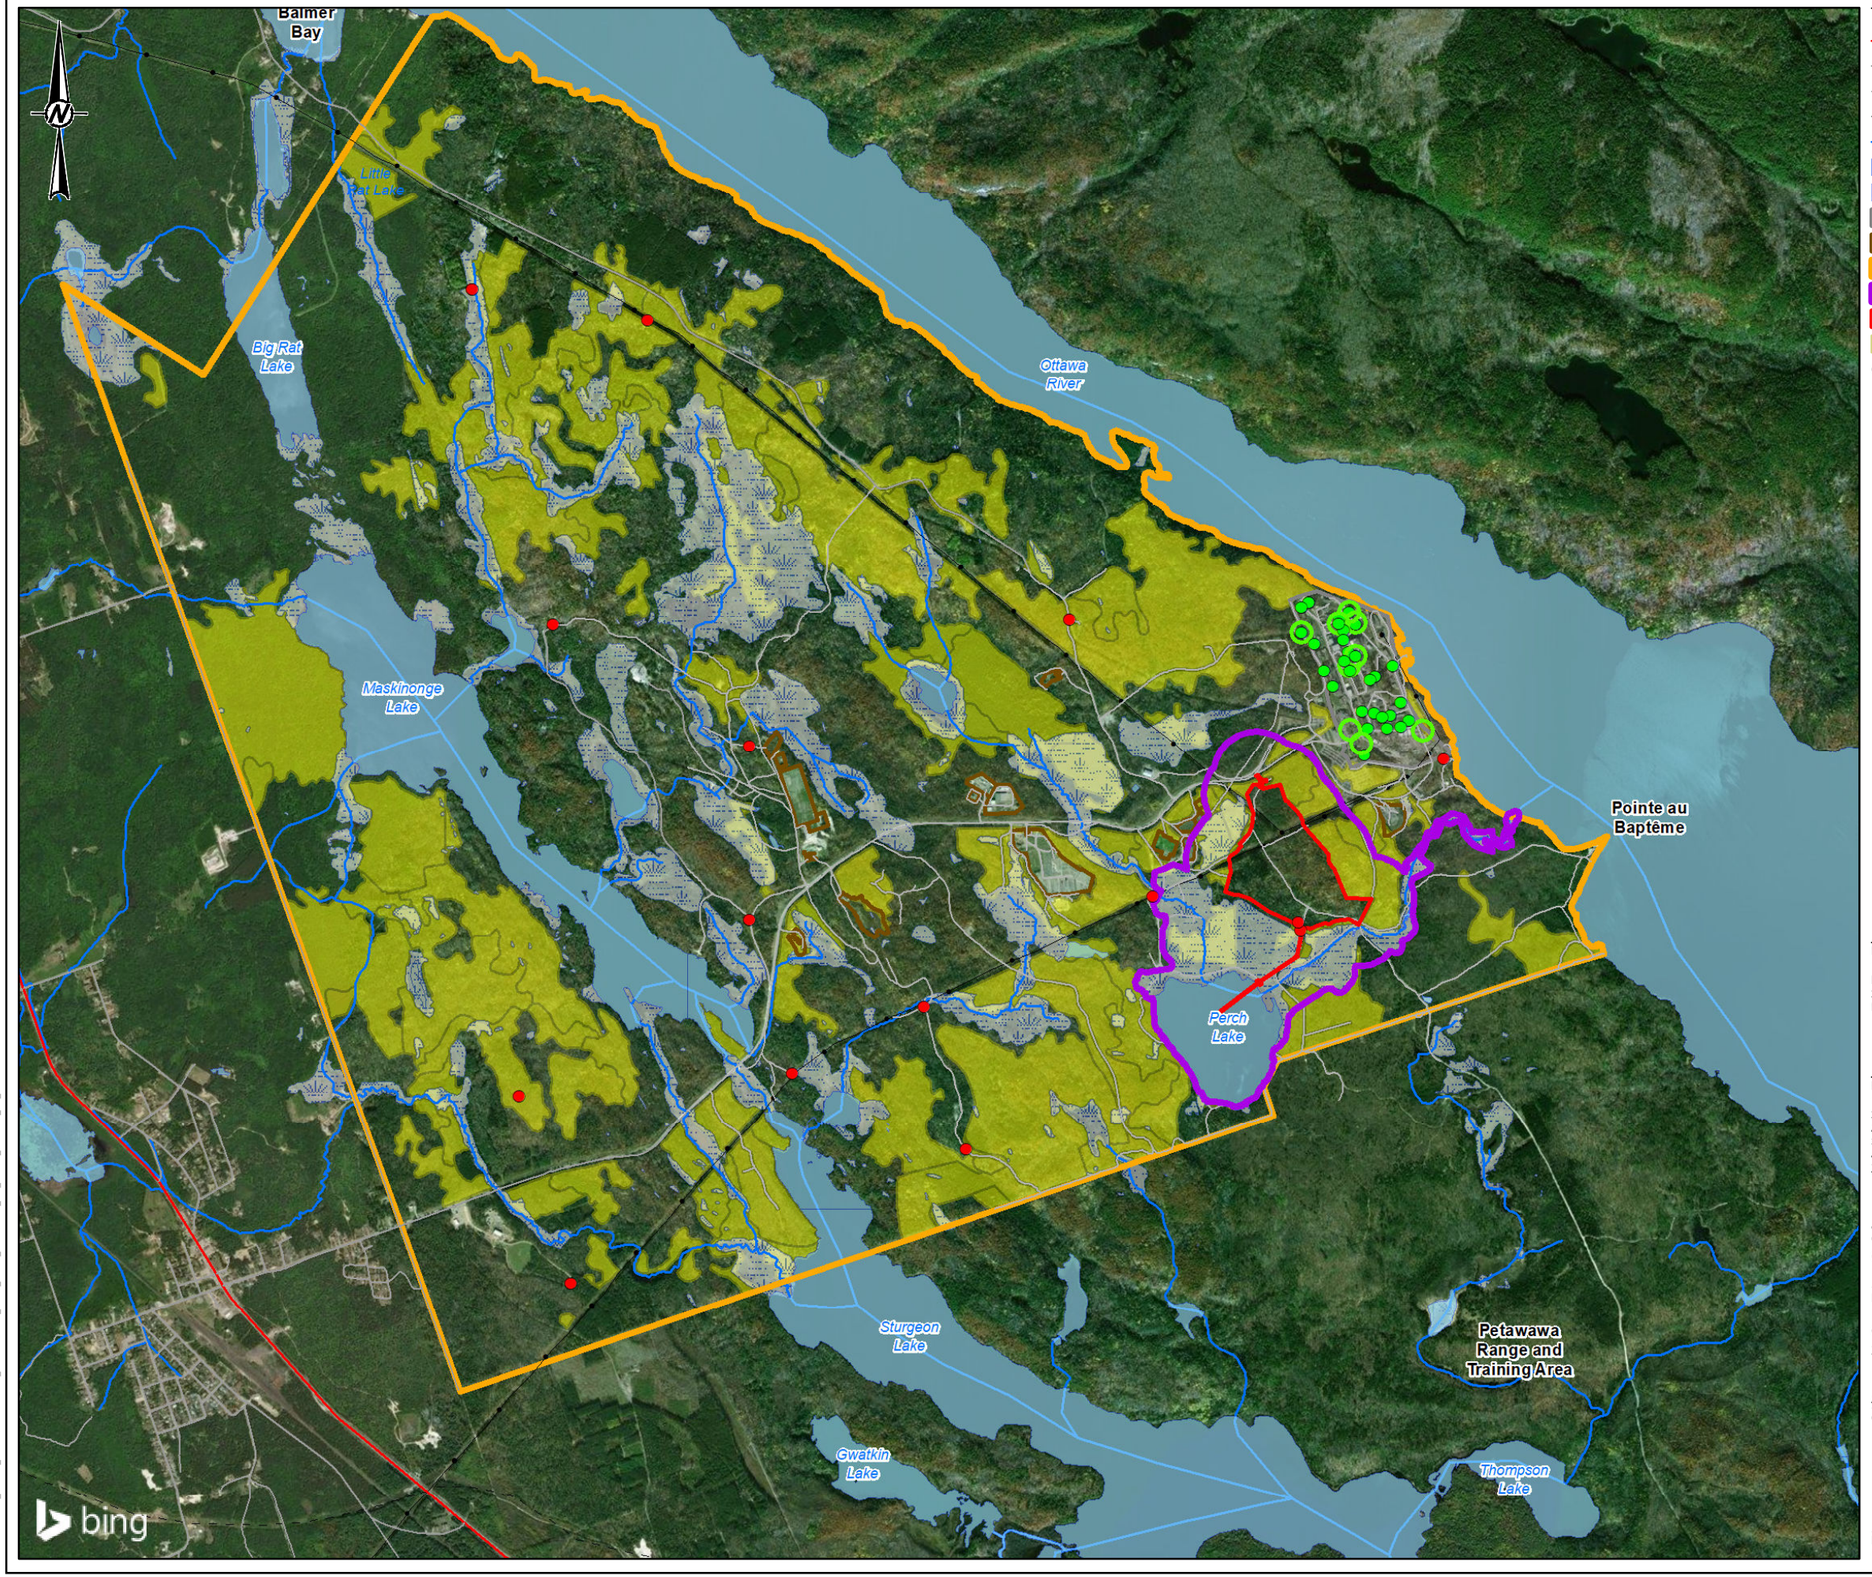
222	Immature	0.3	0.9	Predicted – 30.8	2.4	75
223	Immature	0.3	2.0	Predicted – 30.8	1.6	49
232	Unclassified	Not assessed (not treed)			<0.1	—
354	Mature	0.4	13.5	86.7	2.2	188
501	Unclassified	Not assessed (not treed)			3.8	—
				Totals	37.2	6,485

SARA = *Species at Risk Act*; SSA = Site Study Area.

Some roosting habitat adjacent to the SSA could be adversely affected (i.e., through sensory disturbance) while it is occupied. All three species of bat exhibit high site fidelity to their maternity roosting sites, and therefore, the loss of maternity roosting habitat, even while unoccupied, has the potential to displace some roosting bats that return to the area the summer after disturbance has occurred and their former roost tree(s) have been removed.

Sensory disturbance during the construction and operations phases is assumed to degrade the quality of potential roosting habitat for bats in the LSA; however, the degree to which habitat would be avoided by bats is unknown and the effect is considered to be probable to occur. The effect would be highest during construction, with some low-level disturbance occurring through the operations phase.

The federal recovery strategy for the three bat species considered here describes the threat of roost destruction in WNS-affected areas as having a high level of concern and causal certainty (meaning there is strong evidence to link the threat to stresses on population viability; Environment Canada 2015). Active and inactive maternity roosts are considered residences for bats under SARA.



Habitat Distribution

On the regional landscape, the SSA will result in the creation of a minor gap in otherwise relatively contiguous area of potential roosting habitat (Figure 5.6.7-13). The SSA contained linear gaps in the otherwise contiguous area of potential roosting habitat caused by East Mattawa Road and the two hydroelectric corridors in the Base Case. At the local scale, the NSDF Project will result in a relatively larger gap in the local distribution of potential maternity roost habitat in the Application Case, compared to the regional distribution (Figure 5.6.7-14).

The distribution of potential maternity roost habitat is also related to gaps and corridors between forested areas that are used for commuting and foraging. Little brown myotis, northern myotis and tri-colored bat commute between their forest roost habitat and forage areas and use watercourses (i.e., streams), forest edges, or travel above the forest canopy. They may use newly created edges of the SSA, which would improve their ability to disperse or search for food and water in the Application Case. There is uncertainty with this prediction because not all species use edge habitats in the same way and they have differences in their tolerance for gap size in forest canopy coverage.

Although a positive change in movement patterns at a local scale is possible during the operations phase, the overall net effect of the NSDF Project on habitat distribution is negative because there will be a loss of potential maternity roosting habitat for little brown myotis, northern myotis and tri-colored bat and a gap in potential maternity roosting habitat distribution, with the highest relative effects at the local scale. At a broader, national level, the NSDF Project is not expected to reduce the extent of occurrence of these three species.

Survival and Reproduction

Little brown myotis, northern myotis and tri-colored bat are already impaired at a population level in the Base Case due to the devastating effects of WNS at hibernacula. There will be no direct mortality of bats as a result of the NSDF Project, as the largest potential cause of mortality, removal of trees containing maternity roosts with juveniles that are not yet mobile, has been avoided through clearing outside of the period when roosts are occupied. Blasting activities are also not expected to result in direct bat mortality to bats that may be roosting under rocks as blasting will occur outside of the roosting period.

Sensory effects of noise and vibration from industrial activities (i.e., the construction and operations phases of the NSDF Project) has the potential to affect bat survival by altering their ability to effectively carry out echolocation (Mackay and Barclay 1989; Schaub et al. 2008; Siemers and Schaub 2011). Available research has not resulted in definition of measurable thresholds that may negatively affect bat activity (e.g., decibel levels). Noise has been found to negatively affect foraging by passive-listening bat species, especially when noise frequencies occur at the same frequency as prey noises (Jones 2008, Schaub et al. 2008, Siemers and Schaub 2011). Consequently, passive-listening bats have been found to avoid areas with high noise levels (e.g., adjacent to highways) (Schaub et al. 2008). However, echolocating species, such as little brown myotis, have been found to adapt the amplitude and duration of their calls to the ambient noise level of an environment (Luo and Wiegrebe 2016). Because bats are highly mobile, they are able to avoid areas with elevated noise. The creation of noise therefore likely represents more of an effect on habitat availability, if the noise causes bats to avoid previously occupied maternity roost habitat that is in or around areas with high noise levels (see Habitat Availability discussion above). Habitat availability is likely not limiting for bat species that already occur below carrying capacity because of WNS.

5.6.7.7.2 Prediction Confidence

CNL has initiated a research project in collaboration with Trent University to capture and track bats back to roost trees. This work is on-going and will provide valuable information on roost tree preference characteristics for the bat species at risk present at CRL and likely being displaced by the NSDF Project. Prior to this study, the surveys conducted by CNL during the summer of 2017 provided field assessment and quantification of the abundance and distribution of suitable maternity roost trees within the area to be cleared (i.e., within the SSA). The acoustic and roost tree data collected by CNL during the summer of 2017 indicate there are suitable and not fully occupied maternity roost trees in the RSA outside of the SSA. It is likely these suitable and not fully occupied maternity roost trees are in sufficient abundance to accommodate the three SARA-listed bat species that will be displaced as a result of the NSDF Project (Appendix 5.6-4). There is a high level of certainty that some roosts used by SARA-listed bats will be damaged or destroyed by the NSDF Project, but that potential roost tree occupancy is low. Based on acoustic monitoring in 2017 conducted in the SSA and elsewhere in the RSA, there is a moderate level of certainty that large maternity roosting colonies of little brown myotis and northern myotis are not present within the SSA. Northern myotis are not known to have large maternity roost colonies (i.e., in the 100s of individuals), and based on activity patterns from the acoustic data, it is unlikely, albeit possible, that there are large maternity roost colonies for little brown myotis within the SSA. High certainty that maternity roosting colonies are not present can only be achieved through visual emergence counts at individual roost trees.

There is a moderate level of certainty that noise from vehicles, construction equipment and the NSDF Project will not negatively affect roosting or foraging bats through sensory disturbance, as noise frequencies generated by vehicles, construction equipment and industrial facilities are generally below the hearing range of bats.

The predictions of the availability and distribution of maternity roosting habitat within the RSA has been updated with some field survey effort in 2017; however, it is still largely based on desktop vegetation community data, which itself is primarily based on a relatively old spatial dataset. There are attendant levels of error in using spatial data that have not undergone a high degree of ground-truthing. The ground-truthing of the number of suitable roost trees at a high degree of survey intensity within the SSA has improved the prediction of the availability and distribution of maternity roosting habitat within the SSA. However, the survey intensity in other areas of the RSA was not as high, and predictions on the availability and distribution of maternity roosting habitat has a higher degree of uncertainty as a result of having to use greater levels of predictions to fill in gaps in spatial coverage.

5.6.7.7.3 Residual Effects Classification

A summary of the classification of incremental adverse residual effects of the NSDF Project on bats in the Application Case is provided for each indicator in Table 5.6.7-17. Residual effects after the implementation of effective mitigation are described, and are summarized according to direction, magnitude, geographic extent, duration/reversibility, frequency/timing and likelihood of the effect occurring following the methods described in Section 5.6.6.3 and the definitions provided in Table 5.6.6-1.

Table 5.6.7-17: Classification of Residual Effects on Bats in the Application Case

Indicator	Characteristic	Rating/Effect Size
Habitat Availability	Direction	Negative
	Magnitude	Direct loss of 28 ha of potential maternity roosting habitat (1% of RSA Base Case or 32.6% of LSA Base Case); potential avoidance of adjacent maternity roosting habitat due to sensory disturbance in the LSA
	Geographic Extent	SSA (direct habitat loss); Local (sensory disturbance)
	Duration/Reversibility	Permanent/Irreversible (direct habitat loss); Medium-term (sensory disturbance)
	Frequency/Timing	Continuous
	Likelihood	Probable (direct habitat loss) Possible (avoidance of maternity roosting habitat)
Habitat Distribution	Direction	Negative
	Magnitude	Creation of a gap in potential maternity roost habitat but overall a negligible change in movement corridors between maternity roosting habitat patches due to high mobility of species and relatively small gap created in area with high forest cover
	Geographic Extent	Local
	Duration/Reversibility	Permanent/Irreversible
	Frequency/Timing	Continuous
	Likelihood	Possible
Survival/ Reproduction	Direction	Neutral
	Magnitude	n/a
	Geographic Extent	n/a
	Duration/Reversibility	n/a
	Frequency/Timing	n/a
	Likelihood	Possible

Note: If a net effect was identified as positive or neutral, no additional effects characteristics, other than probability of occurrence were summarized.

LSA = Local Study Area; RSA = Regional Study Area; SSA = Site Study Area; n/a = not applicable.

5.6.7.7.4 Determination of Significance

Populations of little brown myotis, northern myotis and tri-colored bats that overlap the RSA are highly sensitive to changes in survival and reproduction because WNS has resulted in dramatic declines of these species across the eastern portions of their Canadian range, which includes the RSA. Because of their rapidly declining populations, these species are more vulnerable to additional threats, including changes in habitat availability, distribution, or other factors affecting the survival and reproduction of the remaining individuals (ECCC 2018c). Therefore, the existing level of pressure on these bat species in the Base Case has likely already exceeded their resilience and adaptability limits.

The grouping behaviour shown by bats in maternity roosts also makes them more sensitive to the loss of certain habitat features because the removal of relatively small numbers of habitat features, such as snags, can have a disproportionately large effect on local populations, if large numbers of bats previously congregated in snags that will be permanently removed. However, because WNS is such a strong limiting factor that overrides other potential causes of decline, maternity roosting habitat availability is not likely a limiting factor, at least not in places where such habitat is abundant, such as within the RSA. In the RSA, relatively undisturbed, mature forest stands are available and interspersed with numerous small lakes and wetland areas, which represent high quality and widely available foraging habitat.

All three species are inherently resilient to changes in their habitat based on their high degree of mobility, and one of the three species, little brown myotis, is well adapted to human disturbance, commonly using human structures for maternity roosting habitat and confirmed using the bat boxes at the CRL site, including as maternity roosts. Northern myotis have been recorded to roost in bat boxes (Whitaker et al. 2006) and tri-colored bats will possibly roost in anthropogenic structures, but not as commonly as little brown myotis.

Rapid declines in abundance due to WNS may have already exceeded the resilience and adaptability limits of bats in the Base Case. Therefore, in the Base Case, little brown myotis, northern myotis and tri-colored bat populations that overlap with the RSA are considered unlikely to be self-sustaining or ecologically effective. Consequently, the cumulative effects of existing disturbance and especially the introduced WNS are considered significant in the Base Case.

In the Application Case, the NSDF Project will remove a small amount of roosting habitat. Importantly, because vegetation clearing and blasting will be undertaken outside of the maternity roosting season, no mortality of roosting bats is expected as a result of the NSDF Project and effects of the NSDF Project to survival and reproduction are considered neutral. The SSA will permanently remove 28 ha of potential maternity roosting habitat. This represents approximately 30% of available maternity roosting habitat in the LSA and 1% in the RSA. Additional areas of roosting habitat in the LSA that are immediately adjacent to the SSA may also be avoided due to sensory disturbance during the construction and operations phases of the NSDF Project. The NSDF Project may also result in changes in local movement patterns by widening existing gaps in the forest canopy created by East Mattawa Road and the two hydroelectric corridors, and installation of a six-foot high perimeter fence. These local-scale changes are not expected to alter the extent of populations that overlap with the RSA because bats are highly mobile and capable of long commute distances, well beyond the boundaries of the RSA. The remaining availability of potential maternity roosting habitat in the Application Case is not likely a limiting factor in the RSA, and CNL has committed to mitigation such as bat boxes and a comprehensive Sustainable Forest Management Plan. Therefore, the contribution of the NSDF Project to the existing significant adverse cumulative effect to bats is predicted to be negligible (i.e., no detectable changes to bat populations), and the NSDF Project does not contribute to the spread of WNS, which is the primary driver of the existing significant adverse cumulative effect.

On-going fire suppression in the RSA may increase bat habitat availability as forests progress towards old growth age and habitat attributes preferred by these species (e.g., snags, large-diameter cavity trees) become increasingly available. Climate change is also likely to affect bat populations for the foreseeable future, although the direction and magnitude of changes are uncertain because predictions are based on simulations that can be highly variable and many scenarios are possible. Severity of climate change as a threat to the sustainability of species at risk bat populations in Canada is identified as unknown (ECCC 2018c). Warmer and drier conditions in Ontario due to climate change may alter the onset of spring and summer and the timing of insect hatches (Nituch and Bowman 2013). Therefore, climate change may affect synchronization between bat breeding and peak food abundance by creating a temporal mismatch between reproduction and optimal foraging conditions for prey (ECCC 2018c). Overall, the weight of evidence from the analysis of primary pathways predicts that changes to bat habitat availability, habitat distribution, and survival and reproduction in the RSA as a result of the NSDF Project are expected to result in no detectible adverse effect to bat population in the RSA. In addition, CNL had implemented and committed to mitigation that may offset the potential adverse effects of the NSDF Project. Therefore, the contribution of the NSDF Project is not significant, nor is it expected to contribute to potential future adverse effects associated with climate change.

5.6.7.8 Blanding's Turtle

5.6.7.8.1 Residual Effects Analysis

Habitat Availability

The NSDF Project is estimated to remove 26 ha of critical habitat for Blanding's turtle, which represents a loss of 14.5% of the critical habitat in the LSA and 0.9% of the critical habitat in the RSA (Table 5.6.7-18). The direct removal of 26 ha is mainly composed of upland habitat. The transfer line to Perch Lake was included in the NSDF Project footprint and, as such, some wetland habitat was conservatively assumed to be removed by the transfer line. However, the transfer line will be installed underground using high-pressure directional drilling and so will not require surface disturbance (i.e., avoids the destruction of critical habitat). A small trench (2 m depth) will be excavated in the shoreline of Perch Lake to install the discharge transfer line, and a steel pile foundation will be used to suspend the line over the soft sediments in the open water section of the lake.

The destruction of critical habitat for the Blanding's turtle will require a permit under Section 73 of SARA. ECCC issues permits for activities affecting species listed on Schedule 1 of SARA on a case-by-case basis. CNL is in on-going engagement with ECCC regarding this species at risk and the management of the CRL site and consequent protection and conservation of the population and its habitats. Critical habitat will be assessed annually to ensure no significant loss at CRL and to determine compensation measures initiated at CRL or elsewhere. As such, the residual effect from the NSDF Project on Blanding's turtle habitat availability is predicted to be neutral.

Four Priority 2 culverts will be replaced within two years after the approval of the NSDF Project. Artificial nest mounds will be constructed on both sides of these culverts following guidelines developed by the Northeast Blanding's Turtle Working Group (NBTWG, no date). These artificial nesting mounds will be monitored for use by turtles during the nesting period using methods adapted from provincial protocols (MNR 2013b). Specifically, nesting surveys will be conducted at least once per week during the nesting period (May 15 to June 30); additional surveys will be completed after periods of rain to capture potential increases in nesting behaviour associated with even light rainfall (MNR 2013b; Golder 2019a). Nest mound maintenance (e.g., vegetation removal) will also be completed during nest mound inspections, if females are not present. More details on the locations of nesting mounds are presented under Survival and Reproduction.

Table 5.6.7-18: Changes to Blanding's Turtle Critical Habitat and Potential Habitat Availability in the Application Case

Habitat Suitability	Regional Study Area				Local Study Area			
	Base Case (ha)	Application Case (ha)		Base Case (ha)	Application Case (ha)		Base Case (ha)	Application Case (ha)
Critical Habitat	2,788	2,762	-26	-0.9	179	153	-26	-14.5
Potential Critical Habitat	571	571	0	0	0	0	0	0
Unsuitable Habitat	493	519	26	5.3	31	57	26	83.9

Sensory disturbance (e.g., noise, light) during the construction, operations and closure phases could indirectly reduce Blanding's turtle habitat availability in the LSA if Blanding's turtles avoid areas adjacent to the SSA. The population of turtles using the RSA has likely adapted somewhat to the current level of activity in the RSA. Additionally, records of this species nesting in active sand and gravel pits, as well as along roadsides are not uncommon (ECCC 2018b), which suggests Blanding's turtles can tolerate some level of anthropogenic sensory disturbances. The incremental increase in noise and light caused by the NSDF Project is not predicted to have a measurable effect on the behaviour of Blanding's turtles in adjacent habitats (such as Perch Lake). Blasting activities in the SSA are expected to meet the DFO guidelines for protection of fish and fish habitat from vibrations, chemicals and sedimentation, and it is anticipated that this protection will also extend to turtles and turtle habitat. Additionally, Blanding's turtles will be excluded from access to the SSA, so it is not anticipated that vibrations from activities within the SSA will have an effect on Blanding's turtles.

The measures included in the Blanding's Turtles Road Mortality Mitigation Plan serve to compensate for the removal of 26 ha of critical turtle habitat due to NSDF Project construction by: increasing connectivity of habitat on either side of Plant Road using culverts, promoting turtle abundance through protection of nesting mounds and installation of exclusionary fencing. These compensatory measures are designed to meet the species population and distribution objectives outlined in the Recovery Strategy for the Blanding's Turtles (ECCC 2018b).

A neutral net change to critical habitat availability for Blanding's turtles as a result of the NSDF Project is probable because CNL has committed to assessing the amount of critical habitat on the CRL site on an annual basis to ensure no significant loss at CRL. Effects from changes to habitat availability will occur at the regional to beyond regional scale depending on where compensation measures are initiated. Effects from direct habitat loss will be infrequent (i.e., occur once during NSDF Project construction) and reversible in the long-term with the implementation of compensation measures and the creation of nesting habitat at four Priority 2 culverts. Effects from sensory disturbance are not expected to be measurable, but any minor effects that might occur would be reversible over the long-term.

Habitat Distribution

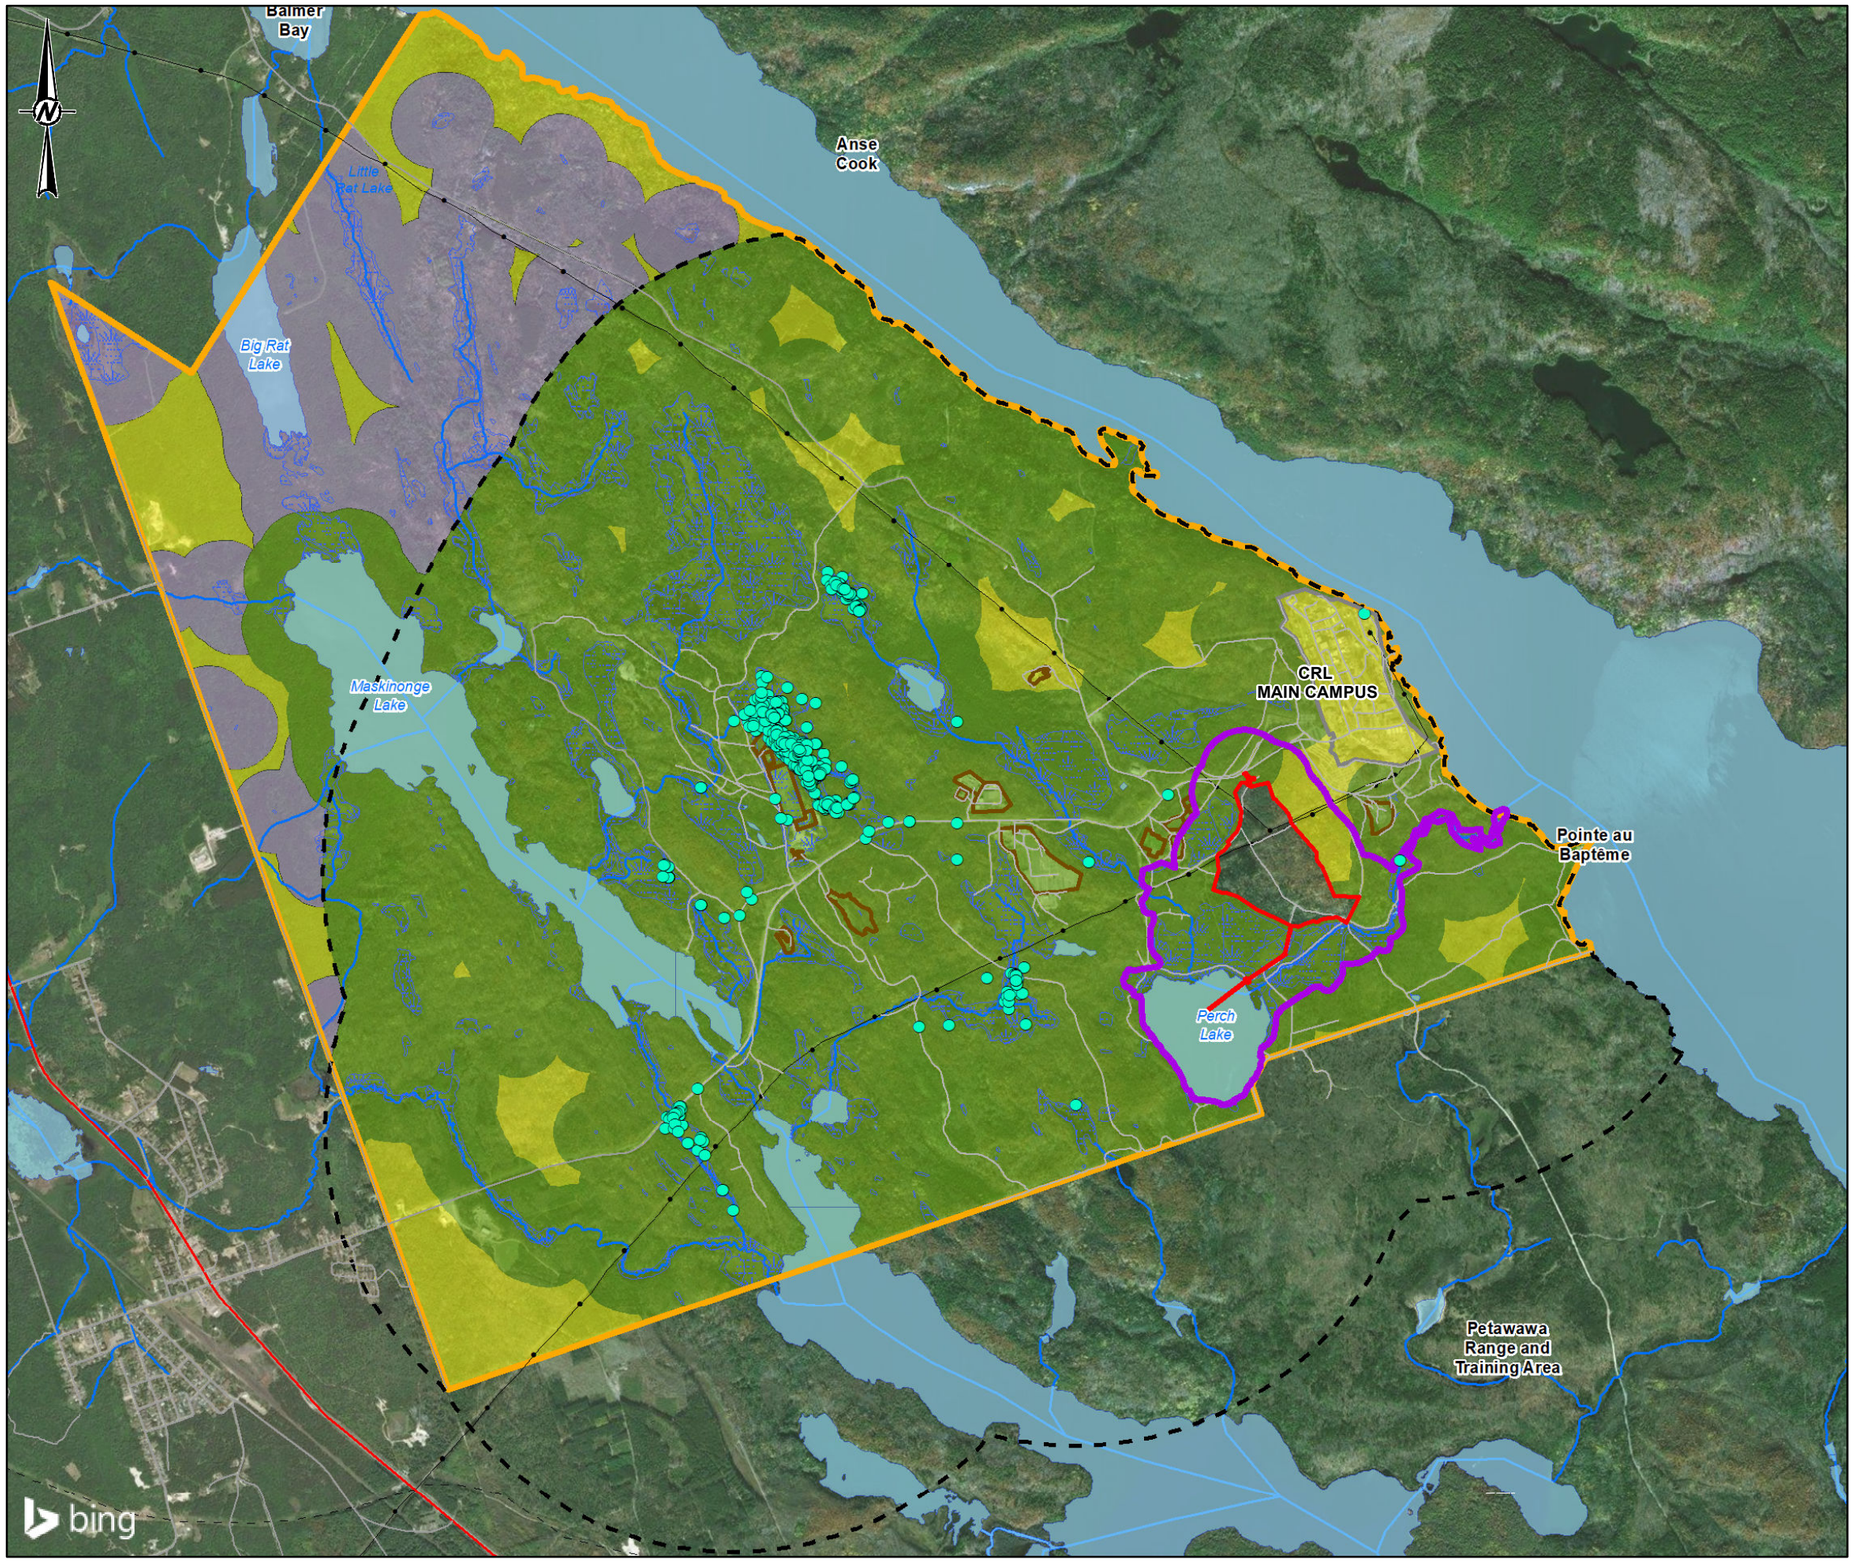
The development of the NSDF Project will have a minor effects on critical habitat distribution and connectivity for Blanding's turtle in the RSA. Critical habitat and potential critical habitat remains abundant and well connected in the RSA in the Application Case (Figure 5.6.7-15). Mitigation will be implemented to avoid and minimize the loss and fragmentation of critical habitat:

- The NSDF Project will use many existing roads instead of creating new ones, and road upgrades will occur at the local scale.
- The transfer line to Perch Lake will be installed underground using high-pressure directional drilling.
- Four Priority 2 culverts will be replaced within two years after approval of the NSDF Project. Replaced culverts will be enhanced by having nesting mounds created on both sides of the culvert, as well as by planting native vegetation around the culvert entrances, while maintaining a clear line of site through the culvert (Golder 2019a). These changes are anticipated to increase habitat connectivity for turtles at Application Case. Additionally, Priority 2 culverts are currently inspected weekly during the turtle active season (May to October) and after periods of heavy rainfall (≥7 mm/hr) (Golder 2019a). These inspections will continue throughout the life of the CRL site. During the inspections, barriers that can impede the passage of turtles through the culverts are removed or modified (Golder 2019a). More details on Priority 2 culverts are presented in the Blanding's turtle Survival and Reproduction section, below.

The main Blanding's turtle migration corridors will remain intact within the LSA and RSA. In particular, the wetland complexes which are likely the principal movement routes will remain in their existing condition and the NSDF Project will not alter their connectivity. The replacement of four Priority 2 culverts may improve habitat connectivity relative to baseline conditions. The creation of artificial nesting mounds near the four Priority 2 culverts will increase the availability of nesting habitat and mitigate potential barrier effects from erecting exclusion fencing (i.e., it is uncertain if Blanding's turtles use existing culverts to cross roads).

The NSDF Project is surrounded by wetlands that are known to provide habitat for Blanding's turtles (Figure 5.6.7-16) and there are some areas within the SSA and LSA that have the potential to be nesting habitat for Blanding's turtle. The development of the NSDF Project will alter Blanding's turtle movement patterns and access to potential nesting habitat in the SSA because the SSA will be surrounded by a fence that will exclude wildlife, including Blanding's turtles, from accessing the site.

This species shows site fidelity to wetlands that are used as overwintering habitat and to areas that are used for nesting year after year. Therefore, the movements of this species from overwintering areas to nesting areas could be disrupted by the development of the NSDF Project. However, despite a two-year telemetry study and considerable search effort in and around the SSA (Section 5.6.4.9.2), no evidence of Blanding's turtle occurrence or movement through the SSA has been recorded. The local change in connectivity may therefore affect only a small portion of the regional population, namely individuals that overwinter around Perch Lake and that travel northwards through the SSA during the active period (May 1 to September 30). These individuals would have to travel around the outside of the fence if they need to move around the SSA to reach locations they require to carry out their life history requirements such as foraging, thermoregulation and nesting. If Blanding's turtles use the SSA as a movement corridor between habitats, the NSDF Project will increase travel distances.



Effects on Blanding's turtles from changes to habitat distribution are probable because the SSA could alter the movement of turtles in the LSA; however, it is uncertain if the SSA is used for movement and nesting functions at baseline. Effects will be continuous and permanent because the development of the NSDF Project will result in the permanent reconfiguration of habitat on the landscape.

Survival and Reproduction

Site clearing is not expected to cause Blanding's turtle mortality because it will be performed in the winter when individuals are hibernating and wetlands (i.e., potential hibernation habitat) will be affected only by the addition of the transfer line to Perch Lake. Additionally, to avoid negative interactions with nesting turtles, road grading and levelling activities will not be completed during the turtle terrestrial season (May 15 to September 30). In addition, in-water work will not occur between October 1 and April 15 to avoid adverse effects to hibernating turtles.

Temporary exclusion fencing will be installed around the NSDF EMR footprint during construction of the NSDF Project. This temporary exclusion fencing will be replaced by permanent fencing by the end of construction of the NSDF Project. This permanent reptile exclusion fencing will be installed around the perimeter of the site and will remain in place for the life of the NSDF Project to avoid having Blanding's turtles access the active site and become at risk of injury or mortality. Exclusion fencing will be installed according to provincial guidelines for the target species, including Blanding's turtle (MNR 2013c). Inspection of temporary and permanent fencing will be undertaken annually. Therefore, effects on Blanding's turtle survival from NSDF Project activities within the fenced perimeter are neutral.

As the SSA supports Blanding's turtle critical habitat, specifically upland habitat adjacent to wetlands that has the potential to be nesting habitat, the permanent loss of critical habitat due to the NSDF Project has the potential to result in a change in reproductive success until the females using this habitat find new nesting areas. Effects on Blanding's turtle reproduction from the loss of critical habitat are possible at the local scale. Effects from habitat loss are anticipated to be continuous and permanent. To help limit movement requirements for females to reach nesting areas and to compensate for potential losses caused by the NSDF Project, nesting mounds will be created on both sides of the Priority 2 culverts (culverts J2, K1, C9, and V22) after the culverts have been replaced (Figure 5.6.7-17). These nest mounds will be created after the approval of the NSDF Project. To improve the chance of successful nesting wire-screen cages will be deployed over areas were eggs have been laid. Up to a total of 30 cages will be deployed in the RSA. These nest cages will be designed according to guidelines adapted from Gillingwater (2008) and Ratnaswamy et al. (1997) (Golder 2019a). Nest cages will be deployed during the nesting season (May 15 to June 30) and weekly inspections of the cages will be completed from the end of the nesting period through to the end of the hatchling emergence period (July 1 to October 15). Cages will be retrieved prior to May 15 of the following year. Implementation of this mitigation has the potential to result in a net benefit to Blanding's turtle nesting habitat and reproductive success because of the NSDF Project.

This page intentionally left blank

Road mortality is one of the main threats to Blanding's turtles and is thought to lead to population declines for this species. CNL has committed to reducing road mortality through implementation of the *Blanding's Turtle Road Mortality Mitigation Plan*. Application of the plan is predicted to greatly reduce potential for road mortality in the Base Case. However, increased traffic as a result of the NSDF Project has the potential to increase the road mortality risk for Blanding's turtles in some places around the SSA. East Mattawa Road will be upgraded to accommodate the traffic going to and from the ECM. Traffic to the SSA during construction will predominantly be from Plant Road to East Mattawa Road and during the operations phase will predominantly be from ER-3 (Emergency Road) to East Mattawa Road.

Four Priority 2 culverts (culverts J2, K1, C9, and V22) will be replaced within two years after the NSDF Project has been approved (Figure 5.6.7-17) and will mitigate effects from the NSDF Project. After replacement, these culverts will have appropriate permanent fencing installed for 200 m on either side of the culvert to guide turtles through the tunnel. Following approval of the NSDF Project, additional permanent exclusion fencing will be installed in reptile hotspots along Plant Road (Figure 5.6.7-17). Inspection of permanent fencing and culverts will be undertaken weekly during the active turtle season (April to October) and after heavy rainfall events (≥7 mm/hr) (Golder 2019a).

Once Priority 2 culverts are replaced, they will be enhanced by planting native vegetation around the culvert entrances, while maintaining a clear line of site through the culvert (Golder 2019a). To monitor the use of culverts by turtles, game cameras will be installed at all new and replaced Priority 1 and Priority 2 culverts; camera installation will occur during construction of the NSDF Project. These cameras will be programmed to take at least three photos at one-minute intervals throughout the nesting period.

To reduce potential road mortality of turtles during the construction of the NSDF Project, a "sentinel" will drive in front of big trucks that travel along Plant Road, ER-3 (Emergency Road), and East Mattawa Road. Additional monitoring for turtles will also be completed along Plant Road during peak traffic hours.

To increase employee, contractor, and visitor awareness about the presence of turtles on the CRL site, the following mitigations will be implemented prior to the construction of the NSDF Project:

- An additional 12 permanent turtle crossing signs will be installed along Plant Road and secondary roads (Figure 5.6.7-17); and
- The presence of turtles on the NSDF site will be communicated to contractors and visitors at the outer gate or B700 lobby.

Road mortality surveys will continue to be completed weekly along Plant Road and along hotspots on secondary roads during the active turtle season (April to October) (Figure 5.6.7-17; Golder 2019a). As part of the adaptive management component of the *Blanding's Turtle Road Mortality Mitigation Plan*, results from the road mortality surveys will be used to consider the implementation of additional mitigation. For example, if there are road mortality hotspots, permanent exclusion fencing, crossing structures, and/or reduced speed limits during the nesting period may be implemented at these locations.

Adaptive management is an important part of the *Blanding's Turtle Road Mortality Mitigation Plan*. Depending on results of monitoring, CNL is committed to taking additional actions, as required, to achieve a neutral or positive contribution to Blanding's turtles. Potential additional actions would be developed as needed, but could include activities such as incubating Blanding's turtle eggs in facilities that would be located on the CRL Site, which would result in improved recruitment into the population. Eggs that are incubated would be those rescued from the CRL

site and more broadly from Renfrew County and hatchlings would be released in the RSA or other areas where eggs were collected to support the local Blanding's turtle population.

If the mitigations listed above are effective, then the risk of road mortality on Blanding's turtle from the increased traffic associated with the NSDF Project is not anticipated to affect the local population. Effects on Blanding's turtle survival and reproduction from road mortality are possible at the local scale. Effects from road mortality due to the NSDF Project are anticipated to be infrequent but irreversible (permanent). Mitigation implemented for the NSDF Project has the potential to reduce mortality of Blanding's turtles. This reduction in mortality would be in addition to the reductions in turtle mortality predicted for Base Case after all mitigation is implemented (Section 5.6.4.9.3). Implementation of adaptive management by CNL, including potential for additional measures to improve survival and reproduction of Blanding's turtles, such as egg incubation, provides confidence that the NSDF Project will not cause a net reduction is Blanding's turtle survival and reproduction.

5.6.7.8.2 Prediction Confidence

The residual effects assessment for Blanding's turtle is based on an adequate knowledge of the species' life history characteristics and some understanding of the sensitivities of populations of long-lived organisms to anthropogenic disturbance.

CNL conducted surveys for Blanding's turtles from 2009 to 2018, which resulted in observations of individual Blanding's turtles and confirmation of some hibernation habitat in the RSA and LSA. There is high confidence that a Blanding's turtle population is present in the RSA and a high likelihood that they use the LSA. However, their use of the SSA has not been confirmed and the location of suitable nesting habitat in the RSA, LSA, and SSA has not been confirmed. The use of the habitat within the SSA by Blanding's turtles is not known. This assessment used a precautionary approach to manage uncertainty and assumed that nesting habitat was present in the SSA. This approach may have resulted in an overestimation of the potential effects of the NSDF Project on Blanding's turtles. As part of the SARA permitting process for the removal of critical habitat, ECCC will require the identification and mapping of Blanding's turtle habitats within the SSA to characterize the habitat loss and determine site-specific actions to be taken to compensate for the habitat loss due to the NSDF Project.

The effectiveness of the *Blanding's Turtle Road Mortality Mitigation Plan* remains uncertain as it has only recently been implemented and monitoring has just been initiated. However, other road mitigation plans for this species have been effective in keeping turtles off roads and reducing roadkill. Therefore, this mitigation has a moderate level of certainty. Adaptive management committed to by CNL provides additional confidence that mitigation implemented for the NSDF Project will result in no net loss to Blanding's turtles as a result of the NSDF Project relative to the Base Case.

There is a high level of uncertainty associated with the long-term conservation prospects for the Great Lakes / St. Lawrence population of Blanding's turtle. Evidence suggests that populations are declining across the species' range in Canada. If the declining population trend is not reversed or accelerates over the next decade, then Blanding's turtle may be up-listed from Threatened to Endangered, as recommended by COSEWIC (2016).

5.6.7.8.3 Residual Effects Classification

A summary of the classification of incremental adverse residual effects of the NSDF Project on Blanding's turtle in the Application Case is provided for each indicator in Table 5.6.7-19. Residual effects after the implementation of effective mitigation are described, and are summarized according to direction, magnitude, geographic extent, duration/reversibility, frequency/timing and likelihood of the effect occurring following the methods described in Section 5.6.6.3 and the definitions provided in Table 5.6.6-1.

Table 5.6.7-19: Description of Residual Effects on Blanding's Turtle in the Application Case

Indicator	Characteristic	Rating/Effect Size
Habitat Availability	Direction	Neutral
	Magnitude	No loss of critical habitat
	Geographic Extent	Regional to beyond regional[(a)]
	Duration/Reversibility	Long-term
	Frequency/Timing	Infrequent / Once during construction
	Likelihood	Probable
Habitat Distribution	Direction	Negative
	Magnitude	Potential change in movement corridors between habitat patches due to development of the NSDF Project
	Geographic Extent	Local
	Duration/Reversibility	Permanent/Irreversible
	Frequency/Timing	Continuous
	Likelihood	Probable
Survival and Reproduction	Direction	Neutral
	Magnitude	No reduction in reproductive success
	Geographic Extent	Regional to beyond regional[(a)]
	Duration/Reversibility	Long-term
	Frequency/Timing	Continuous
	Likelihood	Probable

RSA = Regional Study Area; LSA = Local Study Area; SSA = Site Study Area.

[(a)] Effects will be beyond regional if compensation measures are implemented outside of the RSA

5.6.7.8.4 Determination of Significance

The population of Blanding's turtles that overlaps with the RSA is considered highly sensitive to changes in habitat availability, distribution, and survival and reproduction. Two of the primary threats (noted as the highest levels of concern) to this species are road and networks and exotic and invasive species (European common reed [*Phragmites australis* ssp. *australis*]) (ECCC 2018b). Isolation of local populations resulting from land conversion and habitat loss is also of special concern for this species (ECCC 2018b).

Blanding's turtles display fidelity to hibernation and nesting habitat, and therefore its elimination can result in long distance travel in search of new habitat and the use of lower quality habitat. A total of 179 ha and 2,788 ha of critical habitat for Blanding's turtle is estimated to be present in the LSA and RSA, respectively, in the Base Case. An additional 571 ha of potential critical habitat is estimated to be present in the RSA. Hibernation habitat has been confirmed in several wetlands/waterbodies in the RSA and the LSA. Likely nesting habitat occurs throughout

the LSA and RSA in numerous sandy outcrops that CNL has noted. In particular, there is some potential within the hydroelectric corridors that run through the SSA, the sandy outcrop adjacent to Perch Lake and the sand dunes at Pointe au Baptême. However, nesting locations have not yet been confirmed. Movement corridors likely exist through wetlands such as the Perch Creek riparian corridor and the north–south trending wetlands across Plant Road, though movement across Plant Road remains unconfirmed. Roadkill is a particular concern to the survival and reproduction of this species because it has low rates of recruitment and population growth. Two individuals from this population have been killed on the roads within the RSA in the last six years.

The Ottawa Valley Forest, which encompasses the RSA, is one of the last remaining “strong holds” for Blanding’s turtle in Ontario and Canada (Van Dyke 2011). Available data suggest that Blanding’s turtles survive and reproduce successfully in the RSA and that the RSA likely is important for the conservation of this species. Because the RSA may act as a refuge for Blanding’s turtles, road mortality on the CRL site is a primary concern for the sustainability of the regional Blanding’s turtle population. That is, there is concern that the RSA could function as a population sink because turtles are attracted to the abundant habitat on the CRL site but may suffer high rates of road mortality. For this reason, CNL started implementing a detailed *Blanding’s Turtle Road Mortality Mitigation Plan* (Golder 2019a) in 2019, and will continue to implement the plan moving forward. The *Blanding’s Turtle Road Mortality Mitigation Plan* is designed to reduce or eliminate turtle road mortality at CRL and increase connectivity among habitats.

With the implementation of the comprehensive mitigation outlined in the *Blanding’s Turtle Road Mortality Mitigation Plan*, along with monitoring and adaptive management, CNL’s activities in the RSA are predicted to have a net neutral or positive effect on the local Blanding’s turtle population during the Base Case. That is, the mitigation that is or will be implemented on the CRL site is considered sufficient to limit and offset mortality from previous an existing anthropogenic activities in the RSA. There is uncertainty regarding the effectiveness of mitigation, but CNL is committed to monitoring and adaptive management, including implementing additional conservation actions should these be necessary, such that CRLs operations result in a net neutral or positive effect on the Blanding’s turtle population in the RSA.

In the Application Case, the SSA would result in a long-term loss of 26 ha of critical habitat during construction. This is a loss of upland habitat and riparian habitat within the SSA that has the potential to be used for nesting, thermoregulation and summer inactivity. Females who use the SSA for nesting have the potential to experience a reduction in reproductive success until they find new areas within which to nest. Additionally, females may need to travel greater distances if the availability of new nesting sites is limited and/or use lower quality habitats. The use of lower quality habitats could affect hatchling success rates. In searching for new habitats, individual Blanding’s turtles may become exposed to other risks (e.g., roads). Potential effects associated with critical habitat loss have been identified according to a precautionary approach. The importance of effects may be overestimated because the occupancy of critical habitat identified in the SSA remains unconfirmed despite considerable survey effort. To mitigate these potential effects, CNL will create new nesting mounds on both sides of Priority 2 culverts after they are replaced. Nest mounds will be monitored weekly during the nesting season and after periods of rain and maintenance of these mounds (e.g., vegetation removal) will also be completed at this time, if females are not present. Additionally, critical habitat will be assessed annually to ensure no significant loss at CRL and to determine compensation measures initiated at CRL or elsewhere.

Climate change is expected to affect Blanding’s turtle habitat availability, habitat distribution, and survival and reproduction in the RSA. Although the severity of climate change as a threat to the sustainability of Blanding’s turtle populations in Canada is currently unknown, available evidence suggests this species is highly sensitive to

climate change (ECCC 2018b). Mitigation implemented on the CRL site during the Base Case and Application Case are anticipated to result in net neutral or positive effects on the local Blanding's turtle population. However, effects from climate change in the RSA may result in a negative effect (independent of CNL operations) on the Blanding's turtle population that overlaps with the RSA.

The weight of evidence suggests that, with mitigation committed to by CNL, effects from the NSDF Project will not jeopardize the survival of the regional Blanding's turtle population. With sufficient mitigation implemented at the CRL site, reductions in Blanding's turtle road mortality are possible, even with increased traffic volumes associated with the NSDF Project. Moreover, critical habitat will be assessed annually to ensure no significant loss at CRL and to determine compensation measures initiated at CRL or elsewhere (see Section 5.6.8).

5.6.7.9 Eastern Milksnake

5.6.7.9.1 Residual Effects Analysis

Habitat Availability

The LSA and SSA contain a variety of habitats (i.e., wetlands, forests, open areas) that may contain the microhabitat features to support egg laying, thermoregulation and/or hibernation (Section 5.6.4.10.1), and therefore suitable habitat for eastern milksnake is predicted to be lost due to the NSDF Project. The amount of suitable habitat for eastern milksnake affected by the NSDF Project could not be quantified for this assessment because targeted surveys for milksnakes have not been completed in the SSA, and their habitat preferences could not be determined from vegetation community mapping due to their generalist behaviour and reliance on microhabitats (e.g., rotting logs, stumps, mammal burrows, sand, rock crevices and natural or human debris) to carry out their life history requirements.

This species uses microhabitats such as rotting logs to lay eggs, and this type of microhabitat is likely abundant in the RSA and LSA due to the prevalence of mature forest habitat (Section 5.6.4.1.1). The likelihood of a natural hibernaculum being found in the SSA is low given its proximity to built structures on the CRL main campus northeast of the SSA, which are favoured for hibernacula and correspond with the majority of milksnake observations in the RSA (Figure 5.6.4-20). Because the SSA is dominated by closed canopy forest, opportunities for thermoregulation are likely limited and this likely reduces the overall quality of other potential microhabitats in the SSA compared to the RSA. In the absence of more detailed information on milksnake habitat availability in the SSA, a precautionary approach is followed and the NSDF Project is predicted to have an adverse, measurable effect on milksnake habitat availability at the LSA scale in the Application Case. This effect is predicted to be negligible at the RSA scale because the available information suggests that higher quality habitats are relatively more abundant in the RSA than the LSA.

Sensory disturbance associated with noise, light and vibration during construction, operations and closure phases may indirectly reduce eastern milksnake habitat availability in the LSA if snakes avoid otherwise suitable habitat. Given their preference for utilizing built structures, eastern milksnake may be somewhat tolerant of human disturbance. Moreover, snakes have lost the anatomy for hearing airborne sounds and instead detect sounds via vibration, suggesting that they are less sensitive to noise but may be particularly sensitive to vibrations (Christensen et al. 2012). The potential for vibrations to interfere with their hunting behaviour may be low given their preference to hunt at night and given that construction activities will primarily be restricted to daylight hours. As a precaution, vibration from the NSDF Project is predicted to reduce habitat availability for milksnake in the LSA due to avoidance in the Application Case.

Habitat Distribution

The development of the NSDF Project may alter the movement patterns of milksnakes and could restrict access to potential hibernacula and egg-laying habitat in the SSA. The SSA will be surrounded by a fence that will exclude wildlife, including milksnakes, from accessing the site. Individuals would need to travel around the outside of the fence if they need to move around the SSA to reach locations they require to carry out their life history requirements such as foraging, thermoregulation and egg-laying. If milksnakes use the SSA as a movement corridor between habitats, the NSDF Project will increase travel distances. The SSA is surrounded by wetlands that may provide habitat for milksnake and will not be disturbed by the NSDF Project. Therefore, migration corridors through these wetland complexes will remain intact within the LSA and RSA.

Changes in habitat distribution due to the NSDF Project are predicted to be local and will have a minor effect on the potential habitat distribution and connectivity for milksnake in the RSA. Habitat for this species is predicted to remain abundant and well connected in the RSA in the Application Case.

Survival and Reproduction

The NSDF Project has the potential to result in the incidental take of hibernating snakes during vegetation clearing and grubbing, which is proposed to take place during hibernation (i.e., October/November to April). Clearing during the milksnake hibernation period is necessary to avoid incidental take of migratory birds and bats during the migratory bird nesting period and bat maternity roosting period (Section 5.6.5.2.1). The likelihood of a natural hibernaculum being found in the SSA is low given its proximity to built structures on the CRL main campus northeast of the SSA, which are favoured for hibernacula and correspond with the majority of milksnake observations in the RSA (Figure 5.6.4-20).

Reptile exclusion fencing will be installed prior to the hibernation period (prior to August) and remain in place for the life of the NSDF Project so that snakes cannot re-enter the site prior to site clearing or access the site during operation. Exclusion fencing will be installed according to provincial guidelines for the target species, including milksnake (MNR 2013c). The area within the fence will be searched prior to site clearing and construction to capture and relocate any herpetofauna including milksnakes to outside of the fenced area.

The permanent loss of suitable habitat due to the NSDF Project may displace individuals and reduce their survival and reproductive success. Milksnakes are known to display fidelity to their hibernation sites. Therefore, if a hibernaculum is discovered within the SSA, the removal of this feature would displace the snake(s) that hibernate there and jeopardize their survival. Compensation habitat would be required to accommodate the displaced snakes. Likewise, females using potential egg-laying sites in the SSA would need to find other suitable locations for this activity. The reproductive success of these females may be reduced until a new egg-laying site can be found.

The population of milksnakes overlapping the RSA is predicted to be resilient to potential mortality from the destruction of a hibernaculum during vegetation clearing because populations in Ontario are not considered at risk by the Committee on the Status of Species at Risk in Ontario, which delisted the species in 2016, and predation by natural predators appears to be the only source of adult mortality in the RSA.

Road-related mortality is predicted to increase in the RSA and LSA due to the NSDF Project because new roads will be created and traffic will increase during the construction and operations phases. This effect will be minimized through the road mitigation strategy (largely developed for Blanding's turtle), which includes safe crossing structures under roads and fencing along roads, which will act to prevent all herpetofauna from accessing roadways. Additional mitigations to avoid road mortality for this species include enforcement of existing

CRL site speed limits on access roads, driver education, speed bumps and signage. Therefore, the risk of road mortality due to increased traffic as a result of the NSDF Project will be small.

5.6.7.9.2 Prediction Confidence

There is high confidence that a milksnake population is present in the RSA based on the location of known occurrence records in the RSA at the CRL main campus. There is a reasonable possibility that milksnakes use the LSA given its proximity to known occurrence records and an understanding of their home range sizes. However, their use of habitat in the SSA and LSA to carry out egg laying, hibernation and/or thermoregulation has not been confirmed. Much of the SSA is heavily forested, which would limit basking opportunities for thermoregulation, but it may contain microhabitats suitable for egg-laying and hibernating. Milksnake has been shown to avoid forested habitat because of its low thermal quality (Row and Blouin-Demers 2006b). Nevertheless, in the absence of specific data on milksnake habitat use in the SSA and LSA, this assessment used a precautionary approach to manage uncertainty and assumed that milksnakes are present in the SSA. This approach may overestimate the potential effects of the NSDF Project on milksnakes.

There is a high degree of confidence in CNL's ability to manage road mortality for this species because a comprehensive *Blanding's Turtle Road Mortality Mitigation Plan* is being developed for Blanding's turtle that will also benefit milksnakes, and because CNL has a demonstrated record of zero milksnake fatalities due to vehicle collision in the RSA, despite the majority of milksnake observations occurring in an area of high vehicle use (i.e., the CRL main campus).

5.6.7.9.3 Residual Effects Classification

A summary of the classification of incremental adverse residual effects of the NSDF Project on eastern milksnake in the Application Case is provided for each measurement indicator in Table 5.6.7-20. Residual effects after the implementation of effective mitigation are described, and are summarized according to direction, magnitude, geographic extent, duration/reversibility, frequency/timing and likelihood of the effect occurring following the methods described in Section 5.6.6.3 and the definitions provided in Table 5.6.6-1.

Table 5.6.7-20: Description of Residual Effects on Eastern Milksnake in the Application Case

Indicator	Characteristic	Rating/Effect Size
Habitat Availability	Direction	Negative
	Magnitude	Direct loss of some suitable milksnake habitat; potential avoidance of otherwise suitable habitat due to sensory disturbance in the LSA
	Geographic Extent	SSA (direct habitat loss); Local (sensory disturbance)
	Duration/Reversibility	Permanent/Irreversible (direct habitat loss); Medium-term (sensory disturbance)
	Frequency/Timing	Continuous
	Likelihood	Probable
Habitat Distribution	Direction	Negative
	Magnitude	Change in movement corridors around the perimeter of the NSDF Project
	Geographic Extent	Local
	Duration/Reversibility	Permanent/Irreversible
	Frequency/Timing	Continuous
	Likelihood	Probable
Survival and Reproduction	Direction	Negative
	Magnitude	Change in survival and/or reproduction due to incidental take or loss of habitat used for hibernation and/or egg-laying; increased risk of injury/mortality on roads
	Geographic Extent	Local
	Duration/Reversibility	Medium-term (loss of egg-laying habitat and/or hibernacula); Permanent/Irreversible (roadkill)
	Frequency/Timing	Infrequent (loss of egg-laying habitat, loss of hibernacula, roadkill)
	Likelihood	Possible (loss of egg-laying habitat, roadkill), Unlikely (incidental take/loss of hibernacula

LSA = Local Study Area; RSA = Regional Study Area; SSA = Site Study Area.

5.6.7.9.4 Determination of Significance

The population of eastern milksnake that overlaps with the RSA is considered sensitive to changes in habitat availability, distribution, and survival and reproduction. However, milksnakes are habitat generalists, meaning they use a variety of habitats and microhabitats that have the likelihood to be available throughout the RSA. They use man-made structures such as old building foundations for hibernation and roadways to thermoregulate and so are somewhat tolerant to human disturbances. These characteristics suggest some resilience and adaptability to changes in habitat availability and distribution. Although eastern Ontario represents some of the best remaining habitat for milksnakes in the province, populations are thought to occur at low densities across the species' range (COSEWIC 2014).

The known occurrence records for this species in the RSA occur within the CRL main campus. Therefore, it is likely that at least a portion of the milksnake population in the RSA is hibernating on or near the campus and likely in the foundations of old buildings. The likelihood of a natural hibernaculum being found in the SSA is somewhat unlikely given the proximity of the SSA to built structures, which are favoured for hibernacula. As such, the change in habitat availability for hibernation due to the SSA is unlikely to have an ecologically measurable effect on the survival of the population. This species uses microhabitats such as rotting logs to lay eggs. Given the likely abundance of this type of microhabitat in the RSA, the removal of such habitat within the SSA is unlikely to have

an ecologically measurable effect on the survival of the population. Although it is assumed that milksnakes are using habitats within the SSA for some of their life history requirements, the reduction of habitat availability due to the NSDF Project is considered to be within the resilience and adaptability limits of this species.

The NSDF Project may result in a change in movement patterns at the local scale, but this change is not expected to alter the extent of occurrence of the population that overlaps with the RSA because the area of disturbance is small and localized, and eastern milksnakes are habitat generalists capable of using a variety of habitats to carry out their life history requirements.

Roadkill has been identified as a primary concern for the survival and reproduction of this species (COSEWIC 2014). Although it is not currently a concern in the RSA, road mortality risk is predicted to increase with the NSDF Project. In the Application Case, the SSA would be fenced with reptile exclusion fencing to prevent direct injury or mortality to this species from construction activities. Fencing of the SSA would require individual milksnakes to travel greater distances around the perimeter of the site to seek new habitats. In searching for new habitats, the risk of road mortality due to vehicle strikes may increase for milksnake. Populations of this species may be particularly vulnerable to increases in adult mortality because they are long-lived, have delayed sexual maturity and may only produce a clutch of eggs every second year (Environment Canada 2015). The increase in traffic related to the NSDF Project and consequently the risk of road injury or mortality will be mitigated through the comprehensive *Blanding's Turtle Road Mortality Mitigation Plan*, which will also serve other reptiles such as milksnake.

There is no evidence to suggest that the milksnake population that overlaps the RSA is not self-sustaining and ecologically effective in the Base Case; environmental stresses of primary concern in other portions of the species' range (i.e., habitat loss and road mortality) do not appear to be important factors affecting the milksnake population that overlaps with the RSA. The NSDF Project has the potential to affect habitat availability, distribution, and survival and reproduction. However, with effective implementation of mitigation, the incremental changes due to the NSDF Project are not predicted to adversely affect the population of milksnake that overlaps with the RSA because habitat is unlikely to be a limiting factor in the RSA and direct mortality of individuals will be minimized or avoided by implementing appropriate mitigation. Therefore, effects from the NSDF Project are not predicted to exceed the resilience and adaptability limits of the milksnake population that overlaps with the RSA. Consequently, cumulative effects from the NSDF Project and previous and existing activities and developments in the RSA on the milksnake population that overlaps with the RSA are predicted to be not significant in the Application Case.

Given that milksnakes are habitat generalists, on-going fire suppression in the RSA is unlikely to have a substantial effect on the population that overlaps the RSA, though forested habitat has low thermal quality and therefore may be used less frequently than more open habitats (Row and Blouin-Demers 2006b). Climate change has not been identified as a threat to this species (Environment Canada 2015). Consequently, cumulative effects of previous and existing developments, the incremental effect of the NSDF Project, and consideration of future, beyond regional disturbance factors (e.g., climate change) on the eastern milksnake population that overlaps the RSA are predicted to be not significant. The contributions of the NSDF Project are therefore also considered not significant.

5.6.7.10 Monarch Butterfly

5.6.7.10.1 Residual Effects Analysis

Habitat Availability

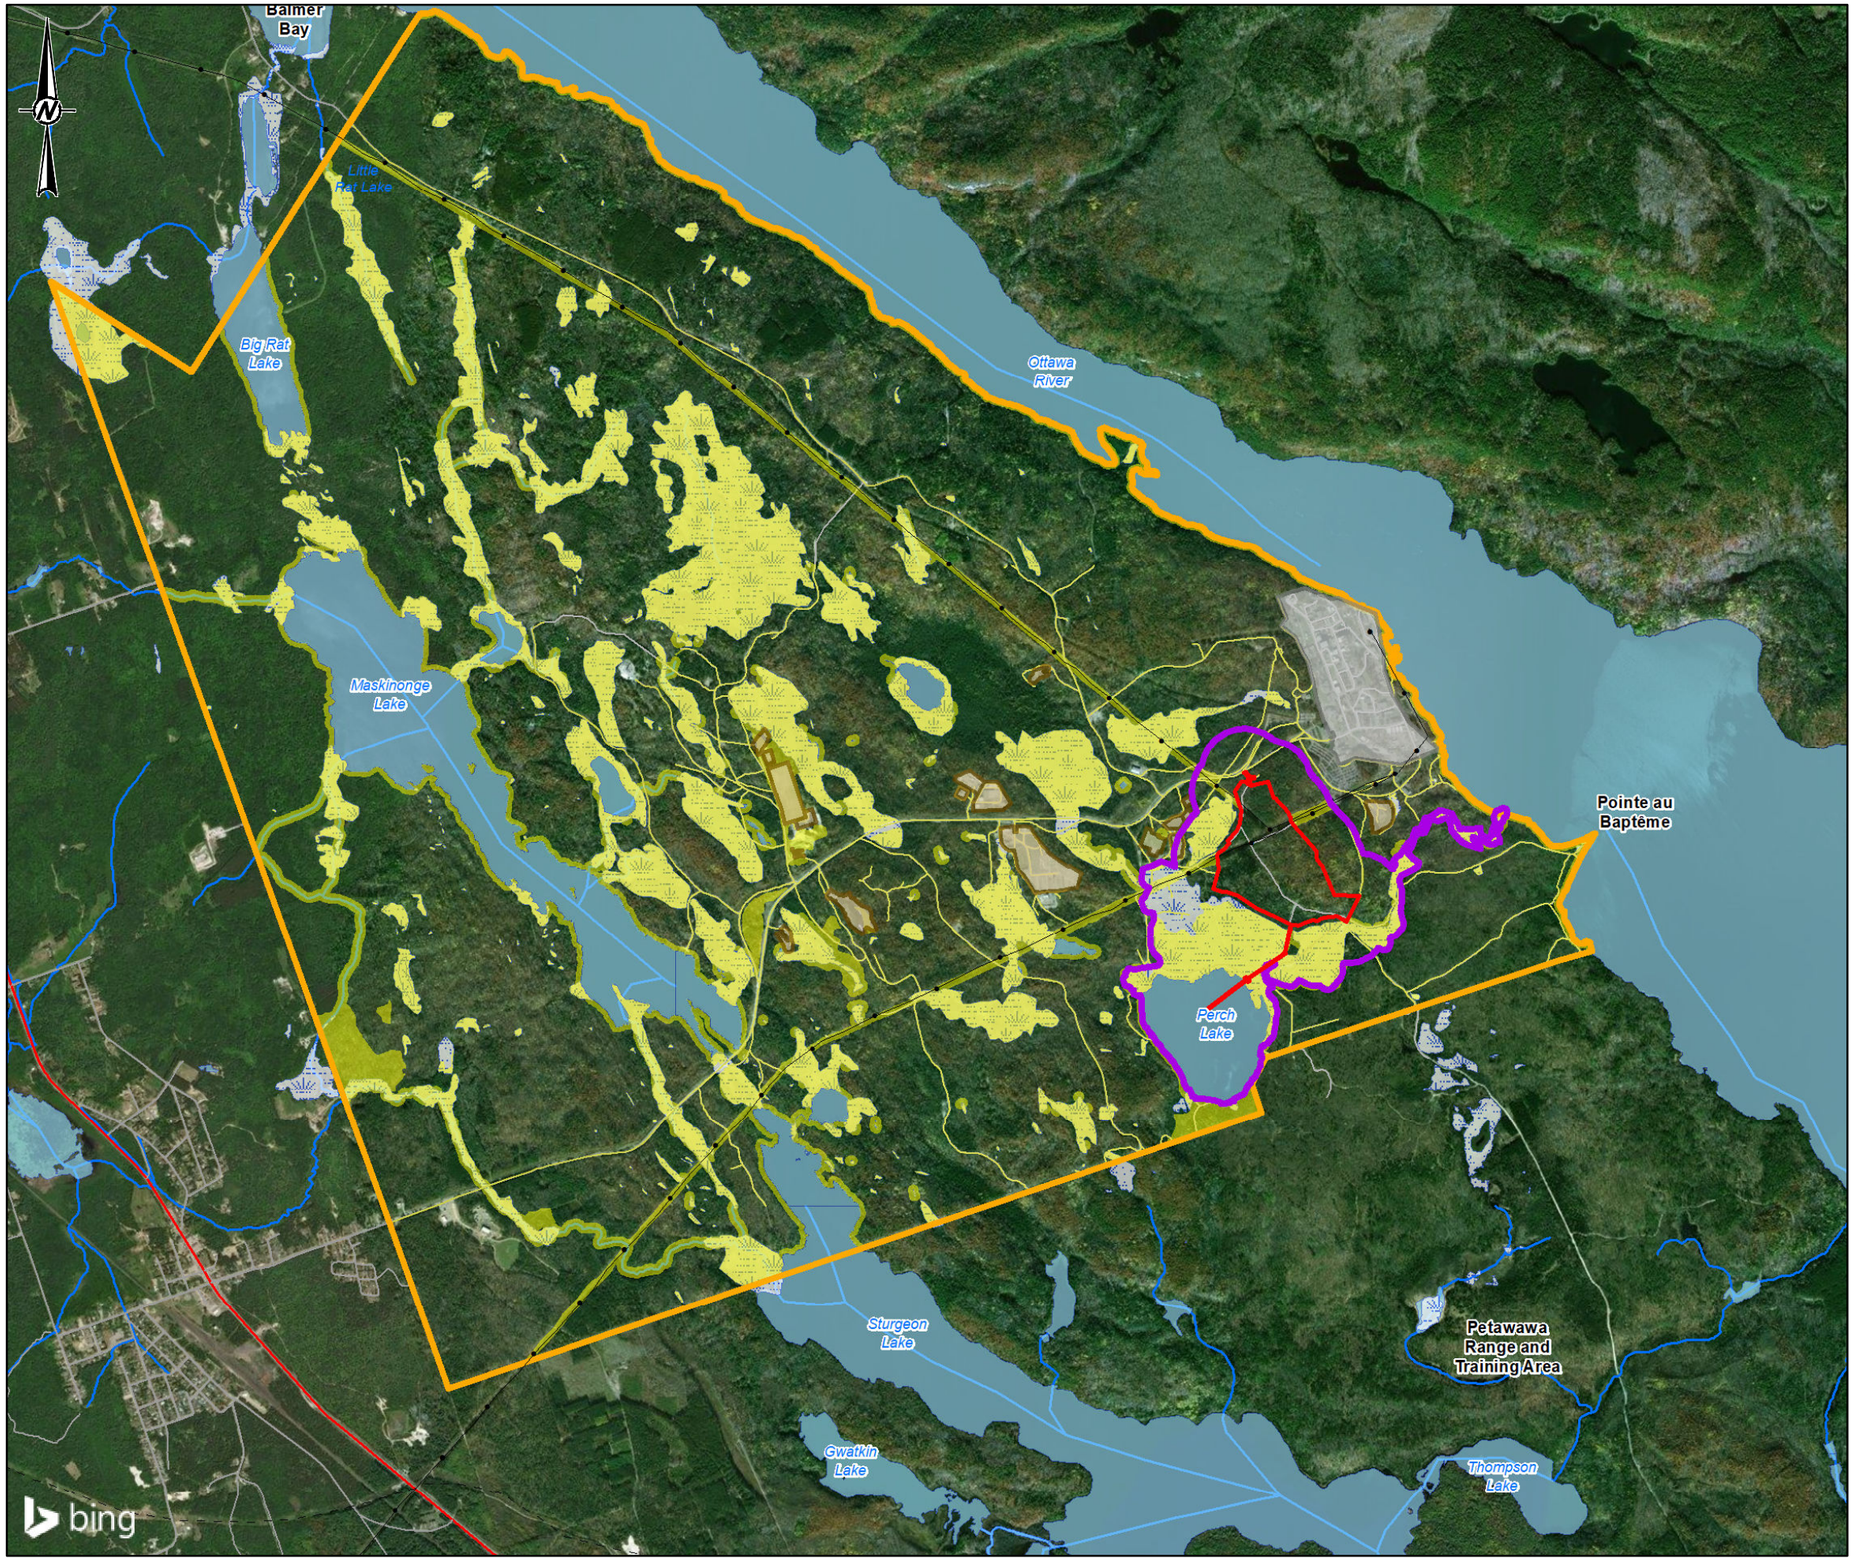
The NSDF Project is estimated to remove about 5 ha of suitable summer breeding habitat for monarch butterfly, which is 6.3% of suitable habitat in the LSA and 0.6% of suitable habitat in the RSA (Table 5.6.7-21). All of the removed habitat will be in the form of roadside and utility corridor habitat. However, there may be some opportunity for milkweed to establish in the SSA along roadsides and in other vegetated areas around the NSDF Project infrastructure during the operations phase, temporarily offsetting habitat loss before the footprint is planted to grass at closure and maintained into perpetuity. Additionally, some habitat may be formed along the edges of the SSA post-closure, permanently offsetting some of the habitat loss during construction.

Table 5.6.7-21: Changes to Monarch Butterfly Summer Habitat Availability in the Application Case

Habitat Suitability	Regional Study Area				Local Study Area			
	Base Case (ha)	Application Case (ha)	Change in Area (ha)	Percent Change (%)	Base Case (ha)	Application Case (ha)	Change in Area (ha)	Percent Change (%)
Suitable	805	800	-5	-0.6	80	75	-5	-6.3
Unsuitable	3,047	3,052	5	0.2	130	135	5	3.8

Sensory disturbance associated with noise and vibration during the construction, operations and closure phases may indirectly reduce monarch butterfly habitat availability in the LSA if monarch butterflies avoid these sources of disturbance. Noise effects on invertebrates are generally poorly understood and largely unstudied; however, many invertebrates including lepidopterans (butterflies and moths) are capable of hearing and may respond to anthropogenic noise (Morley et al. 2014). It has been demonstrated that moths and nocturnal butterflies respond to high- and ultrasonic-frequency airborne vibrations, which helps them avoid echolocating bats (Treat 1955; Yack and Fullard 1999). Some diurnal butterflies have been shown to be sensitive to low-frequency sounds, and it has been postulated that this may be a defense mechanism against vocalizing avian predators (Ribarič and Gogala 1996). Caterpillars of a number of lepidopterans including monarch butterfly have also been found to respond to sound; individuals freeze, contract, flick their bodies and even drop off vegetation presumably as a predator or parasitoid defense mechanism (Taylor 2008 and references within).

Studies also demonstrate some lepidopterans can produce sounds. Some moths have been found to emit ultrasonic clicking sounds to confuse echolocating bats (Miller 1991) and some diurnal butterflies produce clicking sounds during specific flight behaviours that presumably serve as a communication method (e.g., Kane 1982), but this phenomenon does not appear prevalent among butterfly families (Ribarič and Gogala 1996; Murillo-Hiller 2006). Caterpillars of 49 butterfly species that form symbiotic relationships with ants have been found to emit low- to mid-frequency substrate-borne calls (pulses), presumably to maintain ant association, whereas no sound production by caterpillars has been identified in 81 butterfly species (DeVries 1991).



Although there is a paucity of literature on invertebrate response to sound and vibration, available evidence suggests it is unlikely that most butterflies and other diurnal invertebrates that do not emit sounds (which could be affected by interference) respond measurably to anthropogenic noise. Diurnal butterflies generally use visual mechanisms for communication and predator avoidance (Silberglied 1984 in Yack and Fullard 1999). Monarch butterflies are not known to emit sound and their primary predator defense mechanism is based on visual avoidance of the bold patterning of both caterpillars and adults once the predator discovers that the

butterfly tastes bad and subsequently avoids other individuals with similar patterning. Additionally, monarch butterflies are frequently observed foraging along roadsides and in public spaces and flying over highways, suggesting high tolerance to anthropogenic noise. Based on these conclusions, habitat availability for monarch butterflies in the LSA is not predicted to change due to avoidance resulting from sensory disturbance from the NSDF Project.

Habitat Distribution

The development of the NSDF Project is unlikely to have a measurable effect on monarch butterfly habitat distribution and movement in the RSA, given the small size of the SSA and the limited amount of suitable habitat available in the SSA in the Base Case (Figure 5.6.7-18 and Figure 5.6.7-19). Most of the suitable habitat in the LSA is in the form of wetlands, which will not be disturbed by the NSDF Project and will continue to serve as a movement corridor through the LSA. Adult monarch butterflies are highly mobile and capable of moving around or over the NSDF Project infrastructure. Additionally, most of land cleared during construction of the NSDF Project is forested in the Base Case and forest clearing may increase movement opportunity in the LSA due to the increase in open land cover.

Survival and Reproduction

Site clearing for the NSDF Project is not predicted to cause monarch butterfly mortality. Adult monarch butterflies are highly mobile and can avoid interactions with activities that could result in direct mortality, and mitigation will be implemented to avoid mortality of other life stages (Section 5.6.5.2.1).

The loss of summer breeding habitat may affect reproductive success if individuals are displaced or return the following summer to find habitat removed. The loss of suitable breeding habitat due to the NSDF Project is predicted to result in a small reduction in the carrying capacity of the LSA and RSA. However, this is unlikely to have a measurable effect on the monarch butterfly population in the RSA given the small area of predicted habitat loss (0.6% of suitable habitat in the RSA) and overall good representation of suitable habitat remaining in the RSA (20.8% of RSA) in the Application Case.

5.6.7.10.2 Prediction Confidence

Suitability of habitat for breeding ultimately depends on the availability of milkweed host plants for monarch caterpillars and this information cannot be determined from the vegetation mapping. Therefore, there is a moderate level of uncertainty about the amount of suitable habitat present in the study areas. The assumption that all open habitats provide summer breeding habitat represents a conservative overestimate of habitat availability in the Base Case and the amount of habitat to be removed by the NSDF Project in the Application Case.

There is a moderate level of uncertainty associated with the future population status of monarch butterfly in Canada. Although threats to overwintering populations in Mexico are perceived to be the most direct causes of overall decline in monarch butterfly numbers in North America, some studies have reported declining trends in summer breeding populations, though these findings have not been consistent among studies and locations (COSEWIC 2010).

5.6.7.10.3 Residual Effects Classification

A summary of the classification of incremental adverse residual effects of the NSDF Project on monarch butterfly in the Application Case is provided for each measurement indicator in Table 5.6.7-22. Residual effects after the implementation of effective mitigation are described, and are summarized according to direction, magnitude, geographic extent, duration/reversibility, frequency/timing and likelihood of the effect occurring following the methods described in Section 5.6.6.3 and the definitions provided in Table 5.6.6-1.

Table 5.6.7-22: Description of Residual Effects on Monarch Butterfly in the Application Case

Indicator	Characteristic	Rating/Effect Size
Habitat Availability	Direction	Negative
	Magnitude	Loss of 5 ha of suitable habitat (6.3% in LSA; 0.6% in RSA)
	Geographic Extent	SSA
	Duration/Reversibility	Permanent/Irreversible (though some habitat may form temporarily during the operations phase and permanently in the post-closure phase)
	Frequency/Timing	Continuous
	Likelihood	Certain
Habitat Distribution	Direction	Neutral
	Magnitude	Small change in habitat distribution due to habitat loss, but increased movement opportunity due to increase in open land cover in LSA
	Geographic Extent	Local
	Duration/Reversibility	Permanent/Irreversible
	Frequency/Timing	Continuous
	Likelihood	Probable
Survival and Reproduction	Direction	Negative
	Magnitude	Small reduction in reproductivity from habitat loss
	Geographic Extent	Local
	Duration/Reversibility	Permanent/Irreversible
	Frequency/Timing	Continuous
	Likelihood	Probable

LSA = Local Study Area; RSA = Regional Study Area; SSA = Site Study Area.

5.6.7.10.4 Determination of Significance

The population of monarch butterflies that overlaps with the RSA is not considered sensitive to changes in habitat availability or distribution because breeding habitat is not considered a limiting factor for this criterion in the RSA, and suitable habitat is well represented (20.8% of RSA) and well distributed in the RSA. Fire suppression has likely reduced habitat availability for this species in the RSA, but monarch butterflies are highly mobile and they demonstrate flexibility in habitat selection, including use of human disturbances such as road verges and utility corridors, which are maintained in early seral stages preferred by this species. These characteristics suggest resilience and adaptability to changes in habitat availability and distribution. Although southern Ontario supports some of the highest concentrations of breeding monarch butterflies in Canada (COSEWIC 2010; ECCC 2016b), the RSA is unlikely to be an important breeding area given that it is mostly forested and approaching the northern limit of milkweed distribution in Ontario. Mortality of individuals (all life stages) due to deleterious vegetation management practices along linear corridors and reductions in carrying capacity of the RSA due to reductions in habitat availability are unlikely to have had ecologically measurable effects on the population. Therefore, changes to monarch butterfly survival and reproduction in the Base Case are considered to be within the resilience and adaptability limits of this species. Overall, there is no evidence to suggest the population that overlaps the RSA is not self-sustaining and ecologically effective in the Base Case.

In the Application Case, the SSA would permanently remove about 5 ha of suitable breeding habitat during construction. The NSDF Project may result in a change in movement patterns at the local scale, but this change is not expected to alter the extent of occurrence of the population that overlaps with the RSA because the area of disturbance is small and localized, monarch butterflies are highly mobile and capable of using disturbed habitats for breeding and clearing of forest in the SSA may increase movement in the LSA. With effective implementation of mitigation, the incremental changes due to the NSDF Project are not predicted to adversely affect the population of monarch butterflies that overlaps with the RSA because habitat is unlikely to be a limiting factor in the RSA and direct mortality of individuals will be avoided by implementing appropriate mitigation. Therefore, effects from the NSDF Project are not predicted to exceed the resilience and adaptability limits of the monarch butterfly population that overlaps with the RSA. Consequently, cumulative effects from the NSDF Project and previous and existing activities and developments in the RSA on the monarch butterfly population that overlaps with the RSA are predicted to be not significant in the Application Case.

On-going fire suppression in the RSA may reduce monarch butterfly habitat availability as early successional land cover types progress towards mature and old growth forest. However, most of the suitable habitat for monarch butterfly in the RSA is in the form of wetland and linear disturbance, which are not expected to succeed to forest.

Climate change modelling predicts significant negative effects on overwintering and migrating populations of monarch butterfly (COSEWIC 2010). Climate change may also affect breeding populations. Climate change is predicted to increase the frequency and intensity of extreme weather events, including droughts, forest fires and heavy precipitation (ECCC 2016b; Huff and Thomas 2014). Extreme weather events during the breeding season can result in reduced survival, reproduction and growth rates (ECCC 2016b). Forest fires may increase habitat availability by creating open habitat preferred by this species. Individuals may also be susceptible to extreme weather events outside of the breeding season. The frequency and intensity of hurricanes are predicted to increase as a result of climate change, which may negatively affect migrating and overwintering individuals. However, the direction and magnitude of effects from climate change are uncertain because predictions are based on simulations that can be highly variable and many scenarios are possible.

Overall, the weight of evidence from the analysis of the primary pathways predicts that changes to monarch butterfly habitat availability, habitat distribution, and survival and reproduction in the RSA as a result of the NSDF Project are within the resilience and adaptability limits of the species. Continued fire suppression in the RSA and climate change are expected to also affect monarch butterfly habitat availability, habitat distribution, and survival and reproduction in the RSA. However, neither of these threats has been identified as being of high concern to breeding populations (ECCC 2016b). Therefore, effects from continued fire suppression and climate change in conjunction with the effects of the NSDF Project and past and present activities and developments in the RSA are not predicted to exceed the resilience and adaptability limits of the monarch butterfly population that overlaps with the RSA. Consequently, cumulative effects of previous and existing developments, the incremental effect of the NSDF Project, and consideration of future, beyond regional disturbance factors (e.g., climate change) on the monarch butterfly population that overlaps the RSA are predicted to be not significant. The contributions of the NSDF Project are therefore also considered not significant.

5.6.7.11 Reasonably Foreseeable Developments Case

For the terrestrial environment, the RSA was used as the scale at which cumulative effects to terrestrial biodiversity VCs were assessed. Regional disturbance factors (e.g., forestry and climate change) were considered if they were likely to affect vegetation communities or populations of wildlife VCs that overlap with the RSA. The assessment considered the Base Case, which represents existing conditions and characterizes effects from

previous and existing developments and activities, as well as the Application Case, which represents the effects of the Base Case combined with the predicted incremental effects from the NSDF Project through all project phases for each VC. The Base Case reflects the effects of existing disturbances in the area, such as forestry, transportation, agricultural, mining, and residential and recreational development.

As defined in the preceding sections, residual effects on terrestrial VCs are primarily associated with vegetation clearing and grubbing and the associated loss or alteration of existing vegetation and topographical features, sensory disturbance from NSDF Project activities during construction and operations, and increased risk of injury or mortality on roads due to equipment and vehicle traffic. The cumulative effects from the NSDF Project and previous and existing activities and developments in the RSA on the population of terrestrial biodiversity VCs that overlap with the RSA are predicted to be not significant for all VCs, with the exception of bats and Blanding's turtle, discussed in the following sub-sections.

RFDs expected within the CRL site (i.e., the RSA) that may interact with the terrestrial environment include new or upgrades to research and development facilities, construction and operation of the SMR, new support infrastructure, and on-going decommissioning and environmental remediation activities. New support infrastructure and research and development facilities will generally be located within existing disturbed areas on the CRL site (i.e., no disturbance to largely undeveloped areas) where erosion and sediment control practices and surface water management systems already in place will be implemented. Disturbance of approximately 3.5 ha including potentially undisturbed areas of the CRL site, may be required for development of the SMR based on the candidate site selected (Global First Power 2019). The three candidate sites for locating SMR on the CRL site are located away from the SSA (Figure 8.2.1-1). It is expected that removal of and other potential effects on terrestrial habitat including to species at risk through development of SMR will be reduced through consideration of siting and through mitigation similar to that implemented for the NSDF Project. Potential effects from these revitalization activities, as well as construction and operation of the SMR, are not expected to spatially overlap with potential effects on terrestrial biodiversity from the NSDF Project, which are limited to the SSA and LSA.

The revitalization of the CRL site is planned to occur over the 10 year period 2016 to 2026. The workforce numbers and types of work required for site revitalization activities over that period are expected to maintain a similar condition to the site revitalization activities occurring at present on-site, therefore reflected in Base Case characterization such as traffic monitoring. This workforce is anticipated to be approximately equal to that required for the construction of the NSDF Project and the existing roads within the CRL site will continue to be used to access the site. Traffic generated for construction and operations of the SMR will be small compared to that required for NSDF and negligible compared to on-going CRL site operations. Mitigation has been or will be implemented on the CRL Site to limit and offset traffic-related wildlife mortality from previous and existing anthropogenic activities in the RSA.

The end-state plan for the CRL site will be to return lands disturbed by site activities to a condition that is physically stable and safe in keeping with the land use and landscape of the day. Therefore, decommissioning and environmental remediation activities are anticipated to positively affect terrestrial biodiversity. Once existing infrastructure is removed and the CRL site is reclaimed and ceases to be frequented by large numbers of employees, the level of anthropogenic disturbance within the site will be greatly reduced, benefiting the terrestrial environment in the RSA.

RFDs, as currently understood, will either have no spatial overlap or are likely to positively affect terrestrial biodiversity, so no residual adverse cumulative effects are identified. Future, beyond regional disturbance factors (e.g., climate change) were considered qualitatively as part of the Application Case.

5.6.7.11.1 Bats

As noted in Section 5.6.7.7, populations of little brown myotis (*Myotis lucifugus*), northern myotis (*Myotis septentrionalis*) and tri-colored bats (*Perimyotis subflavus*) that overlap the terrestrial environment RSA are highly sensitive to changes in survival and reproduction because white nose syndrome has resulted in dramatic declines of these species across the eastern portions of their Canadian range, which includes the RSA. Therefore, the existing level of pressure on these bat species in the Base Case has likely already exceeded their resilience and adaptability limits and they are unlikely to be self-sustaining or ecologically effective. Consequently, the cumulative effects of existing disturbance and especially the introduced white nose syndrome are considered significant in the Base Case (i.e., even before the NSDF Project).

The NSDF Project will contribute a small increment to this existing significant adverse cumulative effect. Importantly, because vegetation clearing will be undertaken outside of the maternity roosting season, no mortality of roosting bats is expected as a result of the NSDF Project and effects of the NSDF Project to survival and reproduction are considered neutral. In addition, the remaining availability of potential maternity roosting habitat is not likely a limiting factor in the terrestrial environment RSA. The contribution of the NSDF Project to the existing significant adverse cumulative effect to bats is predicted to be negligible (i.e., no detectable changes to bat populations), and the NSDF Project does not contribute to the spread of white nose syndrome, which is the primary driver of the existing significant adverse cumulative effect.

Maternity roost habitat is currently not considered critical habitat under the *Species At Risk Act* (ECCC 2018) and as such, offsetting the removal of potential bat maternity roost trees is not required. However, the use of appropriately designed bat boxes can increase the availability of maternity roosting locations and may aid in the recovery of bats (ECCC 2018). Bat boxes have been installed in suitable locations in the terrestrial environment RSA is recommended to mitigate the incremental contribution of the NSDF Project. Monitoring is being conducted to determine if boxes are being used. As well, a comprehensive Sustainable Forest Management Plan is being developed for the CRL site, with an objective to ensure the long-term retention of trees serving as maternity roosts for bat species.

5.6.7.11.2 Blanding's Turtle

The SSA would results in the long-term removal of 26 ha of critical habitat for Blanding's turtle critical habitat during construction, which represents 14.5% of the currently available critical habitat in the LSA. The upland habitat and riparian habitat affected by the NSDF Project has the potential to be used by Blanding's turtle for nesting, thermoregulation and summer inactivity. Females who use the area for nesting may experience a reduction in reproductive success until they find new areas within which to nest. Additionally, females may need to travel greater distances if the availability of new nesting sites is limited and/or use lower quality habitats. The use of lower quality habitats could affect hatchling success rates. In searching for new habitats, individual Blanding's turtles may become exposed to other risks (e.g., roads).

With the implementation of the comprehensive mitigation outlined in the *Blanding's Turtle Road Mortality Mitigation Plan*, along with monitoring and adaptive management, CNL's activities in the RSA are predicted to have a net neutral or positive effect on the local Blanding's turtle population during the Base Case. That is, the mitigation that is or will be implemented on the CRL site is considered sufficient to limit and offset mortality from previous an existing anthropogenic activities in the RSA. There is uncertainty regarding the effectiveness of mitigation, but CNL is committed to monitoring and adaptive management, including implementing additional conservation actions should these be necessary, such that CRLs operations result in a net neutral or positive effect on the Blanding's turtle population in the RSA.

Potential effects associated with critical habitat loss have been identified according to a precautionary approach. The importance of effects may be overestimated because the occupancy of critical habitat identified in the SSA remains unconfirmed despite considerable survey effort. To mitigate these potential effects, CNL will create new nesting mounds on both sides of Priority 2 culverts after they are replaced. Nest mounds will be monitored weekly during the nesting season and after periods of rain and maintenance of these mounds (e.g., vegetation removal) will also be completed at this time, if females are not present. Additionally, critical habitat will be assessed annually to ensure no significant loss at CRL and to determine compensation measures initiated at CRL or elsewhere.

The weight of evidence suggests that, with mitigation committed to by CNL, effects from the NSDF Project will not jeopardize the survival of the regional Blanding's turtle population. With sufficient mitigation implemented at CRL, reductions in Blanding's turtle road mortality are possible, even with increased traffic volumes associated with the NSDF Project. Moreover, critical habitat will be assessed annually to ensure no significant loss at CRL and to determine compensation measures initiated at CRL or elsewhere.

5.6.8 Monitoring and Follow-up

This section of the EIS provides the conceptual outline for any monitoring and follow-up programs recommended to confirm the predictions made in the terrestrial biodiversity assessment (Table 5.6.8-1). Monitoring programs recommended for Canada warbler, eastern whip-poor-will, eastern wood-pewee, golden-winged warbler, wood thrush, bats, Blanding's turtle and eastern milksnake will be integrated into CNL's existing Species at Risk Program.

Table 5.6.8-1: Monitoring and Follow-up Programs for Terrestrial Biodiversity

Valued Component	Project Phase and Potential Effects	Monitoring Program Objective	Conceptual Monitoring/ Follow-up Program	Suggested Duration	Implementing Program
Canada warbler	▪ Habitat Availability: Permanent, direct loss of 28 ha of suitable habitat. Long-term reduction in quality of nesting habitat and possible avoidance in the LSA from sensory disturbance. ▪ Habitat Distribution: Small, permanent change in local movement. ▪ Survival and Reproduction: Small reduction in reproductivity from habitat loss and sensory disturbance.	Verify environmental assessment predictions through collection of data on relative abundance and other key demographic parameters for breeding bird populations that overlap with the RSA.	Data on relative abundance and other key demographic parameters for breeding birds in the RSA will be collected during pre- and post-construction surveys using automated recording units. Collected data will be used to evaluate trends in populations of breeding birds that overlap with the RSA, including Canada warbler, eastern whip-poor-will, eastern wood-pewee, golden-winged warbler and wood thrush. If declining trends are observed for these species in the RSA, then the need for additional mitigation will be evaluated.	Every 5 years.	Monitoring will be integrated into CNL's existing Species at Risk Program.
Eastern whip-poor-will	▪ Habitat Availability: Permanent, direct loss of 2 ha of suitable habitat. ▪ Habitat Distribution: Small, permanent change in local movement. ▪ Survival and Reproduction: Small reduction in reproductivity from habitat loss and sensory disturbance.				
Eastern wood-pewee	▪ Habitat Availability: Permanent, direct loss of 18 ha of suitable habitat. ▪ Habitat Distribution: Small, permanent change in local movement. ▪ Survival and Reproduction: Small reduction in reproductivity from habitat loss and sensory disturbance.				
Golden-winged warbler	▪ Habitat Availability: Permanent, direct loss of 27 ha of suitable habitat. ▪ Habitat Distribution: Small, permanent change in local movement. ▪ Survival and Reproduction: Small reduction in reproductivity from habitat loss and sensory disturbance.				
Wood thrush	▪ Habitat Availability: Permanent, direct loss of 28 ha of suitable habitat. ▪ Habitat Distribution: Small, permanent change in local movement. ▪ Survival and Reproduction: Small reduction in reproductivity from habitat loss and sensory disturbance.				
Bats	▪ Habitat Availability: Permanent, direct loss of 28 ha of potential maternity roosting habitat. ▪ Habitat Distribution: Gap in potential maternity roosting habitat, but negligible change in local movement patterns. ▪ Survival and Reproduction: No residual effects due to the NSDF Project.	▪ Verify effectiveness of bat boxes as maternity roosting habitat offsetting measure, by determining number of individuals and species of bats using boxes for roosting habitat	▪ Installation of bat boxes in suitable locations in the RSA is recommended to offset the incremental contribution of the NSDF Project to cumulative effects on SARA-listed bats. Monitoring is being conducted at least weekly to determine if bat boxes are being used. Boxes not being used may be moved to an alternate location. ▪ A project in collaboration with Trent University is currently underway, where bats are being trapped and tracked back to the roost site (natural tree or bat box). ▪ Guano collection is being performed as well. This work has a duration of two years and will provide CNL with a better understanding of habitat occupancy by the bat species at risk, including bat boxes, and habitat preference. This work will support the objective of addressing knowledge gaps on the three bat species at risk.	Bat boxes will remain in place throughout the construction and operations phases. Visual monitoring of bat boxes will be conducted weekly every year during the pre-construction phase and will continue through construction and for three years after start of operations.	Monitoring will be integrated into CNL's existing Species at Risk Program.

Table 5.6.8-1: Monitoring and Follow-up Programs for Terrestrial Biodiversity

Valued Component	Project Phase and Potential Effects	Monitoring Program Objective	Conceptual Monitoring/ Follow-up Program	Suggested Duration	Implementing Program
Blanding's turtle	▪ Habitat Availability: Direct, long-term loss of 26 ha of critical habitat. ▪ Habitat Distribution: Permanent change in local movement. ▪ Survival and Reproduction: Reduced reproductive success and mortality of individuals over the lifespan of the NSDF Project.	Confirm effectiveness of mitigation through tracking wildlife mortality and use information for adaptive management.	Wildlife-vehicle collision monitoring will be conducted in the SSA. —Vehicle-caused Blanding's turtle mortality will be reported and data will be compiled in a database that can be used to inform adaptive management for the site.	On-going during the construction and operations phases and closure.	Monitoring will be integrated into CNL's existing Species at Risk Program.
		Identify and map critical habitat in the .	As part of the SARA permitting process for the removal of critical habitat, critical habitat will be assessed annually to ensure no significant loss at CRL and to determine compensation measures initiated at CRL or elsewhere. Monitoring will be integrated into CNL's existing Species at Risk Program.	Critical habitat will be assessed annually to ensure no significant loss at CRL and to determine compensation measures initiated at CRL or elsewhere.	Habitat compensation will be implemented as part of the SARA permitting process and consist of the creation of nest mounds for the species.
		Confirm integrity temporary and permanent of exclusion fencing.	Exclusion fencing will be inspected for integrity	Annually during the construction and operations phases and closure.	Monitoring will be integrated into CNL's existing Species at Risk Program.
		Confirm integrity of culverts	Culverts will be inspected for barriers to turtle movements	Weekly during the active season for Blanding's turtle (April 15 to October 15)	Monitoring will be integrated into CNL's existing Species at Risk Program.
		Confirm integrity of artificial nest mounds	Nesting mounds will be inspected for suitability and mounds will be maintained by removing vegetation as needed.	Weekly during the nesting season for Blanding's turtle (May 15 to June 30).	Monitoring will be integrated into CNL's existing Species at Risk Program.
		Confirm integrity of nest cages	Nest cages will be inspected for integrity.	Weekly during the nesting and hatchling emergence season for Blanding's turtle (May 15 to October 15)	Monitoring will be integrated into CNL's existing Species at Risk Program.
		Confirm use of culverts by Blanding's turtles	Cameras will be installed at culverts and will record photographs on a time-lapse basis. Photographs will be reviewed and data compiled.	Continuously during the active season for Blanding's turtle (April 15 to October 15) every year for the next 5 years.	Monitoring will be integrated into CNL's existing Species at Risk Program.
Eastern milksnake	▪ Habitat Availability: Direct, permanent loss of habitat. ▪ Habitat Distribution: Permanent change in local movement. ▪ Survival and Reproduction: increased risk of injury/mortality on roads	Confirm effectiveness of road mitigation to minimize or eliminate the potential for road mortality in the LSA.	Exclusion fencing will be inspected for integrity	Annually during the construction and operations phases and closure.	Monitoring will be integrated into CNL's existing Species at Risk Program.
		Confirm effectiveness of road mitigation to minimize or eliminate the potential for road mortality in the LSA.	Road mortality surveys to be conducted weekly during pre-construction and operations within the NSDF Project site. During construction, mortality survey to be conducted daily during the species active period (April 15 to September 30).	On-going during construction and operation phases.	Monitoring will be integrated into CNL's existing Species at Risk Program.
Monarch butterfly	▪ Habitat Availability: Permanent, direct loss of 5 ha of suitable habitat. ▪ Habitat Distribution: Small, permanent change in local movement. ▪ Survival and Reproduction: Small reduction in reproductivity from habitat loss.	N/A[(a)]	N/A[(a)]	N/A[(a)]	N/A[(a)]

SSA = Site Study Area; LSA = Local Study Area; RSA = Regional Study Area; ECCC = Environment and Climate Change Canada; SARA = *Species at Risk Act*; N/A = not applicable.

[(a)]Monitoring programs are not proposed for monarch butterfly.

5.6.9 Conclusions

VCs refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Selection of VCs for the terrestrial biodiversity assessment was accomplished using a coarse and fine filter approach. Coarse filter VCs were identified to permit an assessment of the effects of the NSDF Project to terrestrial biodiversity broadly, whereas fine filter VCs focused the assessment on individual biodiversity features, such as species. Combined, the coarse and fine filter VCs were selected to provide a holistic assessment of the potential effects of the NSDF Project on terrestrial biodiversity.

All SARA-listed species with confirmed observation records within the CRL site were considered as potential VCs at the species level. Species with a very low likelihood of occurrence in the LSA, for which habitat was not present in the LSA, or for which effects of the NSDF Project were unlikely, were excluded as VCs. Rationale for inclusion and exclusion of each species at risk identified during surveys undertaken in the CRL site is presented in Appendix 5.6-1.

The VCs selected for the terrestrial biodiversity assessment were: vegetation communities migratory birds, Canada warbler, eastern whip-poor-will, eastern wood-pewee, golden-winged warbler, wood thrush, bats, Blanding's turtle, eastern milksnake and monarch butterfly. The assessment endpoint for terrestrial biodiversity is the maintenance of self-sustaining and ecologically effective vegetation communities or wildlife populations. Ecosystem availability, ecosystem distribution and ecosystem composition were selected as the measurement indicators for the vegetation communities VC. Habitat availability, habitat distribution, and survival and reproduction were selected as the measurement indicators for the terrestrial biodiversity species VCs.

Residual effects to terrestrial VCs are primarily associated with vegetation clearing and grubbing and the associated loss or alteration of existing vegetation and topographical features; sensory disturbance from NSDF Project activities during the construction and operations phases; and increased risk of injury/mortality on roads to Blanding's turtle and eastern milksnake due to equipment and vehicle traffic.

The cumulative effects from previous and existing activities and developments in the RSA on the population of terrestrial biodiversity VCs that overlaps with the RSA are predicted to be not significant for most VCs in the Base Case. Populations of little brown myotis, northern myotis and tri-colored bats that overlap the RSA are highly sensitive to changes in survival and reproduction because WNS has resulted in dramatic declines of these species across the eastern portions of their Canadian range, which includes the RSA. Therefore, the existing level of pressure on these bat species in the Base Case has likely already exceeded their resilience and adaptability limits and they are unlikely to be self-sustaining or ecologically effective. Consequently, the cumulative effects of existing disturbance and especially the introduced WNS are considered significant in the Base Case.

With the implementation of comprehensive mitigation, CNL's activities in the RSA are predicted to have a net neutral or positive effect on the local Blanding's turtle population during the Base Case. That is, the mitigation that is or will be implemented on the CRL Site is considered sufficient to limit and offset mortality from previous and existing anthropogenic activities in the RSA. There is uncertainty regarding the effectiveness of mitigation, but monitoring and adaptive management will be implemented so that CNL achieves a net neutral or positive effect (i.e., not significant) on the Blanding's turtle population at CRL.

In the Application Case, the NSDF Project will contribute small incremental adverse effects to most VCs, but in no case does the NSDF Project jeopardize the survival of the regional population of a VC. In the case of bats and Blanding's turtles, potential adverse effects are reduced or eliminated with substantial mitigation. For example, because vegetation clearing will be undertaken outside of the maternity roosting season, no mortality of roosting bats is expected as a result of the NSDF Project and effects or the NSDF Project to survival and reproduction are considered neutral. In addition, the remaining availability of potential maternity roosting habitat in the Application Case is not likely a limiting factor in the RSA, and CNL has committed to a comprehensive Sustainable Forest Management Plan to protect and improve roosting habitat in the RSA through time. Installation of bat boxes in suitable locations in the RSA has been undertaken to mitigate the incremental contribution of the NSDF Project to roost habitat loss. Monitoring conducted by CNL on existing bat boxes (installed in 2017) suggests that these are used, including as maternity roosts. This mitigation will further reduce the residual effect of the NSDF Project on bats. Therefore, the contribution of the NSDF Project to the existing significant adverse cumulative effect to bats is predicted to be negligible.

The NSDF Project would result in the long-term removal of 26 ha of proposed Blanding's turtle critical habitat during construction. This is a loss of upland habitat within the SSA that has the potential to be used for nesting, thermoregulation and summer inactivity. Critical habitat will be assessed annually to ensure no significant loss at CRL and to determine compensation measures initiated at CRL or elsewhere. Females who use the SSA for nesting may experience a reduction in reproductive success until they find new areas within which to nest. In addition, the interruption or barrier to Blanding's turtles moving through the SSA will result in the need to travel longer distances around the SSA in search of resources and will increase their risk of injury or mortality on roads. Increased traffic volume associated with the NSDF Project has the potential to increase road mortality, which is the primary potential contribution of the NSDF Project to existing significant adverse effects identified for Blanding's turtles.

The increase in traffic related to NSDF Project and consequently the risk of road injury or mortality, will not be significant, as CNL is currently upgrading infrastructures located in priority areas for the Blanding's turtle. The *Blanding's Turtle Road Mortality Mitigation Plan* is also currently being implemented at CNL. Mitigation specific to the NSDF Project will also improve conditions for Blanding's turtle on the CRL Site. In addition, the existing CNL Employee Education Program will be adapted to the NSDF Project prior to construction. All employees and contractors will be trained on the identification and safe handling of Blanding's turtle to help the turtles across the road. The removal of critical habitat for Blanding's turtle will require a SARA permit under Section 73(3).

With mitigation, the contribution of the NSDF Project to significant effects in the RSA is considered minor (Table 5.6.9-1). The weight of evidence suggests that, with mitigation committed to by CNL, effects from the NSDF Project will not jeopardize the survival of the regional Blanding's turtle population. With enough mitigation implemented at CRL, reductions in Blanding's turtle road mortality are possible, even with increased traffic volumes associated with the NSDF Project.

Table 5.6.9-1: Summary of Predicted Residual Adverse Effects for Terrestrial Biodiversity Valued Components

Valued Components	Assessment Endpoint	Residual Adverse Effects	Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation	Significance of the NSDF Project
Vegetation communities	Maintenance of self-sustaining and ecologically effective vegetation communities.	▪ Permanent loss of 33 ha of forested communities. ▪ Permanent changes to the distribution of forested habitats; no changes to the distribution of wetlands. ▪ Permanent edge effects may alter adjacent vegetation community richness.	All phases	▪ Vegetation clearing and grubbing	▪ The SSA has been designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. ▪ A 30 m buffer will be established along identified wetlands near the SSA; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion. ▪ A 5 m treeline buffer is established from all property lines on the SSA to limit disturbance to vegetation and large tree roots at the treeline.	Not Significant
Canada warbler	Maintenance of self-sustaining and ecologically effective populations.	▪ Permanent loss of 28 ha of suitable habitat. ▪ Possible long-term avoidance in the LSA from sensory disturbance. ▪ Permanent small change in movement in the LSA. ▪ Permanent small reduction in carrying capacity.	All phases	▪ Vegetation clearing and grubbing ▪ Mobilization of equipment ▪ Hauling of materials ▪ Blasting	▪ The SSA has been designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. ▪ A 30 m buffer will be established along identified wetlands near the SSA; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion. ▪ A 5 m treeline buffer is established from all property lines on the SSA to limit disturbance to vegetation and large tree roots at the treeline. ▪ Avoid conducting the activities with highest levels of noise and habitat disturbance during most sensitive life history phase (i.e., breeding and nesting for birds) by conducting vegetation clearing and grubbing before April 8 or after August 31 to avoid effects on nesting birds.	Not Significant
Eastern whip-poor-will		▪ Permanent loss of 2 ha of suitable habitat. ▪ Possible long-term avoidance in the LSA from sensory disturbance. ▪ Permanent small change in movement in the LSA. ▪ Permanent small reduction in carrying capacity.				Not Significant
Eastern wood-pewee		▪ Permanent loss of 18 ha of suitable habitat. ▪ Possible long-term avoidance in the LSA from sensory disturbance. ▪ Permanent small change in movement in the LSA. ▪ Permanent small reduction in carrying capacity.				Not Significant
Golden-winged warbler		▪ Permanent loss of 27 ha of suitable habitat. ▪ Possible long-term avoidance in the LSA from sensory disturbance. ▪ Permanent small change in movement in the LSA. ▪ Permanent small reduction in carrying capacity.				Not Significant
Wood thrush		▪ Permanent loss of 28 ha of suitable habitat. ▪ Possible long-term avoidance in the LSA from sensory disturbance. ▪ Permanent small change in movement in the LSA. ▪ Permanent small reduction in carrying capacity.				Not Significant

Table 5.6.9-1: Summary of Predicted Residual Adverse Effects for Terrestrial Biodiversity Valued Components

Valued Components	Assessment Endpoint	Residual Adverse Effects	Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation	Significance of the NSDF Project
Bats	Maintenance of self-sustaining and ecologically effective populations.	▪ Permanent loss of 28 ha of potential maternity roost habitat. ▪ Potential long-term avoidance of adjacent maternity roosting habitat in the LSA from sensory disturbance. ▪ Permanent negligible change in movement corridors between maternity roosting habitat patches.	All phases	▪ Vegetation clearing and grubbing ▪ Mobilization of equipment ▪ Hauling of materials ▪ Blasting	▪ The SSA has been designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. ▪ A 30 m buffer will be established along identified wetlands near the SSA; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion. ▪ A 5 m treeline buffer is established from all property lines on the SSA to limit disturbance to vegetation and large tree roots at the treeline. ▪ Avoid conducting the activities with highest levels of noise and habitat disturbance during most sensitive life history phase (i.e., maternity roosting for bats) by conducting vegetation clearing and grubbing before April 8 or after August 31 to avoid effects on bat maternity roosts. ▪ Bat boxes are relatively inexpensive and can be highly effective at providing habitat for roosting little brown myotis and possibly northern myotis. Tri colored bats are less likely to use bat boxes, but may use other forms of artificial roosting habitat; these options may be considered. Installation of bat boxes in suitable locations in the RSA is recommended to offset the incremental contribution of the NSDF Project to cumulative effects on SARA listed bats. ▪ In consultation with CNL biologists and in consideration of future losses of anthropogenic structures that may provide roosting habitat, offsetting in the form of 16 bat boxes was recommended. Bat boxes were installed in May 2017. Each two chambered box (Bat Conservation International approved design) was installed back to back on wooden poles in eight different locations around the proposed NSDF location. Occupancy was confirmed in July 2018 and has been increasing since then. This box design is suggested to have capacity for 350–400 individual bats per box, providing roosting habitat for a potential maximum of 6,400 individual bats (with 16 boxes). ▪ Criteria for appropriate siting included accessibility of box locations for installation and future monitoring of utilization/effectiveness, avoidance of areas with radiological contamination in surface water features and appropriate distance to anthropogenic disturbances to avoid sensory effects (i.e., noise). Immature forested areas adjacent to larger uncontaminated waterbodies and wetlands are high priority locations because these forest types do not currently provide high quality roosting habitat and would be most benefited by installation of bat roost boxes to expand the spatial coverage of potential roosting habitat within the RSA. Final site selection will be at the discretion of CNL biologists. ▪ Monitoring is being conducted at least weekly to determine if boxes are being used. Boxes not being used may be moved to an alternate location. ▪ A project in collaboration with Trent University is currently underway, where bats are being trapped and tracked back to the roost site (natural tree or bat box). Guano collection is being performed as well. This work has a duration of two years and will provide CNL with a better understanding of habitat occupancy by the bat species at risk, including bat boxes, and habitat preference. This work will support the objective of addressing knowledge gaps on the three bat species at risk ▪ A comprehensive Sustainable Forest Management Plan will be implemented to ensure the long-term retention of trees serving as maternity roosts for the bat species	Not Significant

Table 5.6.9-1: Summary of Predicted Residual Adverse Effects for Terrestrial Biodiversity Valued Components

Valued Components	Assessment Endpoint	Residual Adverse Effects	Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation	Significance of the NSDF Project
Blanding's turtle	Maintenance of self-sustaining and ecologically effective populations.	▪ Long-term loss of 26 ha of critical habitat with implementation of mitigation to ensure no significant loss of critical habitat; ▪ Permanent change in potential movement corridors between habitat patches ▪ Long-term increased risk of injury or mortality on roads from increased traffic (but mitigation may be sufficient to prevent this effect) ▪ Permanent increased risk of mortality from changes to movement patterns	All phases	▪ Vegetation clearing and grubbing ▪ Mobilization of equipment ▪ Hauling of materials ▪ Installation and maintenance of perimeter fencing	▪ The SSA has been designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. ▪ A 30 m buffer will be established along identified wetlands near the SSA; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion. ▪ A 5 m tree-line buffer is established from all property lines on the NSDF site to limit disturbance to vegetation and large tree roots at the treeline ▪ Critical Blanding's turtle habitat will be assessed annually to ensure no significant loss at CRL and to determine compensation measures initiated at CRL or elsewhere. ▪ Artificial nest mounds will be constructed on both sides of new and replaced culverts ▪ New and replaced culverts will be enhanced by planting native vegetation around the culvert entrances, while maintaining a clear line of site through the culvert ▪ Reptile exclusion fencing will be installed around the perimeter of the SSA prior to initiating activities during the construction phase and prior to the active Blanding's turtle season (i.e., prior to April). This mitigation will also benefit milksnakes. ▪ Damaged or ineffective fencing and signage will be repaired. ▪ Road grading and levelling activities will not be completed during the turtle terrestrial season (May 15 to September 30). ▪ Temporary exclusion fencing will be installed around the NSDF EMR footprint during construction of the NSDF Project. This temporary exclusion fencing will be replaced by permanent fencing by the end of construction of the NSDF Project. Exclusion fencing will benefit both Blanding's turtles and milksnakes. ▪ A road mortality survey will be completed for turtles and milksnake in the species' active seasons of April 15 to September 30 ▪ After replacement, culverts will have appropriate permanent fencing installed for 200 m on either side of the culvert to guide turtles through the tunnel. ▪ Following approval of the NSDF Project, additional permanent exclusion fencing will be installed in reptile hotspots along Plant Road ▪ Drivers have standard safety training and are provided with environmental awareness training. ▪ Enforce existing CRL site speed limits on access roads. ▪ Post signs warning drivers of high use wildlife areas and reduce speed limits in these areas. ▪ Employees in vehicles encountering wildlife of concern (e.g., Blanding's turtle) on roads are required to communicate the presence of wildlife on the roads to other employees working in the area and to CNL's Environmental Staff. ▪ The existing CNL Employee Education Program will be adapted to the NSDF Project prior to construction. All employees and contractors will be trained on the identification and safe handling of Blanding's turtle to help the turtle across the road. ▪ As per CNL's *Management of Land, Habitat and Wildlife* procedure (CNL 2018b), dead or wounded animals on roads must be reported to the environmental department. ▪ Blanding's turtle collisions with vehicles will be monitored, which provides feedback for adaptive management.	Not Significant

Table 5.6.9-1: Summary of Predicted Residual Adverse Effects for Terrestrial Biodiversity Valued Components

Valued Components	Assessment Endpoint	Residual Adverse Effects	Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation	Significance of the NSDF Project
Eastern milksnake	Maintenance of self-sustaining and ecologically effective populations.	▪ Direct loss of some suitable milksnake habitat ▪ Potential avoidance of otherwise suitable habitat due to sensory disturbance in the LSA Permanent small change in movement in the LSA ▪ Permanent small reduction in carrying capacity	All phases	▪ Vegetation clearing and grubbing ▪ Mobilization of equipment ▪ Hauling of materials ▪ Blasting	▪ A 5 m tree-line buffer is established from all property lines on the NSDF site to limit disturbance to vegetation and large tree roots at the treeline ▪ Temporary exclusion fencing will be installed around the NSDF EMR footprint during construction of the NSDF Project. This temporary exclusion fencing will be replaced by permanent fencing by the end of construction of the NSDF Project ▪ Damaged or ineffective fencing and signage will be repaired. ▪ Drivers have standard safety training and are provided with environmental awareness training. ▪ Enforce existing CRL site speed limits on access roads. ▪ Post signs warning drivers of high use wildlife areas and reduce speed limits in these areas. ▪ Employees in vehicles encountering wildlife of concern (e.g., milksnake) on roads are required to communicate the presence of wildlife on the roads to other employees working in the area and to CNL's Environmental Staff. ▪ The existing CNL Employee Education Program will be adapted to the NSDF Project prior to construction. All employees and contractors will be trained on the identification and safe handling of milksnake to help the snake across the road. ▪ As per CNL's *Management of Land, Habitat and Wildlife* procedure (CNL 2018b), dead or wounded animals on roads must be reported to the environmental department. ▪ Milksnake collisions with vehicles will be monitored, which will provide feedback for adaptive management	Not Significant
Monarch butterfly	Maintenance of self-sustaining and ecologically effective populations	▪ Permanent loss of 5 ha of suitable habitat. ▪ Permanent small change in movement in the LSA. ▪ Permanent small reduction in carrying capacity.	All phases	▪ Vegetation clearing and grubbing	▪ The SSA has been designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. ▪ A 30 m buffer will be established along identified wetlands near the SSA; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion. ▪ If vegetation clearing is scheduled in open habitat between late May and October, the habitat will be searched in advance of construction for the presence of milkweed. Removal of milkweed between May and October will be managed in accordance with CNL Environmental Protection Program.	Not Significant

5.7 Ambient Radioactivity and Ecological Health

This section of the Environmental Impact Statement (EIS) for the Canadian Nuclear Laboratories (CNL) Near Surface Disposal Facility (NSDF) Project seeks to understand and characterize existing ambient radioactivity at the Chalk River Laboratories (CRL) site. The focus of this section is to summarize the results of the ecological health assessments, specifically as they relate to effects to ecological (i.e., non-human) receptors from changes in ambient radioactivity as well as non-radiological effects to ecological receptors.

5.7.1 Scope of the Assessment

The ambient radioactivity and ecological health assessment follows the overall environmental assessment approach and methods described in Section 5.1 Environmental Assessment Approach. The assessment was completed following the key steps listed below:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** for the ambient radioactivity and ecological health assessment (refer to Sections 5.7.2 Valued Components and Section 5.7.3 Assessment Boundaries). The VCs and measurement indicators used to assess NSDF Project-related changes to ecological health are described, along with the spatial and temporal boundaries at which the assessment occurred and the assessment cases considered.
- **Step 2 – Describe the existing conditions** (refer to Section 5.7.4 Description of the Environment). Existing ambient radioactivity conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation), and provide a reference to which the effects of the NSDF Project can be compared.
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 5.7.5 Project Interactions and Mitigation). Project components and/or activities with the potential to change ecological health are identified and mitigation developed to limit or avoid effects are presented. A pathways analysis is then used to focus further assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects to ecological health. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects to ecological health after incorporating mitigation are carried forward to Step 4 for further analysis and residual effects characterization.
- **Step 4 – Present the methods and results of the residual effects analysis** (refer to Section 5.7.6 Residual Effects Analysis). This section summarizes the methods used to predict and characterize residual effects to ecological health from primary effects pathways. The results of the ecological risk assessment are presented including the characterization of residual incremental effects of the NSDF Project and the cumulative effects of the NSDF Project in combination with other reasonably foreseeable developments (if applicable).

- **Step 5 – Describe the level of certainty and management of uncertainty** (refer to Section 5.7.7 Prediction Confidence and Uncertainty). Evaluate the available literature, data and models used for the ecological health assessment and describe the level of certainty that can be placed on predicted residual effects. This section will also identify how the uncertainty has been managed so that the effects are not underestimated.
- **Step 6 – Classify and determine the significance of the predicted residual effects** (refer to Section 5.7.8 Residual Effects Classification and Determination of Significance). Residual effects predicted from primary pathways are classified and a determination of the significance of the predicted residual effects of the NSDF Project on ecological health is made. Relative to other sections, the ecological health assessment uses a slightly different approach to the classification of residual effects and evaluation of significance, because several of the criteria (e.g., geographical extent, duration, frequency and reversibility) are already incorporated into the risk estimates and, therefore, are not independent variables.
- **Step 7 – Identify monitoring and follow-up** required to confirm effects predictions and address uncertainty (refer to Section 5.7.9 Monitoring and Follow-up).
- **Step 8 – Present a consolidated summary of conclusions** and outcomes of the assessment of residual effects on ecological health (refer to Section 5.7.10 Conclusions).

Information and concerns raised by the public, communities of interest, and Indigenous Peoples during engagement that influenced the scope of the ecological health assessment are summarized in Table 5.7.1-1. Other general areas of interest and questions raised during the engagement that pertain to the ecological health assessment (if any) are documented in CNL's Indigenous Engagement Report (CNL 2021) and Stakeholder Activity Reports (CNL 2017a,b, 2019a).

Table 5.7.1-1: Summary of Issues Raised During Engagement Activities that Influenced the Scope of the Ecological Health Assessment

Issue	How the Issue Was Included in the Assessment
Effects on fish from potential for contamination in the Ottawa River from the NSDF Project	The spatial boundaries of the assessment were selected to include consideration of potential effects to the Ottawa River. The ecological health assessment considered potential changes in surface water in Perch Creek and meeting guidelines within the Perch Creek basin is protective of fish in the Ottawa River. The RSA was expanded to include a reach of the Ottawa River extending 8 km downstream of CRL in response to comments received from Indigenous communities and organizations, and the public.
Potential for radioactivity from gases from the capped facility	Potential changes in air quality from the NSDF Project were evaluated in the ecological health assessment during the operations phase.
Potential for changes in groundwater quality to affect uses downstream of the ECM	Potential changes in groundwater quality from the NSDF Project were evaluated in the ecological health assessment and included potential changes from treated effluent discharge from the WWTP, and seepage from the ECM during the operations phase and post-closure phase.
Treatment of leachate	Leachate from the ECM will be collected and pumped to the WWTP for treatment prior to discharge.
Potential leakage of leachate from the ECM	Potential leakage of leachate from the ECM during operations will be mitigated through the design and implementation of a composite base liner system, a leachate detection system and a leak collection system. Potential leakage from the ECM during the operations phase and post-closure phase is considered in the ecological health assessment.

WWTP = Wastewater Treatment Plant; ECM = engineered containment mound; RSA = Regional Study Area

5.7.2 Valued Components

VCs refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). A functioning ecosystem involves interactions of multiple species ranging in size and complexity from bacteria to apex wildlife predators. Each species is likely to respond differently to levels of substances present in environmental media (air, water, soil, vegetation, foodstuffs). Because it is not possible to directly assess the risk for each individual species, it is necessary to simplify the complex ecosystem into organism groups and trophic linkages. To this end, the general ecology of the NSDF Project site was reviewed using existing information and the species present were divided into major ecosystem components representing different potential health exposure pathways. Representative receptor taxa were selected as indicator species for each valued component and are listed in Table 5.7.2-1.

Representative receptor taxa were selected from those that are documented to occur or potentially occur in the local and regional study areas (see Section 5.7.3.1 Spatial Boundaries), have a relatively high potential for exposure to potentially affected media, play a key role in the food web and represent a variety of habits and trophic levels (CNL 2016a). A smaller group of indicator species was chosen to represent VCs selected for assessment. Indicator species were chosen based on at least one of the following criteria:

- reflective of the main exposure pathways, feeding habits and habitats, on the site, and particularly those associated with the highest exposures;
- known to reside on the site, and therefore, are potentially exposed to environmental effects from the NSDF Project;
- represent a major plant or animal group;
- represent their trophic level, resulting in representation for all trophic levels and therefore, all exposure pathways;
- sensitive to stressors;
- occupy a unique niche in the habitat or have a unique diet;
- ecologically significant (e.g., classified as species at risk); and
- have a special socio-economic importance or value (e.g., due to their economic value or cultural importance).

These indicator species (VCs) were used in the effects assessment to estimate potential exposures to radiological and non-radiological constituents. The indicator species listed in Table 5.7.2-1 include those species identified and assessed for biodiversity effects in Section 5.5 and Section 5.6.

Table 5.7.2-1: Valued Components and Indicator Species for Ecological Health Assessment

Environmental Component	Taxa	Category	Valued Components		Effects (Habitat, Exposure)	Indicator Species	Justification for Inclusion in Exposure Assessment
			Population Group or Habitat Type	Species (including Species at Risk or Regionally Rare Species)			
Aquatic environment	Benthic Macroinvertebrate	Crustaceans	n/a	n/a	Exposure	Benthic Invertebrates	Indicator species for changes in sediment quality
	Zooplankton	Crustaceans	Pelagic invertebrate	n/a	Exposure	Zooplankton	Indicator species for changes in water quality
	Fish	Small Pelagic forage (omnivores)	Fish and Fish Habitat	▪ Bluntnose Minnow ▪ Common Shiner ▪ Creek Chub ▪ Pumpkinseed ▪ Blacknose Shiner ▪ Fathead Minnow ▪ Pearl Dace	Habitat, Exposure	Bluntnose Minnow	Present in Perch Creek, represents small pelagic fish
		Small - Benthivorous	Fish and Fish Habitat	▪ Johnny Darter ▪ Brown Bullhead ▪ Black Bullhead Longnose Dace	Habitat, Exposure	Black Bullhead	Present in Perch Creek, represents small benthivorous fish
		Large - Benthivorous	Fish and Fish Habitat	▪ Lake Sturgeon ▪ White Sucker	Habitat, Exposure	n/a[(a)]	Not present in the LSA, where surface water concentrations are higher than in the Ottawa River
		Small - Carnivorous	Fish	▪ Logperch ▪ Fallfish ▪ Yellow Perch ▪ Mottled Sculpin	Habitat, Exposure	n/a[(a)]	Not present in the LSA, where surface water concentrations are higher than in the Ottawa River
		Large - Carnivorous	Fish	▪ Northern Pike	Habitat, Exposure	Northern Pike	Present in Perch Lake, represents Large Carnivorous fish

Table 5.7.2-1: Valued Components and Indicator Species for Ecological Health Assessment

Environmental Component	Taxa	Category	Valued Components		Effects (Habitat, Exposure)	Indicator Species	Justification for Inclusion in Exposure Assessment
			Population Group or Habitat Type	Species (including Species at Risk or Regionally Rare Species)			
Terrestrial Environment	Plant	Aquatic	Vegetation Communities	n/a	Exposure	Reed (food for predators)	Present in the wetlands in the LSA, represents aquatic vegetation communities, food chain
		Terrestrial	Vegetation Communities	n/a	Exposure	Red maple	Present in the LSA, represents terrestrial vegetation communities
	Insect	Pollinator	n/a	▪ Monarch butterfly	Exposure	Monarch butterfly	Present in the LSA, represents Pollinators
	Detritivore	Terrestrial Invertebrate	n/a	n/a	Exposure	Earthworm	Indicator species for changes in soil quality
	Mammal	Small - Insectivores	Bats	▪ Little brown myotis ▪ Eastern small-footed myotis ▪ Northern myotis ▪ Tri-coloured bat	Habitat, Exposure	Little brown myotis	Present in the LSA, represents small insectivores
		Small – Herbivore	n/a	n/a	Exposure	Meadow vole	Present in the LSA, represents small herbivorous mammals
		Large – Herbivore	n/a	n/a	Exposure	White-tailed deer[(b)]	Present in the LSA, represents large herbivorous mammals, public interest
		Large - Herbivore	n/a	n/a	Exposure	Moose	Present in the LSA, make use of aquatic habitat, represents large herbivorous mammals, Indigenous interest

Table 5.7.2-1: Valued Components and Indicator Species for Ecological Health Assessment

Environmental Component	Taxa	Category	Valued Components		Effects (Habitat, Exposure)	Indicator Species	Justification for Inclusion in Exposure Assessment
			Population Group or Habitat Type	Species (including Species at Risk or Regionally Rare Species)			
Terrestrial Environment (continued)	Mammals (continued)	Small - Omnivorous	n/a	n/a	Exposure	Short-tailed shrew	Present in the LSA, represents small omnivorous mammals
		Large - Omnivorous	n/a	n/a	Exposure	Black bear[(b)]	Present in the LSA, represents large omnivorous mammals, public interest
		Large - Carnivorous	n/a	▪ Eastern wolf	Exposure	Eastern wolf[(b)]	Present in the LSA, represents large carnivorous mammals, public interest
	Reptile	Semi-terrestrial	Turtle	▪ Blanding's turtle ▪ Snapping turtle	Habitat, Exposure	Snapping turtle[(c)]	Present in the LSA, represents semi-terrestrial reptiles (turtle)
		Semi-terrestrial	Snake	n/a	Exposure	Common watersnake	Present in the LSA, represents semi-terrestrial reptiles (snake)
		Terrestrial	Snake	n/a	Exposure	Eastern milksnake	Present in the LSA, represents terrestrial reptiles (snake)
	Amphibian	Semi-aquatic	Frog	n/a	Exposure	Green frog	Present in the wetlands in the LSA, represents semi-aquatic amphibians

Table 5.7.2-1: Valued Components and Indicator Species for Ecological Health Assessment

Environmental Component	Taxa	Category	Valued Components		Effects (Habitat, Exposure)	Indicator Species	Justification for Inclusion in Exposure Assessment
			Population Group or Habitat Type	Species (including Species at Risk or Regionally Rare Species)			
Terrestrial Environment (continued)	Bird	Small – Insectivores	Migratory birds	▪ Wood thrush ▪ Veery ▪ Eastern wood-pewee ▪ Black-throated blue warbler ▪ Least flycatcher ▪ Chestnut-sided warbler ▪ Common yellowthroat ▪ Mourning warbler ▪ Brown thrasher ▪ Golden-winged warbler ▪ Canada warbler	Habitat, Exposure	Canada warbler	Present in the LSA, represents small insectivores birds
		Large Insectivores	Migratory birds	▪ Eastern whip-poor-will ▪ Yellow-bellied sapsucker	Habitat, Exposure	Eastern whip-poor-will	Present in the LSA, represents large insectivore birds
		Small Omnivores	Migratory birds	▪ Purple finch ▪ Rose-breasted grosbeak ▪ White-throated sparrow	Exposure	Purple finch	Present in the LSA, represents small omnivore birds

Table 5.7.2-1: Valued Components and Indicator Species for Ecological Health Assessment

Environmental Component	Taxa	Category	Valued Components		Effects (Habitat, Exposure)	Indicator Species	Justification for Inclusion in Exposure Assessment
			Population Group or Habitat Type	Species (including Species at Risk or Regionally Rare Species)			
Terrestrial Environment (continued)	Bird (continued)	Large Omnivores	n/a	▪ Northern flicker ▪ Ruffed grouse	Exposure	Ruffed grouse	Present in the LSA, represents large omnivore birds
		Small Carnivores	n/a	▪ Belted kingfisher	Exposure	Belted kingfisher	Present in the LSA, represents small carnivore birds
		Large Carnivores	Raptors	▪ Bald eagle	Exposure	Bald eagle	Present in the LSA, represents large carnivore birds, public interest
		Small semi-aquatic	Waterfowl	▪ American black duck ▪ Mallard	Exposure	Mallard	Present in the LSA, represents small semi-aquatic birds, public interest
		Large semi-aquatic	n/a	▪ Great blue heron	Exposure	Great blue heron	Present in the LSA, represents large semi-aquatic birds, public interest

(a) These species are not selected as they do not represent the bounding case from dose assessment perspective.

(b) These species were not selected on basis of their large home range

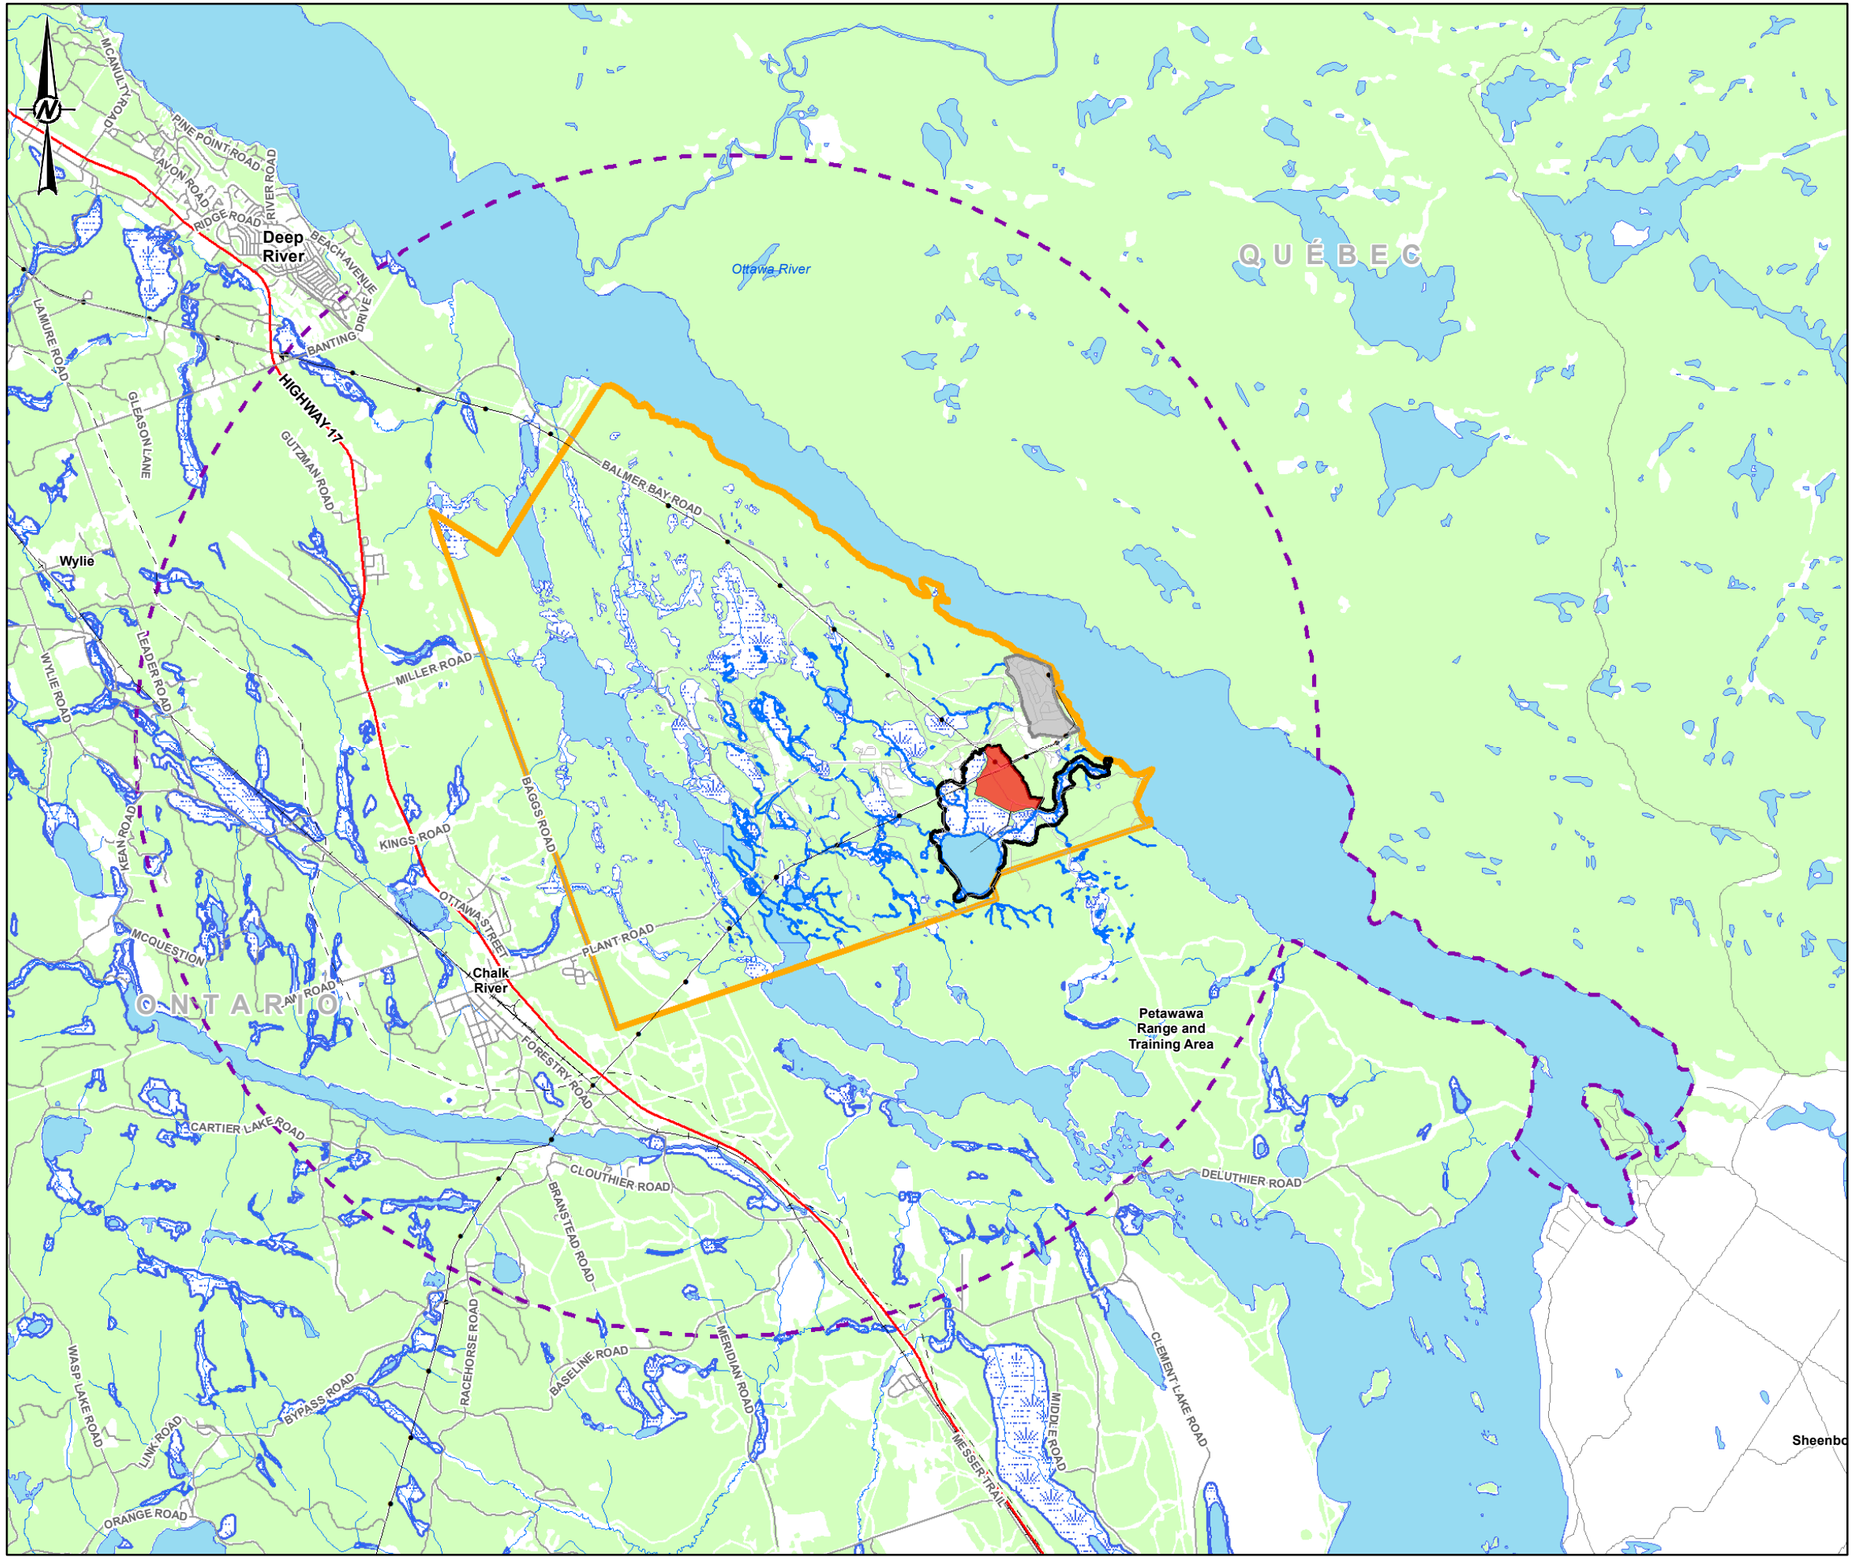
(c) Snapping turtle is selected as the surrogate for Blanding's turtle for exposure.

LSA = Local Study Area; n/a = not applicable.

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future human generations (i.e., incorporates sustainability). The assessment endpoint is the protection of ecological health. Measurement indicators represent properties of the environment, that when changed, could result in or contribute to an effect on an assessment endpoint. The measurement indicators for the ecological health assessment are outlined in Table 5.7.2-2.

Table 5.7.2-2: Assessment Endpoint and Measurement Indicators for the Ecological Health Assessment

Valued Component	Assessment Endpoint	Measurement Indicators
Indicator species listed in Table 5.7.2-1	Protection of ecological health	■ Changes to air quality ■ Changes to groundwater quality ■ Changes to sediment quality ■ Changes to surface water quality ■ Changes to soil quality ■ Changes to vegetation quality



5.7.3 Assessment Boundaries

5.7.3.1 Spatial Boundaries

The spatial boundaries for ecological health were thus selected to incorporate relevant portions of the study areas for air quality, groundwater quality and surface water quality to evaluate the environmental changes that could contribute to effects on ecological health. The spatial boundaries for the characterization of ambient radioactivity and subsequent effects assessment are as follows (Figure 5.7.3-1):

- **Site Study Area (SSA):** The SSA is the NSDF Project footprint (i.e., where NSDF Project activities would be undertaken, including the NSDF Project's proposed facilities, buildings and infrastructure).
- **Local Study Area (LSA):** The LSA is selected in consideration of the NSDF Project footprint and the spatial extent of potential direct effects of the NSDF Project on the VCs. The LSA adapted from the groundwater and surface water LSA and is designated as the spatial extent of the Perch Creek and Perch Lake Watershed, and includes Perch Lake and its tributaries and Perch Creek. The Ottawa River in the vicinity of the mouth of Perch Creek is also included in the LSA.
- **Regional Study Area (RSA):** The RSA is defined as the area within which the potential effects of the NSDF Project may interact with the effects of other existing or reasonably foreseeable developments. Ecological receptors in the vicinity of the engineered containment mound (ECM) could be exposed to airborne and waterborne emissions, as well as direct gamma radiation from the waste. Doses to ecological receptors exposed to the aquatic habitat of East Swamp Stream were calculated to provide a bounding estimate of potential exposure. Therefore, the RSA for ecological health is a combination of the air quality and aquatic environment RSAs as this is the largest extent of potential cumulative effects on ecological health. The air quality RSA is defined as an approximately 7.4 km circular radius surrounding the LSA, and the aquatic RSA extends roughly 8 km downstream in the Ottawa River to Harrington Bay.

5.7.3.2 Temporal Boundaries

Temporal boundaries (i.e., project phases) establish the timeframe during which NSDF Project effects are assessed. The temporal boundary represents the timeframe during which project activities are actively occurring and considers the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a Project activity or stressor (which is related to the project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the NSDF Project or if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the NSDF Project:

- **Construction phase**: This phase includes site preparation and all activities associated with the construction of the NSDF Project. This phase includes activities such as installing the necessary supporting and/or ancillary facilities and infrastructure to facilitate NSDF Project operations, inactive commissioning and systems testing, and transportation of construction materials. Construction activities are expected take place from 2022 to 2024.
- **Operations phase**: This phase includes all activities associated with waste placement, water management, Wastewater Treatment Plant (WWTP) operations, vehicle movements into and from the SSA, and maintenance activities. Operations activities are expected to last approximately 50 years (i.e., 2025 to 2070).
- **Closure phase:** includes activities necessary to complete the installation of the final cover and implementation of long-term monitoring. Closure activities are expected to start in 2070 and continue through to 2100, after which the NSDF Project will transfer into the post-closure phase.
- **Post-closure phase:** has two discrete periods: institutional control and post-institutional control. The institutional control period includes implementation of controls throughout 2100 to 2400 (i.e., 300 years). During institutional control, environmental monitoring will continue to demonstrate compliance with the environmental assessment conditions. Post-institutional control occurs after year 2400 and continues indefinitely.

5.7.3.3 Assessment Cases

The assessment cases considered in the ambient radioactivity assessment include the Base Case and Application Case (the Reasonably Foreseeable Developments Case has not been considered for the reasons outlined below):

- **Base Case:** This scenario represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural, mining, and residential and recreational development. Current effects from the existing CRL facilities and operations, for example, are considered part of the Base Case.
- **Application Case:** This scenario represents predictions of the effects of the Base Case combined with the effects that may result from the NSDF Project. The Application Case considers potential effects from the NSDF Project during the operations phase and the post-closure phase.

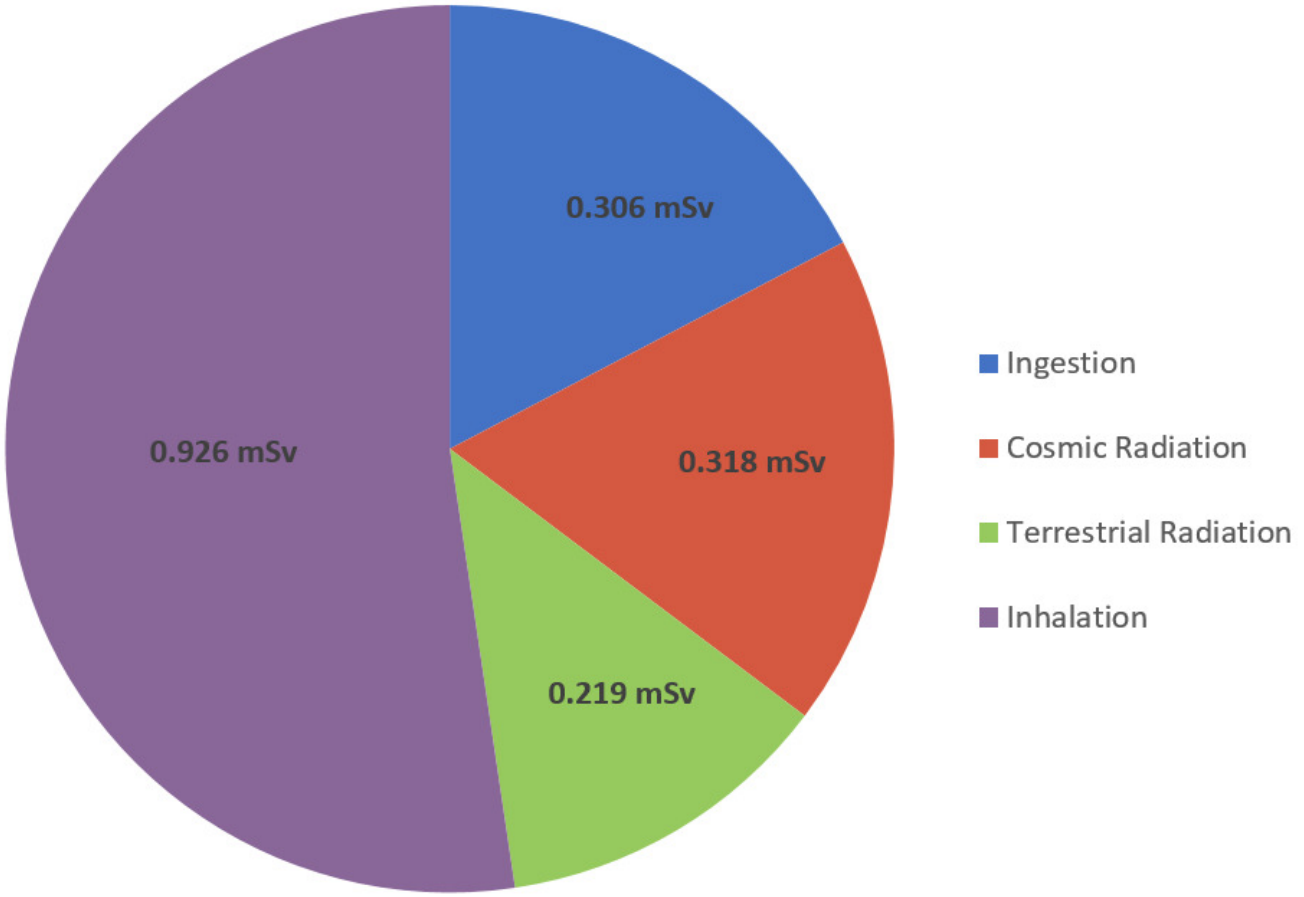
- **Reasonably Foreseeable Developments (RFD) Case:** This scenario represents predictions of the cumulative effects of the Application Case, which includes the Base Case, plus projects that are currently under application review or that have officially entered a regulatory application process, and are therefore, considered reasonably foreseeable. Because RFDs will either have no spatial overlap or are likely to positively affect ecological health, an RFD Case is not presented as part of this assessment. RFDs within the CRL site (i.e., the RSA) include only the new or upgrades to research and development facilities, construction and operations of the Small Modular Reactor, new support infrastructure, and on-going decommissioning and environmental remediation activities. Revitalization projects at the site (i.e., new or upgrades to research and development facilities, new support infrastructure) and decommissioning include several small projects staged over a 10-year period where best practices, mitigation and monitoring for management of emissions will to be followed. No process intakes of water from or discharges to surface or groundwater, or releases to air beyond the potential for a limited amount of steam from dry cooling towers are identified in the description of the planned Small Modular Reactor (Global First Power 2019). During normal operations, the Small Modular Reactor will introduce a very small radiological exposure to the environment near the plant, within the CRL site (Global First Power 2019). The incremental radiological (in proximity to the Small Modular Reactor) and non-radiological emissions from RFD Projects at any one time are expected to be small, distributed across the CRL site and removed from the more intensive activities within the SSA (i.e., the NSDF Project footprint).
- The NSDF Project will enable the remediation of contaminated lands and legacy waste management areas (WMAs) and decommissioning of outdated infrastructure at the site and CNL's other business locations to support future CNL work. The end-state plan for the CRL site will be to return lands disturbed by site activities to a condition that is physically stable and safe in keeping with the land use and landscape of the day. Therefore, decommissioning and environmental remediation activities are anticipated to positively affect ecological health.

5.7.4 Description of the Environment

This section uses effluent and environmental monitoring data from CRL and the surrounding area to establish a Base Case characterization of ambient radioactivity in environmental media. It describes the current CRL radiological effluents and the environmental concentrations of radiological contaminants for each environmental medium that could potentially be affected by the NSDF Project. Where possible, five-year datasets (e.g., from 2014 to 2018) are provided.

5.7.4.1 Background Sources of Radiation and Radioactivity

Background radiation and radioactivity is present in the environment due to natural and anthropogenic (human-made) sources independent of CRL operations. The magnitude of radiation dose from natural sources varies greatly, both spatially and temporally. The main natural sources of radiation are cosmic rays; naturally occurring radionuclides in air, water and food; and naturally occurring radionuclides in the soil, rocks and building materials used in homes (CNSC 2013).



Cosmic radiation originates from celestial events and the sun. This cosmic radiation and the secondary particles produced penetrate the Earth's atmosphere and give an external radiation dose at the Earth's surface. Naturally occurring radionuclides such as uranium, potassium and thorium are present in soils, rocks and building materials. These naturally occurring radionuclides also contribute to the external gamma radiation dose. Naturally occurring radionuclides are also incorporated into plants, animals and water from surrounding soils and rocks. Humans ingest these foodstuffs and receive an internal radiation dose. Radon gas, a product of the decay of uranium in soil, is inhaled and also contributes to the internal radiation dose.

The average annual doses in Canada are shown on Figure 5.7.4-1; the total annual dose of natural background radiation is approximately 1.8 millisieverts (mSv) (CNSC 2013).

Some radionuclides released from CRL are already present in environmental media due to natural and anthropogenic sources, such as atmospheric fallout from global weapons testing. Where applicable, environmental concentrations are compared to expected background levels or measurements of samples from reference areas outside the RSA, in order to distinguish the effect of CRL operations from radiological contamination that is present due to other sources.

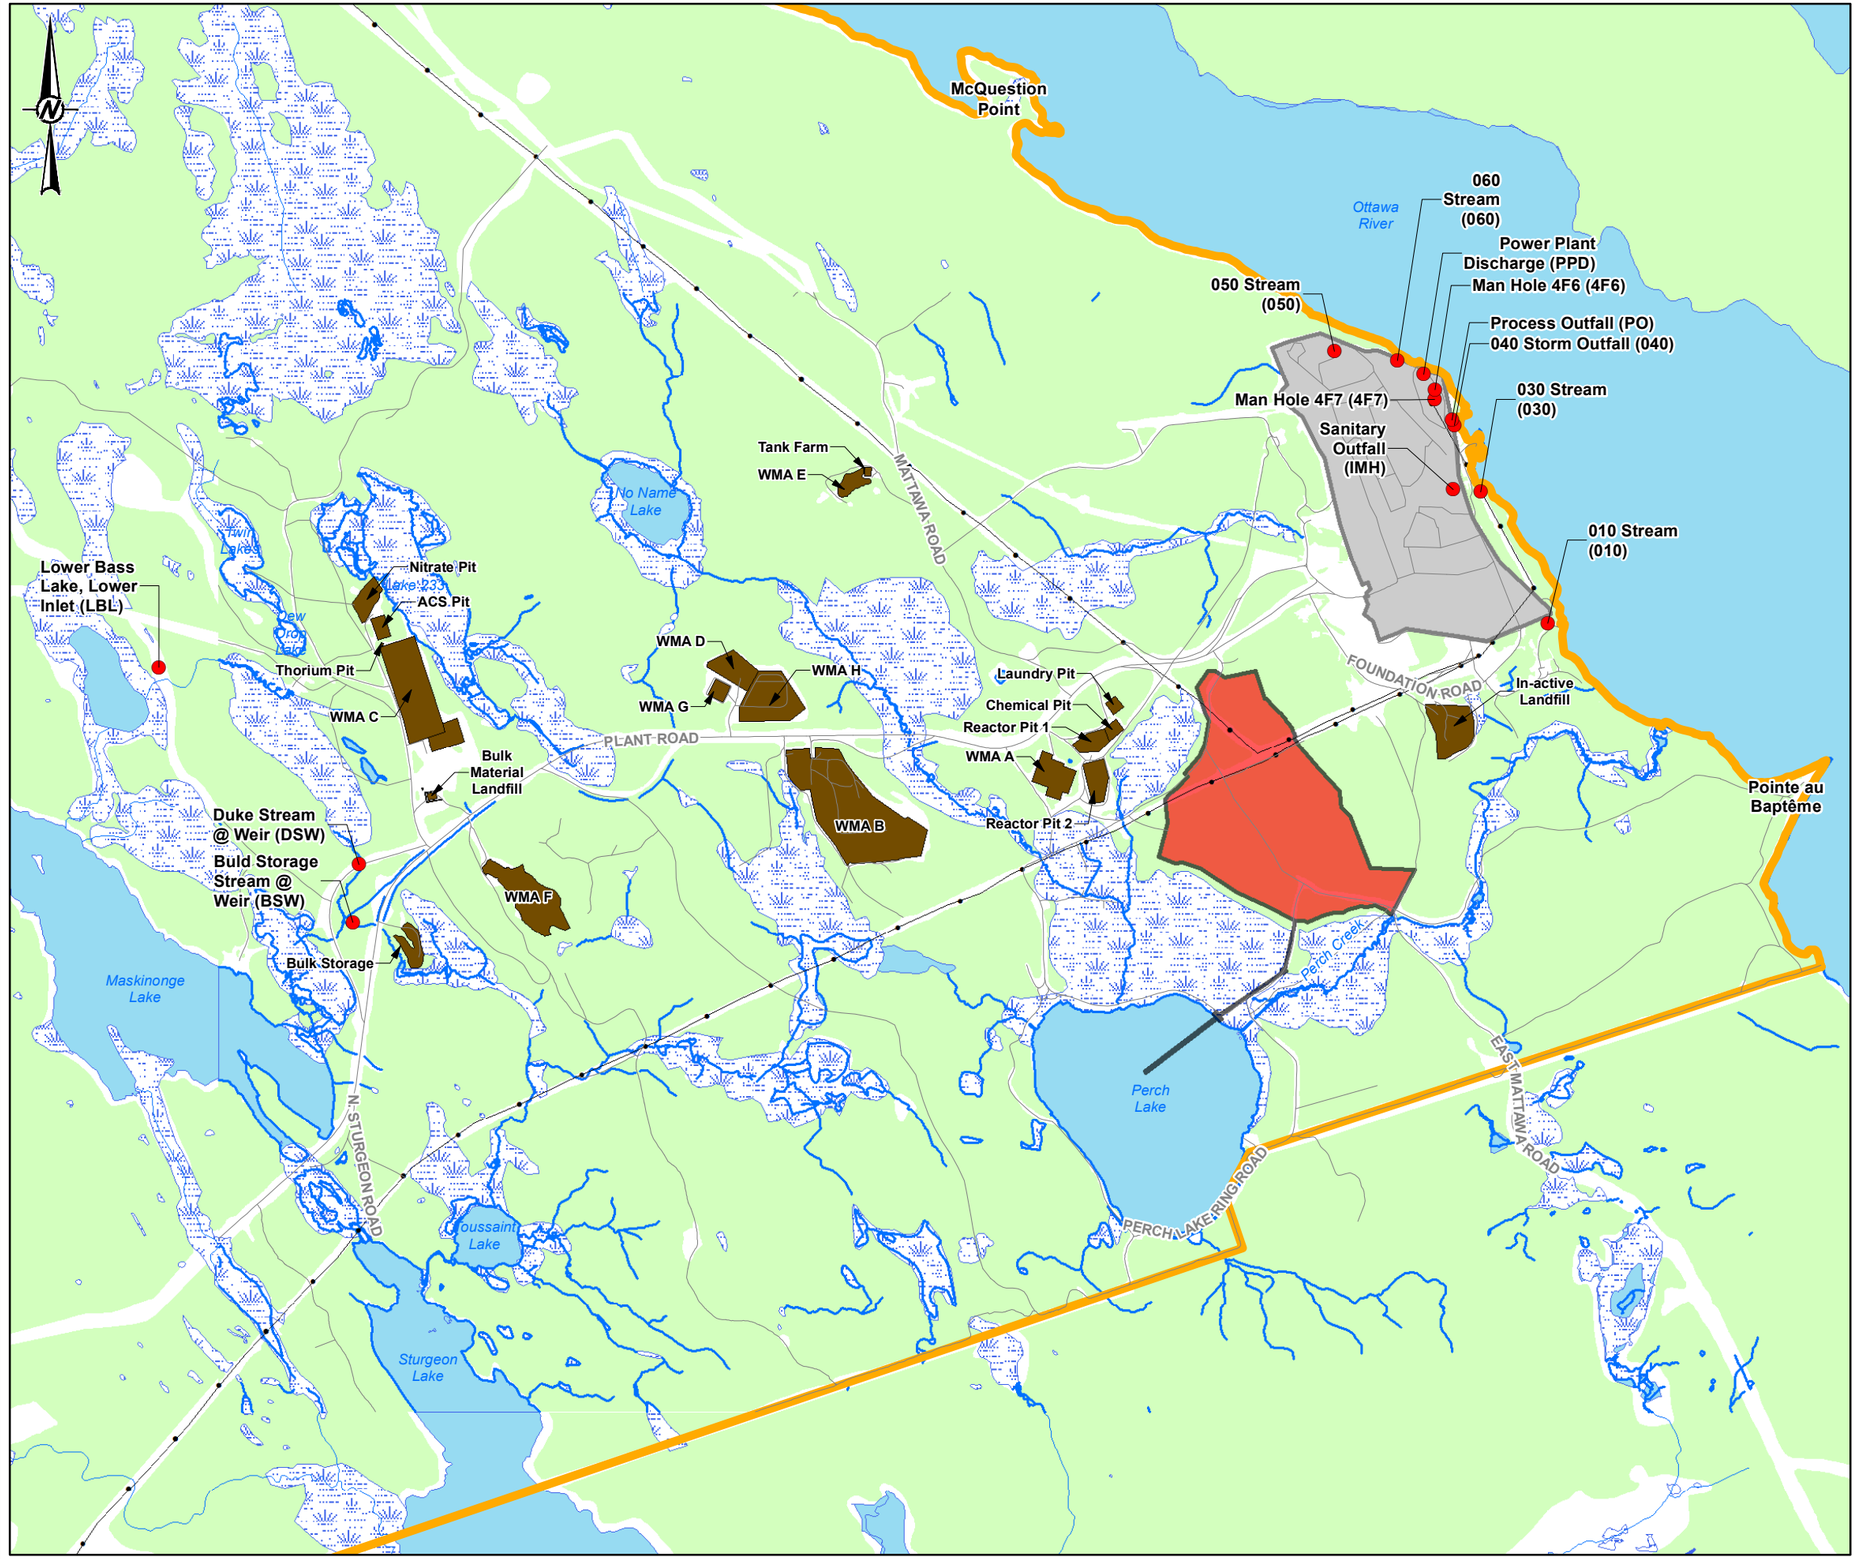
5.7.4.2 Radioactive Releases from Chalk River Laboratories

This section summarizes the radioactive releases from CRL operations to the environment, including airborne and liquid effluents. The airborne radiological Effluent Verification Monitoring Program includes continuous monitoring of argon-41, mixed fission product noble gases, carbon-14, tritium oxide, elemental tritium, iodine-125, iodine-131, gross alpha particulates and gross beta particulates, from applicable operational facilities on the CRL site.

In 2018, the major sources of airborne radiological effluent from CRL operations (CNL 2019b) were:

- the B109 stack that exhausts ventilation and cooling air from the National Research Universal (NRU) reactor; and
- secondary roof vents and fugitive emissions exhausting various rooms within NRU.

The liquid radiological Effluent Verification Monitoring Program includes 13 monitoring points, in addition to upstream monitoring points used for reference. These locations are routinely monitored for gross alpha particulates, gross beta particulates and tritium oxide. Depending on the monitoring location, liquid effluent monitoring is performed at these locations using automatic samplers, weekly or monthly grab samples, or composite sampling. Tritium, gross alpha and gross beta are analyzed at least monthly for all monitoring locations, and weekly for the CRL site Process Sewer and Sanitary Outfall. Gamma spectroscopy is performed on liquid effluent samples at a frequency ranging from weekly to annually or as needed, depending on the effluent stream. CRL's radiological liquid effluent monitoring locations are shown on Figure 5.7.4-2. The environmental monitoring locations are discussed later in this section.



In 2018, the major sources of liquid radiological effluent at CRL site and the associated monitoring locations (CNL 2019b) are as follows:

- NRU reactor, Waste Treatment Centre (monitored at the Process Outfall);
- active laundry facility (monitored at the Sanitary Outfall);
- surface water and groundwater runoff from the WMAs (monitored at on-site surface waters); and
- groundwater discharges to the Ottawa River from sources inside the Controlled Area (monitored with on-site groundwater wells).
- It is noted that the NRU reactor and Moly Production Facility were placed in a safe shutdown state on March 31, 2018, and the active laundry facility ceased operations during 2018.

Leachate from WMA A and the Liquid Dispersal Area (LDA) may be particularly relevant due to their proximity to the SSA. These are sources of strontium-90 and tritium, which are monitored as part of the CRL Environmental Monitoring Program (CNL 2018a), and are monitored downstream at the Perch Creek weir effluent monitoring location. Monitoring includes monitoring downgradient of the WMAs and surface waterbodies in various locations.

The annual sum of airborne and liquid effluent releases from 2014 to 2018 is presented in Table 5.7.4-1. Derived Release Limits (DRLs) have been developed for the CRL site based on Canadian Standard Association (CSA) Standard N288.1-14 (CSA Group 2014). They are calculated limits for airborne and liquid releases of radionuclides such that the highest radiation dose to a member of the public does not exceed 1 mSv. While DRLs are relevant to the dose received by off-site human receptors, they are provided in this section only for context regarding the magnitude of releases. The major radiological contaminants in terms of percentage of DRL are argon-41 (0.74% of DRL in 2018), iodine-131 (0.0003% of DRL in 2018), mixed fission product noble gases (0.003% of DRL in 2018) and airborne tritium oxide (0.002% of DRL in 2018).

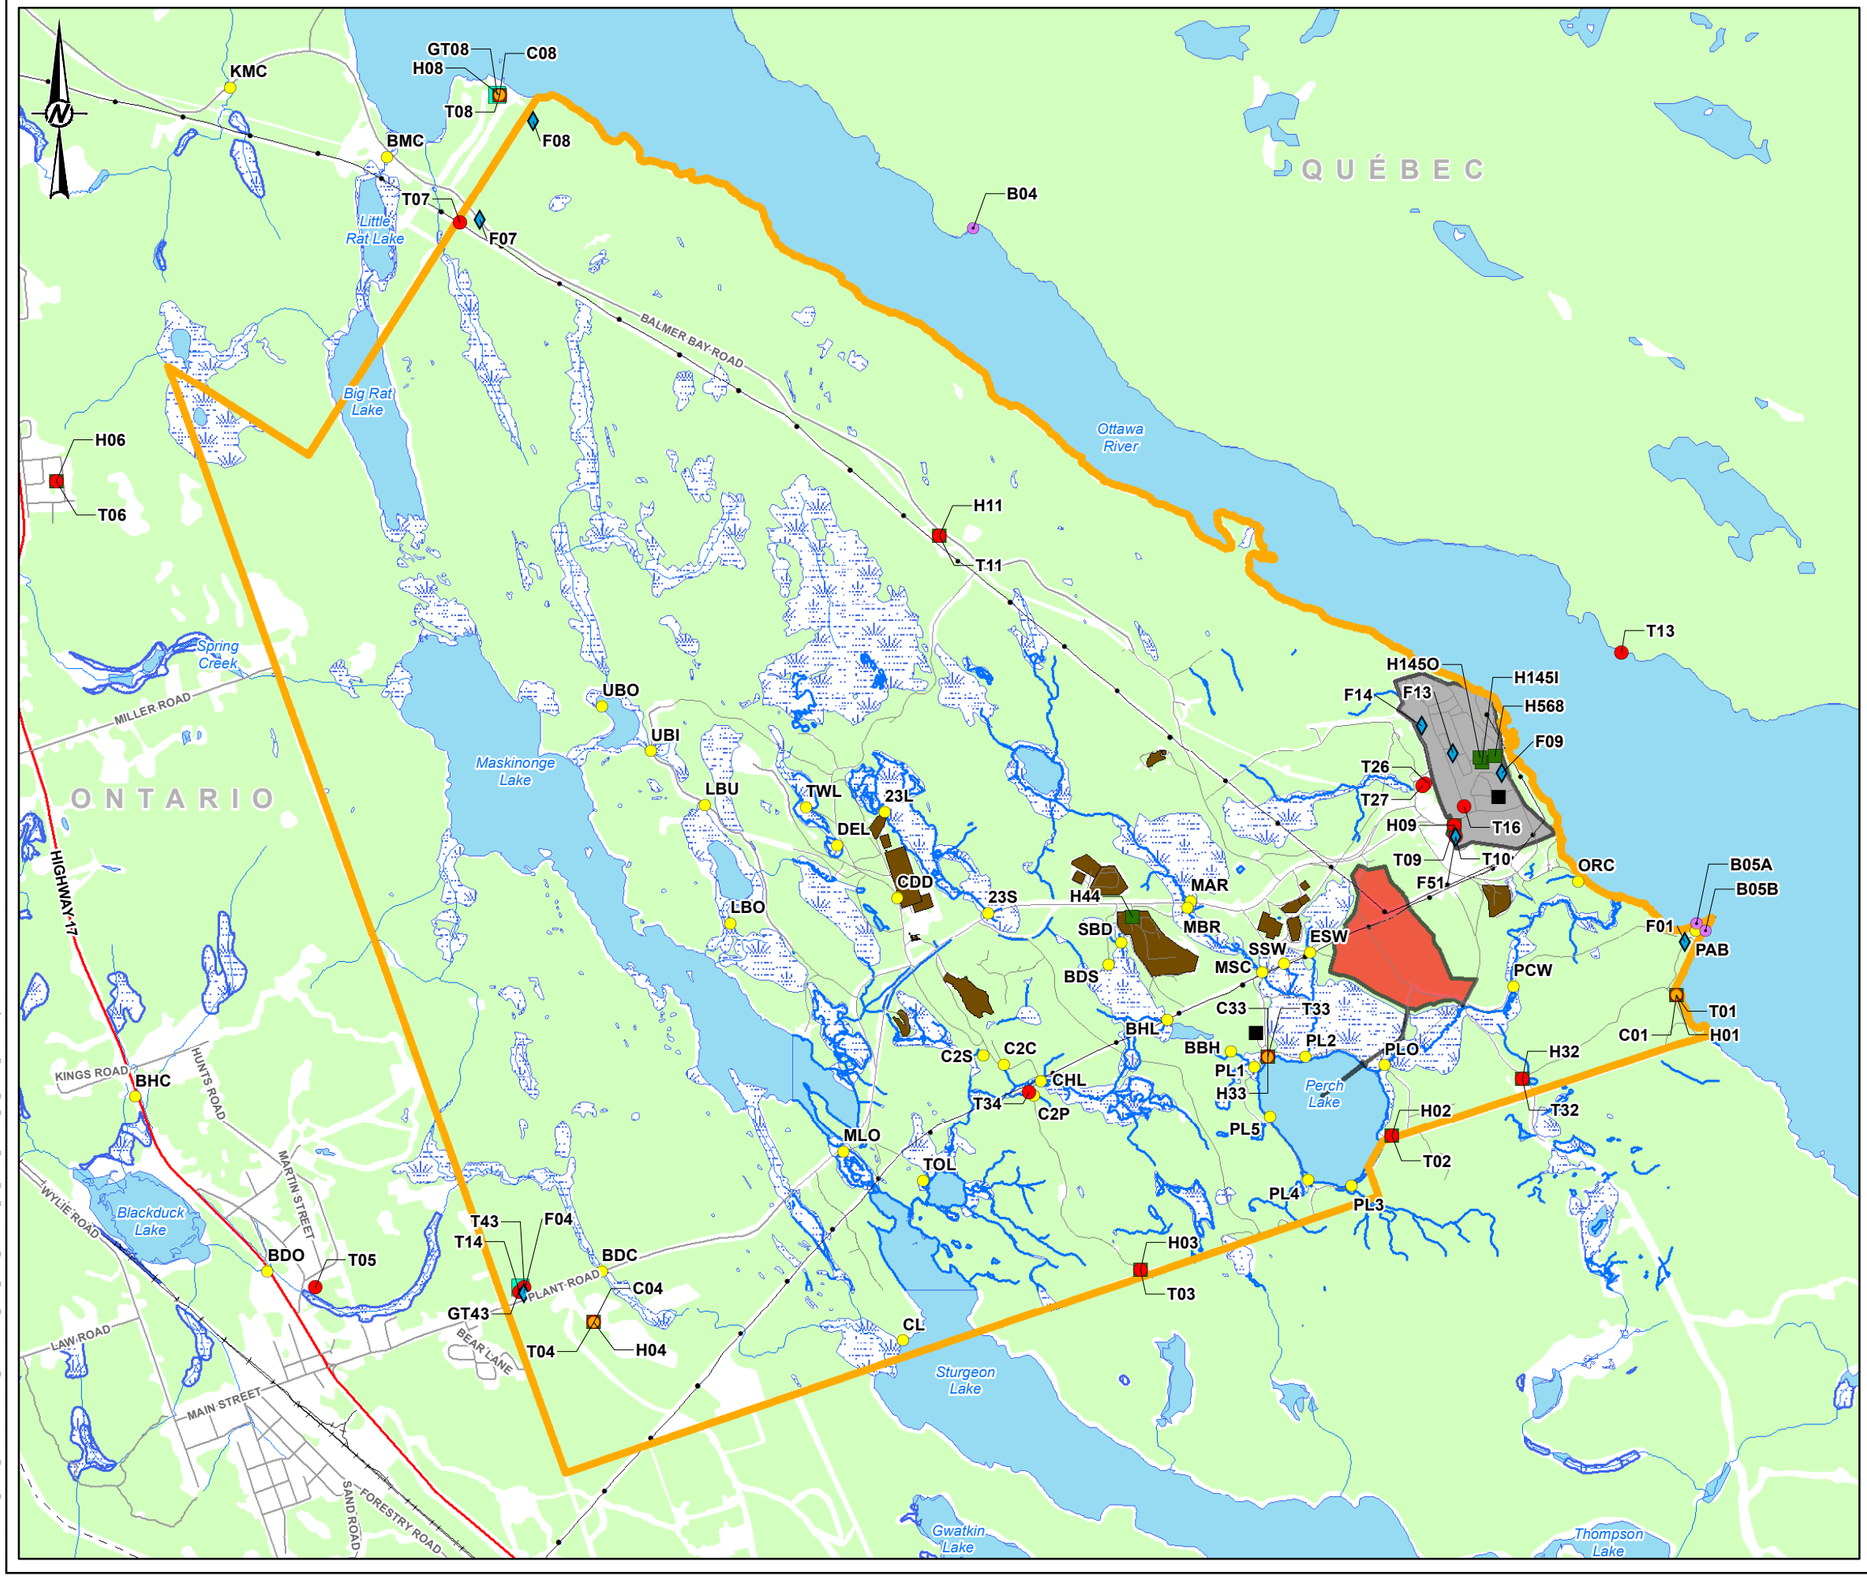
Source: CNL 2019b, c.

Note: The release limits listed above are about one third of the Derived Release Limits to account for the CRL site dose constraint of 0.3 mSv/yr to the most exposed critical group

Bq/yr = Becquerels per year; BqMeV/yr = Becquerels-mega-electron volts per year; mSv/yr = millisieverts per year.



1) Derived Release Limits for airborne releases are effluents released from CRL Stacks. Derived Release Limits for airborne releases are calculated in Bq/week and are listed here as Bq/year. Derived Release Limits for liquid releases are for liquid effluents from the CRL Process Outfall to the Ottawa River. Derived Release limits for liquid releases are calculated in Bq/month and are listed here in Bq/year.

5.7.4.3 Environmental Monitoring Program

This section describes the Environmental Monitoring Program within and outside of the CRL site boundary. The environmental monitoring program is the source of the Base Case radioactivity characterization data described in subsequent sections. The characterization of Base Case radioactivity utilizes an eight-year dataset from 2011 to 2018; this is considered to be the most accurate dataset in terms of representing the background radioactivity at CRL prior to NSDF operations. It is noted that additional future site activities may affect the Base Case radioactivity prior to NSDF operations. For example, on March 31, 2018, the NRU was placed into a guaranteed safe shutdown state followed by storage with surveillance thus an overall reduction in related emissions is anticipated in future years. The reactor will remain in that state until decommissioning, which is currently scheduled to begin in 2028 (CNL 2019b).

The CRL Environmental Monitoring Program includes sampling and analysis of surface water, groundwater, sediment, soil, vegetation, ambient air, milk, garden produce, game animals, farm animals and fish (CNL 2018a). Environmental monitoring of radiation in air includes continuous monitoring stations for ambient gamma, noble gases, carbon-14 and tritium. Results are reported in the annual CRL Environmental Monitoring Report. Monitoring of soil and vegetation on the CRL site has been performed through supplementary studies, including plume update studies and wetland contamination surveys conducted through the CRL Groundwater Monitoring Program.

Monitoring locations are displayed for the on-site portion of the CRL Environmental Monitoring Program on Figure 5.7.4-3. Off-site monitoring locations for radioactive air monitoring and radioactive liquid/biological monitoring are shown on Figure 5.7.4-4 and Figure 5.7.4-5, respectively. A summary of the radiological Environmental Monitoring Program monitoring parameters is shown in Table 5.7.4-2 and are described in more detail in the following sections.

TLD = Thermoluminescent Dosimeters.

5.7.4.4 Radioactivity in the Atmospheric Environment

Airborne radiological contaminants are monitored as part of the CRL Environmental Monitoring Program. This includes measurements of ambient gamma dose, noble gas dose, tritium in air and carbon-14 in air. Monitoring is undertaken on the CRL main campus, at the CRL site boundary and at relevant off-site locations.

5.7.4.4.1 Ambient Gamma Dose

Ambient gamma dose measurements performed using Thermoluminescent Dosimeters (TLDs) yield total annual dose, including dose imparted by natural background sources and dose associated with releases from CRL operations. All TLD measurements have been corrected for exposure during storage, handling and transport by subtracting the exposure received by control TLDs. These control TLDs are housed during the measurement period within lead shielding in a specifically constructed building at CRL, where background radiation from subsoil, radon and building materials is very low. Consequently, the reported TLD results do not include exposure from high-energy cosmic radiation that penetrates the low background building and lead shielding in which the control TLDs are stored. The locations of all TLDs are shown in Section 5.7.4.3.

The TLD results are compared to the expected terrestrial gamma radiation dose in Ottawa, which occurs as a result of naturally occurring radionuclides in the earth, air and building materials. The outdoor external radiation dose rate in locations throughout Canada has been characterized based on TLD measurements at Canadian Environmental Stations from 1976 to 1984 (NCRP 1987). The closest monitoring location utilized in this study is Ottawa, approximately 185 km southeast of the CRL site. After subtracting the contribution of cosmic radiation, the average external gamma radiation dose from terrestrial radiation in Ottawa is approximately 282 plus/minus 114 microgray[1] (µGy) per year. The annual doses measured from 2014 to 2018 in the SSA, LSA and RSA are shown in Table 5.7.4-3.

While no TLDs are placed within the NSDF Project site, one is located near Perch Lake within the LSA. Remaining TLDs in the vicinity of the CRL site are considered to be representative of the RSA, and additional TLDs are located at population centres beyond the RSA. The Perch Lake TLD has measured annual doses ranging from 298 to 327 µGy from 2014 to 2018 (CNL 2019b). The TLDs placed within the RSA have measured annual doses ranging from 265 to 644 µGy from 2014 to 2018 (CNL 2019b). Doses were comparable to the average terrestrial gamma radiation in Ottawa for all LSA monitoring locations except the Main Gate location, which is within the CRL main campus. This monitoring location recorded the highest doses of all TLDs in the monitoring program, with 2014 to 2018 annual doses ranging from 482 to 644 µGy (CNL 2019b). Annual doses at locations beyond the RSA have ranged from 263 to 461 µGy from 2014 to 2018 (CNL 2019b). Doses at some of these locations exceed the average terrestrial gamma radiation measured in Ottawa (282 ±114 µGy/yr). Additional discussion regarding the contribution of CRL emissions to ambient gamma dose is included in Section 5.7.4.4.2 Radioactive Noble Gas.

In addition to these TLD doses recorded annually, ambient radiation surveys have been conducted at specific areas throughout CRL, as a means of assessing possible contamination associated with groundwater plumes. Of particular interest with respect to the NSDF are ambient radiation surveys conducted at the East Swamp, which is immediately west of the NSDF and may be affected by NSDF operations. The East Swamp has existing contamination due to groundwater plumes from the Chemical Pit and Reactor Pit 2 as a result of legacy operations. Surveys conducted in 2002 and 2012 at the East Swamp have included measurements of ambient

[1] Note: 1 Gy = 1 Sv for external gamma radiation.

radiation over a 15 m by 15 m grid, covering a 150 m by 250 m area, and collected ambient dose rates at approximately 1 m height. In 2002, the ambient radiation levels in the East Swamp coincided with the Chemical Pit groundwater plume and reached a maximum of 13,500 nanosieverts per hour (nSv/hr). In the 2012 survey, radiation field locations were similar, but the maximum dose rate was 4,000 nSv/hr. Dose rates primarily resulted from gamma-emitting radionuclides in surface soil and vegetation. Monitoring of these media is discussed in Section 5.7.4.7 Radioactivity in Soil. Ambient radiation fields measured in East Swamp in 2012 are shown on Figure 5.7.4-6.

5.7.4.4.2 Radioactive Noble Gas

Continuous monitoring of dose rate from airborne noble gases is performed at five locations of interest. This is accomplished with dual Geiger tube GammaTRACER systems, allowing the external gamma dose rate resulting from CRL operations to be distinguished from background. This contribution is primarily from the noble gas argon-41. Measurements of total noble gas ambient dose equivalent are shown in Table 5.7.4-4.

No monitoring of noble gas is performed within the SSA. One GammaTRACER is placed at the southwestern edge of the CRL site, and one is at the northwestern edge near Balmer Bay. These locations are within the RSA.

From 2014 to 2018, the annual gamma dose within the RSA attributable to noble gases released from CRL operations have ranged from 6.1 microsieverts (µSv) to 83.2 µSv. Doses are generally highest near Balmer Bay since it is in the path of prevailing wind from the atmospheric releases on site (CNL 2019d). It is noted that due to variability in releases and environmental conditions, this observation is not necessarily true each year (e.g., noble gas dose is higher at Harrington Bay in 2015). Three GammaTRACERs are placed at population centres beyond the RSA. From 2014 to 2018, the annual gamma dose at these locations attributable to noble gases released from CRL operations have ranged from 7.4 to 90.6 µSv.

Table 5.7.4-4: Noble Gas Annual Dose Measured by GammaTRACERs (µSv)

	2014	2015	2016	2017	2018	2014–2018 Average

Deep River (GT24)	26.5	32.1	57.4	48.1	7.4	34.3
Petawawa (GT35)	24.1	40.8	49.8	31.7	10.4	31.4

Source: CNL 2019b.

Note: GammaTRACER units are calibrated to ambient dose equivalent, H*(d), with d = 10 mm (ICRP 1991).

µSv = microsieverts; N/A = not available.

Measurements of noble gas dose at the locations above provide an indication of the contribution of CRL emissions to the annual ambient gamma doses described in Section 5.7.4.4.1 Ambient Gamma Dose. By subtracting noble gas doses from TLD measurements[2], the terrestrial background dose in the absence of CRL noble gas emissions may be distinguished. This is shown in Table 5.7.4-5 for the four locations where TLDs and GammaTRACERs are co-located. It is observed that after subtracting the contribution of CRL noble gas emissions, the terrestrial gamma dose at all four locations is comparable to the average terrestrial gamma dose for Ottawa (282 ±114 µGy/yr).

[2] Prior to subtracting noble gas dose from TLD values, the noble gas doses in µSv were converted to absorbed dose in air (air kerma [i.e., kinetic energy released in matter]) using a conversion factor of 1.2 µSv/µGy (Klemic et al. 1999).

Table 5.7.4-5: Average Annual Chalk River Laboratories Noble Gas Dose Compared to Ambient Gamma Dose

	2014–2018 Average Ambient Gamma Dose Measured by Thermoluminescent Dosimeters (µGy)	2014–2018 Average Noble Gas Dose Measured by GammaTRACER (µGy)	2014–2018 Ambient Gamma Dose Without CRL Noble Gas Contribution (µGy)
Balmer Bay (A08/GT08)	373	64	316
Building 560 (A43/GT43)	361	22	318
Harrington Bay (A15/GT15)	415[(a)]	48	392
Petawawa (A35/GT35)	370	31	347

(a) This average omits the value recorded in 2014, in order to achieve consistency with respect to the GammaTRACER dataset, which does not include a measurement from 2014.

µGy = microgray.

5.7.4.4.3 Tritium in Air

Ambient tritium in air is monitored at locations throughout the CRL main campus, at the CRL site boundary and at population centres off site. Tritium is monitored using passive diffusion samplers. These are liquid scintillation vials containing a solution of 50% glycol and 50% water, designed to sample air at a rate of 1 L/day. These samples are collected and analyzed quarterly using liquid scintillation counting[3]. The reported annual average tritium concentrations are calculated based on these quarterly measurements; uncertainties are reported in the CRL *Environmental Monitoring Report* based on counting statistics (CNL 2019b).

No ambient tritium monitors are within the boundary of the SSA. The Perch Lake Main monitoring station is located within the LSA. From 2014 to 2018, the average tritium concentrations in air at this location are less than 2.3 Becquerels per cubic metre (Bq/m^3). From 2014 to 2018, average tritium concentrations in the RSA range from less than 0.4 Bq/m^3 at the C-2 Fire Trail location to 21.6 Bq/m^3 at the on-site Sewage Treatment Plant. Tritium monitoring is performed at off-site population centres beyond the RSA. Tritium concentrations at these locations are below the detection level, and have averaged less than 0.26 Bq/m^3 from 2014 to 2018 (Table 5.7.4-6).

Elevated tritium concentrations have been measured at the Sewage Treatment Plant and Main Gate locations. These locations are close to the NRU stack, which is the primary source of tritium emissions at the CRL site. Additionally, elevated tritium concentrations have been observed at the WMA B Gate monitoring station. This location is near WMA B, which has been a source of airborne tritium releases.

[3] Liquid scintillation counting (LSC) is the standard laboratory method to quantify the radioactivity of low energy radioisotopes, mostly beta-emitting and alpha-emitting isotopes (PerkinElmer Inc. 2019).

a) Monitoring at Demers Centre was discontinued at the end of 2013.

Bq/m^3 = Becquerels per cubic metre; <= results below the detection level; ”V” indicates an average calculated using one or more results below detection level; N/D = results below the critical level (i.e., not detected); N/A = Not available.

5.7.4.4.4 Carbon-14 in Air

Carbon-14 is monitored in air at locations on the CRL main campus, at the CRL site boundary and off site at local population centres. Carbon-14 is monitored with the use of passive samplers employing mixed calcium-sodium hydroxide pellets. Carbon-14 evolved from the pellets was analyzed by liquid scintillation counting. No carbon-14 monitoring is within the boundaries of the SSA. The Perch Lake Main monitoring location is close to the SSA, and is considered to be representative of the LSA. Carbon-14 is monitored at three locations within the CRL main campus, which are considered to be within the RSA. Four carbon-14 monitoring locations exist in population centres beyond the RSA. These are in Deep River, Harrington Bay, Petawawa and Sheenboro. At all locations, concentrations of carbon-14 in air are close to or below the detection level (Table 5.7.4-7).

Table 5.7.4-7: Annual Average Carbon-14 Concentration in Air (Bq/m^3)

5.7.4.5 Radioactivity in Surface Water

Surface water is monitored at on-site lakes and streams, off-site streams and locations in the Ottawa River both upstream and downstream of the CRL site. The results of radiological monitoring of off-site streams are not discussed in this Base Case characterization, as there are no direct liquid emissions to these streams from the NSDF Project.

No surface waterbodies are present within the boundaries of the SSA. The SSA is located within the Perch Lake basin. Surface waterbodies in the Perch Lake basin are currently affected by the presence of several WMAs, including the CRL LDA. The surface water monitoring locations that are closest to the SSA are the East Swamp weir, Perch Lake Inlet 2, Perch Lake Outlet and Perch Creek weir. The location of these monitoring stations is displayed on Figure 5.7.4-7. Note that while this figure displays non-radiological sampling locations, these are not considered in the assessment of Base Case radioactivity.

Table 5.7.4-8 displays the radioactivity in surface waterbodies that are closest to the SSA. These locations have the highest potential to be affected by NSDF Project operations, and are considered to be within the LSA. Additional surface water monitoring stations exist within the CRL site, within the Maskinonge Lake Basin and upstream locations within the Perch Lake Basin (e.g., B Hydro Line) and Main Stream Culvert). These monitoring locations are not included within this Base Case characterization, as they are not expected to be affected by the NSDF Project.

The East Swamp weir is located immediately west of the SSA. This monitoring location is downstream of the Laundry Pit, Reactor Pit 2 and Chemical Pit. The Perch Lake Inlet 2 monitoring station is located farther downstream, and receives discharge from the East Swamp Stream, South Swamp Stream and Main Stream. The Perch Lake Outlet and Perch Creek weir monitoring stations represent downstream locations at the exit point of Perch Lake and along Perch Creek, which flows from Perch Lake to the Ottawa River

<= results below the detection level; "V" indicates an average calculated using one or more results below detection level;
Bq/L = Becquerels per litre.

The primary radiological contaminants of concern in Perch Lake Basin waters are tritium and gross beta (consisting mainly of strontium-90 and its daughter yttrium-90). Tritium levels at Perch Lake Basin monitoring stations near the SSA have ranged from 286 to 4,233 Becquerels per litre (Bq/L) from 2014 to 2018. Additionally, elevated gross beta readings have been recorded, particularly at the East Swamp weir location, where levels have reached 256 Bq/L. Trace amounts of cobalt-60 and caesium-137 have been measured in the Perch Lake Basin waters and have been at or below detection levels at the Perch Lake and Perch Creek weir monitoring stations.

Off-site monitoring of surface water includes inland streams, as well as locations in the Ottawa River both upstream and downstream of CRL site. There are no liquid emissions to off-site streams from the proposed NSDF Project, and therefore these are not described in the background characterization.

Radioactivity at upstream and downstream locations in the Ottawa River is presented in Table 5.7.4-9. Annual average background tritium concentrations are less than 4 Bq/L at locations upstream of CRL. Of particular relevance to the NSDF Project is the Pointe au Baptême monitoring location. This is downstream of the CRL site near the boundary, and is immediately downstream of the Perch Creek Outlet, which could potentially be affected by the NSDF. The tritium concentrations at this location are slightly above background, with annual average values up to 67.9 Bq/L from 2014 to 2018.

Monitoring stations located farther downstream on the Ottawa River are considered to be representative of the area beyond the RSA. Concentrations of radiological contaminants at these locations are low, with annual average tritium concentrations less than 9 Bq/L.

<= results below the detection level; ”V” indicates an average calculated using one or more results below detection level; n/a = not applicable (analysis only conducted when gross beta levels are significantly higher than normal); Bq/L = Becquerels per litre; N/D = results below the critical level (i.e., not detected).

5.7.4.6 Radioactivity in Groundwater

Groundwater is monitored at locations throughout the CRL site as part of the CRL Groundwater Monitoring Program. This program evaluates and reports groundwater concentrations of a large suite of radiological and non-radiological parameters for samples collected from approximately 180 monitoring wells located at 32 different monitoring sites. Monitoring sites include CRL WMAs, lands previously affected by past operational activities, and the developed part of the CRL site. These monitoring activities are performed annually or twice-yearly around the perimeters of operating areas as a means of monitoring the conditions and behaviour of the facilities and operations. Results of the Groundwater Monitoring Program are presented each year in the CRL Groundwater Monitoring Program annual report. These data provide operational feedback on the conditions and behaviour of facilities, including the performance of existing remedial measures (e.g., infiltration barriers). The Groundwater Monitoring Program includes wells that are upgradient of the monitored areas, in order to provide reference values.

Where groundwater contamination is present, this routine monitoring is augmented by periodic detailed evaluations of subsurface contaminant distributions and movement. These provide characterization of existing contaminant plumes. The monitoring of contaminant plumes provides the basis for observing environmental effects and evaluating future effects, including confirming the applicability of remedial measures.

Groundwater monitoring is performed in the LSA at locations within the CRL site where contamination is of concern. Reference wells located upstream of WMAs are considered representative of ambient radiological contaminant concentrations in these areas. The highest concentrations and widest variety of radioactive contaminants in groundwater on the CRL site are located downgradient of the Chemical Pit (CNL 2019d). Total beta activity associated with strontium-90 in groundwater between the Chemical Pit and the East Swamp is on the order of 10,000 to 70,000 Bq/L. Gross alpha, caesium-137 and cobalt-60 in groundwater are also elevated (AECL 2014a). For the groundwater monitoring locations downstream of the Chemical Pit, the highest concentrations of these contaminants in 2014 were 12 Bq/L for caesium-137 (LDA-22), 6.39 Bq/L for cobalt-60 (LDA-21) and 4.57 Bq/L for gross alpha (LDA-22). Characterization of the groundwater plume from the Chemical Pit has also included the sampling of pore water from the East Swamp (indicative of groundwater discharging to the surface water). Gross alpha, total beta and strontium-90 activities were found to range from <3 to <8 Bq/L, 230 to 4,900 Bq/L and 120 to 2,960 Bq/L, respectively (CNL 2015a). Downgradient of WMA A, total beta activity in groundwater was generally between 3,000 and 10,000 Bq/L with a peak of 30,000 Bq/L. Downgradient of Reactor Pit 2, total beta activity in groundwater was generally between 2,000 and 15,000 Bq/L with a peak of 22,100 Bq/L (CNL 2015b).

The reference wells closest to the SSA are labelled LDA-3 and GD-42. LDA-3 is located upgradient of Reactor Pit 1, west of the SSA. The GD-42 well is located upgradient of the non-radiological landfill, northeast of the SSA, although this is not directly applicable to the Base Case characterization as it is located in a different drainage basin. The location of WMAs adjacent to the NSDF Project and routine groundwater monitoring locations are shown on Figure 5.7.4-8. Figure 5.7.4-8 also shows the location of individual monitoring wells relative to the Reactor Pit. The location of individual monitoring wells relative to the non-radiological landfill is shown on Figure 5.7.4-9. The concentration of radiological contaminants, as measured by spring and fall measurements, in these reference (i.e., background) wells is shown in Table 5.7.4-10. It is noted that gamma spectral analysis of samples in the groundwater monitoring program is only performed where the concentration of total beta activity exceeded 2 Bq/L, or where gross alpha activity was detected (CNL 2019d). Therefore, gamma spectral analysis was not performed at the reference wells LDA-3 and GD-42. Full gamma spectrum results for all applicable

monitoring wells in the groundwater monitoring program are available in the CRL *Groundwater Monitoring Program Annual Report for 2017* (CNL 2019d). The results for specific radionuclides where concentrations have exceeded detection limits (e.g., caesium-137 and cobalt-60) in Chemical Pit samples are discussed above.

Table 5.7.4-10: Radioactivity in Reference Wells near the Site Study Area (Bq/L)

	2013	2014	2015	2016	2017	2013–2017 Average
Reference wells near Site Study Area (SSA)						
LDA-3[(a)], upgradient of Reactor Pit 1, West of SSA (Same drainage basin as NSDF)

This page left intentionally blank

Investigations of contamination in East Swamp have included measurements of radioactivity in pore water (CNL 2015b). The East Swamp has existing contamination due to groundwater plumes from the Chemical Pit and Reactor Pit 2. Since it is immediately west of the SSA, this contamination is relevant to the Base Case radioactivity characterization for the SSA. Surveying conducted in 2012 included collection and analysis of pore water at seven locations, labelled Z-1 to Z-7 on Figure 5.7.4-10. The radiological contamination in these samples is shown in Table 5.7.4-11. All gross alpha concentrations in these pore water samples were less than detection limits (<8 Bq/L). Total beta ranged from 180 Bq/L to a maximum of 4,900 Bq/L. Strontium-90 concentrations ranged from 120 Bq/L to a maximum of 2,960 Bq/L. The East Swamp contamination study utilized these concentrations to estimate distribution coefficients of radionuclides in soil, which is the ratio of radionuclide concentrations in the solid phase to the concentrations in solution.

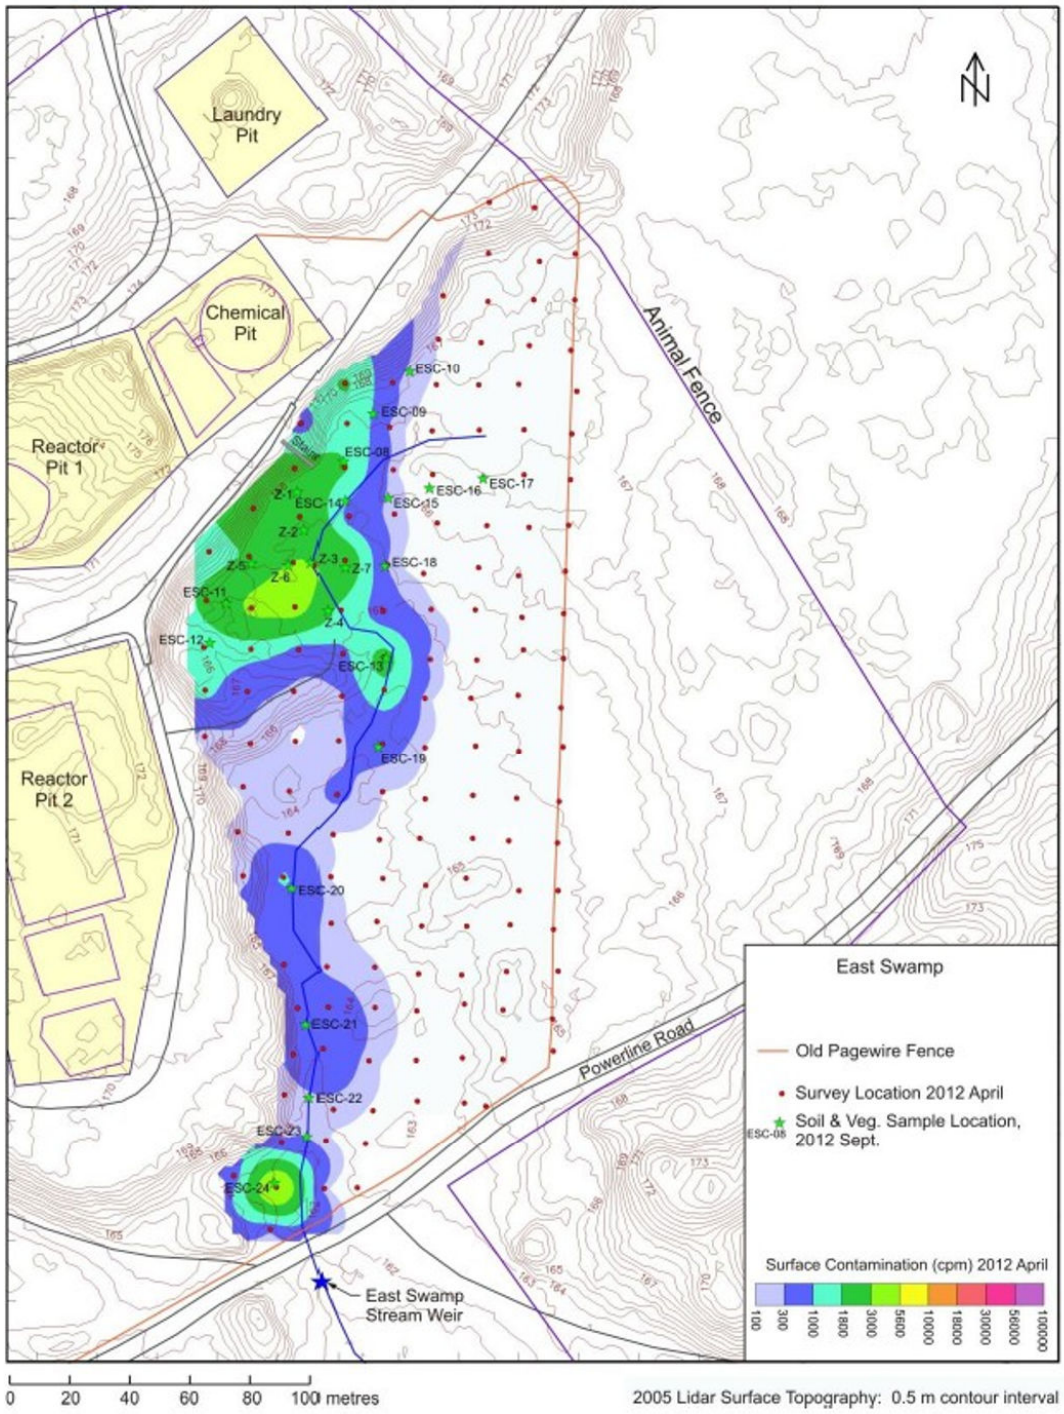

Table 5.7.4-11: Radioactivity in Pore Water Samples from 2012 East Swamp Survey (Bq/L)

Location	Gross Alpha	Total Beta	Strontium-90
Z-1	<3	1,300	770
Z-2	<7	4,900	2,960
Z-3	<6	520	308
Z-4	<3	980	500
Z-5	<3	1,600	950
Z-6	<6	180	120
Z-6 Replicate	<8	230	130
Z-7	<3	780	482

<= results below the detection level; Bq/L = Becquerels per litre.

Tritium concentrations in pore water in the East Swamp stream have averaged 430 Bq/L in the period 2008 to 2012 compared to background tritium concentrations of approximately 300 Bq/L (CNL 2015b).

Further groundwater sampling at the SSA was completed by AMEC Foster Wheeler in October and December 2016 (AMEC 2016, 2017). Tritium, gross alpha and total beta activities were found to range from <64 to 155 Bq/L, <0.009 to 0.552 Bq/L and <0.01 to 1.06 Bq/L, respectively. These results are slightly elevated in comparison to ambient radiological conditions in groundwater observed near the SSA for some parameters (i.e., gross alpha). It is noted that these ranges are based on two monitoring events for the SSA.

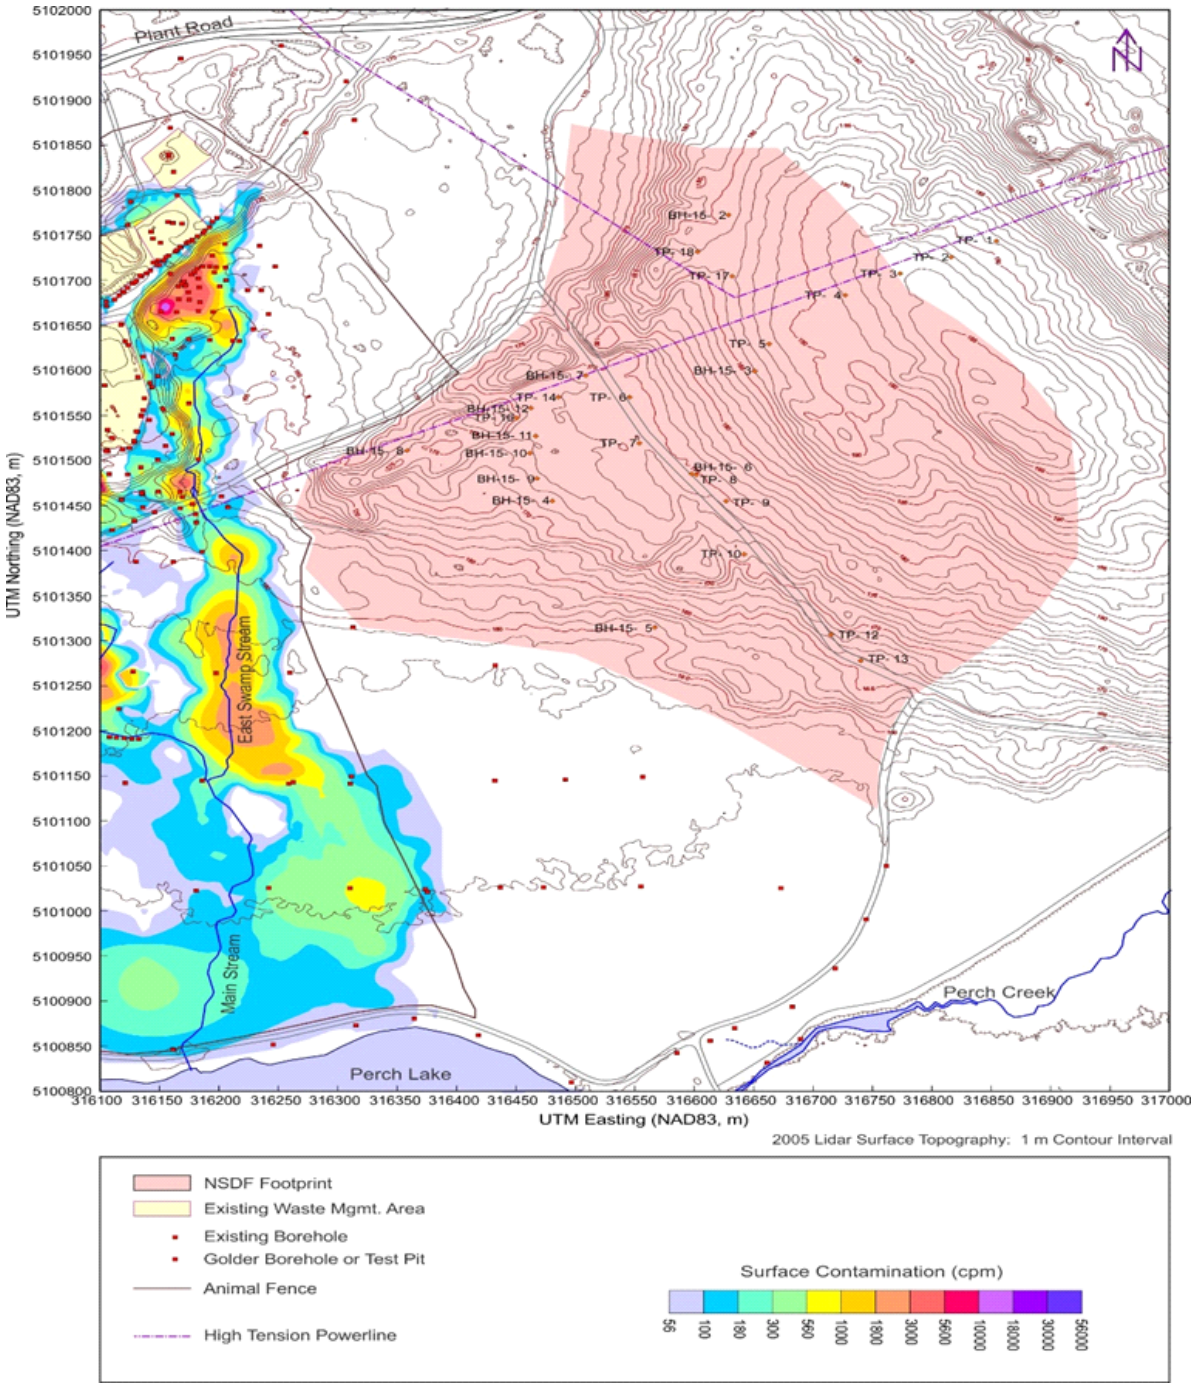
5.7.4.7 Radioactivity in Soil and Vegetation

Geotechnical investigations in 2016 (Golder 2016) included a radiological screening of soil samples prior to off-site non-radiological analysis. No radiological contamination was found at the SSA, although it is noted that no quantitative analysis was performed for radiological contaminants beyond screening with a contamination meter.

Measurements of radionuclide concentrations in soil have been performed at specific areas of concern within the CRL site, and included studies of ambient radiation, as well as soil, groundwater and vegetation contamination in areas affected by groundwater plumes from WMAs at CRL.

Radiological contamination in the East Swamp Wetland is relevant to the NSDF Project, as this area is immediately west of the SSA. Because this wetland is potentially downgradient of parts of the SSA, characterization of the contamination present is important in defining Base Case conditions. The East Swamp Wetland has existing contamination associated with a shallow subsurface plume from the Chemical Pit (see Figure 5.3.2-4 in Section 5.3) and a second plume from Reactor Pit 2 (see Figure 5.3.2-5 in Section 5.3). The surface contamination distribution in the East Swamp has been characterized on a five-year frequency with radiation field surveys, surface surveys and vegetation contamination surveys performed in 2002, 2007 and 2012. In 2002 and 2012, these surveys included wetland soil and vegetation sampling to determine the radionuclide concentrations in these media. Surveying was conducted over a 150 m by 350 m area, using a 15 m by 15 m grid spacing. Additional relevant surveying has been performed to characterize the Chemical Pit plume; this has included measurements of radionuclides in soil (AECL 2014a). Surveying in East Swamp is done on a five-year cycle.

Sub-surface Soil in the Chemical Pit Plume



Surveying of the Chemical Pit plume conducted in 2002 included measurements of subsurface soil immediately downgradient of the Chemical Pit in the East Swamp (AECL 2014a). Figure 5.7.4-8 provides an indication of the spatial extent of the Chemical Pit plume in the East Swamp. Total beta concentrations in borehole samples ranged from 580 to 345,000 Becquerels per kilogram (Bq/kg). Gross alpha activity ranged from less than 110 to 760 Bq/kg. Gamma spectroscopy was performed on samples with more than 2,000 Bq/kg of total beta activity, and the anthropogenic gamma emitters cobalt-60, caesium-137 and americium-241 were detected. Concentrations of cobalt-60 in soil ranged from background (<10 Bq/kg) to 2,680 Bq/kg. Concentrations of caesium-137 in soil ranged from background (<20 Bq/kg) to 970 Bq/kg. Concentrations of americium-241 ranged from background (<70 Bq/kg) to 1,110 Bq/kg.

Surficial Soil in the East Swamp

The 2002 East Swamp soil survey found total beta concentrations ranging from 850 Bq/kg at background locations east of the contaminated region to 1,845,000 Bq/kg at locations where the plume discharges to surface (CNL 2015b). Alpha activity concentrations ranged from background levels (100 Bq/kg) in reference locations to a maximum of 8,570 Bq/kg in the Chemical Pit groundwater discharge zone. Cobalt-60 soil concentrations in East Swamp range from background (100 Bq/kg) to 151,000 Bq/kg. Caesium-137 soil concentrations range from 3,000 Bq/kg to 5,700 Bq/kg. For cobalt-60 and caesium-137, the highest concentrations were observed within the Chemical Pit groundwater plume discharge zone.

The 2012 soil survey found total beta concentrations ranging from 1,040 Bq/kg to 1,562,000 Bq/kg, with the maximum levels occurring where the Chemical Pit groundwater plume discharges to surface (CNL 2015b). Alpha activity concentrations ranged from 170 to 74,300 Bq/kg, with the maximum occurring in the Chemical Pit groundwater discharge zone. Cobalt-60 concentrations were measured ranging from 20 Bq/kg to 102,000 Bq/kg, while caesium-137 concentrations ranged from 40 to 105,000 Bq/kg. Both maximum concentrations occurred within the Chemical Pit groundwater plume.

Figure 5.7.4-11 displays a map of surface contamination in the Perch Lake Wetland based on a compilation of data collected in 2009, 2011 and 2012 and with some data from 1997. This map is useful for visualizing the spatial extent of contamination in the Perch Lake Wetland, and locations of contamination with respect to the SSA.

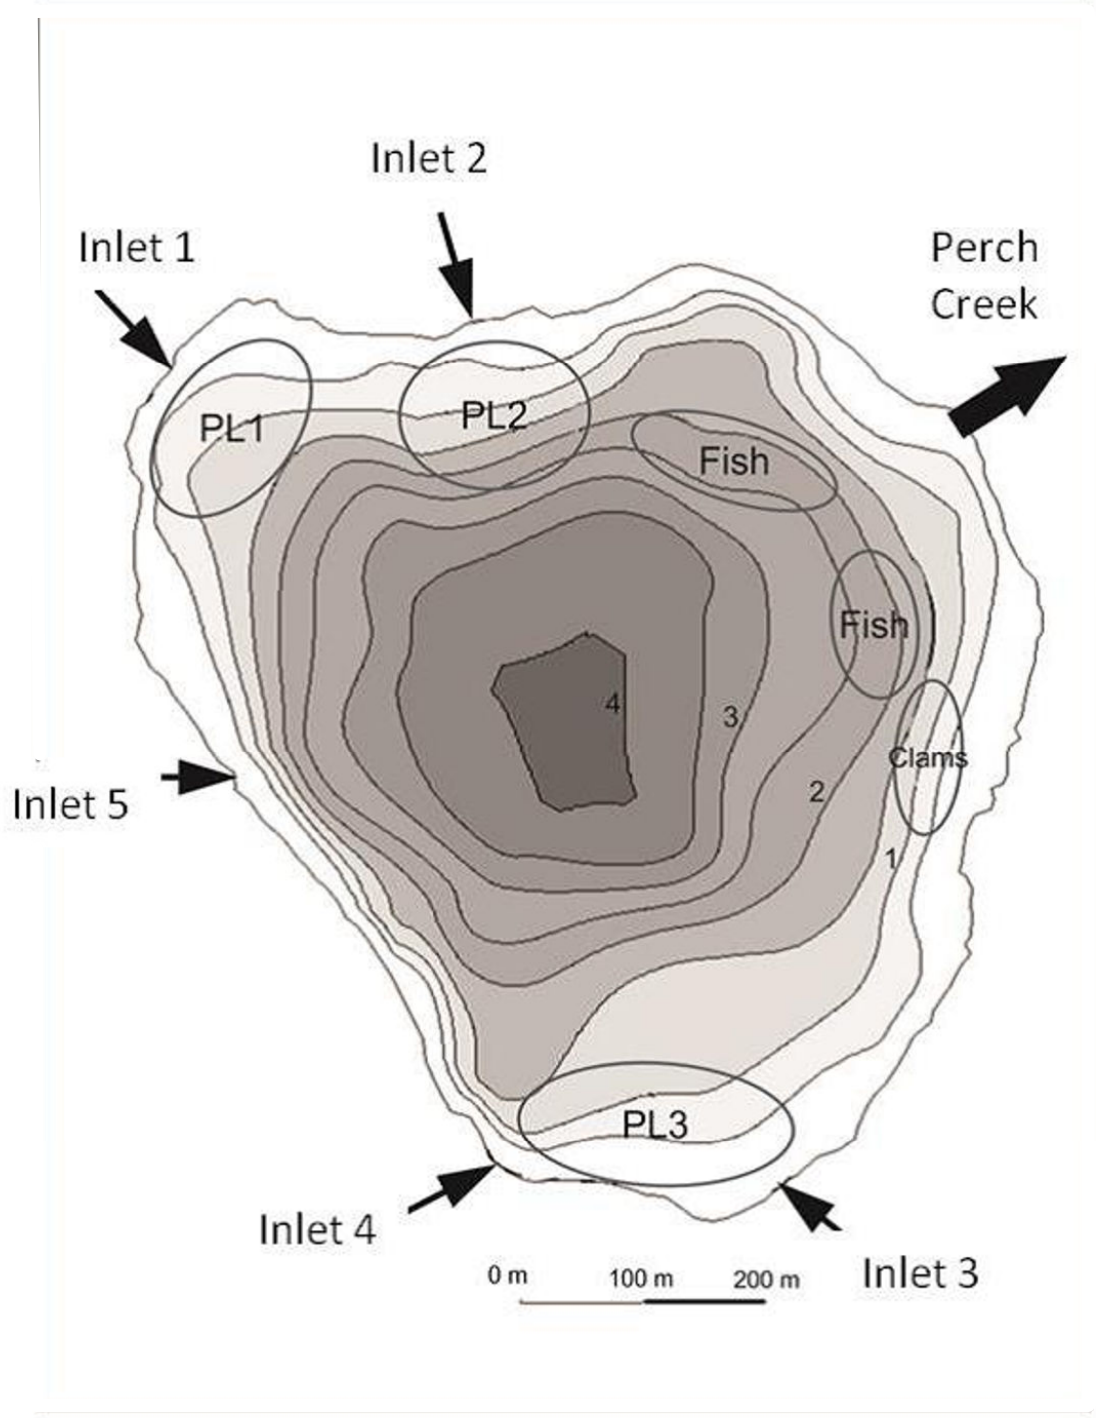
No monitoring of soil is performed in the RSA as part of the CRL Environmental Monitoring Program. The CNSC *Independent Environmental Monitoring Program* (CNSC 2016) has included measurements of radioactivity in soil near the towns of Chalk River (approximately 8 km southwest of CRL) and Chapeau (approximately 25 km southeast of CRL). In 2014, caesium-137 measured in soil near Chalk River was present at a concentration of 5.81 Bq/kg dry weight, while at Chapeau, 6.54 Bq/kg dry weight was measured (CNSC 2016).

Site-specific background values for radiological contaminants in soil have been established by the *Environmental Risk Assessment of Chalk River Laboratories* (CNL 2019e), *Analysis of Surface Soil Samples from the Proposed NSDF Site Technical Report* (CNL 2017c) and *Additional Radionuclide Information for the NSDF Surface Soils* (CNL 2018b). Soil data from 43 locations on the Chalk River site, generally unaffected by CNL operations, were used to calculate the upper limit of background concentrations. Background concentrations of additional radiological parameters were taken from northeastern Ontario regional measurements or Ministry of the Environment, Conservation and Parks background site condition standard values (MOE 2011). Upper-limit background values for caesium-137 in soil have been calculated as 23.8 Bq/kg (CNL 2019e). It is noted that higher background values may exist. For example, Milton et al. (2001) measured caesium-137 concentrations in soil of approximately 200 Bq/kg at the CRL site, and approximately 35 Bq/kg at Petawawa.

Site-specific background concentrations of metals in soil were also established in the *Background Concentrations of Metals in Soils at the CRL Site* memorandum (CNL 2018c). Local background levels were estimated considering 37 sampling locations across the CRL site. The 97.5th percentile was calculated for each metal, which is the same method used by the Ministry of the Environment, Conservation and Parks in the development of the Ontario Typical Range (OTR_{98}). Concentrations were generally less than the established OTR_{98}, with the exception of mercury (0.15 micrograms per gram [µg/g]) which was marginally greater than its OTR_{98} of 0.13 µg/g.

In 2017, 142 trees in the SSA were sampled for tritium, gross alpha, and gross beta radiation (AECL 2017). All tritium, gross alpha, and total beta concentrations measured in the composite samples of tree wood collected from the SSA met CNL criteria for unrestricted off-site release of the wood as well as the CNSC's unconditional clearance criteria.

5.7.4.8 Radioactivity in Aquatic Sediment



No sediment is present within the SSA. Sediment has been monitored periodically in Perch Lake, which may be affected by the NSDF and is considered to be representative of the LSA. Sampling locations for studies completed in 2003 and 2013 are shown on Figure 5.7.4-12. The measurements of tritium oxide and organically bound tritium from these studies are shown in Table 5.7.4-12.

Table 5.7.4-12: Perch Lake Sediment Sampling Results

Site	Year 2003		Year 2013	
	Tritium Oxide (Bq/L)	Organically Bound Tritium (Bq/L)	Tritium Oxide (Bq/L)	Organically Bound Tritium (Bq/L)
PL1	3,960 ±75	1,995 ±88	1,706 ±13	691 ±18
PL2	12,550 ±250	2,970 ±149	1,729 ±17	741 ±15
PL3	1,320 ±26	490 ±25	1,579 ±16	952 ±38

Additionally, concentrations of strontium-90, caesium-137 and cobalt-60 in Perch Lake sediments have been reported in the CRL *Environmental Risk Assessment* (CNL 2019e). Concentrations of strontium-90 in Perch Lake sediment ranged from 845 Bq/kg to a maximum of 4,290 Bq/kg dry weight. Concentrations of caesium-137 in Perch Lake sediment ranged from 63.4 Bq/kg to a maximum of 355 Bq/kg dry weight. Concentrations of cobalt-60 in Perch Lake sediment ranged from 124 Bq/kg to a maximum of 296 Bq/kg dry weight.

Beach sand is routinely monitored at locations on the Ottawa River, including four upstream reference locations, two locations at the CRL site downstream boundary (both near Pointe au Baptême), and five locations farther downstream of the CRL site. The upstream locations are used to establish background concentrations of radionuclides. The CRL site boundary locations are considered to represent the RSA. Concentrations of caesium-137 are slightly elevated at the CRL site boundary, with annual averages ranging from 2.7 to 29.8 Bq/kg from 2014 to 2018. Sediment monitoring locations farther downstream of the CRL site are considered to be representative of the area beyond the RSA. Sediment monitoring results averaged for upstream, property boundary and downstream locations from 2014 to 2018 are shown in Table 5.7.4-13.

5.7.4.9 Radioactivity in Fish

Fish are collected annually from upstream and downstream locations on the Ottawa River and from Chalk Lake. There are no fish habitats located in the SSA. Fish have periodically been sampled from Perch Lake. Studies conducted in 2003 and 2013 included measurements of tritium oxide in water as well as tritium oxide and organically bound tritium in fish and clams (CNL 2016b). The results of these studies are shown on Figure 5.7.4-13 and Figure 5.7.4-14. Tritium oxide concentrations in water are less than the maximum acceptable concentration of 7,000 Bq/L specified for drinking water (Health Canada 2019). Based on a water content of 75% by mass (CSA Group 2014) and an internal dose conversion coefficient of 0.000138 micrograys per day per Becquerel per kilogram (µGy/day) / (Bq/kg) as presented in the Environmental Risk Assessment (AECL 2014c), the concentrations of tritium in fish and clams are significantly less than concentrations that would result in doses exceeding the benchmark of 400 µGy/hr for aquatic biota.

Fish are sampled from Chalk Lake, which is partly within the CRL site boundary and is therefore considered to be representative of the RSA. While this location is within the CRL site, it is not expected to be affected by the NSDF Project, since the NSDF will not drain to the Maskinonge Lake Basin, which contains Chalk Lake. Radioactivity in fish at these locations is presented in Table 5.7.4-14. Elevated tritium concentrations have been measured in fish from Chalk Lake. Average concentrations in 2018 of tritium oxide and organically bound tritium in Chalk Lake fish were 15.6 Bq/kg and 12.32 Bq/kg, respectively. For comparison, in 2018 Ottawa River fish upstream of CRL at Mackey had concentrations of less than 0.88 Bq/kg and less than 1.11 Bq/kg for tritium oxide and organically bound tritium.

Fish are sampled from one upstream location and two downstream locations in the Ottawa River. Radioactivity in fish from downstream locations could potentially be affected by the SSA via discharge from the Perch Lake basin to the Ottawa River. The RSA fish monitoring results are displayed in Table 5.7.4-15.

Only the radiological parameters that were detected in at least one sample from any fish species have been listed in the table.

1) Bullhead dataset includes 6 discrete tissue samples.

2) Pumpkinseed dataset includes 5 discrete tissue samples.

3) Perch and pike datasets include 1 discrete sample each.

5.7.4.10 Radioactivity in Terrestrial Foodstuffs

5.7.4.10.1 Terrestrial Animals

No monitoring of terrestrial animals is performed specifically within the SSA or LSA. Radioactivity in large game animals (e.g., deer) is measured when animals are hunted or killed accidentally in the vicinity of the CRL site. Samples obtained from within 25 km are considered to be representative of the RSA. The concentration of radioactivity in the flesh and bones of terrestrial animals are shown in Table 5.7.4-19 and Table 5.7.4-20, respectively.

Historically, elevated levels of radioactivity have been measured in large game animals from within 25 km of the CRL site (e.g., approximately 1,100 Bq/L tritium in large game animal flesh sample in 2001). This is related to historical contamination of the CRL WMAs (CNL 2016c). Fences installed in 2004 to prevent game animal access to areas with surface contamination have led to a reduction in radioactivity in local game animals. The average tritium concentrations in the flesh of large game animals collected within 25 km of the CRL site from 2014 to 2018 have ranged from 11 to 510 Bq/kg. Average gross beta activity ranged from 111 to 313 Bq/kg, where naturally occurring potassium-40 was the primary contributor (Table 5.7.4-19 and Table 5.7.4-20). Tritium concentrations in the flesh of large game animals collected beyond 50 km of the CRL site from 2014 to 2018 have ranged from less than 0.87 to 11 Bq/kg.

Table 5.7.4-19: Radioactivity in Flesh of Large Game Animals (Bq/kg fresh weight)

	2014	2015	2016	2017	2018	2014–2018 Average

Caesium-137	V 2.0	V 4	V 2	<0.89	5	V 2.8

Source: CNL 2019b.

Note: Values reported for each year represent the average radionuclide concentrations measured from multiple animals. The “average” column indicates the average of these annual values (not weighted by number of samples).

<= results below the detection level; ”V” indicates an average calculated using one or more results below detection level; Bq/kg = Becquerels per kilogram

The dose to large mammals was estimated in the CRL *Environmental Risk Assessment* (AECL 2014a), based on measured radionuclide concentrations in flesh and bone from animals accidentally killed on CRL site and on modelled concentrations of radionuclides in air. The dose to deer from radionuclides in tissue and argon-41 in air was estimated to range from 0.038 to 0.064 µGy/hr. The estimated total dose to eastern wolf (*Canis lupus lycaon*) is similar and considerably less than the benchmark of 100 µGy/hr.

5.7.4.10.2 Terrestrial Plants

Garden produce is sampled annually from gardens and farmers markets at off-site population centres. Additionally, garden produce is sampled from Killaloe, 55 km south of the SSA, to evaluate background radioactivity. Samples are collected annually and analyzed for tritium (free tritium is shown in Table 5.7.4-21 and organically bound tritium in Table 5.7.4-22), gross beta (Table 5.7.4-23), gross alpha (Table 5.7.4-24) and caesium-137 (Table 5.7.4-25). Results are grouped into fruit, root or vegetable categories. The Chalk River and Balmer Bay sampling locations are within the RSA, while remaining locations are beyond the RSA.

No produce is grown for human consumption at the SSA or within the CRL site boundary. It is noted that the SSA will be subject to vegetation management procedures, such that no vegetation that could penetrate waste will be allowed to grow.

At the reference location (Killaloe), free water tritium concentrations in produce have averaged less than 3 Bq/kg. This is comparable to reference measurements from across Ontario, which range from 1 to 6 Bq/kg (OPG 2013). Elevated tritium concentrations were measured at the locations closest to the CRL site. At Balmer Bay, tritium concentrations in all produce from 2014 to 2018 averaged 18 Bq/kg, with an average of 21.3 Bq/kg in vegetable produce (Table 5.7.4-21). At Deep River, tritium concentrations in all produce from 2014 to 2018 have averaged 11.5 Bq/kg. Additionally, elevated tritium concentrations have been measured at Pembroke, but this is likely associated with a local non-CNL industry in the area.

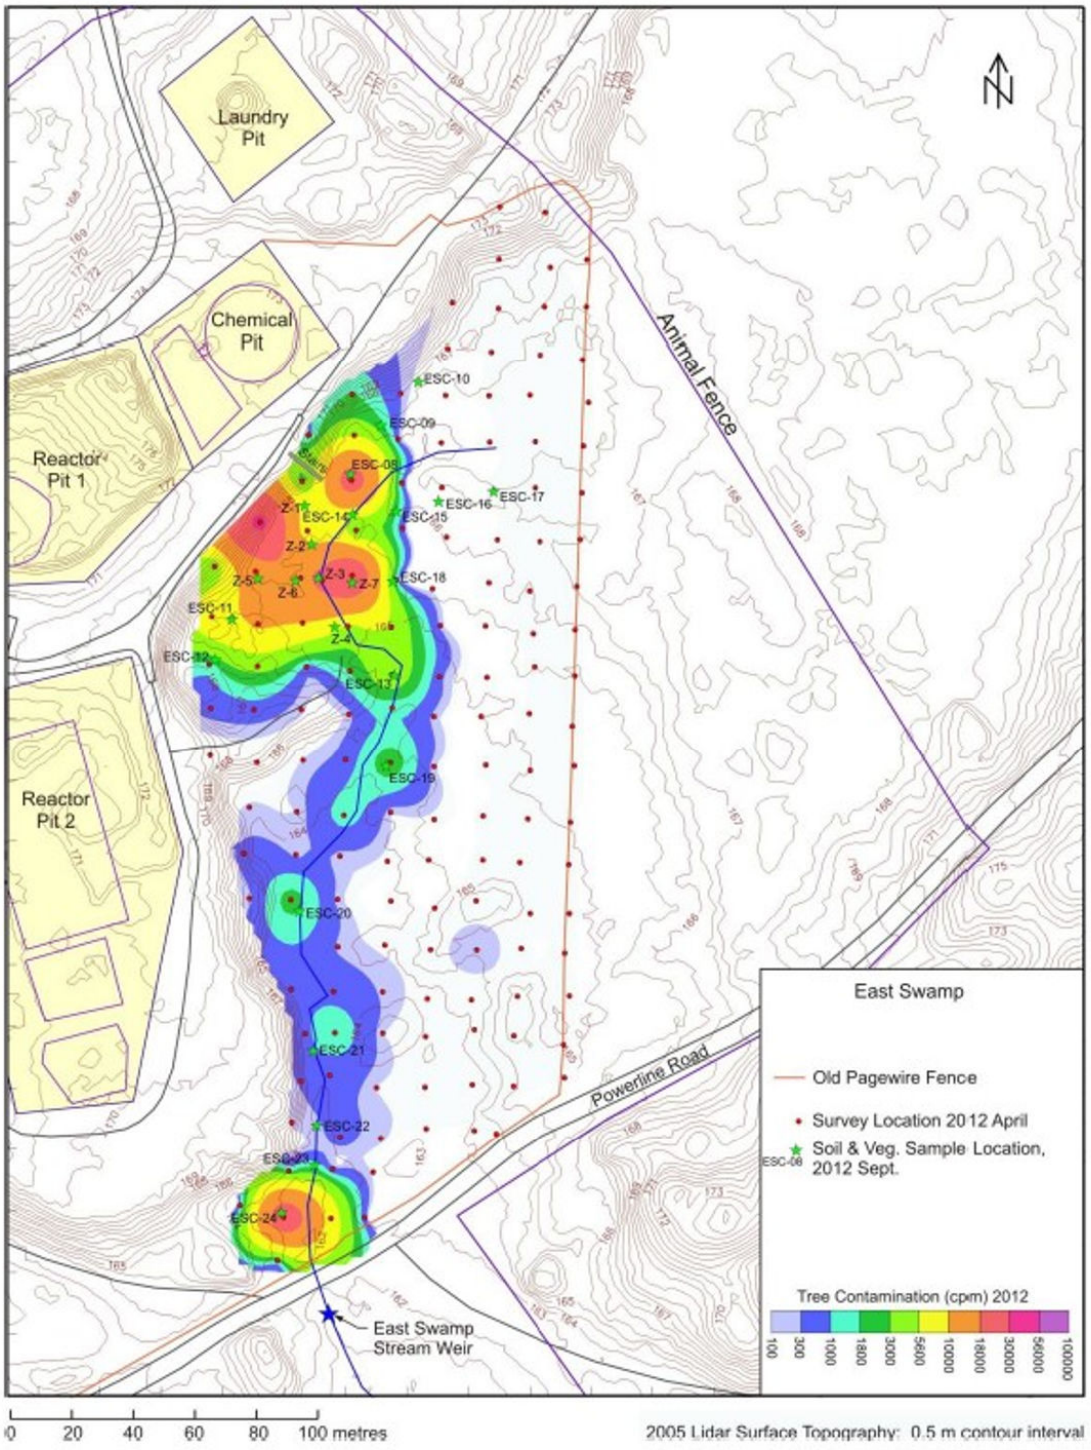
<= results below the detection level; ”V” indicates an average calculated using one or more results below detection level; Bq/kg = Becquerels per kilogram; N/A = not available.



Gamma spectroscopy has demonstrated that the majority of gross beta activity is due to naturally occurring potassium-40. Gross beta results are highly variable due to the variability in naturally occurring radionuclides at the monitoring locations. Low-level gross alpha activity was detected in produce samples from all areas, including the reference area. Naturally occurring alpha emitters likely account for the observed alpha activity. The caesium-137 measurements in garden produce are frequently below the detection level. Some low-level (approximately 2.0 Bq/kg) caesium-137 concentrations have been detected in local produce. Caesium-137 is not solely attributable to CRL operations as it is present in the environment from atmospheric fallout from global weapons tests and the Chernobyl nuclear accident.

In addition to monitoring garden produce as part of the Environmental Monitoring Program, surveys of contamination resulting from groundwater plumes at CRL have included sampling and analysis of vegetation. Radiological surveying conducted at the East Swamp is particularly relevant to the NSDF Project, as it is immediately west of the SSA and may be affected by NSDF Project activities. Contamination exists in the East Swamp as a result of groundwater plumes from the Chemical Pit and Reactor Pit 2. Vegetation sampling was conducted in the East Swamp during 2002, 2007 and 2012 surveys. These surveys included measuring contamination of tree surfaces, leaves/ferns (in 2002), tree cores/branches (in 2012) and surface vegetation (in 2012).

Tree surface contamination was measured with a Ludlum 44-9 pancake Geiger-Mueller detector, which responds to alpha, beta and gamma radiation, and was used with the detector in contact with the trunk, approximately 1 m off the ground. Tree surface contamination results from 2012 are shown on Figure 5.7.4-15.

Total beta activities in tree leaves surveyed in 2002 were on average 1.25 times higher than beta activity in soil (see East Swamp soil monitoring results in Section 5.7.4.7 Radioactivity in Soil). Alpha activity in tree leaves and ferns at the East Swamp background location were 7 Bq/kg and 13 Bq/kg dry weight, respectively. Throughout East Swamp, alpha activity in tree leaves average 10 Bq/kg, with a maximum of 24 Bq/kg. Activity in ferns was slightly higher, with average values of 15 Bq/kg and a maximum of 47 Bq/kg. These results are considered to be very close to background, indicating negligible alpha emitter uptake into vegetation. Caesium-137 concentrations were generally greater in vegetation than in soil at East Swamp, with an average factor of 4.9 times higher for ferns and 1.2 times higher for trees. Cobalt-60 concentrations in vegetation were a small fraction of that in soil.

In 2012, total beta activity in vegetation was on average 1.2 times higher than that in soil, with ratios ranging from 0.17 to 6.2 more beta activity in vegetation than corresponding soil samples. Gross alpha activity in vegetation was at or near background levels of 13 Bq/kg, with the exception of vegetation from the Chemical Pit groundwater discharge zone where levels were elevated (260 Bq/kg). Caesium-137 concentrations ranged from background to a maximum of 11,400 Bq/kg. Cobalt-60 concentrations in vegetation were a small fraction of that observed in soil.

5.7.4.10.3 Milk

No milk production occurs within the SSA, LSA or RSA. Milk is sampled monthly from a dairy farm in Pembroke, considered to be beyond the RSA. Samples are analyzed to quantify the concentration of tritium and other radionuclides. The average annual concentration of radionuclides in milk from the dairy in Pembroke is shown in Table 5.7.4-26.

The contaminants tritium, carbon-14 and caesium-137 are associated with CRL operations and were measured in milk samples at detectable levels. Tritium concentrations were comparable to the natural background range of 5 to 11 Bq/L (CNL 2017d; NCRP 1987). Local non-CNL industries in Pembroke may influence the measured tritium concentrations in milk samples. Concentrations of carbon-14 in milk samples have ranged from 15 to 18 Bq/L. This is comparable to the natural background level of 15 Bq/L (CNL 2017d; UNSCEAR 1993).

Concentrations of caesium-137 have remained at approximately 0.02 Bq/L from 2012 to 2016. This is comparable to the estimated background concentrations of caesium-137 in milk in Canada, which are estimated to range from 0.0017 Bq/L to 0.024 Bq/L due to atmospheric nuclear weapons testing and the Chernobyl nuclear accident (CNL 2017d; Health Canada 2001). Naturally occurring radionuclides such as potassium-40 were also detected in milk samples.

Table 5.7.4-26: Average Concentration of Radioactivity in Milk (Bq/L) from the Dairy in Pembroke

5.7.5 Project Interactions and Mitigation

5.7.5.1 Methods

This section describes the process by which interactions between NSDF Project components and activities and ecological health were identified and evaluated. Potential effects pathways are identified and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment. As such, this section helps to focus the remainder of the assessment on those interactions (effects pathways) with the potential to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all stages of the NSDF Project. The next step in the analysis was the development of environmental design features and mitigation that could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects to ecological receptors. Environmental design features included project design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the NSDF Project's engineering and environmental teams, combined with input from project-specific or regional engagement with other interested parties. The design features and/or mitigation were selected considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effects pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation:

- **No linkage:** The pathway is removed by environmental design features or mitigation such that the NSDF Project would not be expected to result in a measurable environmental change relative to Base Case values and therefore would have no residual effects to ecological receptors.
- **Secondary pathway:** The pathway could result in a measurable minor environmental change, but would have a negligible residual effect to ecological receptors relative to guideline values and is not expected to contribute cumulatively to other NSDF Project effects or to the effects of other previous, existing or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway:** The pathway is likely to result in an environmental change relative to the guideline values that could contribute to residual effects to ecological receptors.

Environmental design features and mitigation that have been or could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to ecological receptors through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment.

Primary pathways were carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the NSDF Project and the NSDF Project in combination with other previous, existing and reasonably foreseeable developments.

5.7.5.2 Results

Pathways through which all stages of the NSDF Project may interact with and result in changes to measurement indicators for ecological health is provided in Table 5.7.5-1.

Table 5.7.5-1: Pathways Analysis for Ambient Radioactivity and Ecological Health Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment

▪ Project activities during the operations and closure phase:
  ▪ Phased development of disposal cells in the ECM
  ▪ On-site transportation of waste and placement in the ECM
  ▪ Progressive closure of disposal cells and installation of final cover
  ▪ Surface water management
  ▪ Operation of the WWTP
  ▪ Discharge of treated effluent from the WWTP
	▪ Dust may be created during the handling of bulk materials, and emissions of gases may be released during storage and disposal of radioactive materials, which can affect ecological health.
	▪ Emissions may be released from the WWTP to air during operations, which can affect ecological health.
		▪ CNL's procedure for Management and Monitoring of Emissions (CNL 2018e), which includes operational control monitoring and verification monitoring will be implemented.
		▪ The buildup of gaseous emission from waste in closed cells is mitigated by gas venting in the final cover.
		▪ The Dust Management Plan (AECOM 2018a) for the NSDF Project will include:
		  ▪ restricting or suspending activities if unacceptable amounts of dust are generated due to winds or other site conditions;
		  ▪ use of water spraying or misting techniques (e.g., water trucks) as the primary dust control method;
		  ▪ use of fixatives (e.g., chemical suppressant) for dust control, and for use as daily/interim cover;
		  ▪ suspension of excavating, loading, hauling and disposal operations when wind speeds exceed the specified criterion; and
		  ▪ vehicles that have come into contact with contamination will be required to pass through the vehicle decontamination facility
		▪ Processed wastewater will not be heated within the WWTP (raising the temperature increases potential release rates).
		▪ There is active ventilation within the WWTP building and active ventilation exhaust will be filtered through HEPA prior to release.
		▪ A perimeter fence around the NSDF will be implemented to prevent terrestrial land-based wildlife from gaining access to the ECM. Given the transient nature of exposure to birds and the low expected ambient concentrations, low exposures are expected for birds and as such no specific mitigations have been proposed.
			Primary

	▪ Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) may cause changes to groundwater quality in the wetland and downstream surface water quality, which can affect ecological health.	▪ The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses the best available technology that is economically achievable and capable of meeting regulatory requirements.
		▪ Effluent discharge targets for wastewater discharges are protective of the environment and human health.
		  ▪ Discharge targets for non-radiological contaminants are sourced from federal and provincial guidelines for protection of aquatic biota.
		  ▪ Discharge targets for radionuclides are the Canadian Drinking Water Guidelines with the exception of tritium for which a site-specific target is developed (Section 3.4.2.5.1).
		▪ Treated effluent will be sampled to confirm that it meets effluent discharge targets before release to the environment.
		▪ When applied, the proposed exfiltration gallery will promote the exfiltration of treated water into the local groundwater regime where further retention of radioactivity by the geosphere is anticipated.
		▪ The Perch Lake diffuser design provides additional dilution of treated effluent at the point of release
		▪ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water quality.
		▪ Appropriate procedures will be in place to effectively identify spill occurrences in the event treated effluent is released to areas other than directly to the exfiltration gallery and initiate appropriate emergency responses
			Primary

▪ Project activities during the operations and closure phase:
  ▪ Surface water management
  ▪ Operation of the WWTP
  ▪ Discharge of treated effluent from the WWTP
	▪ Leakage of leachate from the ECM during operations and closure may cause changes to groundwater quality in the wetland and downstream surface water quality, which can affect ecological health.	▪ Design of the ECM includes base grading configured in a herringbone pattern with ridges and valleys to promote leachate transport to the leachate collection system for removal.
		▪ The base liner design includes primary and secondary liner systems designed to have redundancy in case of premature degradation and are a combination of natural and synthetic barrier systems. These include a compacted clay liner (CCL), two geosynthetic clay liners (GCL) and an HDPE geomembrane.
		▪ Clay materials were selected for the CCL and GCL components of the liner system as these materials are anticipated to maintain their function as hydraulic barriers throughout and beyond the design life of the disposal facility (i.e., 550 years; 50 years of operations and 500 years post-closure).
		▪ The HDPE geomembrane design for the liner will be compatible with the leachate generated by the waste and provide a long service life.
		▪ The base liner system will include an underlying compacted clay liner to supplement the primary and secondary liner system.
		▪ The leachate collection system design will provide access points for inspections, maintenance, repairs, and replacements.
		▪ Appropriate responses to leachate leakage and contamination will be implemented as described in the Operations and Maintenance Plan (AECOM 2019).
			No Linkage

▪ Project activities during the post-closure phase:	▪ Volatiles (e.g., radon, tritium) may be released to air, which can affect ecological health.	▪ A passive landfill gas venting system will be constructed at the same time as installation of the ECM final cover system.	▪ Primary

Table 5.7.5-1: Pathways Analysis for Ambient Radioactivity and Ecological Health Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
▪ On-going long-term performance monitoring, transfer of NSDF Project into the post-institutional control period		▪ The landfill gas monitoring probes will also be installed around the perimeter of the ECM to detect evidence of potential landfill gas migration away from the ECM. ▪ Radon-emitting wastes will be preferentially placed in the lower levels of the ECM.	
	▪ Leachate may be released to soil via overtopping the berm, which can affect ecological health.	▪ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound and minimize leachate generation. ▪ The cover system design incorporates a series of shallow, trapezoidal, riprap-lined drainage channels that are designed to convey water at low velocity. ▪ The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the cover and underlying waste materials, destabilization of the ECM structure and damage to access roads. ▪ The ECM final grading and drainage plan includes collection ditches along the top of the ECM berm road to collect side slope drainage. ▪ Environmental monitoring will be completed as required during the institutional control period for the NSDF Project to confirm that the final cover is functioning as intended.	Primary
	▪ Leachate may be released through the base liner to groundwater, which can affect ecological health.	▪ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound and minimize leachate generation. ▪ The cover system design incorporates a series of shallow, trapezoidal, riprap-lined drainage channels that are designed to convey water at low velocity. ▪ The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the cover and underlying waste materials, destabilization of the ECM structure and damage to access roads. ▪ The ECM final grading and drainage plan includes collection ditches along the top of the ECM berm road to collect side slope drainage. ▪ The design life for the ECM is 550 years to meet the required time period to allow for radioactive decay of the waste placed in the facility (i.e., until it has decayed to levels that do not present a risk to the public and environment). ▪ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to groundwater quality.	Primary

ECM = engineered containment mound; WWTP = Wastewater Treatment Plant; HDPE = high density polyethylene.

5.7.5.2.1 No Linkage Pathways

The following pathway was assessed as having no measurable environmental change and hence, no linkage to residual effects on ecological health VCs.

- **Leakage of leachate from the ECM during operations and closure may cause changes to groundwater quality in the wetland and downstream surface water quality, which can affect ecological health.**

Design of the ECM includes base contours that have been developed using a herringbone pattern with ridges and valleys to promote leachate transport to the leachate collection system for removal. The base liner design includes both primary and secondary liner systems that are designed to have redundancy in case of premature degradation and are a combination of natural and synthetic barrier systems. The primary liner will include a leachate collection system with the secondary liner housing a leak detection system. The composite base liner will contain perforated high density polyethylene (HDPE) collection and monitoring pipes. The HDPE geomembrane was selected as it is compatible with the leachate generated by the waste and is expected to perform as an effective hydraulic and diffusion barrier over the 550-year design life (i.e., 50 years of operations and 500 years post-closure, see Section 3.4.1.4). The base liner system will include an underlying compacted clay liner to supplement the primary and secondary liner system. The leachate collection and monitoring system design will provide access points for monitoring, inspections, maintenance, repairs and replacements.

The primary liner system will contain the leachate collection system and will convey leachate to a single collection point for removal from the ECM, for transfer to the WWTP for treatment. The primary liner system serves as the primary source of protection for the natural environment below the ECM from leachate migration. The secondary liner system will contain the leak detection system, which will be used to detect leaks in the unlikely event that the primary liner system fails. Leachate collected by the leachate collection system will be pumped to the on-site WWTP for treatment.

Perimeter berms consist of three main geotechnical elements, or layers, each contributing to the soundness and integrity of the berm itself and the whole ECM. A *Slope Stability Analysis* (AECOM 2018b) was completed to provide the information needed to support the design of the base slopes, sidewalls and side slopes of the ECM. The *Slope Stability Analysis* addresses the range of anticipated loading conditions, under both short-term and long-term scenarios, to confirm that the slope designs will satisfy minimum factor-of-safety requirements for stability. Size and shape of the berms and each of the elements and layers were determined using a seismic design basis, including the *National Building Code of Canada 2015* (NRCC 2015).

The implementation of the design of the ECM, the liner systems, and the perimeter berms will reduce the potential for changes to groundwater and surface water quality from the NSDF Project site. As such, this pathway was determined to have no linkage to effects on ecological health.

5.7.5.2.2 Secondary Pathways

No secondary pathways were identified as having residual effect on ecological health.

5.7.5.2.3 Primary Pathways

Primary pathways identified for ecological health and that are evaluated in the residual effects analysis (Section 5.7.6 Residual Effects Analysis) include:

- During the operations and closure phases:
  - **Dust may be created during the handling of bulk materials and emissions of gases may be released during storage and disposal of radioactive materials, which can affect ecological health.**
  - **Emissions may be released from the WWTP to air during operations, which can affect ecological health.**
  - **Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) can cause changes to groundwater quality in the wetland and downstream surface water quality, which can affect ecological health.**
- During the post-closure phase:
  - **Volatiles (e.g., radon, tritium) may be released to air, which can affect ecological health.**
  - **Leachate may be released to soil via overtopping the berm, which can affect ecological health.**
  - **Leachate may be released through the base liner to groundwater, which can affect ecological health.**

5.7.6 Residual Effects Analysis

This section describes the specific methods used to assess the residual effects on ecological health for the NSDF Project activities and pathways identified as primary in Table 5.7.5-1. The approach used to predict residual effects is described below, along with the scenarios, models, policies, guidelines and standards considered in the analysis. The radiological dose assessment is discussed Section 5.7.6.1 and the non-radiological exposure assessment is discussed in Section 5.7.6.2.

5.7.6.1 Radiological Dose Assessment

5.7.6.1.1 Application Case Methods

The majority of the information in the Residual Effects Analysis for the radiological dose assessment is taken from the following sources:

- NSDF *Safety Analysis Report* (SAR) (CNL 2020) presents the analysis and results of radiological atmospheric emissions during the operations phase;
- groundwater quality modelling (Section 5.3.2) presents the analysis and results of radioactivity in groundwater during the operations phase;
- surface water quality modelling (Section 5.4.2) presents the analysis and results of radiological waterborne effluent during the operations phase;
- PostSA (Arcadis and Quintessa 2020b) presents the analysis and results for radiological contaminants in environmental media during the post-closure phase; and
- EcoRA (Arcadis 2020a) presents the analysis and results of the radiological dose assessment to ecological receptors during the post-closure phase.

The radiological dose assessment considers the ways in which ecological receptors (introduced in Section 5.7.2) could be exposed to radioactivity present in the various environmental media.

5.7.6.1.1.1 Operations and Closure Phases

For the assessment of environmental media and ecological health in the pre-closure (operations) phase of the NSDF Project, the main supporting information is from modelling completed for groundwater quality (Section 5.3.2.6) and surface water quality (Section 5.4.2.6). The main supporting document for the atmospheric emissions of radiological contaminants is the NSDF *Safety Analysis Report* (SAR) (CNL 2020). A general background of the methods of the SAR follows.

Safety Analysis Report – Atmospheric Emissions

The SAR describes the design of the facility, and subsequently analyzes the hazards and potential consequences present in the operations of the facility. The purpose of the SAR is:

- to demonstrate the adequacy of the NSDF Project design in support of the licensing process;
- to demonstrate that the proposed design of the facility conforms to CNSC regulatory requirements and guidance provided by the International Atomic Energy Agency, and will provide for safe operation over the operational life;

- to identify the hazards, describe how hazards are controlled and/or mitigated, and describe the management system in place to ensure the controls are effectively and consistently applied;
- to undertake a quantitative and qualitative assessment of the radiological and non-radiological safety of the NSDF Project during the operations and closure phases;
- to undertake a quantitative and qualitative assessment of the radiological and non-radiological safety of the NSDF Project during the operations and closure phases; and
- to provide necessary information to support an EIS which will address the requirements of the *Canadian Environmental Assessment Act, 2012* (CEAA 2012) and *REGDOC-2.11.1, Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* (CNSC 2018).

The scope of the SAR is to present the operational safety analysis of the NSDF Project based on the detailed design package, proposed operations and identified hazards. The SAR uses the most up-to-date information about the NSDF Project design to form the basis of the assessment. In the SAR, nuclear safety is assessed for normal operations as well as accident conditions for on- and off-site human receptors and the environment. The timeframe assessed includes the construction period, approximate 50-year operations period, and 30-year closure period.

Normal Operations refers to the most likely, expected process and work tasks that take place on a day-to-day basis. The assessment of Normal Operations assumes that all processes and procedures are followed, that workers are properly trained, and that all CNL compliance programs are being adhered to.

For Normal Operations, the dose constraint for workers is 20 mSv/yr and for the public a dose constraint of 0.3 mSv/yr is applied in accordance with the CRL *Licence Conditions Handbook* (CNSC 2019). The dose constraint for the public is achieved by ensuring that off-site radionuclide releases are well below *Derived Release Limits (DRL) for AECL's Chalk River Laboratories* (CNL 2018f). The NSDF Project is designed so the potential release of radionuclides during normal operations is less than a target of 1% of the corresponding release limits and DRL.

Accident conditions are separated into three categories based on frequency of occurrence, and are evaluated further in Section 7.0:

- Anticipated Operational Occurrence: An event that deviates from normal operations and is expected to occur once to several times during the operating lifetime of the facility. An Anticipated Operational Occurrence does not result in significant damage.
- Design Basis Accident: A rare event that is expected to occur once in 10,000 years, but much less frequently than an Anticipated Operational Occurrence. The NSDF Project is designed to perform under the conditions of a Design Basis Accident.
- Beyond Design Basis Accident: A very rare event that has more severe consequences, but occurs less frequently than a Design Basis Accident. A Beyond Design Basis Accident is expected to occur less than once in 10,000 years.

The objectives of the safety analysis are to demonstrate the following requirements under normal operations, Anticipated Operational Occurrences, Design Basis Accidents and Beyond Design Basis Accidents in the NSDF Project:

- the safety of the off-site public and on-site workers is protected;
- the dose acceptance criteria are met;
- there are no significant adverse effects on the environment;
- the adequacy of the NSDF Project design; and
- the proposed design of the NSDF Project conforms to regulatory requirements and guidance provided by the CNSC and the International Atomic Energy Agency (IAEA).

The SAR considers the following primary pathways in the evaluation of environmental effects:

- Dust may be created during handling of bulk materials and emissions of gases may be released during storage and disposal of radioactive materials, which can affect ecological health.
- Emissions may be released from the WWTP to air during operations, which can affect ecological health.

Gases and dust released from the ECM or WWTP can diffuse into the environment where they will be dispersed by wind. Some contaminants will be absorbed by vegetation which could then be consumed by animals and people.

Contaminants released through the treated effluent will reach Perch Lake. Once in the aquatic environment, there will be further dilution in Perch Creek and then in the Ottawa River. Contaminants may be taken up by aquatic flora and fauna. However, given that the effluent discharge meets applicable discharge requirements, exposure to humans and biota through this pathway are considered negligible during the operations and closure phase.

The radiological inventory of the ECM includes low-level waste associated with bulk unpackaged wastes and packaged wastes. The radionuclides assessed in the SAR are presented in Table 5.7.6-1.

Table 5.7.6-1: Radionuclides Assessed in the Safety Analysis Report

Radionuclides	
Ag-108m (metastable isotope silver-108)	Pu-239 (isotope plutonium-239)
Am-241 (isotope Americium-241)	Pu-241 (isotope plutonium-241)
Am-243 (isotope Americium-243)	Pu-242 (isotope plutonium-242)
C-14 (isotope carbon-14)	Ra-226 (isotope radium-226)
Cl-36 (isotope chlorine-36)	Se-79 (isotope selenium-79)
Co-60 (isotope cobalt-60)	Sn-126(isotope tin-126)
Cs-135 (isotope caesium-135)	Sr-90 (isotope strontium-90)
Cs-137 (isotope caesium-137)	Tc-99 (isotope technetium-99)
H-3 (isotope hydrogen-3 [Tritium])	Th-230 (isotope thorium-230)
I-129 (isotope Iodine-129)	Th-232 (isotope thorium-232)
Mo-93 (isotope molybdenum-93)	U-233 (isotope uranium-233)
Nb-94 (isotope Niobium-94)	U-234 (isotope uranium-234)
Ni-59 (isotope nickel-59)	U-235 (isotope uranium-235)
Ni-63 (isotope nickel-63)	U-238 (isotope uranium-238)
Np-237 (isotope neptunium-237)	Zr-93 (isotope zirconium-93)

Source: CNL 2020

The SAR examines the potential hazards that could result from normal operations and the consequences of abnormal events and accidents. The SAR uses a systematic and comprehensive method to identify all hazards and accident scenarios which includes:

- hazard identification;
- identification of major hazards and postulated initiating events associated with the NSDF Project design and operations;
- hazard analysis of the consolidated list of major hazards and postulated initiating events for the NSDF Project facilities;
- failure mode, effects and criticality analysis (FMECA) of the WWTP; and
- safety analysis of normal operation, Anticipated Operational Occurrences, Design Basis Accidents and Beyond Design Basis Accidents using credible/relevant scenarios.

The hazard identification was conducted early in the design process (AECOM 2016). The objective of the hazard identification was to list characteristics associated with systems, structures and components with the potential for radiological or chemical harm to people or the environment.

The hazards posed by the NSDF Project, with the exception of the WWTP, were identified based on the safety analysts' engineering judgement, and were recorded on the Safety Hazards Checklist and documented in Hazard Identification (AECOM 2016). The Safety Hazards Checklist was used to record relevant details and safeguards for the identified hazards.

The WWTP hazard identification involved completing a preliminary failure modes and effects analysis (FMEA) for the WWTP components and subcomponents based on the 30% design piping and instrumentation diagrams (AECOM 2016). The preliminary FMEA for the WWTP components was developed to identify failure modes and effects based on the safety analysts' engineering judgement. The WWTP preliminary FMEA is documented in Hazard Identification (AECOM 2016).

Groundwater Quality

As described in Section 5.3.2.6.2.1, effects to groundwater quality is from discharge of treated wastewater to ground via the exfiltration gallery. The treated effluent discharge will meet ecological-based guidelines for all non-radiological. The treated effluent discharge will meet Canadian drinking water guidelines for all radionuclides at the point of discharge with the exception of tritium which will meet Canadian drinking water guidelines at Perch Creek discharge to the Ottawa River. The assessment of radiological discharges to surface water (Section 5.4.2) has confirmed no impacts on aquatic biota from the treated effluent discharges. Additionally, although expected to be negligible, monitoring of effluent (surface water) quality against the effluent discharge targets will be carried out.

Waterborne Effluent

As considered in Section 5.4.2, the total average annual volume of leachate, contact stormwater and decontamination water under this operating scenario is 13,320 m^3/yr. This operating scenario represents the anticipated wastewater generated over approximately 50 years of the ECM for one active cell and nine filled (closed) cells based on:

- two weeks of 22.5 m^3/hr discharge (8 hr/day) corresponding to a storm event (i.e., 2,520 m^3); and
- 120 days of 11.25 m^3/hr discharge (8 hr/day) corresponding to normal operations (i.e., 10,800 m^3).

This single annual effluent flow of 13,302 m^3/yr is discharged under two receiving environment scenarios:

- **Scenario 1:** 50% of WWTP effluent discharges to an exfiltration gallery ultimately leading to the East Swamp Wetland and the remaining 50% directly discharges to Perch Lake via an end-of-pipe diffuser.
- **Scenario 2:** 100% of WWTP effluent discharges directly to Perch Lake via an end-of-pipe diffuser.

For the operations phase modelling, it is conservatively assumed that no dilution occurs along the groundwater flowpath from the WWTP effluent discharge to the East Swamp Stream. The annual average flow rate of the East Swamp stream, which drains the wetland, is 72,000 m^3/yr. Average annual outflow from this wetland is via East Swamp Stream to Perch Lake, which discharges to the Ottawa River via Perch Creek at approximately 2,200,000 m^3/yr.

Both aquatic and terrestrial species will be exposed to contaminated surface water and sediment in the East Swamp Stream, Perch Lake, Perch Creek and Ottawa River. As further dilution will occur in the Perch Lake, Perch Creek and Ottawa River, exposure within the aquatic environment of the East Swamp Stream is bounding. Therefore, doses to ecological receptors were calculated based on water and sediment concentrations in East Swamp Stream.

Treated effluent discharged to the exfiltration gallery will contain small quantities of residual contaminants. Treated effluent will enter the East Swamp Stream, and proceed to Perch Lake, Perch Creek and the Ottawa River as described above. The concentrations of radionuclides in the treated effluent are assumed to be equal to

CNL's effluent discharge targets, as presented in Table 5.7.6-2. This is a conservative assumption, as the majority of releases will be below these target values as a result of treatment. Concentrations of radionuclides in the East Swamp Stream can be derived by applying a dilution factor of 0.19, which was calculated based on the flow rate of 72,000 m^3/yr in the East Swamp Stream and the treated effluent flow rate of 13,320 m^3/yr.

Releases of tritium represent a special case as tritium in the form of tritium oxide will not be removed from the leachate during processing at the WWTP via filtration and ion exchange treatment. For this reason, concentration of tritium in effluent was estimated based on its inventory in bulk waste, leachate generation rate and the total quantity of wastewater.

Table 5.7.6-2: Maximum Concentrations of Radionuclides in the Treated Effluent

Radionuclide	Maximum Concentrations in Treated Effluent (Bq/L)[(a)]
Ag-108m (metastable isotope silver-108)	60
Am-241 (isotope Americium-241)	0.7
Am-243 (isotope Americium-243)	0.7
C-14 (isotope carbon-14)	200
Cl-36 (isotope chlorine-36)	100
Co-60 (isotope cobalt-60)	40
Cs-135 (isotope caesium-135)	70
Cs-137 (isotope caesium-137)	10
H-3 (isotope hydrogen-3 [Tritium])	360,000
I-129 (isotope Iodine-129)	1
Mo-93 (isotope molybdenum-93)	40
Nb-94 (isotope Niobium-94)	80
Ni-59 (isotope nickel-59)	2,000
Ni-63 (isotope nickel-63)	900
Np-237 (isotope neptunium-237)	1
Pu-239 (isotope plutonium-239)	0.6
Pu-241 (isotope plutonium-241)	30
Pu-242 (isotope plutonium-242)	0.6
Ra-226 (isotope radium-226)	0.5
Se-79 (isotope selenium-79)	50
Sn-126 (isotope tin-126)	30
Sr-90 (isotope strontium-90)	5
Tc-99 (isotope technetium-99)	200
Th-230 (isotope thorium-230)	0.7

Table 5.7.6-2: Maximum Concentrations of Radionuclides in the Treated Effluent

Radionuclide	Maximum Concentrations in Treated Effluent (Bq/L)[(a)]
Th-232 (isotope thorium-232)	0.6
U-233 (isotope uranium-233)	3
U-234 (isotope uranium-234)	3
U-235 (isotope uranium-235)	3

Bq/L = Becquerels per litre.

5.7.6.1.1.2 Post-closure Phase

The main supporting documents for the assessment of environmental media and ecological health in the post-closure phase of the NSDF Project are the PostSA (Arcadis and Quintessa 2020b) and the EcoRA (Arcadis 2020a). A general background of these documents is provided below.

Post-Closure Safety Assessment

The PostSA (Arcadis and Quintessa 2020b) analyzes the long-term implications (i.e., during the institutional control and post-institutional control periods) of the NSDF Project. The purpose of the PostSA is:

- to undertake a quantitative assessment of the radiological (and non-radiological) safety of the NSDF during the post-closure phase;
- to identify those uncertainties that have the greatest potential effect on the long-term performance of the closed facility; and
- to provide necessary information to support an EIS which will address the requirements of the *Canadian Environmental Assessment Act, 2012* and CNSC's *REGDOC-2.11.1, Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* (CNSC 2018).

Evaluating post-closure safety requires projections of the future condition of the NSDF Project and its environment, and how receptors might interact with it. Approaches have been developed to undertake such evaluations, centred on a "system analysis" method. This involves representing the NSDF Project, the facility inventory present and all potentially relevant media, with mathematical models to represent the key processes that may occur (e.g., corrosion of wastes, dissolution into groundwater, uptake by plants). It is essential that the models used are relevant, well grounded and auditable. This is achieved through a systematic approach to safety assessment. The international community has developed best practice guidance on the process, which is documented in a report of the International Atomic Energy Agency's Improving Safety Assessment Methodologies program (IAEA 2004) and incorporated into a more recent safety guide (IAEA 2012). This process has been applied internationally since its publication, is consistent with CNSC's *REGDOC-2.11.1, Waste Management,*

Volume III: Assessing the Long-Term Safety of Radioactive Waste Management (CNSC 2018) and underpins the PostSA analysis.

The PostSA considers three pathways of release of contaminants into the environment:

- Volatiles (e.g., radon, tritium) may be released to air, which can affect ecological health.
- Leachate may be released to soil via overtopping the berm, which can affect ecological health.
- Leachate may be released through the base liner to groundwater, which can affect ecological health.

Gases released above the ECM will diffuse through the soil and into the atmosphere, where they will be dispersed by wind. Some contaminants will be taken up into vegetation and could then be consumed by animals and people.

Contaminants released by overtopping the ECM berm will move through the shallow environment by overland flow and interflow resulting in contamination of surface soils. Exposures can arise by external irradiation, inhalation of dust, inadvertent ingestion and consumption of food stuffs grown in the soil, or consumption of animals that have grazed in the contaminated area.

Contaminants released to groundwater beneath the ECM will move through the geological and hydrogeological environment by advection and dispersion and may sorb to sediments. Once in the aquatic environment, there will be dilution, firstly in Perch Creek and then in the Ottawa River. Contaminants may be taken up by aquatic flora and fauna.

The PostSA considers both radiological and non-radiological contaminants, based on the inventory of the ECM. The radioactive inventory of the ECM includes low-level waste associated with bulk unpackaged wastes as well as wastes in packages. The radionuclide inventory has been screened to reduce the number of radionuclides being considered to those that are relevant for the post-closure phase. Radioactive decay and ingrowth are accounted for during the assessment time frame. The radionuclides assessed in the PostSA are presented in Table 5.7.6-3 (refer to Section 5.7.6.2.1.2 for a description of non-radiological contaminants).

Table 5.7.6-3: Radionuclides Assessed in the PostSA

Radionuclides	
Ag-108m (metastable isotope silver-108)	Pu-239 (isotope plutonium-239)
Am-241 (isotope Americium-241)	Pu-241 (isotope plutonium-241)
Am-243 (isotope Americium-243)	Pu-242 (isotope plutonium-242)
C-14 (isotope carbon-14)	Ra-226 (isotope radium-226)
Cl-36 (isotope chlorine-36)	Sr-90 (isotope strontium-90)
Co-60 (isotope cobalt-60)	Tc-99 (isotope technetium-99)
Cs-135 (isotope caesium-135)	Th-230 (isotope thorium-230)
Cs-137 (isotope caesium-137)	Th-232 (isotope thorium-232)
H-3 (isotope hydrogen-3 (Tritium)	U-233 (isotope uranium-233)
I-129 (isotope Iodine-129)	U-234 (isotope uranium-234)
Nb-94 (isotope Niobium-94)	U-235 (isotope uranium-235)
Ni-59 (isotope nickel-59)	U-238 (isotope uranium-238)
Ni-63 (isotope nickel-63)	Zr-93 (isotope zirconium-93)
Np-237 (isotope neptunium-237)	

The PostSA uses the best available information on the NSDF Project and its surrounding environment to form the basis of the mathematical models developed specifically to represent the system. These have been used to calculate results that can be compared with relevant Canadian criteria and standards, as well as inform on uncertainties and identify the most important aspects of the system. These uncertainties and important aspects are captured using a number of scenarios, which are summarized in the PostSA and within the groupings below:

- Normal Evolution Scenario;
- Disruptive Event Scenarios;
- Defence-in-Depth Cases;
- “What-If” Cases; and
- Sensitivity Analysis Cases.

The **Normal Evolution Scenario** is a description of the most likely, expected, evolution of the ECM and its surrounding environment. The Normal Evolution Scenario accounts for the expected degradation of the engineered barriers over the post-closure phase. It starts immediately following the operations and closure phase, to capture the entire post-closure phase (i.e., institutional control and post-institutional control periods). It is assumed that during the institutional control period (year 2100 to year 2400), the base liner and cover will be functional and no leachate will seep through the base liner.

Disruptive Event Scenarios are variants on the Normal Evolution Scenario, designed to address uncertainties that have arisen during the definition of scenarios and conceptual models. Each is described with scenario-specific assumptions. The following Disruptive Event Scenarios were assessed in the PostSA:

- **Human Intrusion (Borehole):** This scenario assesses the potential of humans drilling, extracting and examining a core sample from the facility, potentially leading to internal or external exposures.
- **Human Intrusion (House with Basement):** In this scenario, a potential basement is constructed on top of the ECM and excavated soil/waste is spread over the garden area.
- **Enhanced Erosion Case:** This scenario investigates the potential faster erosion of the cap such that wastes are exposed at the ground surface and eroded materials spread downslope in the swamp area between the ECM and Perch Creek. This could be caused by seismic events.
- **Localized Cover Failure:** In this scenario, it is assumed that potential high infiltration through a failure in the final cover occurs, resulting in earlier bathtubbing[4] of the ECM (relative to the Normal Evolution Scenario).
- **Localized Liner Failure:** This scenario assesses increased leaching through a potential failure in the base liner, resulting in delayed bathtubbing of the ECM (relative to the Normal Evolution Scenario).
- **Damage to the Berm:** This scenario assesses potential damage to the berm; the reduced height of the berm results in increased flow of water over the berm during bathtubbing and a reduced water level in the wastes.

[4] “Bathtubbing” refers to a process in which waste material degrades, producing voids within a disposal trench followed by subsidence of the overlying soil and the entry of surface water into the trench.

In addition to Normal Evolution Scenario and Disruptive Event Scenarios, the PostSA also considers other types of scenarios, including “What-If” Cases, Defence-in-Depth Cases and Sensitivity Analysis Cases.

- “What-If” Cases represent a deliberately extreme set of assumptions that can be used to understand the absolute limits of safety performance. These have been identified as potentially of interest in the same way as other scenarios, but discounted from the main set of assessment calculations on the basis that they are of very low or negligible likelihood. Nevertheless, they inform on the underlying bounds to post-closure safety and, as such, provide valuable perspective. However, due to their very low likelihood, they are not considered in the identification and assessment of residual effects.
- Defence-in-Depth Cases are aimed at building confidence in the performance of the ECM after closure. These cases examine the extent to which the NSDF Project depends on key engineered barriers and what would happen if those barriers were not present. This group of scenarios therefore involves hypothetical combinations in order to analyze the barriers in the system. Each scenario involves a change in one or more parameters related to a particular barrier; by comparing the results to those of the Normal Evolution Scenario, the influence of the barrier is tested.
- Sensitivity Analysis Cases are used to directly examine the effect of important uncertainties in the models and data used to represent the system. As many modelling aspects can in practice be expressed through parameter values, sensitivity cases focus on using alternative parameter value choices. The alternative parameter values that are assigned need not represent specific bounds on uncertainty (as in some cases these cannot easily be established); in other words, the alternative parameters need not necessarily be the “highest” or “lowest” possible values. Rather, they are used to test the effect of uncertainty; for example, if parameter x is increased by a factor of 10, by what factor does the dose increase?

These cases serve to illustrate the importance of facility design features, address uncertainty in model parameters and provide perspective on the limits of safety performance. They are not relevant for the EIS effects assessment and are therefore not discussed further in this section. Further information on these scenarios and the PostSA calculations and results in general, is available in the PostSA (Arcadis and Quintessa 2020b).

Environmental data from the PostSA was incorporated into the EcoRA (Arcadis 2020a) to assess potential effects to ecological receptors during the post-closure phase.

Ecological Risk Assessment

The EcoRA (Arcadis 2020a) assesses the effects of radiological (and non-radiological) contaminants on ecological receptors during the post-closure phase of the NSDF Project. Other stressors associated with the NSDF Project (e.g., noise, dust, changes in habitat) are assessed directly within the EIS. Following the *CSA N288.6, Environmental Risk Assessment at Class 1 Nuclear Facilities and Uranium Mines and Mills* (CSA Group 2012) process/framework, the EcoRA uses results from the PostSA on contaminant concentrations in various environmental media, to assess ecological risk.

The EcoRA screens the contaminant concentrations calculated in each relevant PostSA scenario against the most conservative available criteria such as the Environmental Media Concentrations (EMCs) from the ERICA Tool (ERICA 2019) and No-Effect Concentrations (NECs) (Arcadis 2019a) where gaps existed, for radiological contaminants. Based on this, aluminum, copper, lead, and uranium were screened into the non-radiological assessment for all scenarios during the post-closure phase. Nine radionuclides (actinium-227, molybdenum-93, niobium-93m, plutonium-242, thorium-229, uranium-233, zirconium-93) were ‘screened-in’ due to a lack of

available screening criteria to screen them out, and not necessarily because they had elevated environmental concentrations. If a contaminant was ‘screened in’, it was then carried forward for assessment in the EcoRA.

The indicator species selected for inclusion in the EcoRA were chosen based on the VCs defined in this EIS, as well as selection criteria outlined in CSA N288.6 (CSA Group 2012). The VCs and their respective indicator species are provided in Table 5.7.2-1. These indicator species are considered appropriate because they reflect a variety of diets/feeding habits, cover a variety of trophic levels, are representative of the biota expected to be found in the RSA, and are of interest to the facility and stakeholders. In addition to these indicator species, the EcoRA also includes moose as an ecological receptor in response to Indigenous interests.

The indicator species are assessed using assessment endpoints, which are expressions of the actual environmental values to be protected. In general, the assessment endpoints selected in this study were healthy populations of the identified indicator species within the RSA.

The list of indicator species chosen for assessment in the EcoRA included the following species at risk, as defined under the *Species at Risk Act:*

- Canada warbler (*Cardellina canadensis*; Threatened);
- eastern milksnake (*Lampropeltis Triangulum*; Species of Concern);
- eastern whip-poor-will (*Antrostomus vociferous*; Threatened);
- eastern wolf (*Canis lupus lycaon*; Species of Concern);
- little brown myotis (*Myotis lucifugus*; Endangered);
- monarch butterfly (*Danaus plexippus*; Species of Concern); and,
- snapping turtle (*Chelydra serpentine*; Species of Concern).

For example, the snapping turtle is selected as a surrogate for Blanding's turtle exposure. In the EcoRA, potential effects of the NSDF Project on these species at risk were considered on an individual level, rather than population-level effects.

The EcoRA assessed potential effects to ecological receptors for the various scenarios discussed above under the PostSA, such as Normal Evolution Scenario, Disruptive Event scenarios, and others. It is noted that some of the Disruptive Event scenarios do not have relevant pathways to ecological receptors, and as such were not assessed in the EcoRA. The scenarios omitted from the EcoRA are typically Human Intrusion scenarios (e.g., Borehole). Although the Human Intrusion (House with Basement) scenario is included in the EcoRA, because the displacement of waste onto the surface presents a potential pathway to wildlife.

Further information on the EcoRA assumptions, calculations and results is available in the EcoRA.

5.7.6.1.2 Application Case Results

5.7.6.1.2.1 Operations and Closure Phases

This section presents a summary of the assessment of ecological health prior to the post-closure phase (i.e., construction, operations and closure) for the Normal Operations. Anticipated Operational Occurrences, Design Basis Accidents and Beyond Design Basis Accidents are considered in Section 7.0 (Accidents and Malfunctions).

Safety Analysis Report – Atmospheric Emissions

The LLW disposed in the ECM, ECM waste placement activities, and wastewater processing (tank emissions) are the primary sources of the NSDF radiological airborne emissions (CNL 2019c).

Table 5.7.6-4 provides the estimated airborne concentrations of radon, tritium and C-14 in the disposal cell, and the estimated dose to the ECM worker (CNL 2019c). The estimated airborne radon concentration in the disposal cell is 0.5 Bq/m^3, which is lower than the current Canadian guideline of 200 Bq/m^3 for radon in indoor air for dwellings (Health Canada 2017). The dose to the ECM worker dose is negligible from ECM airborne concentrations of radon, tritium and C-14. Since the dose to the ECM worker is negligible, the radiological effect on ecological receptors will also be negligible from ECM airborne concentrations of radon, tritium and C-14.

Table 5.7.6-4: Radionuclide Atmospheric Concentrations and ECM Worker Dose

Radionuclide	Atmospheric Concentration in Disposal Cell (Bq/m^3)	ECM Worker Dose (mSv/year)
Radon	0.5	9.6E-04
Tritium	61	1.6E-05
Carbon-14	0.53	2.2E-06

Source: CNL 2020.

Airborne emissions from the Equalization Tanks and the WWTP process tanks occur because of evaporative loss of the liquid in storage and as a result of changes in liquid level. The emissions from a single Equalization Tank and the WWTP filter press feed tank were calculated in the SAR (CNL 2020) and compared to the CRL site Derived Release Limit (DRL) (CNL 2018f). The DRLs represent release rates that correspond to critical groups at the public dose limits. The filter press feed tank emissions were estimated, since this tank has the largest radiological source term of the WWTP process tanks (CNL 2019c). There are no appreciable radiological airborne releases from a single Equalization Tank vent and from the filter press feed tank vent, since the total radioactive material losses are 0.04% and 0.004% of the DRL, respectively (CNL 2019c). The radiological effect on ecological receptors from the NSDF wastewater tanks air emissions is expected negligible, based on the tanks air emissions being a fraction of the CRL site DRLs.

Further radiological doses to ecological receptors arising from exposure to air plumes at the points-of-impingement locations for the principal atmospheric sources at the CRL site such as the NRU Reactor were assessed in the 2005 Ecological Effects Review (EcoMetrix 2005). Dose to terrestrial biota was much less than the benchmark for protection of biota of 9.6 mGy/day (400 µGy/h). Atmospheric emissions from the NSDF Project (ECM and WWTP) will be a small fraction of those from the (now shutdown) NRU Reactor; therefore no further assessment is required.

Waterborne Effluent – Operations Phase

The surface water quality modelling confirms that environmental concentrations of contaminants are below the No Effect concentrations for protection of aquatic biota for radiological contaminants with the exception of one parameter, gross beta as Strontium-90. Existing gross beta concentrations are elevated at East Swamp Stream. The elevated concentrations are associated with an existing Strontium-90 groundwater plume in the area (Section 5.7.4.6). Surface water quality modelling indicates that the impacts on baseline concentrations are negligible (see

Table 5.4.2-14). No further assessment is therefore required. For the methods and numerical results of the surface water modelling, refer to Section 5.4.2.

By ensuring that releases and subsequent environmental concentrations are below the relevant guidelines or are below levels that would result in potential adverse effects on aquatic life, there will be no adverse effects to biota during the operations phase of the NSDF Project. Therefore, a quantitative assessment of radiological dose to biota is not required.

The predicted concentrations for the Ottawa River for each of the radionuclides that screened into the assessment are well below No Effect Concentrations based on 400 uGy/hr radiation benchmark used in the assessment. Accordingly, radiation doses to Aquatic Biota in the Ottawa River are predicted to be well below the Province of Quebec criteria of 10 µGy/hr.

5.7.6.1.2.2 Post-Closure Phase

This section presents results for radiological contaminants in environmental media, as well as radiological dose for ecological receptors for the Normal Evolution Scenario and Disruptive Event Scenarios during the post-closure phase.

Ecological risks are assessed by estimating the total dose rate received by an ecological receptor and comparing it to the selected benchmark values. The recommended radiological dose benchmarks used in the EcoRA are consistent with UNSCEAR (2008) and consist of 100 µGy/hr (2.4 mGy/d) for terrestrial biota and 400 µGy/h (9.6 mGy/d) for aquatic biota. A safety factor of 10 was applied to the selected benchmark values for species at risk to assess risks at the individual as opposed to population level. It is noted that part of the Ottawa River is located in the Province of Quebec, whose criteria for aquatic biota (10 µGy/hr) is 40 times lower than the benchmarks recommended by CSA N288.6-12 (CSA Group 2012). For species located in the Ottawa River, the Quebec benchmark has been applied.

Normal Evolution Scenario

During the post-closure phase, once the cap has degraded and water infiltrates the facility, contaminants are leached from the waste. Water drains through the base liner of the ECM and enters the groundwater pathway to Perch Creek. If the infiltration rate through the cap exceeds the drainage rate through the base liner, then overtopping occurs, with water containing dissolved contaminants being released directly to the ground surface and cap perimeter soils. Rates of infiltration through the cap and drainage through the base liner are calculated in the PostSA (Arcadis and Quintessa 2020b).

The total radioactivity associated with the wastes decreases over time due to radioactive decay. During the first 100 years, the decline is quite rapid as shorter-lived radionuclides decay. Thereafter the decline is much slower, as only longer-lived radionuclides remain.

Environmental contaminant concentrations are presented in detail in the PostSA (Arcadis and Quintessa 2020b). The application case results for radiological contaminants with respect to ecological health is summarized below.

Atmospheric Environment

During the post-closure phase, the gases of interest are radon-222, water vapour labelled with tritium, and methane and carbon dioxide labelled with carbon-14. Radon-220 gas will be generated but is not of interest as it will decay before it migrates through the cap. Radon-222, tritium and carbon-14 labelled gases will only be present in small quantities (i.e., they are trace gases).

The effects in the atmospheric environment during the post-closure phase are assessed with respect to the potential effect on indicator species in the EcoRA (Arcadis 2020a). The EcoRA determined that negligible residual effects were expected.

Geological and Hydrogeological Environment

Contaminants can be released to the geological and hydrogeological environment via:

- Water overtopping the berm will move through the shallow environment by overland flow and interflow resulting in contamination of surface soils. This soil contamination has the potential to effect external irradiation, inhalation of dust and vegetation quality, as well as ecological receptors.
- Leaching to groundwater beneath the ECM, and possible sorption to sediments. Leachate will migrate to the surface water and aquatic environments, where the leachate will be further diluted in Perch Creek and then in the Ottawa River. Contaminants may be taken up by aquatic biota.

The effects in the geological and hydrogeological environment during the post-closure phase are assessed with respect to the potential effect on indicator species in the EcoRA (Arcadis 2020a). The EcoRA determined that negligible residual effects were expected.

Surface Water Environment

As contaminants reach Perch Creek, there will be sorption in creek sediments and dilution in surface water and transport downstream to the Ottawa River. In the Ottawa River there will be significant dilution and transport downstream. The river level can rise following periods of snowmelt and higher rainfall. Under these conditions, suspended sediments, containing absorbed contaminants, may be deposited on the shore.

Peak environmental concentrations in water are low in the context of environmental effects. For example, as calculated in the PostSA (Arcadis and Quintessa 2020b), the peak concentration of tritium in surface water during the post-closure phase is 0.000055 Bq/L, as compared to the Maximum Acceptable Concentration of 7,000 Bq/L of tritium in drinking water (Health Canada 2019).

The potential effects of screened-in radiological contaminants are further assessed with respect to potential effects on indicator species in the EcoRA. As discussed in the Aquatic Environment and Terrestrial Environment below, the EcoRA determined that negligible residual effects were expected.

Aquatic Environment

Using maximum predicted concentrations calculated in the PostSA (Arcadis and Quintessa 2020b), the EcoRA (Arcadis 2020a) assessed the effect of radiological releases on aquatic biota during the post-closure phase.

An SI is the ratio (i.e., unitless) of an estimated exposure level (e.g., estimated environmental concentration) divided by a corresponding toxicity reference value or benchmark value. An SI value greater than 1 indicates the potential for undue effects.

SI values calculated for all radionuclides assessed were below a value of 1 for aquatic receptors. An SI below 1 indicates no undue effects.

Based on the effects assessment undertaken in the EcoRA, negligible residual effects from radiological exposure were predicted for aquatic biota in the post-closure phase.

Terrestrial Environment

Using maximum predicted concentrations calculated in the PostSA (Arcadis and Quintessa 2020b), the EcoRA (Arcadis 2020a) assessed the effect of radiological releases on terrestrial biota during the post-closure phase.

- SI values for all radionuclides were below a value of 1 for terrestrial receptors. An SI below 1 indicates no undue effects.

Based on the effects assessment undertaken in the EcoRA, negligible residual effects from radiological exposure were predicted for terrestrial biota in the post-closure phase.

Overall, negligible residual effects were identified for ambient radioactivity and ecological health for the Normal Evolution Scenario.

Disruptive Event Scenarios

Human Intrusion (House with Basement)

A potential basement is constructed on the top of the ECM and excavated soil/waste is spread over the garden area.

SI values for all radionuclides were below 1, indicating no undue effects to terrestrial or aquatic biota from radiological contaminants. Therefore, negligible residual effects were expected to result from the Human Intrusion (House with Basement) Disruptive Event Scenario.

Enhanced Erosion Case

In the Enhanced Erosion case, the potential faster erosion of the cap such that wastes are exposed at the ground surface and eroded materials spread downslope in the swamp area between the ECM and Perch Creek. Additionally, there is increased suspended sediment loading to Perch Creek. Therefore, potential effects in the geological and hydrogeological environment and the surface water environment are assessed under this scenario.

SI values for all radionuclides were below 1, indicating no undue effects to terrestrial or aquatic biota from radiological contaminants. Therefore, negligible residual effects were expected to result from the Enhanced Erosion Case Disruptive Event Scenario.

Localized Cover Failure

There is initially increased infiltration through the failure in the cap, resulting in earlier bathtubbing of the ECM (relative to the Normal Evolution Scenario). The increased infiltration alters the leachate release to groundwater, swamp soils and eventually Perch Creek. Therefore, potential effects in the geological and hydrogeological environment and the surface water environment are assessed under this case.

SI values for all radionuclides were below 1, indicating no undue effects to terrestrial or aquatic biota from radiological. Therefore, negligible residual effects were expected to result from the Localized Cover Failure Disruptive Event Scenario.

Localized Liner Failure

There is increased leaching through a potential failure in the base liner, resulting in delayed bathtubbing of the ECM (relative to the Normal Evolution Scenario). Therefore, potential effects in the geological and hydrogeological environment and the surface water environment are assessed under this scenario.

SI values for all radionuclides were below 1, indicating no undue effects to terrestrial or aquatic biota from both radiological contaminants. Therefore, negligible residual effects were expected to result from the Localized Liner Failure Disruptive Event Scenario.

Damage to the Berm

The reduced height of the berm results in increased flow of water over the berm during bathtubbing and reduced water level in the wastes. Therefore, potential effects in the geological and hydrogeological environment and the surface water environment are assessed under this scenario.

SI values for all radionuclides were below 1, indicating no undue effects to terrestrial or aquatic biota from radiological contaminants. Therefore, negligible residual effects were expected to result from the Damage to the Berm Disruptive Event Scenario.

Overall, no potential residual effects were identified for ambient radioactivity and ecological health for the Disruptive Event Scenarios.

5.7.6.2 Non-Radiological Exposure Assessment

5.7.6.2.1 Application Case Methods

The majority of the information in the Residual Effects Analysis for the non-radiological exposure assessment is taken from the following sources:

- air quality modeling (Section 5.2.2) presents the analysis and results of non-radiological airborne emissions during the operations phase;
- surface water quality modelling (Section 5.4.2) presents the analysis and results of non-radiological waterborne effluent during the operations phase;
- PostSA (Arcadis and Quintessa 2020b) presents the analysis and results for non-radiological contaminants in environmental media during the post-closure phase; and
- EcoRA (Arcadis 2020a) presents the analysis and results of non-radiological exposure for ecological receptors during the post-closure phase.

The non-radiological exposure assessment considers the ways in which ecological receptors (introduced in Section 5.7.2) could be exposed to contaminants present in the various environmental media.

5.7.6.2.1.1 Operations and Closure Phases

Atmospheric Emissions

Effects to air quality for non-radiological constituents are expected to be not significant (see Section 5.2.1.6) and localized to the LSA for all constituents when considering the conservatism built into the predictive models and the realistic operation of equipment during NSDF Project operations (i.e., that not all equipment would be operating at full capacity all of the time, but would rather be idling for part of the time resulting in lower emissions than predicted). Therefore, impacts on air quality and ecological receptors from non-radiological emissions was not considered further for these phases of the NSDF Project.

Inhalation by wildlife cannot be adequately assessed because there is a relative lack of toxicity data related to inhalation exposure for wildlife. As well, respirable particles (i.e., greater than 5 µm) are most likely ingested as a result of lung clearance rather than being inhaled (Witshchi and Last 1996). At equal exposure concentrations, it has been determined that inhalation of contaminants associated with dust particles is expected to contribute less than 0.1% of total risk compared to oral exposure to wildlife (US EPA 2005). As such, inhalation exposure is expected to be minimal, if not negligible, in comparison to the oral route of exposure. Therefore, exposure via inhalation was not assessed.

Waterborne Effluent

For the operations phase of the NSDF Project, the main supporting information is from modelling completed for surface water quality (Section 5.4.2). The non-radiological exposure assessment for ecological health considered the following two model scenarios for surface water environment (described in Section 5.4.2.6.1.2):

- **Scenario 1**: This scenario divides the total annual discharge equally between the exfiltration gallery at East Swamp weir and Perch Lake (direct pumping to Perch Lake via transfer line). The exfiltration gallery is considered to be the downstream portion of East Swamp (upstream of East Swamp weir) and the outfall location is considered to be at the northeastern shoreline of Perch Lake.

- **Scenario 2**: This scenario discharges 100% of the total annual discharge directly into Perch Lake at the northeastern shoreline. Scenario 2 was modelled to examine the “worst case” scenario of projected Perch Lake concentrations (i.e., no available mixing nor dilution upstream of Perch Lake).

The two surface water model scenarios were completed for a selected group of parameters termed constituents of potential concern (COPCs) as defined in Section 5.4.2.6.1.4. Key elements of the COPC selection process included identifying those parameters that were expected to change as a result of the NSDF Project, those with available guidelines, those with existing ambient concentrations and those that were expected to be toxic to aquatic organisms (including parameters that characterize general water properties with the potential to modify toxicity). The full list of COPCs is provided in Table 5.4.2-5, and the COPCs forwarded to the aquatic risk assessment include aluminum, barium, copper, iron, lead, manganese, phosphorus, selenium, silver and zinc as these parameters showed exceedances above their respective effluent discharge targets.

5.7.6.2.1.2 Post-Closure Phase

For the assessment of environmental media and ecological health in the post-closure phase of the NSDF Project, the main supporting documents are the PostSA (Arcadis and Quintessa 2020b) and the EcoRA (Arcadis 2020a). A general background of these documents is provided below.

Post-Closure Safety Assessment

The PostSA (Arcadis and Quintessa 2020b) analyzes the long-term implications during the post-closure phase on ecological health of the NSDF Project.

Evaluating post-closure safety requires projections of the future condition of the NSDF Project and its environment, and how receptors might interact with it. Approaches have been developed to undertake such evaluations, centred on a “system analysis” method. This involves representing the NSDF Project, the facility inventory present and all potentially relevant media, with mathematical models to represent the key processes that may occur (e.g., corrosion of wastes, dissolution into groundwater, uptake by plants). It is essential that the models used are relevant, well grounded and auditable. This is achieved through a systematic approach to safety assessment. The international community has developed best practice guidance on the process, which is documented in the International Atomic Energy Agency’s report *Improvement of Safety Assessment Methodologies for Near Surface Disposal Facilities* (IAEA 2004) and incorporated into a more recent safety guide (IAEA 2012). This process has been applied internationally since its publication, is consistent with CNSC’s *REGDOC-2.11.1, Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* (CNSC 2018) and underpins the PostSA analysis. Although this approach has been developed with radiological contaminants in mind, the same principles are considered to be appropriate for non-radiological contaminants and offers consistency in the approach used to assess both contaminant types for the NSDF Project.

The PostSA considers two primary pathways of release of non-radiological contaminants into the environment:

- leachate may be released to soil via overtopping the berm, which can affect human health; and
- leachate may be released through the base liner to groundwater, which can affect human health.

Contaminants released by overtopping the berm will move through the shallow environment by overland flow and interflow resulting in contamination of surface soils. Exposures can arise by external irradiation, inhalation of dust, inadvertent ingestion and consumption of food stuffs grown in the soil, or consumption of animals that have grazed in the contaminated area.

Contaminants released to groundwater beneath the ECM will move through the geological and hydrogeological environment by advection and dispersion and may sorb to sediments. Once in the aquatic environment, there will be further dilution in Perch Creek and then in the Ottawa River. Contaminants may be taken up by aquatic flora and fauna.

It is noted that release of volatiles to air was not considered a primary pathway for non-radiological contaminants given that no volatile non-radiological contaminants have been identified as COPCs.

As noted in Section 3.3.1.3.1, the NSDF Project will follow the guidelines of Ontario's *Regulation 347, General – Waste Management*, thus constraining the non-radiological inventory and limiting the environmental effects in the post-closure phase of the NSDF Project. However, an estimate on the quantity of discrete metals and organics in the NSDF at closure which is comprised of primarily wood, metals and bulk solid wastes. The non-radionuclides explicitly assessed in the PostSA include:

- aluminum;
- copper;
- lead; and
- uranium.

Similar to the radiological dose assessment, six scenarios were considered for the post-closure phase for the non-radiological exposure assessment. These scenarios are described in Section 5.7.6.1.1.2

Ecological Risk Assessment

The EcoRA (Arcadis 2020a) assesses the effects of chemical (and radiological) contaminants on ecological receptors during the post-closure phase of the NSDF Project. Other stressors associated with the NSDF Project (e.g., noise, dust, changes in habitat) are assessed directly within the EIS. Following the *CSA N288.6, Environmental Risk Assessment at Class 1 Nuclear Facilities and Uranium Mines and Mills* (CSA Group 2012) process/framework, the EcoRA uses results from the PostSA on contaminant concentrations in various environmental media, to assess ecological risk.

The EcoRA screens the contaminant concentrations calculated in each relevant PostSA scenario against the most conservative available criteria such as the CCME Canadian Environmental Quality Guidelines for non-radiological contaminants. Based on this, aluminum, copper, lead, and uranium were screened into the non-radiological assessment for all scenarios during the post-closure phase.

The indicator species selected for inclusion in the EcoRA were chosen based on the VCs defined in this EIS, as well as selection criteria outlined in CSA N288.6 (CSA Group 2012). The VCs and their respective indicator species are provided in Table 5.7.2-1. These indicator species are considered appropriate because they reflect a variety of diets/feeding habits, cover a variety of trophic levels, are representative of the biota expected to be found in the RSA, and are of interest to the facility and stakeholders. In addition to these indicator species, the EcoRA also includes moose as an ecological receptor in response to Indigenous interests.

The indicator species are assessed using assessment endpoints, which are expressions of the actual environmental values to be protected. In general, the assessment endpoints selected in this study were healthy populations of the identified indicator species within the RSA.

The list of indicator species chosen for assessment in the EcoRA included the following species at risk, as defined under the *Species at Risk Act:*

- Canada warbler (*Cardellina canadensis*; Threatened);
- eastern milksnake (*Lampropeltis Triangulum*; Species of Concern);
- eastern whip-poor-will (*Antrostomus vociferous*; Threatened);
- eastern wolf (*Canis lupus lycaon*; Species of Concern);
- little brown myotis (*Myotis lucifugus*; Endangered);
- monarch butterfly (*Danaus plexippus*; Species of Concern); and,
- snapping turtle (*Chelydra serpentine*; Species of Concern).

In the EcoRA, potential effects of the NSDF Project on these species at risk were considered on an individual level, rather than population-level effects.

The EcoRA assessed potential effects to ecological receptors for the various scenarios discussed above under the PostSA, such as Normal Evolution Scenario, Disruptive Event scenarios, and others. It is noted that some of the Disruptive Event scenarios do not have relevant pathways to ecological receptors, and as such were not assessed in the EcoRA. The scenarios omitted from the EcoRA are typically Human Intrusion scenarios (e.g., Borehole). Although the Human Intrusion (House with Basement) scenario is included in the EcoRA, because the displacement of waste onto the surface presents a potential pathway to wildlife.

Further information on the EcoRA assumptions, calculations and results is available in the EcoRA.

5.7.6.2.1.3 Guidelines

This section discusses the guidelines that were used to assess the effects from non-radiological elements on ecological receptors.

Guidelines Used in the Operations Phase

The RBs for non-radiological constituents (Table 5.7.6-5 are based on the Lowest Observable Effect Level (LOEL) with acute exposure at which population level effects may occur. They are based on:

- Federal and provincial guidelines for acute exposure; and
- Lowest observable effect concentrations from the literature.

Exceedance of an RB does not necessarily indicate that ecological effects would occur, but instead indicates that there may be some potential for effects (CNL 2019c).

Table 5.7.6-5: Selected Risk Benchmark Values for Non-Radiological Parameters in Surface Water

Parameter	Units	Selected Risk Benchmark Value	Reference
Aluminum	µg/L	100	AESRD (2014)
Barium	µg/L	110	Suter and Tsao (1996)
Copper	µg/L	Narrative[(a)]	AESRD (2014)
Iron	mg/L	3.4	SAVEX (2013)
Lead	µg/L	7	AESRD (2014)
Manganese	µg/L	2,300	Suter and Tsao (1996)
Phosphorus	µg/L	No data	—
Selenium	µg/L	20	Suter and Tsao (1996)
Silver	µg/L	4.1	Suter and Tsao (1996)
Zinc	µg/L	120	Suter and Tsao (1996)

(a) Other factors need to be considered in the risk assessment (e.g., water hardness).

AESRD = Alberta Environment and Sustainable Resource Development; µg/L = micrograms per litre; mg/L = milligrams per litre.

Guidelines Used in the Post-closure Phase

Overall, ecological toxicity benchmark values for non-radiological contaminants were obtained based on a hierarchy of sources which included federal and provincial guidelines such as CCME (1995, 2003, 2019) and MOE (2011) as well as the U.S. EPA ECOTOX Database, U.S. EPA Ecological Soil Screening Levels, Suter and Tsao (1996) and Sample et al. (1996). These hierarchies include credible, recognized references that are used in EcoRAs as common industry practice. The hierarchies generally incorporate CSA N288.6-12 guidance (CSA 2012) but in cases where N288.6-12 sources were considered outdated, values from more recent credible sources were used preferentially (with supporting rationale). More detailed descriptions of the methodologies used in selecting these toxicity benchmark values are presented in the EcoRA.

5.7.6.3 Application Case Results

5.7.6.3.1 Operations and Closure Phases

Aquatic Environment

The predicted non-radiological concentrations of the ten selected COPCs at six water quality nodes for two scenarios are provided in Section 5.4.2.6.2. The predictions were compared to effluent discharge targets and to local background at the six water quality nodes. The predicted concentrations of the 10 selected COPCs exceeded their respective effluent discharge targets and local background concentrations and as such were forwarded for further consideration in the ecological health assessment.

Comparison of the predicted concentrations of the ten COPCs to the selected risk benchmark values as well as the water quality criteria set by the Quebec Ministry of Environment (MELCC) is shown in Table 5.7.6-6.

Table 5.7.6-6: Comparison of Risk Benchmark Values to Maximum Predicted Surface Water Concentrations for Each Parameter for All Modelled Scenarios and Locations

Parameter	Risk Benchmark Values (µg/L)	Quebec Criteria[a] (µg/L)	Maximum at Any Assessment Node (µg/L)	Maximum at Perch Creek Outlet (µg/L)	Scenarios with Exceedances	Locations with Exceedances of Risk Benchmark Values
Aluminum	100	730[b]	631	98	Scenario 1 Scenario 2	▪ East Swamp weir (local ambient, all stats) ▪ Perch Lake Inlet 2 (local ambient, all stats) ▪ Perch Lake (local ambient, all stats) ▪ Perch Creek weir (local ambient, 95th and max) ▪ Ottawa River (local ambient)
Barium	110	100[c]	18.8	12.4	None	None
Copper	2	2.9[c]	8.4	5.38	Scenario 1 Scenario 2	All nodes (ambient, all stats)
Iron	3,400	**1,300**	2,870	1,580	None	None
Lead	7	**0.54**[c]	5.9	1.36	None	None
Manganese	120	570[c]	97	45	None	None
Phosphorus	—	30[d]	120	40	Scenario 1 and 2 – however, phosphorus is considered non-toxic	All nodes – however, phosphorus is considered non-toxic
Selenium	20	5	1.28	0.778	None	None
Silver	4.1	**0.1**	1.047	0.700	None	None
Zinc	120	37[b]	7.91	4.51	None	None

(a) Québec criteria are most appropriately compared to water quality for the Perch Creek Outlet (PCO) assessment node.

(b) Criterion calculated on the basis of hardness (25 mg/l), dissolved organic carbon (7.0 mg/l) and pH (7.4) water quality station located in the Ottawa River at Portage-du-Fort).

(c) Criterion calculated on the basis of hardness (25 mg/l) (water quality station located in the Ottawa River at Portage-du-Fort).

(d) Criterion is based upon protection of rivers and streams, and does not necessarily imply protection of down-gradient lakes (Gouvernement du Québec. 2020).

Bold = Quebec criteria (Gouvernement du Québec. 2020) is more stringent than Risk Benchmark Value

µg/L = micrograms per litre; — = no value.

The predicted concentrations for the non-radiological COPCs in the discharge from the WWTP were compared to the benchmark values derived for the NSDF Project and to local ambient water quality at the six water quality nodes (see Section 5.4.2.6.2). The predicted concentrations of all the parameters measured, with the exception of aluminum and copper, met their respective benchmark values at all sampling nodes. The Quebec guidelines for the compounds assessed in the EIS for the operations and closure phases are equal to or greater than the

benchmarks used in the EIS (i.e., aluminum, phosphorus and manganese), or are equal to or greater than the maximum predicted concentrations in surface water (i.e., barium, selenium and zinc), for all compounds except copper, iron, lead, and silver.

As shown in Table 5.4.2-7 (aluminum) and 5.4.2-17 (copper) in Section 5.4.2.6.2, the predicted concentrations of these parameters for both Scenario 1 and Scenario 2 were equal to or less than background at all nodes with the exception of Perch Lake Inlet 2. However, the highest predicted concentrations at this node were within typical measurement error (i.e., 12% for aluminum and 7% for copper) and therefore there is no increase in incremental risk to aquatic life from discharge of these substances. As such, no detailed assessment of risks to ecological receptors is warranted for these substances.

No risk benchmark is provided for phosphorus given it is not directly toxic to aquatic life; the Quebec guideline is based upon productivity rather than toxicity (i.e., maintaining lower phosphorus concentrations is protective of excessive algal growth). Concentrations of phosphorus at baseline and for all modelled scenarios and assessment nodes were greater than the Quebec guideline. The modelled scenarios are only marginally higher than the baseline at all nodes where an increase was predicted. No increase in phosphorous concentrations is predicted for the Perch Creek Outlet. Monitoring of phosphorus is to be undertaken as part of the monitoring program implemented during operation of the NSDF Project.

Terrestrial Environment

Effects to the terrestrial environment are not expected. As previously summarized (Section 5.7.6.2.1.1), effects to air quality for non-radiological constituents are expected to be not significant (5.2.1.6) and localized to the LSA for all constituents when considering the conservatism built into the predictive models and the realistic operation of equipment during NSDF Project operations (i.e., that not all equipment would be operating at full capacity all of the time, but would rather be idling for part of the time resulting in lower emissions than predicted). Therefore, impacts on air quality and ecological receptors from non-radiological emissions was not considered further for these phases of the NSDF Project. As a result, the effects of uptake into foodstuffs and consumption of prey by ecological receptors are expected to be similarly negligible. Therefore, residual effects to the terrestrial environment during the operations phase of the NSDF Project are considered to be negligible for ecological health.

5.7.6.3.2 Post-closure Phase

This section presents results for chemical concentrations in environmental media, as well as chemical exposure for ecological receptors for the Normal Evolution Scenario and Disruptive Event Scenarios.

Normal Evolution Scenario

During the 10,000-year assessment timeframe of the PostSA, peak concentrations of copper, lead and uranium are below the corresponding environmental quality criteria (EQS) for soil, sediment and water, except for the concentration of lead in groundwater adjacent to the ECM. The concentration of uranium in groundwater is approaching the EQS, and slightly exceeds the EQS for swamp soils.

Aluminum is a key component of clay minerals in soils and sediments. Therefore, there are not environmental quality standards for aluminum. The peak concentration in groundwater immediately downgradient of the ECM is only slightly elevated above background. However, the concentration is much lower in surface waters. For context, concentrations of aluminum in groundwater and surface water are well below the Health Canada

proposed operational guidance value and maximum acceptable concentrations in drinking water (Health Canada 2019). It is noted that these guidance values are not meant for application to environmental concentrations.

Non-radiological contaminants were assessed in the PostSA following a very cautious approach. All non-radiological contaminants were assumed to be readily available for dissolution and leaching upon contact with water, whereas in reality most of the non-radiological inventory will be encased in iron-based matrices. Additionally, as noted in Section 3.3.3.3, the disposal of the remaining small fraction of non-radiological inventory will meet land disposal regulations, which are protective of public health and the environment.

Finally, it is noted that conventional landfills can contain significant quantities of lead. The NSDF ECM meets the design and durability requirements of Ontario landfill regulations and is consistent with best practice for a conventional landfill, and so, in the context of containment of lead, the ECM would provide similar long-term performance to a contemporary conventional landfill.

Therefore, negligible residual effects are expected from non-radiological contaminants associated with the NSDF Project.

Aquatic Environment

Using total concentrations based on maximum predicted incremental concentrations calculated in the PostSA (Arcadis and Quintessa 2020b) combined with background concentrations in environmental media, the EcoRA (Arcadis 2020a) assessed the effect of non-radiological releases on aquatic biota during the post-closure phase.

Screening indices (SI) for copper and lead were above 1 for some aquatic receptors, and below 1 for uranium for all aquatic receptors. An SI is the ratio (i.e., unitless) of an estimated exposure level (e.g., estimated environmental concentration) divided by a corresponding toxicity reference value or benchmark value. An SI value greater than 1 indicates the potential for undue effects. However, the EcoRA determined that these SI exceedances were driven largely by the background concentrations of these contaminants as opposed to contributions from the NSDF Project.

Based on the effects assessment undertaken in the EcoRA, negligible residual effects from non-radiological exposure were predicted for aquatic biota in the post-closure phase.

Terrestrial Environment

Using total concentrations based on maximum predicted incremental concentrations calculated in the PostSA (Arcadis and Quintessa 2020b) combined with background concentrations in environmental media, the EcoRA (Arcadis 2020a) assessed the effect of non-radiological releases on terrestrial biota during the post-closure phase.

- SI values for copper, and uranium were below a value of 1 for terrestrial receptors. An SI below 1 indicates no undue effects. For lead, the SI value was above 1 for the Canada warbler and Eastern whip-poor-will, but these exceedances were driven largely by the background concentrations of the contaminants as opposed to contributions from the NSDF Project.

Based on the effects assessment undertaken in the EcoRA, no potential residual effects from non-radiological exposure were predicted for terrestrial biota in the post-closure phase.

Overall, no potential residual effects were identified for ambient radioactivity and ecological health for the Normal Evolution Scenario.

Disruptive Event Scenarios

Hypothetical disruptive event scenarios were also assessed in the PostSA as mechanisms to test the robustness of the overall waste management system. Non-radiological contaminants were assessed following a very cautious approach. All non-radiological contaminants were assumed to be readily available for dissolution and leaching upon contact with water, whereas in reality most of the non-radiological inventory will be encased in iron-based matrices. Additionally, as noted in Section 3.3.3.3, the disposal of the remaining small fraction of non-radiological inventory will meet land disposal regulations, which are protective of public health and the environment.

For non-radiological contaminants, aluminium, uranium, copper and lead screened in for all disruptive event scenarios. SI values for aluminum and uranium were below a value of 1, indicating no undue effects to terrestrial or aquatic biota. SI values for copper and lead were above 1 similar to the Normal Evolution Scenario exposure assessment. Although an SI value greater than 1 indicates the potential for undue effects, the EcoRA further assessed these contaminants and determined that their corresponding SI exceedances were driven largely by the background concentrations of these contaminants as opposed to contributions from the NSDF Project. In one disruptive event case – namely, the Enhanced Erosion Scenario – the NSDF Project also contributed to the SI value. However, taking the low probability into account, the effective SI would be less than 1, and thus negligible residual effects are anticipated.

Finally, it is again noted that conventional landfills can contain significant quantities of non-radiological contaminants. The NSDF ECM meets the design and durability requirements of Ontario landfill regulations and is consistent with best practice for a conventional landfill, and so, in the context of containment of non-radiological contaminants, the ECM would provide similar long-term performance to a contemporary conventional landfill.

Therefore, negligible residual effects are expected from non-radiological contaminants associated with the NSDF post-closure phase.

5.7.7 Prediction Confidence and Uncertainty

Table 5.7.7-1 describes key uncertainties in assessing residual effects from the NSDF Project on ecological health and how conservatism in the analysis and assumptions addressed these uncertainties.

Table 5.7.7-1: Uncertainties in Ambient Radioactivity and Ecological Health Assessment

Parameter	Uncertainty	Conservatism and Assumptions
Waste inventory	There is uncertainty with regard to the inventory of radionuclides that have been accumulated over the decades of operation of CRL site, as well as the projected inventory of wastes that will be generated in the future.	▪ Both already accumulated wastes and those that will be generated in the future will have to meet NSDF Waste Acceptance Criteria. ▪ The PostSA (Arcadis and Quintessa 2020b) explores the effect of uncertainty in the inventory, in the “Inventory Sensitivity” Sensitivity Analysis Case.
Source term	There is uncertainty associated with airborne and waterborne release rates.	▪ Waterborne releases from the WWTP are assumed to contain contaminants at maximum permissible concentrations.

Table 5.7.7-1: Uncertainties in Ambient Radioactivity and Ecological Health Assessment

Parameter	Uncertainty	Conservatism and Assumptions
ECM performance	There is uncertainty with regard to when protective barriers may begin to fail due to erosion or other natural events.	▪ The ECM includes multiple protective barriers in the cover and base liner, designed to isolate the waste even in the event if one or more of the barriers were to fail. ▪ The ECM can be maintained and monitored during the period of institutional control. Any issues identified during this period can be mitigated. ▪ The PostSA considers two conservative scenarios involving premature failures of the cover and base liner.
Waste package integrity	The current and future integrity of waste packaging is uncertain. Package failure leads to increased leachate concentrations.	▪ For pre-closure design and safety considerations, “Normal” packaged waste is assumed to have an initial failure of 5% upon placement. It is then assumed to fail at a rate of 1% per year. ▪ For post-closure, no credit is given for waste packages or containers. It is assumed that all waste packages have degraded and provide no barrier to the release of contaminants.
Wastewater quantity	The wastewater volumes used in the Leachate and Wastewater Characterization report (AECOM 2018c) are developed for the purpose of determining the long-term average wastewater volumes that are used to establish the flow-rate design capacity of the WWTP. Extreme precipitation events are not considered, as their effects are mitigated by the temporary storage capacity provided by the three EQS.	▪ The pressure boundary failure analysis conservatively assumes that failure occurs when membrane filter feed and process tanks are full. The calculation is, therefore, not affected by changes in wastewater quantity. ▪ The WWTP seismic event analysis conservatively assumes that failure occurs when all three EQS are full (5.6ME+06 L).

Table 5.7.7-1: Uncertainties in Ambient Radioactivity and Ecological Health Assessment

Parameter	Uncertainty	Conservatism and Assumptions
Leachate concentration	Uncertainties in the wastewater concentrations include the effects of uncertainties in the contaminant concentrations in the waste, the waste density, moisture content and the distribution coefficients. Contaminant concentrations in waste are defined by the Waste Characterization report (AECOM 2020), which defines the inventories and is consistent with the PostSA inventory. The waste density and moisture content play minor roles in the uncertainty of the wastewater concentrations. Both are confined to relatively small ranges. The average waste density is assumed to be 1.5 g/cm3 but may vary locally in the disposal cell, by perhaps ±20%, from this nominal value. The waste moisture content (0.2181, volumetric basis) is from the Hydrological Evaluation of Landfill Performance model discussed in the Leachate and Wastewater Characterization report (AECOM 2018c). Moisture content may also vary by ±20% from this value during wet and dry periods of the year. The distribution coefficients, taken from Canadian Standards Association N288.1-14 Table G-2 (CSA Group 2014), may also vary, but alternative values have not been evaluated.	▪ A soil to liquid partition model was used to determine leachate concentrations. Average Kd (water-soil distribution coefficient) values for soil (loam) and a waste density of 1.5 g/cm3 were assumed to apply homogeneously to the waste matrix. Compaction procedures and waste processing to minimize void space will ensure that this approximate waste density is maintained. ▪ During normal operations, higher leachate concentrations would have no effect on the public or environment since wastewater is treated at the WWTP. It would increase contaminant concentrations in the WWTP slightly, but the effect on safety would be minimal.
Environmental transport	Contaminants released to the environment, primarily groundwater and surface water, are transported uniquely, based on their chemical form and specific hydrogeological and hydrological characteristics near the SSA. Some of these characteristics are known from nearby WMAs and recent modelling, albeit with uncertainty.	▪ For the scenario involving waterborne exposure to members of the public, a transit time from the ECM to Perch Creek is not credited. This is conservative given that the groundwater transit time from modelling analysis is expected to be 7 years, which would be applicable to tritium, but conservative for all other radionuclides. No removal of contaminants from groundwater through sedimentation or other processes is assumed. ▪ The PostSA includes a sensitivity analysis case where groundwater transit time to Perch Creek is reduced to 5 and 2 years (from 7 years in the NES).

Table 5.7.7-1: Uncertainties in Ambient Radioactivity and Ecological Health Assessment

Parameter	Uncertainty	Conservatism and Assumptions
Conceptual model	This uncertainty is associated with conceptual model for groundwater flow and potential future effects on it resulting from the climate change.	▪ Current groundwater flow and contaminant transport in Perch Lake area are well understood due to decades of data available for the site. ▪ Groundwater flow model was calibrated against the available datasets based on the existing plumes emanating from WMA and LDA. ▪ The PostSA includes a sensitivity analysis case where groundwater transit time to Perch Creek is reduced to 5 years (from 7 years in the Normal Evolution Scenario). ▪ Characterization of the site includes 25 test pits, 70 boreholes and 47 monitoring wells, among other monitoring and testing activities.
Leaching and transport parameters	Parameter uncertainty may lead to underestimation of doses to members of the public and ecological receptors	▪ The site characteristics are well understood owing to many decades of monitoring. In any case, conservative and bounding assumptions were used as described for the conceptual model parameter. ▪ To test the effect of uncertainty in sorption rates, the PostSA includes a sensitivity analysis case that tests the uncertainty of the parameter Kd (water-soil distribution coefficient).
Future conditions	Due to the timeframe of the PostSA, there is some uncertainty with respect to future conditions at the site, for example, seismicity and climate change.	▪ As part of the NES, the climate is assumed to evolve according to the current scientific interpretation of anthropogenic climate change. Additionally, the PostSA examines the potential for a reduced amount of hydrologically effective rainfall, due to an increase in evapotranspiration. ▪ Although seismic activity is not expected to affect the safety function of the cover, liner, or berm, the PostSA considers the potential for a beyond design-basis earthquake to affect the safety function of these structures, in a number of the PostSA Disruptive Event Scenarios. ▪ In the NES, the PostSA assumes that erosion is balanced by other processes such as deposition. However, the PostSA also examines a case with more severe erosion, e.g., caused by wetter climate, or seismic damage.
Performance of the facility	This uncertainty is related to the degradation of various components of the facility ECM, such as the cover, liner and berm.	▪ The PostSA includes Disruptive Event Scenarios that examine the effect of accelerated degradation of the cover and liner. ▪ Additionally, the PostSA explores the importance of both the cover and liner using two scenarios that assume either the cover or the liner is absent at the time of closure. A third scenario is also included to assess the importance of the berm.

Table 5.7.7-1: Uncertainties in Ambient Radioactivity and Ecological Health Assessment

Parameter	Uncertainty	Conservatism and Assumptions
Assessment of doses to non-human biota	There is uncertainty in the modelling parameters for atmospheric and waterborne exposure pathways.	▪ Conservative exposure parameters were used, consistent with the quantitative risk assessment methods described in CSA N288.6 (CSA Group 2012).
Assessment of radiological risks to populations of ecological receptors	There is uncertainty in the dose criteria used for ecological receptors.	▪ While there is a variation of dose benchmarks in various jurisdictions, care should be taken in ensuring that they are fit for use. ▪ In particular a screening level of 10 µGy/hr should be considered as “below concern” based on generic screening calculations. If this level is exceeded, then a more detailed evaluation is required above such levels (Anderson et al. 2009). As such, this is a minimum level, which is not meant to be a limiting criterion. ▪ Benchmarks selected for this assessment are consistent with CSA N288.6 (CSA Group 2012). They are appropriate for the site-specific quantitative ecological risk assessment conducted for the NSDF.
Modelling tool uncertainty	There is uncertainty associated with conceptual models built within AMBER codes.	▪ The assessment of long-term safety of the NSDF in the PostSA was undertaken in accordance with REGDOC-2.11.1, Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management (CNSC 2018) which states: "Due to the uncertainty of predictions made far into the future, the reliability of quantitative predictions diminishes with increasing timescale. The demonstration of safety will rely less on quantitative predictions and more on qualitative arguments as the timescale increases. Long-term quantitative predictions should therefore not be considered as guaranteed impacts, but rather as safety indicators." ▪ It also states that: "uncertainties in the modeling should be addressed by conservatism built into 1. The assessment model; 2. the scenario design; and 3. parameter choice." ▪ As documented within this table, modelling uncertainty is addressed with conservatism built into the model, scenario design and parameters.
Cumulative effect	There is uncertainty associated with the cumulative effect during post-closure, taking into account releases from WMAs and LDAs in the Perch Creek Basin.	▪ CNL is developing an appropriate environmental remediation concept for contaminated areas. The decision-making process is based on radiological effects. ▪ It is expected that, if there is any potential to have cumulative effects exceeding safety objectives, then contaminated land from WMAs and LDAs will be removed prior to the NSDF closure.

Table 5.7.7-1: Uncertainties in Ambient Radioactivity and Ecological Health Assessment

Parameter	Uncertainty	Conservatism and Assumptions
Receptor occupancy	There is uncertainty in receptor occupancy at the site (e.g., how long would a migratory bird be on the site?).	▪ The EcoRA (Arcadis 2020a) conservatively assumes that all mobile receptors spend all of their time in the location of maximum predicted concentrations.
Receptor characteristics	There is uncertainty with respect to receptor characteristics (e.g., body weight, intake rates for food, soil, water).	▪ The EcoRA addresses this indirectly, through the use of generally conservative assumptions (e.g., assuming that 100% of intake of the COPC is absorbed into the organism).
Environmental concentrations	Concentrations in environmental media are modelled (i.e., information is not measured).	▪ The EcoRA uses maximum concentrations (predicted in the PostSA). As a result, calculated exposures are likely to be conservatively overestimated.
Contaminant migration	Contaminant migration through environmental media and biota are either modelled or estimated using literature or food intake calculations (i.e., information is not measured and not site-specific)	▪ There is uncertainty in the transfer of contaminants between environmental media, or from the environment to biota as transfer factors and data are not site specific; however, in the absence of measured data, this approach provides the only method for estimating concentrations and for estimating transfer up the food chain. Uncertainty can be addressed by selecting conservative transfer parameters.
Effects assessment	Toxicity reference values and benchmark values used in the EcoRA are based on reputable sources; however, there is inherent uncertainty associated with the extrapolation of laboratory testing to field conditions.	▪ Despite being obtained from reputable sources, there is uncertainty associated with toxicity reference values from literature, because they were derived from laboratory conditions and species rather than a field environment. ▪ In the EcoRA, toxicity information for a COPC was used regardless of its form in the test procedure, even though this may not be the same form used in the assessment.
Risk characterization	When dealing with multiple contaminants of potential concern, there is the potential for multi-stressor effects (e.g., interaction between contaminants).	▪ When dealing with toxic chemicals, there is potential interaction with other chemicals that may be found at the same location. It is well established that synergism, potentiation, antagonism or additivity of toxic effects occurs in the environment. These potential interactions were not investigated as part of the EcoRA, which may result in an underestimate of the risk for some COPC combinations.

PostSA = Post-Closure Safety Assessment; WWTP = Wastewater Treatment Plant; ECM = engineered containment mound; EQS = Environmental Quality Standard; NES = Normal Evolution Scenario; SSA = Site Study Area; WMA = Waste Management Area; LDA = Liquid Dispersal Area; EcoRA = Ecological Risk Assessment; CNSC = Canadian Nuclear Safety Commission; COPC = constituent of potential concern.

5.7.8 Residual Effects Classification and Determination of Significance

The residual effects analysis methods for the ecological health assessment are different in some notable ways from those used by other VCs. Specifically, the assessment of potential effects to ecological health VCs (i.e., ecological receptors) results in the generation of risk factors that inherently consider the geographic extent, duration, frequency and other characteristics of the predicted changes to the environment that may result from Project activities. As such, these inherent attributes cannot be used to determine environmental significance, as they can with other components. Instead, significance for ecological health is evaluated based on 1) the potential magnitude of the response, as indicated by the comparison to benchmarks, and 2) the degree of conservatism and uncertainty in the analysis.

During the operations and closure phases radiological doses to terrestrial biota are assessed to be well below benchmark values. The predicted radionuclide concentrations in surface water are well below the No Effect Concentrations with one exception; existing concentrations of one radiological parameter (gross beta as strontium-90) has baseline concentrations that are greater than the No Effect Concentrations. The elevated baseline surface water concentrations for gross beta as strontium-90 are localized to a small area. Further, the impact of operations activities on surface water concentrations for this parameter are negligible. As such, residual effects are considered to be negligible for all ecological receptors during the operations and closure phase.

Results of the radiological dose assessment for the post-closure phase indicate that doses to ecological receptors are below their respective benchmark values. As such, residual effects are considered to be negligible for all ecological receptors during the operations and post-closure phases.

Although uncertainties in the assessment exist (Section 5.7.7), conservatism has been included in the modelling so that residual effects are not greater than predicted.

The predicted non-radiological concentrations in surface water during operations were less than the selected guidelines for most non-radiological parameters, although some predicted concentrations were greater than their guidelines for some scenarios. However, predicted concentrations did not exceed local ambient concentrations in surface waterbodies and as such, residual effects are considered to be negligible for all ecological receptors during the operations and closure phase.

Results of the non-radiological exposure assessment for the post-closure phase indicate that concentrations are below their respective ecological screening values. Non-radiological contaminants were assessed in the PostSA following a very cautious approach. All non-radiological contaminants were assumed to be readily available for dissolution and leaching upon contact with water, whereas in reality most of the non-radiological inventory will be encased in iron-based matrices. Therefore, following this cautious approach, residual effects are considered to be negligible for all ecological receptors during the post-closure phase.

Although uncertainties in the assessment exist as described above, conservatism has been included in the modelling so that residual effects are not greater than predicted. Additionally, wastes placed into the NSDF will be required to meet the facility’s Waste Acceptance Criteria, which will be developed such that concentrations in the receiving environment do not pose a potential risk to indicator species. As such, residual effects are not significant for all ecological receptors during the operations phase and post-closure phase.

5.7.9 Monitoring and Follow-up

Monitoring of environmental media at the CRL site and surrounding area will proceed as described in alignment with CNL's existing Environmental Monitoring Program. As described in Section 5.7.4.3 Environmental Monitoring Program, this includes sampling and analysis of surface water, groundwater, sediment, soil, vegetation, ambient air, milk, garden produce, game animals, farm animals and fish (CNL 2018a). Sections 5.7.4.4 Radioactivity in the Atmospheric Environment to 5.7.4.10 Radioactivity in Terrestrial Foodstuffs, provide additional details regarding the scope of these programs for monitoring radioactivity in environmental media (CNL 2018a).

Emissions and effluents from the NSDF Project during the construction, operations, closure and the institutional control phase will be managed in accordance with CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018e). This standard defines the key requirements, responsibilities and processes for the management of radioactive and non-radioactive emissions at the NSDF Project. The NSDF *Environmental Protection Plan* (AECOM 2018d) expands on the regulatory requirements of CSA N288.5-11 (CSA Group 2011) for the management of these emissions. For example, operational control monitoring will be completed to confirm emission controls and treatment systems are functioning as intended. In addition, effluent monitoring will be completed to verify that emissions meet effluent discharge targets.

The CRL radiological Effluent Verification Monitoring Program will be established for the monitoring of emissions estimated from the NSDF Project. The Effluent Verification Monitoring Program at the NSDF Project site is required to demonstrate compliance with the No-Effect Concentrations for radiological constituents. For non-radiological contaminants, concentrations are maintained below the CCME's guidance levels for the protection of aquatic biota for the non-radiological contaminants. If the environmental monitoring and follow-up program identifies that adverse environmental effects are greater than predicted, then CNL will evaluate whether they result in changes to the conclusions in this EIS. If changes are confirmed, then CNL will evaluate the need for revised mitigation actions and management practices to manage effects. CNL's evaluation process for monitoring data include environmental performance criteria that are based on statistical measures and ecological health benchmarks. An exceedance of environmental performance criteria triggers CNL's non-conformance and corrective action process and includes notifying management and further investigation. Where the need for revised mitigations is identified they will be developed and implemented. The evaluation process is documented in alignment with CNL's Environmental Monitoring Program procedures (CNL 2018a).

Proposed environmental assessment monitoring and follow-up programs for the NSDF Project are documented in Section 11, including activities related to ambient radioactivity and ecological health:

- air quality (i.e., dust) will be monitored at the SSA and air effluent verification monitoring may be required at the WWTP;
- dust samples collected in the high volume air sampler during construction and operations will be screened for radioactivity;
- treated effluent from the WWTP, storm water pond effluent and surrounding surface water quality will be monitored;
- ambient radioactivity will be measured at the SSA; and
- groundwater monitoring will be performed surrounding the ECM, to confirm groundwater quality and detect potential releases of constituents from the ECM containment area.

These monitoring activities will occur during operations, closure and post-closure (institutional control). The need for and duration of monitoring will be reviewed based on annual review of monitoring data.

5.7.10 Conclusions

For ecological health, representative receptor taxa were selected as VCs, as documented in Section 5.7.2. Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future human generations (i.e., incorporates sustainability). The assessment endpoint is the protection of ecological health. Measurement indicators represent properties of the environment, that when changed, could result in or contribute to an effect on an assessment endpoint. Measurement indicators for the ecological health assessment include changes in air quality, groundwater quality and surface water quality.

During the operations and closure phases, airborne emissions are negligible, and waterborne emissions result in environmental concentrations that are below the No-Effect Concentrations for radiological constituents. The predicted radionuclide concentrations in surface water are well below the No Effect Concentrations with one exception; existing concentrations of one radiological parameter (gross beta as strontium-90) has baseline concentrations approximately a factor of two greater than the No Effect Concentrations. The elevated surface water concentrations are localized to a small area. Further the impact of operations activities on surface water concentrations for this parameter are negligible. Therefore, no dose assessment for ecological receptors is required for the operations phase based on the screening process.

For non-radiological contaminants, concentrations are maintained below the CCME's guidance levels for the protection of aquatic biota or are below levels that would result in potential adverse effects on aquatic life. Therefore, an exposure assessment from non-radiological constituents to ecological receptors is not required.

During the post-closure phase, airborne and waterborne releases are modelled in the PostSA to determine environmental concentrations and carry into the EcoRA for assessment of effects on ecological receptors. Results indicate that the predicted doses to all indicator species are below the dose benchmark values during the post-closure period.

Although uncertainties in the assessment exist, conservatism has been included in the modelling so that residual effects are not greater than predicted. As such, residual effects are considered to be not significant for all ecological health VCs during the operations and post-closure phases of the NSDF Project. Monitoring and follow-up programs are described in Section 5.7.9 and include implementation of the existing Effluent Verification Monitoring Program, Groundwater Monitoring Program and Environmental Monitoring Program, as well as NSDF Project-specific environmental monitoring activities. These programs will verify effects predictions for ecological health.

This page intentionally left blank

5.8 Human Health

This section of the Environmental Impact Statement (EIS) for the Canadian Nuclear Laboratories (CNL) Near Surface Disposal Facility (NSDF) Project summarizes the results of the Environmental Risk Assessment (ERA), specifically as it relates to effects to human health from changes in ambient radioactivity and non-radiological substances. Baseline information on radiological parameters in the environment that are relevant to human health are summarized in Section 5.7, and non-radiological parameters are summarized in the discipline-specific sections.

5.8.1 Scope of the Assessment

The human health assessment follows the overall environmental assessment approach and methods described in Section 5.1. The assessment is completed in the following key steps:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** for the human health assessment (refer to Sections 5.8.2 Valued Components and Section 5.8.3 Assessment Boundaries). The VCs and measurement indicators used to assess NSDF Project related effects to human health, the spatial and temporal boundaries at which the assessment occurred, and the assessment cases considered are described.
- **Step 2 – Describe the existing conditions** (refer to Section 5.8.4 Description of the Existing Environment). Baseline data collected from Chalk River Laboratories (CRL) existing operations and background levels across Canada are discussed. The existing conditions provide a reference, from which to compare the effects of the NSDF Project to.
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 5.8.5 Project Interactions and Mitigation). Project components and/or activities with the potential to affect human health are identified and mitigation developed to limit or avoid effects are presented. A pathways analysis is then used to focus further assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects to human health after incorporating mitigation are carried forward to Step 3 for further analysis and residual effects characterization.
- **Step 4 – Present the methods and results of the residual effects analysis** (refer to Section 5.8.6 Residual Effects Analysis). This Section summarizes the methods used to predict and characterize residual effects to human health from primary effects pathways. The results of the human health assessment are presented including the characterization of residual incremental effects of the NSDF Project and the cumulative effects of the NSDF Project in combination with other reasonably foreseeable developments (if applicable).
- **Step 5 – Describe the level of certainty and management of uncertainty** (refer to Section 5.8.7 Prediction Confidence and Uncertainty). Evaluate the available literature, data and models used for the assessment, and describe the level of certainty that can be placed on predicted residual effects. This section will also identify how the uncertainty has been managed so that the effects are not underestimated.

- **Step 6 – Classify and determine the significance of the predicted residual effects** (refer to Section 5.8.8 Residual Effects Classification and Determination of Significance). Residual effects predicted from primary pathways are classified using a common set of criteria: direction, magnitude, geographic extent, duration, reversibility, frequency and likelihood. A determination of the significance of the predicted residual effects of the NSDF Project on human health is made. Relative to other sections, the human health assessment uses a slightly different approach to the classification of residual effects and evaluation of significance, because several of the criteria (e.g., geographical extent, duration, frequency and reversibility) are already incorporated into the risk estimates and, therefore, are not independent variables.
- **Step 7 – Identify monitoring and follow-up** required to confirm effects predictions and address uncertainty (refer to Section 5.8.9 Monitoring and Follow-up).
- **Step 8 – Present a consolidated summary of conclusions** and outcomes of the assessment of residual effects on human and non-human biota (refer to Section 5.8.10 Conclusions).

Information and areas of interest raised by the public, communities of interest, and Indigenous Peoples during engagement that influenced the scope of the human health assessment are summarized in Table 5.8.1-1. Other general concerns and questions raised during the engagement that pertain to the human health assessment (if any) are documented in CNL's Indigenous Engagement Report (CNL 2021) and Stakeholder Activity Reports (CNL 2017a,b, 2019a).

Table 5.8.1-1: Summary of Areas of Interest Raised during Engagement Activities that Influenced the Scope of the Human Health Assessment

Area of Interest	How the Area of Interest Was Included in the Assessment
Effects to fish from potential for contamination in the Ottawa River from the NSDF Project.	The spatial boundaries of the assessment were selected to include consideration of potential effects to the Ottawa River. The human health risk assessment considered potential changes in surface water in Perch Creek. Meeting effluent discharge targets within the Perch Creek and Perch Lake watershed is considered to be protective of the Ottawa River. The RSA was expanded to include a reach of the Ottawa River extending 8 km downstream of CRL in response to comments received from Indigenous communities and organizations, and the public.
Potential for radioactivity from gases from the capped facility	Potential changes in air quality from the NSDF Project were evaluated in the human health assessment during the operations phase.
Potential for changes in groundwater quality to affect uses downstream of the ECM	Potential changes in groundwater quality from the NSDF Project were evaluated in the human health risk assessment and included potential changes from treated effluent discharge from the WWTP, and seepage from the ECM during the operations phase and post-closure phase.
Treatment of leachate	Leachate from the ECM will be collected and pumped to the WWTP for treatment prior to discharge.
Potential leakage of leachate from the ECM	Potential leakage of leachate from the ECM during operations will be mitigated through the design and implementation of a composite base liner system, a leachate detection system and a leak collection system. Potential leakage from the ECM during the operations phase and post-closure phase is considered in the human health risk assessment.

RSA = Regional Study Area; ECM = engineered containment mound; WWTP = Wastewater Treatment Plant

5.8.2 Valued Components

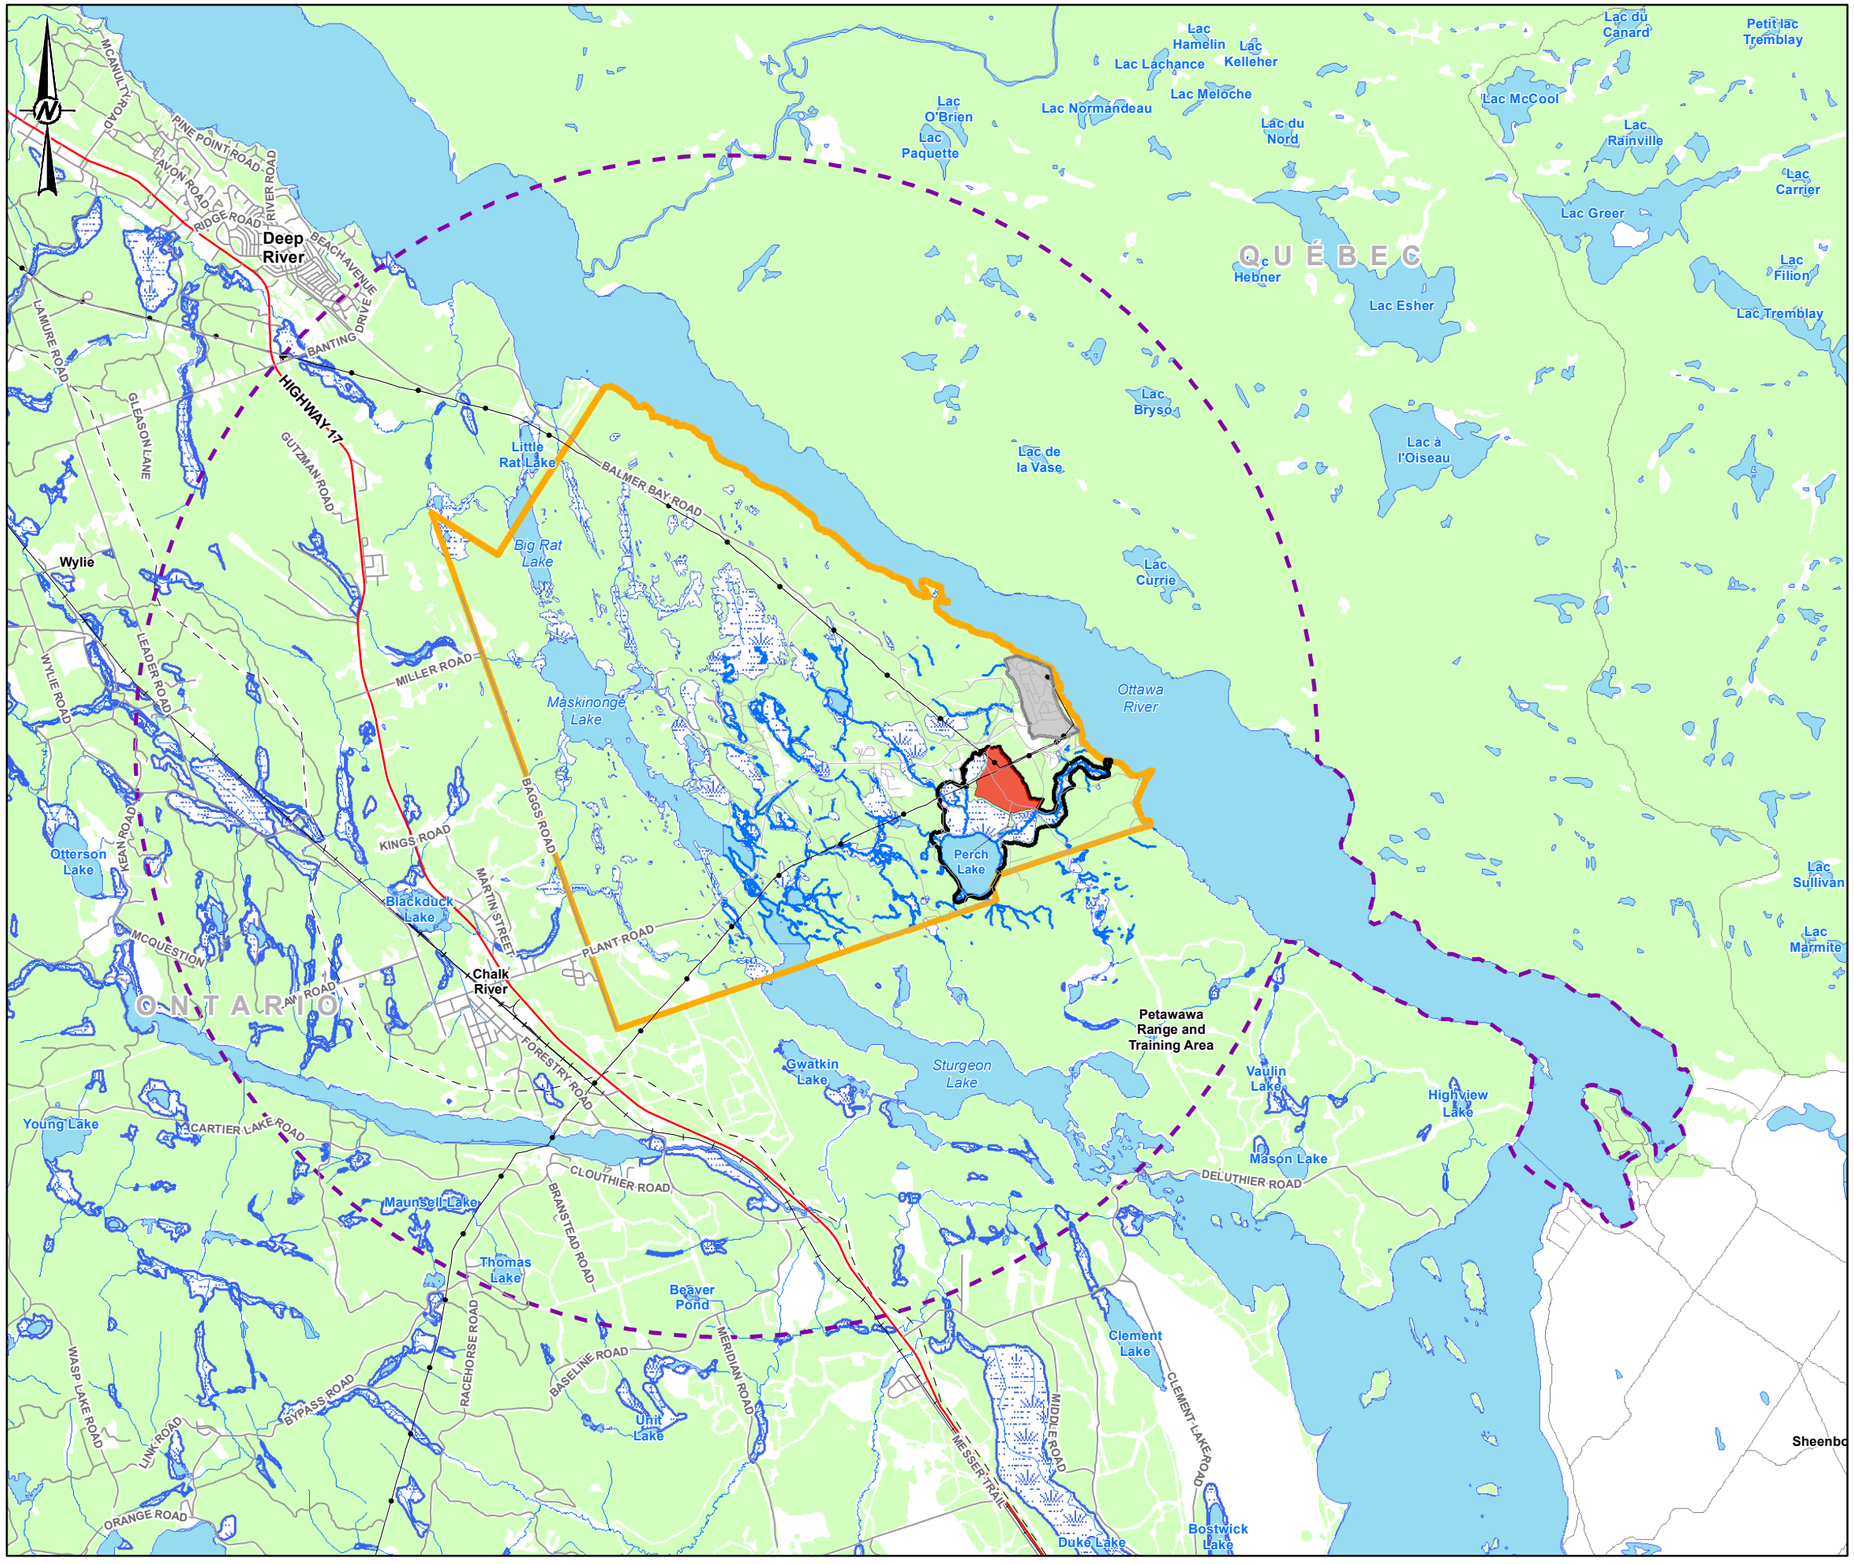
Valued components (VCs) refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). The human health risk assessment focused on Nuclear Energy Workers (herein referred to as “worker”) and public health. The assessment for public health considered locations where people are known to be present (e.g., local communities, farmers and recreational areas). VCs and rationale for their selection for the human health assessment are provided in Table 5.8.2-1.

Table 5.8.2-1: Valued Components for the Human Health Assessment

Valued Component	Rationale for Selection
Worker	▪ Potential external and internal radionuclide exposure; potential non-radionuclide exposure
Public ▪ Residential ▪ Seasonal	▪ Potential exposure to airborne and waterborne radiological emissions; potential non-radionuclide exposure
Self Sufficient Indigenous Group	▪ Potential exposure to airborne and waterborne radiological emissions; potential non-radionuclide exposure from the NSDF Project. ▪ This group represents a group of Indigenous Peoples, including adults and children, using area that surrounds the ECM, including Perch Creek and the Ottawa River, for hunting and gathering during the post-closure phase. ▪ This receptor was assessed as part of the Sensitivity Analysis Case in the Post-Closure Safety Assessment (Arcadis and Quintessa 2020).

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future human generations (i.e., incorporates sustainability). The assessment endpoint is the protection of human health. Measurement indicators represent properties of the environment, that when changed, could result in or contribute to an effect on an assessment endpoint. The measurement indicators for the human health assessment are outlined in Table 5.8.2-2.

Table 5.8.2-2: Assessment Endpoints and Measurement Indicators for the Human Health Risk Assessment



Valued Component	Assessment Endpoint	Measurement Indicators
Worker Public ▪ Residential ▪ Seasonal Indigenous Peoples	Protection of human health	▪ Changes to air quality ▪ Changes to groundwater quality ▪ Changes to surface water quality ▪ Changes to sediment quality ▪ Changes to soil quality ▪ Changes to vegetation quality ▪ Changes to food quality

5.8.3 Assessment Boundaries

5.8.3.1 Spatial Boundaries

The spatial boundaries for the human health risk assessment are defined by the boundary of the Regional Study Area (RSA). The Local Study Area (LSA) is an area of greater focus within the RSA (Figure 5.8.3-1). To define the spatial boundaries for human health, the primary pathways that could contribute to residual effects on human health were determined (see Section 5.8.5). Primary pathways were identified from air quality, groundwater water quality and surface water quality. The spatial boundaries for human health were thus selected to incorporate relevant portions of the study areas for air quality, groundwater quality and surface water quality to evaluate the environmental changes that could contribute to effects on human health. The spatial boundaries for the effects assessment are as follows:

- **Site Study Area (SSA):** The SSA is the NSDF Project footprint (i.e., where NSDF Project activities would be undertaken including the NSDF Project's proposed facilities, buildings and infrastructure).
- **Local Study Area (LSA):** The LSA is defined as the area within which there is potential for measurable changes to measurement indicators resulting from the proposed NSDF Project activities. The LSA adapted from the groundwater and surface water Local Study Area (LSA) and is designated as the spatial extent of the Perch Creek and Perch Lake Watershed, and includes Perch Lake and its tributaries and Perch Creek. The Ottawa River in the vicinity of the mouth of Perch Creek is also included in the LSA.
- **Regional Study Area:** The RSA is defined as the area within which the potential effects of the NSDF Project may interact with the effects of other existing or reasonably foreseeable projects. Humans in the vicinity of the engineered containment mound (ECM) could be exposed to airborne and waterborne emissions as well as direct gamma radiation from the waste. Therefore, the RSA for human health is a combination of the air quality and aquatic environment RSAs as this is the largest extent of potential cumulative effects on human health. The air quality RSA is defined as an approximate 7.4 kilometre (km) circular radius surrounding the LSA, and the aquatic RSA extends roughly 8 km downstream in the Ottawa River to Harrington Bay.

5.8.3.2 Temporal Boundaries

Temporal boundaries (i.e., project phases) establish the timeframe during which NSDF Project effects are assessed. The temporal boundary represents the timeframe during which project activities are actively occurring, and does include the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a Project activity or stressor (which is related to the project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the NSDF Project (e.g., residual effect lasts for thousands of years). The following phases were identified for the NSDF Project and considered in the assessment:

- **Construction Phase**: includes site preparation and all activities associated with the construction of the NSDF Project. This phase includes activities such as installing the necessary supporting and/or ancillary facilities and infrastructure to facilitate NSDF Project operations, inactive commissioning and systems testing, and transportation of construction materials. Construction activities are expected take place from 2022 to 2024.
- **Operations Phase**: includes all activities associated with waste placement, water management, water management, Wastewater Treatment Plant (WWTP) operations, vehicle movements into and from the SSA and maintenance activities. Operations activities are expected to last approximately 50 years (i.e., 2025 to 2070).
- **Closure Phase:** includes activities necessary to complete the installation of the final cover and implementation of long-term monitoring. Closure activities are expected to start in 2070 and continue through to 2100, after which the NSDF Project will transfer into the post-closure phase.
- **Post-closure Phase:** has two discrete periods: institutional control and post-institutional control. The Institutional Control period includes implementation of controls to 2400 (i.e., 300 years). During institutional control, groundwater monitoring and groundwater quality management will continue to demonstrate compliance with the post-closure safety assessment assumptions. Post-institutional control occurs after year 2400 and continues indefinitely. The *Post-Closure Safety Assessment* (PostSA; Arcadis and Quintessa 2020), which supports the assessment, includes consideration of effects of the NSDF Project for 10,000 years post-closure phase.

5.8.3.3 Assessment Cases

The assessment cases considered in the human health assessment include the Base Case and Application Case:

- **Base Case –** This scenario represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural, mining and residential and recreational development. Current effects from the existing CRL facilities and operations, for example, are considered part of the Base Case.
- **Application Case –** This scenario represents predictions of the effects of the Base Case combined with the effects that may result from the NSDF Project. The Application Case considers potential effects from the NSDF Project during the operations phase and the post-closure phase.

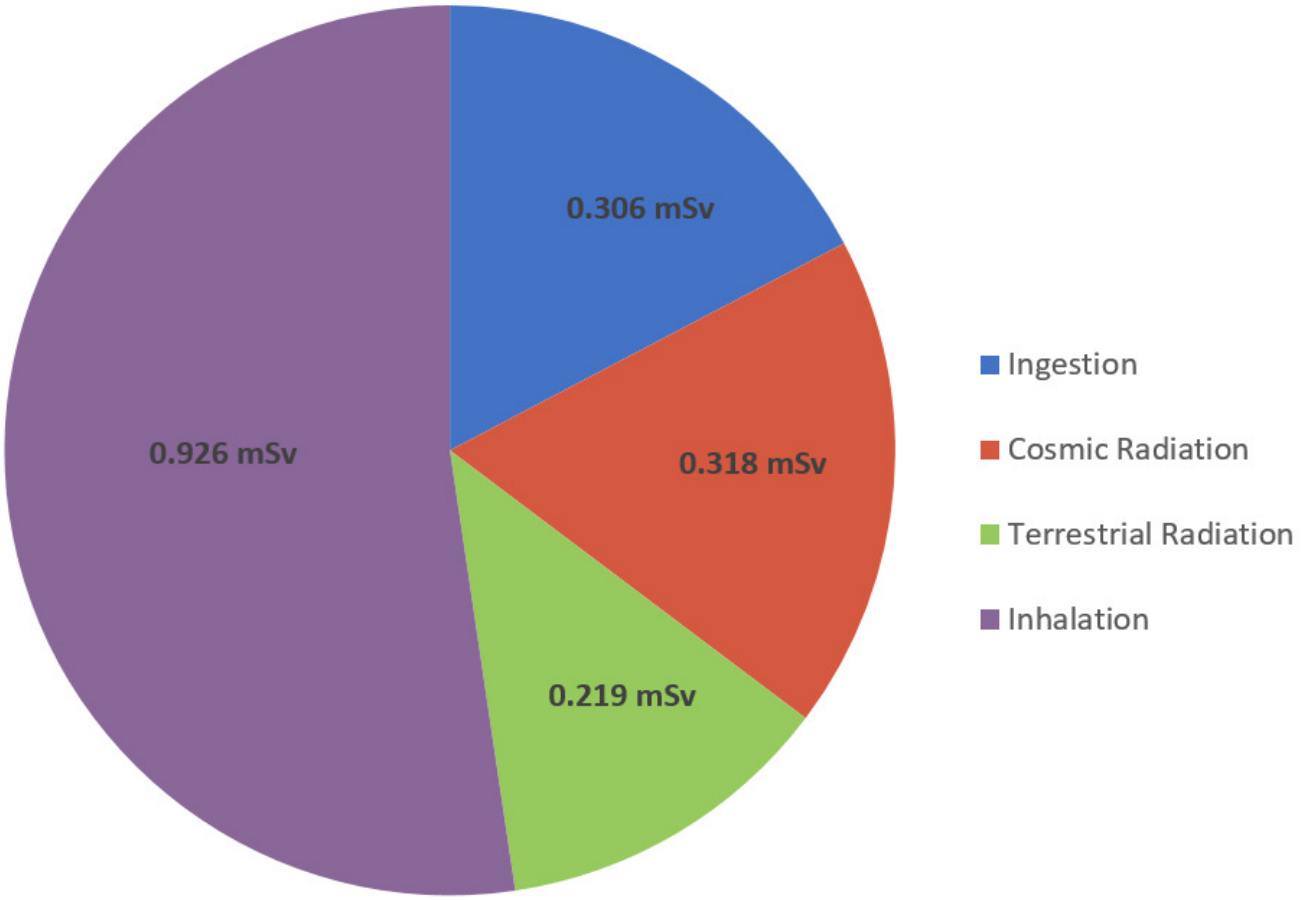
- **Reasonably Foreseeable Developments (RFD) Case –** This scenario represents predictions of the cumulative effects of the Application Case, which includes the Base Case, plus projects that are currently under application review or that have officially entered a regulatory application process and are therefore considered reasonably foreseeable. Because RFDs will either have no spatial overlap in effects or are likely to positively affect human health, an RFD Case is not presented as part of this assessment. RFDs within the CRL site (i.e., the RSA) include only the new or upgrades to research and development facilities, construction and operations of the SMR, new support infrastructure, and on-going decommissioning and environmental remediation activities. Revitalization projects at the CRL site (i.e., new or upgrades to research and development facilities, new support infrastructure) and decommissioning include several small projects staged over a 10-year period where best practices, mitigation and monitoring for management of emissions will be followed. No process intakes of water from or discharges to surface or groundwater, or releases to air beyond the potential for a limited amount of steam from dry cooling towers, are identified in the description of the planned SMR (Global First Power 2019). During normal operations, the SMR will introduce a very small radiological exposure to workers or members of the public near the plant, within the CRL site (Global First Power 2019). The incremental radiological (in proximity to SMR) and non-radiological emissions from RFD Projects at any one time are expected to be small, distributed across the CRL site and removed from the more intensive activities within the SSA (i.e., the NSDF Project footprint).

  The NSDF Project will enable the remediation of contaminated lands and legacy waste management areas, and decommissioning of outdated infrastructure at the CRL site and CNL's other business locations to support future CNL missions. The end-state plan for the CRL site will be to return lands disturbed by site activities to a condition that is physically stable and safe in keeping with the land use and landscape of the day. Therefore, decommissioning and environmental remediation activities are anticipated to positively affect human health.

5.8.4 Description of the Existing Environment

Background radiation dose from natural and anthropogenic sources and historical radiation dose from CRL operations is used to establish a baseline characterization of radiation dose for human health assessment prior to the NSDF Project.

5.8.4.1 Background Sources of Radiation and Radioactivity



This section describes the background radiation and radioactivity that is present in the environment due to natural and anthropogenic sources independent of CRL operations. The magnitude of radiation dose from natural sources varies greatly, both spatially and temporally. The main natural sources of radiation are cosmic rays; naturally occurring radionuclides in air, water and food; and naturally occurring radionuclides in the soil, rocks and building materials used in homes (CNSC 2013).

Cosmic radiation originates from celestial events and the sun. This cosmic radiation and the secondary particles produced penetrate the Earth's atmosphere and give an external radiation dose at the Earth's surface.

- Naturally occurring radionuclides are also incorporated into plants, animals and water from surrounding soils and rocks. Humans ingest these foodstuffs and receive an internal radiation dose. Radon gas, a product of the decay of uranium in soil, is inhaled and contributes to the internal radiation dose.
- Consumer products and services contribute a relatively low amount to the total dose. Naturally occurring radionuclides such as uranium, potassium and thorium are present in soils, rocks and building materials. These naturally occurring radionuclides also contribute to the external gamma radiation dose. Medical diagnostic procedures (such as x-rays) contribute to the external dose.

The average annual doses in Canada are shown on Figure 5.8.4-1; the total annual dose from natural background radiation is approximately 1.8 millisieverts (mSv) (CNSC 2013).

5.8.4.2 Radiation Dose from CRL Operations

CNL reports the results of the CRL Environmental Monitoring Program each year to the Canadian Nuclear Safety Commission (CNSC). The Environmental Monitoring Program data are collected to verify that radiation doses to members of the public as a result of the operations of the CRL site remain As Low As Reasonably Achievable (ALARA). The calculated radiation dose to members of the public from CRL operations is shown in Table 5.8.4-1, and represents the Base Case radiation dose from CRL prior to the NSDF Project. The 2018 dose assessment showed that highest adult radiation dose to the public from CRL operations was 0.032 millisieverts per year (mSv/yr), representing 3.2% of the regulatory dose limit of 1 mSv/yr for members of the public. The 5-year average adult dose from 2014 to 2018 is 0.065 mSv/yr (CNL 2019b). The dose to members of the public is predominantly from airborne emissions.

5.8.5 Project Interactions and Mitigation

5.8.5.1 Methods

This section describes the process by which interactions between NSDF Project components and activities and human health were identified and evaluated. Potential effects pathways related to ecological health are discussed in Section 5.7. Potential effects pathways are identified and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment. As such the “Project Interactions and Mitigation” section helps to focus the remainder of the assessment on those interactions (effects pathways) with the potential to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all stages of the NSDF Project. The next step in the analysis was the development of environmental design features and mitigation that could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects to human health. Environmental design features included NSDF Project design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the NSDF Project’s engineering and environmental teams, combined with input from Project-specific or

regional engagement with other interested parties. The design features and/or mitigation were selected considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effects pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation:

- **No linkage:** The pathway is removed by environmental design features or mitigation such that the NSDF Project would not be expected to result in a measurable environmental change relative to Base Case values and therefore would have no residual effects to human health.
- **Secondary pathway:** The pathway could result in a measurable minor environmental change, but would have a negligible residual effect to human health relative to Base Case (or guideline values) and is not expected to contribute cumulatively to other Project effects or to the effects of other previous, existing or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway:** The pathway is likely to result in an environmental change to measurement indicators identified for human health VCs relative to the Base Case that could contribute to residual effects to human health.

Environmental design features and mitigation that could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects to human health were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to human health VCs through qualitative or quantitative evaluation of the pathway were also not advanced for further assessment.

Primary pathways were carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the NSDF Project on human health VCs.

5.8.5.2 Results

The pathways analysis for human health VC is provided in Table 5.8.5-1. There will be no exposure to construction workers during the construction phase; therefore, no pathways related to construction workers are listed in Table 5.8.5-1. Any accidents and malfunctions during the construction phase are assessed in Section 7.0.

Table 5.8.5-1: Pathways Analysis for Human Health Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment

▪ Project activities during the operations and closure phase:
  ▪ Phased development of disposal cells in the ECM
  ▪ On-site transportation of waste and placement in the ECM
  ▪ Progressive closure of disposal cells and installation of final cover
  ▪ Surface water management
  ▪ Operation of the WWTP
  ▪ Discharge of treated effluent from the WWTP
	▪ Dust may be created during handling of bulk materials and emissions of gases may be released during storage and disposal of radioactive materials, which can affect human health.
	▪ Emissions may be released from the WWTP to air during operations, which can affect human health.
		▪ All activities will be covered by either CNL's work permits with completed Radiological Safety Assessments, as required, or by approved work procedures.
		▪ CNL's procedure for Management and Monitoring of Emissions (CNL 2018b), which includes operational control monitoring and verification monitoring, will be implemented.
		▪ The buildup of gas emissions from waste in closed cells is mitigated by gas venting in the final cover.
		▪ The Dust Management Plan (AECOM 2018a) for the NSDF Project will include:
		  ▪ restricting or suspending activities if unacceptable amounts of dust are generated due to winds or other site conditions;
		  ▪ use of water spraying or misting techniques (e.g., water trucks) as the primary dust control method;
		  ▪ use of fixatives (e.g., chemical suppressant) for dust control, and for use as daily/interim cover;
		  ▪ suspension of excavating, loading, hauling and disposal operations when wind speeds exceed the specified criterion; and
		  ▪ vehicles that have come into contact with contamination will be required to pass through the vehicle decontamination facility
		▪ Processed wastewater will not be heated within the WWTP (raising the temperature increases potential release rates).
		▪ There is active ventilation within the WWTP building and active ventilation exhaust will be filtered through HEPA prior to release.
			Primary

	▪ Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) may cause changes to surface water quality, which can affect human health.	▪ All activities will be covered by either CNL's work permits with completed Radiological Safety Assessments, as required, or by approved work procedures. ▪ The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses best available technology that is economically achievable and capable of meeting regulatory requirements. ▪ Effluent discharge targets for wastewater discharges are protective of the environment and human health. ▪ Discharge targets for non-radiological contaminants are sourced from federal and provincial guidelines for protection of aquatic biota. ▪ Discharge targets for radionuclides are the Canadian Drinking Water Guidelines, with the exception of tritium for which a site-specific target is developed (Section 3.4.2.5.1). ▪ Treated effluent will be sampled to confirm that it meets effluent discharge targets before release to the environment. ▪ When applied, the proposed exfiltration gallery will promote the exfiltration of treated water into the local groundwater regime where further retention of radioactivity by the geosphere is anticipated. ▪ The Perch Lake diffuser design provides additional dilution of treated effluent at the point of release ▪ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water quality. ▪ Appropriate procedures will be in place to effectively identify spill occurrences in the event treated effluent is released to areas other than directly to the exfiltration gallery and initiate appropriate emergency responses.	Primary

▪ Project activities during the operations and closure phase:
  ▪ Surface water management
  ▪ Operation of the WWTP
  ▪ Discharge of treated effluent from the WWTP
	▪ Leakage of leachate from the ECM during operations and closure may cause changes to surface water quality, which can affect human health.	▪ Design of the ECM includes base grading configured in a herringbone pattern with ridges and valleys to promote leachate transport to the leachate collection system for removal.
		▪ The base liner design includes primary and secondary liner systems designed to have redundancy in case of premature failure and are a combination of natural and synthetic barrier systems. These include a compacted clay liner (CCL), two geosynthetic clay liners (GCL) and an HDPE geomembrane.
		▪ Clay materials were selected for the CCL and GCL components of the liner system as these materials are anticipated to maintain their function as hydraulic barriers throughout and beyond the design life of the disposal facility (i.e., 550 years).
		▪ The HDPE geomembrane design for the liner will be compatible with the leachate generated by the waste and provide a long service life.
		▪ The base liner system will include an underlying compacted clay liner to supplement the primary and secondary liner system.
		▪ The leachate collection system design will provide accessible access points for inspections, maintenance, repairs, and replacements.
		▪ Appropriate responses to leachate leakage and contamination will be implemented as described in the Operations and Maintenance Plan (AECOM 2019).
			No Linkage

Table 5.8.5-1: Pathways Analysis for Human Health Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
■ Project activities during the post-closure phase: ■ On-going long-term performance monitoring, transfer of NSDF Project into the post-institutional control period	■ Volatiles (e.g., radon, tritium) may be released to air, which can affect human health	■ A passive landfill gas venting system will be constructed at the same time as installation of the ECM final cover system. ■ The landfill gas monitoring probes will also be installed around the perimeter of the ECM to detect evidence of potential landfill gas migration away from the ECM.	Primary
	■ Leachate may be released to soil via overtopping the berm, which can affect human health	■ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound, and minimize leachate generation. ■ The cover system design incorporates a series of shallow, trapezoidal, riprap-lined drainage channels that are designed to convey water at low velocity. ■ The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the cover and underlying waste materials, destabilization of the ECM structure and damage to access roads. ■ The ECM final grading and drainage plan includes collection ditches along the top of the ECM berm road to collect side slope drainage. ■ Environmental monitoring will be completed as required during the institutional control period for the NSDF Project to confirm that the final cover is functioning as intended	Primary
	■ Leachate may be released through the base liner to groundwater, which can affect human health	■ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the ECM and minimize leachate generation. ■ The cover system design incorporates a series of shallow, trapezoidal, riprap-lined drainage channels that are designed to convey water at low velocity. ■ The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the cover and underlying waste materials, destabilization of the ECM structure and damage to access roads. ■ The ECM final grading and drainage plan includes collection ditches along the top of the ECM berm road to collect side slope drainage. ■ The design life for the ECM is 550 years to meet the required time period to allow for radioactive decay of the waste placed in the facility (i.e., until it has decayed to levels that do not present a risk to the public and environment). ■ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water and groundwater quality.	Primary

ECM = engineered containment mound; CRL = Chalk River Laboratories; WWTP = Wastewater Treatment Plant; LLW = low-level waste.

5.8.5.2.1 No Linkage Pathways

The following pathway was assessed as having no measurable environmental change and hence, no linkage to residual effects on human health VCs.

- **Leakage of leachate from the ECM during operations and closure may cause changes to surface water quality, which can affect human health.**

Design of the ECM includes base contours that have been developed using a herringbone pattern with ridges and valleys to promote leachate transport to the leachate collection system for removal. The base liner design includes both primary and secondary liner systems that are designed to have redundancy in case of premature failure and are a combination of natural and synthetic barrier systems. The primary liner will include a leachate collection system with the secondary liner housing a leak detection system. The composite base liner will contain perforated high-density polyethylene (HDPE) collection and transfer line. The HDPE geomembrane was selected as it is compatible with the leachate generated by the waste and is expected to perform as an effective hydraulic and diffusion barrier over the 550-year design life (i.e., 50 years of operations and 500 years post-closure, see Section 3.4.1.4). The base liner system will include an underlying compacted clay liner to supplement the primary and secondary liner system. The leachate collection system design will provide accessible access points for inspections, maintenance, repairs and replacements.

The primary liner system will contain the leachate collection system and will convey leachate to a single collection point for removal from the ECM, for transfer to the WWTP for treatment. The primary liner system serves as the primary source of protection for the natural environment below the ECM from leachate migration. The secondary liner system will contain the leak detection system, which will be used to detect leaks in the unlikely event that the primary liner system fails. Leachate collected by the leachate collection system will be pumped to the on-site WWTP for treatment.

Perimeter berms consist of three main geotechnical elements, or layers, each contributing to the soundness and integrity of the berm itself and the whole ECM. A *Slope Stability Analysis* (AECOM 2018b) was completed to provide the information needed to support the design of the base slopes, sidewalls and side slopes of the ECM. The *Slope Stability Analysis* addresses the range of anticipated loading conditions, under both short-term and long-term scenarios, to confirm that the slope designs will satisfy minimum factor-of-safety requirements for stability. Size and shape of the berms and each of the elements and layers were determined using a seismic design basis, including the *National Building Code of Canada 2015* (NRCC 2015).

The implementation of the design of the ECM, the liner systems, and the perimeter berms will reduce the potential for changes to groundwater and surface water quality from the NSDF Project site. As such, this pathway was determined to have no linkage to effects on human health.

5.8.5.2.2 Secondary Pathways

No secondary pathways were identified as having residual effects on human health.

5.8.5.2.3 Primary Pathways

Primary pathways identified for human health that are evaluated in the residual effects analysis (Section 5.8.6) include:

During the operations and closure phases:

- **Dust may be created during handling of bulk materials and emissions of gases may be released during storage and disposal of radioactive materials, which can affect human health.**
- **Emissions may be released from the WWTP to air during operations and closure, which can affect human health.**
- **Discharge of treated effluent from the WWTP to ground (via an exfiltration gallery) and to Perch Lake (via a transfer line) can cause changes to surface water quality, which can affect human health.**

During the post-closure phase:

- **Volatiles (e.g., radon, tritium) may be released to air, which can affect human health.**
- **Leachate may be released to soil via overtopping the berm, which can affect human health.**
- **Leachate may be released through the base liner to groundwater, which can affect human health.**

5.8.6 Residual Effects Analysis

This section describes the specific methods used to assess the residual effects on human health for the NSDF Project activities and pathways identified as primary in Table 5.8.5-1. The approach used to predict residual effects is described below, along with the scenarios, models, policies, guidelines and standards considered in the analysis. The radiological dose assessment is discussed Section 5.8.6.1 and the non-radiological exposure assessment is discussed in Section 5.8.6.2.

5.8.6.1 Radiological Dose Assessment

5.8.6.1.1 Application Case Methods

Radiological dose to workers (i.e., Nuclear Energy Workers) in the SSA may result from external exposure to radiation emitted from radioactive waste or wastewater, or inhalation of radioactive contaminants in the ECM, WWTP or support buildings (e.g., vehicle decontamination facility). Dose to workers will be monitored and managed as part of the NSDF *Radiation Protection Plan* (AECOM 2018c), which is in accordance with CNL's site-wide Radiation Protection Program. As a result of the implementation of the NSDF *Radiation Protection Plan*, doses to workers will be kept as low as reasonably achievable, and below the effective dose limit of 100 mSv over five years and below 50 mSv in any single year. Worker dose consequences will be also kept below the CNL Radiation Protection Action Levels, which are lower than the regulatory limits listed in the preceding sentence. Worker dose during operations is assessed as part of the NSDF *Safety Analysis Report* (SAR) (CNL 2020).

Radiological dose to members of the public from the NSDF Project may result from waterborne or airborne emissions. Dose to members of the public from waterborne emissions is assessed during the operations phase, as well as during the post-closure phase. It is assumed that during the institutional control period (year 2100 to year 2400), the base liner and cover will be functional and no leachate will seep through the base liner however other migration pathways of contaminants are taken into account in the pathways analysis. This assumption is consistent with the 550-year design life of the engineered barriers.

Radiological dose to members of the public from airborne emissions is assessed for the operations phase of the NSDF Project as part of the SAR (CNL 2020). This represents a bounding case for the closure phase (i.e., 2070-2100), since it is expected that with the installation of the final cover, doses to members of the public during the closure would be less than the operations phase. Radiological dose to members of the public from airborne emissions during the post-closure phase of the NSDF Project as part of the PostSA (Arcadis and Quintessa 2020).

This EIS relies upon supporting documents, as noted, for the prediction and assessment of potential radiological effects on human receptors.

5.8.6.1.1.1 Operations and Closure Phase

For the assessment of human health in the operations and closure phases of the NSDF Project, the main supporting document is the SAR (CNL 2020). A general background of the methods of the SAR is provided as follows:

Safety Analysis Report

The SAR describes the design of the facility, and subsequently analyzes the hazards and potential consequences present in the operations of the facility. The purpose of the SAR is:

- to demonstrate the adequacy of the NSDF design in support of the licensing process;
- to demonstrate that the proposed design of the facility conforms to CNSC regulatory requirements and guidance provided by the International Atomic Energy Agency, and will provide for safe operation over the operational life;
- to identify the hazards, describe how hazards are controlled and/or mitigated, and describe the management system in place to ensure the controls are effectively and consistently applied;
- to undertake a quantitative and qualitative assessment of the radiological and non-radiological safety of the NSDF Project during the operations and closure phases;
- to undertake a quantitative and qualitative assessment of the radiological and non-radiological safety of the NSDF Project during the operations and closure phases; and
- to provide necessary information to support an EIS which will address the requirements of the *Canadian Environmental Assessment Act, 2012* (CEAA 2012) and *REGDOC-2.11.1 Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* (Vol. III; CNSC 2018).

The scope of the SAR is to present the operational safety analysis of the NSDF Project based on the detailed design package, proposed operations and identified hazards. The SAR uses the most up-to-date information about the NSDF Project design to form the basis of the assessment. In the SAR, nuclear safety is assessed for normal operations as well as accident conditions for on- and off-site human receptors and the environment. The timeframe assessed includes the construction period, approximate 50-year operations period, and 30-year closure period.

Normal Operations refers to the most likely, expected process and work tasks that take place on a day-to-day basis. The assessment of Normal Operations assumes that all processes and procedures are followed, that workers are properly trained, and that all CNL compliance programs are being adhered to.

For Normal Operations, the dose constraint for workers is 20 mSv/yr and for the public a dose constraint of 0.3 mSv/yr is applied in accordance with the CRL Licence Conditions Handbook (CNSC 2019). The dose constraint for the public is achieved by ensuring that off-site radionuclide releases are well below Derived Release Limits (DRL) for the CRL site (CNL 2018d). The NSDF Project is designed so the potential release of radionuclides during normal operations is less than a target of 1% of the corresponding release limits and DRL.

Accident conditions are separated into three categories based on frequency of occurrence, and are evaluated further in Section 7.0:

- Anticipated Operational Occurrence: An event that deviates from normal operations and is expected to occur once to several times during the operating lifetime of the facility. An Anticipated Operational Occurrence does not result in significant damage.
- Design Basis Accident: A rare event that is expected to occur once in 10,000 years, but much less frequently than an Anticipated Operational Occurrence. The NSDF Project is designed to perform under the conditions of a Design Basis Accident.
- Beyond Design Basis Accident: A very rare event that has more severe consequences, but occurs less frequently than a Design Basis Accident. A Beyond Design Basis Accident is expected to occur less than once in 10,000 years.

The objectives of the safety analysis are to demonstrate the following requirements under normal operations, Anticipated Operational Occurrences, Design Basis Accidents and Beyond Design Basis Accidents in the NSDF Project:

- the safety of the off-site public and on-site workers is protected;
- the dose acceptance criteria are met;
- there are no significant adverse effects on the environment;
- the adequacy of the NSDF Project design; and
- the proposed design of the NSDF Project conforms to regulatory requirements and guidance provided by the CNSC and the International Atomic Energy Agency (IAEA).

The SAR considers the following primary pathways in the evaluation of dose to persons on-site (workers) and off-site (public):

- Dust may be created during handling of bulk materials and emissions of gases may be released during storage and disposal of radioactive materials, which can affect human health.
- Emissions may be released from the WWTP to air during operations, which can affect human health.

Gases and dust released from the ECM or WWTP can diffuse into the environment where they will be dispersed by wind. Some contaminants will be absorbed by vegetation which could then be consumed by animals and people. Workers in proximity to the waste or WWTP processes will be exposed to radiation. Pathways include external exposure and inhalation of dust.

Contaminants released through the treated effluent will reach Perch Lake. Once in the aquatic environment, there will be further dilution in Perch Creek and then in the Ottawa River. Contaminants may be taken up by aquatic flora and fauna. However, given that the effluent discharge meets applicable discharge requirements, exposure to humans and biota through this pathway are considered negligible during the operations and closure phase.

The human receptors assessed in the SAR are discussed in Section 5.8.6.1.1.3.

The radiological inventory of the ECM includes low-level waste associated with bulk unpackaged wastes and packaged wastes. The radionuclides assessed in the SAR are presented in Table 5.8.6-1.

Table 5.8.6-1: Radionuclides Assessed in the Safety Analysis Report

Radionuclides	
Ag-108m (metastable isotope silver-108)	Pu-239 (isotope plutonium-239)
Am-241 (isotope Americium-241)	Pu-241 (isotope plutonium-241)
Am-243 (isotope Americium-243)	Pu-242 (isotope plutonium-242)
C-14 (isotope carbon-14)	Ra-226 (isotope radium-226)
Cl-36 (isotope chlorine-36)	Se-79 (isotope selenium-79)
Co-60 (isotope cobalt-60)	Sn-126(isotope tin-126)
Cs-135 (isotope caesium-135)	Sr-90 (isotope strontium-90)
Cs-137 (isotope caesium-137)	Tc-99 (isotope technetium-99)
H-3 (isotope hydrogen-3 [Tritium])	Th-230 (isotope thorium-230)
I-129 (isotope Iodine-129)	Th-232 (isotope thorium-232)
Mo-93 (isotope molybdenum-93)	U-233 (isotope uranium-233)
Nb-94 (isotope Niobium-94)	U-234 (isotope uranium-234)
Ni-59 (isotope nickel-59)	U-235 (isotope uranium-235)
Ni-63 (isotope nickel-63)	U-238 (isotope uranium-238)
Np-237 (isotope neptunium-237)	Zr-93 (isotope zirconium-93)

Source: CNL 2020

The SAR examines the potential hazards that could result from normal operations and the consequences of abnormal events and accidents. The SAR uses a systematic and comprehensive method to identify all hazards and accident scenarios which includes:

- hazard identification;
- identification of major hazards and postulated initiating events associated with the NSDF Project design and operations;
- hazard analysis of the consolidated list of major hazards and postulated initiating events for the NSDF Project facilities;
- failure mode, effects and criticality analysis (FMECA) of the WWTP; and

- safety analysis of normal operation, Anticipated Operational Occurrences, Design Basis Accidents and Beyond Design Basis Accidents using credible/relevant scenarios.

The hazard identification was conducted early in the design process (AECOM 2016). The objective of the hazard identification was to list characteristics associated with systems, structures and components with the potential for radiological or chemical harm to people or the environment.

The hazards posed by the NSDF Project, with the exception of the WWTP, were identified based on the safety analysts' engineering judgement, and were recorded on the Safety Hazards Checklist and documented in Hazard Identification (AECOM 2016). The Safety Hazards Checklist was used to record relevant details and safeguards for the identified hazards.

The WWTP hazard identification involved completing a preliminary failure modes and effects analysis (FMEA) for the WWTP components and subcomponents based on the 30% design piping and instrumentation diagrams (AECOM 2016). The preliminary FMEA for the WWTP components was developed to identify failure modes and effects based on the safety analysts' engineering judgement. The WWTP preliminary FMEA is documented in Hazard Identification (AECOM 2016).

Waterborne Effluent – Operations Phase

The total average annual volume of leachate, contact stormwater and decontamination water under this operating scenario is 13,320 m^3/yr. This operating scenario represents the anticipated wastewater generated over approximately 50 years of the ECM for one active cell and nine filled (closed) cells based on:

- two weeks of 22.5 m^3/hr discharge (8 hr/day) corresponding to a storm event (i.e., 2,520 m^3); and
- 120 days of 11.25 m^3/hr discharge (8 hr/day) corresponding to normal operations (i.e., 10,800 m^3).

This single annual effluent flow of 13,320 m^3/yr is discharged under two receiving environment scenarios:

- Scenario 1: 50% of WWTP effluent discharges to an exfiltration gallery ultimately leading to the East Swamp Wetland and the remaining 50% directly discharges to Perch Lake via an end-of-pipe diffuser.
- Scenario 2: 100% of WWTP effluent discharges directly to Perch Lake via an end-of-pipe diffuser.

For the operations phase modelling, it is conservatively assumed that no dilution occurs along the groundwater flow-path from the WWTP effluent discharge to the East Swamp Stream. The annual average flow rate of the East Swamp Stream, which drains the wetland, is 72,000 m^3/yr. Average annual outflow from this wetland is via East Swamp Stream to Perch Lake, which discharges to the Ottawa River via Perch Creek at approximately 2,200,000 m^3/yr.

The treated effluent will contain small quantities of residual contaminants. The effluent discharge targets for radionuclides are the Canadian Drinking Water guidelines, with the exception of tritium. The tritium effluent discharge target is a site-specific target which will ensure that tritium concentrations in Perch Creek which discharges to the Ottawa River do not exceed the drinking water guideline of 7,000 Bq/L. The concentrations of radionuclides in the treated effluent are assumed to equal the effluent discharge targets and are presented in Table 5.8.6-2.

There is no public access to the CRL site including the Perch Creek and Perch Lake Watershed where treated effluent is discharged. Radionuclide releases from the treated effluent discharges will be negligible compared to the site Derived Release Limits. Radiation doses to off-site members of the public located downstream of the CRL site will be well below the regulatory limits.

Table 5.8.6-2: Maximum Concentrations of Radionuclides in the Treated Effluent

Radionuclide	Maximum Concentrations in Treated Effluent (Bq/L)[(a)]
Ag-108m (metastable isotope silver-108)	60
Am-241 (isotope Americium-241)	0.7
Am-243 (isotope Americium-243)	0.7
C-14 (isotope carbon-14)	200
Cl-36 (isotope chlorine-36)	100
Co-60 (isotope cobalt-60)	40
Cs-135 (isotope caesium-135)	70
Cs-137 (isotope caesium-137)	10
H-3 (isotope hydrogen-3 [Tritium])	360,000
I-129 (isotope Iodine-129)	1
Mo-93 (isotope molybdenum-93)	40
Nb-94 (isotope Niobium-94)	80
Ni-59 (isotope nickel-59)	2,000
Ni-63 (isotope nickel-63)	900
Np-237 (isotope neptunium-237)	1
Pu-239 (isotope plutonium-239)	0.6
Pu-241 (isotope plutonium-241)	30
Pu-242 (isotope plutonium-242)	0.6
Ra-226 (isotope radium-226)	0.5
Se-79 (isotope selenium-79)	50
Sn-126(isotope tin-126)	30
Sr-90 (isotope strontium-90)	5
Tc-99 (isotope technetium-99)	200
Th-230 (isotope thorium-230)	0.7
Th-232 (isotope thorium-232)	0.6
U-233 (isotope uranium-233)	3
U-234 (isotope uranium-234)	3
U-235 (isotope uranium-235)	3
U-238 (isotope uranium-238)	3

Table 5.8.6-2: Maximum Concentrations of Radionuclides in the Treated Effluent

Radionuclide	Maximum Concentrations in Treated Effluent (Bq/L)[(a)]
Zr-93 (isotope zirconium-93)	100

Source: CNL 2020

a) Effluent discharge target concentration, as an upper bound.

Bq/L = Becquerels per litre.

Airborne Releases – Operations Phase

During operations, the ECM may emit airborne radionuclide releases (AECOM 2018d). Potential discharges include emissions of radioactive dust during handling of bulk materials and gaseous emissions during storage and disposal of radioactive materials. The expected gaseous radionuclide releases are:

- tritium in the form of tritium oxide;
- gases containing carbon-14; and
- radon-222 released due to the decay of radium-226, plutonium-242, uranium-234 and uranium-238.

The concentrations of radon, tritium, and carbon-14 in air near the surface of the ECM, as well as the resulting dose to the worker, are presented in Table 5.8.6-3 below. Doses to off-site receptors (public) would be several orders of magnitude less, due to the separation distance of a few kilometers.

Table 5.8.6-3: Radioactive Gas Generation Rates and Worker Doses during Normal Operations

Parameter	Value
Radon gas production rate	3.0×10^{-8} Bq/cm^3-sec
Radon flux to atmosphere, no cover	2.9×10^{-2} Bq/m^2/sec
Radon flux to atmosphere, final cover	6.4×10^{-3} Bq/m^2/sec
Radon concentration in NSDF cell	0.50 Bq/m^3
Radon dose to worker	9.6×10^{-4} mSv/yr
Tritium concentration in air	61 Bq/m^3
Tritium dose to worker	1.6×10^{-5} mSv/yr
Carbon-14 concentration in air	0.53 Bq/m^3
Carbon-14 dose to worker	2.2×10^{-6} mSv/yr

There will also be airborne emissions from the WWTP. The emission rates for radionuclides were calculated in the SAR (CNL 2020). The highest emission rates were for americium-241, cobalt-60 and tritium, at about 0.04% of the CRL Derived Release Limits (DRL). The rest of the radionuclides were below 0.001% of the DRL. The dose to members of the public is therefore predicted to be well below regulatory limits.

5.8.6.1.1.2 Post-Closure Phase

For the assessment of human health in the post-closure phase of the NSDF Project, the main supporting document is the PostSA (Arcadis and Quintessa 2020). A general background of the radiological methods of the PostSA is provided below.

Post-Closure Safety Assessment (PostSA)

The PostSA (Arcadis and Quintessa 2020) analyzes the long-term implications (i.e., during the institutional control and post-institutional control periods) of the NSDF Project. The purpose of the PostSA is:

- to undertake a quantitative assessment of the radiological and non-radiological safety of the NSDF Project during the post-closure phase;
- to identify those uncertainties that have the greatest potential effect on the long-term performance of the decommissioned facility; and
- to provide necessary information to support an EIS which will address the requirements of CEAA 2012 and REGDOC-2.11.1 Vol. III (CNSC 2018).

Evaluating post-closure safety requires projections of the future condition of the NSDF Project and its environment, and how receptors might interact with it. Approaches have been developed to undertake such evaluations, centred on a “system analysis” method. This involves representing the NSDF Project, the facility inventory present and all potentially relevant media (e.g., groundwater, soil, surface water and sediment), with mathematical models to represent the key processes that may occur (e.g., corrosion of wastes, dissolution into groundwater, uptake by plants). It is essential that the models used are relevant, well grounded and auditable. This is achieved through a systematic approach to safety assessment. The international community has developed best practice guidance on the process, which is documented in a report of the IAEA ISAM programme (IAEA 2004) and incorporated into a more recent safety guide (IAEA 2012). This process has been applied internationally since its publication, is consistent with REGDOC-2.11.1 Vol. III (CNSC 2018) and underpins the PostSA analysis.

The PostSA considers three primary pathways of release of contaminants into the environment:

- volatiles (e.g., radon, tritium) may be released to air, which can affect human health;
- leachate may be released to soil via overtopping the berm, which can affect human health; and
- leachate may be released through the base liner to groundwater, which can affect human health.

Gases released above the ECM will diffuse through the soil and into the atmosphere where they will be dispersed by wind. Some contaminants will be absorbed by vegetation which could then be consumed by animals and people.

Contaminants released by overtopping the berm will move through the shallow environment by overland flow and interflow resulting in contamination of surface soils. Exposures can arise by external irradiation, inhalation of dust, inadvertent ingestion and consumption of food stuffs grown in the soil, or consumption of animals that have grazed in the contaminated area.

Contaminants released to groundwater beneath the ECM will move through the geological and hydrogeological environment by advection and dispersion and may sorb to sediments. Once in the aquatic environment, there will be further dilution in Perch Creek and then in the Ottawa River. Contaminants may be taken up by aquatic flora and fauna.

The human receptors assessed in the PostSA are discussed in Section 5.8.6.1.1.3. The radioactive inventory of the ECM includes low-level waste associated with bulk unpackaged wastes and packaged wastes.
The radionuclide inventory has been screened to reduce the number of radionuclides being considered to those that are relevant for the post-closure phase. Radioactive decay and ingrowth are accounted for during the assessment time frame. The radionuclides assessed in the PostSA are presented in Table 5.8.6-4.

Table 5.8.6-4: Radionuclides Assessed in the PostSA

Radionuclides	
Ag-108m (metastable isotope silver-108)	Pu-239 (isotope plutonium-239)
Am-241 (isotope Americium-241)	Pu-241 (isotope plutonium-241)
Am-243 (isotope Americium-243)	Pu-242 (isotope plutonium-242)
C-14 (isotope carbon-14)	Ra-226 (isotope radium-226)
Cl-36 (isotope chlorine-36)	Se-79 (isotope selenium-79)
Co-60 (isotope cobalt-60)	Sn-126(isotope tin-126)
Cs-135 (isotope caesium-135)	Sr-90 (isotope strontium-90)
Cs-137 (isotope caesium-137)	Tc-99 (isotope technetium-99)
H-3 (isotope hydrogen-3 [Tritium])	Th-230 (isotope thorium-230)
I-129 (isotope Iodine-129)	Th-232 (isotope thorium-232)
Mo-93 (isotope molybdenum-93)	U-233 (isotope uranium-233)
Nb-94 (isotope Niobium-94)	U-234 (isotope uranium-234)
Ni-59 (isotope nickel-59)	U-235 (isotope uranium-235)
Ni-63 (isotope nickel-63)	U-238 (isotope uranium-238)
Np-237 (isotope neptunium-237)	Zr-93 (isotope zirconium-93)

Source: Arcadis and Quintessa 2020

In the PostSA, human health acceptance criteria have been defined according to REGDOC-2.11.1 Vol. III (CNSC 2018) which requires reasonable assurance that:

- the regulatory dose limit for public exposure (1 mSv/yr) will not be exceeded;
- the possibility of exposure to multiple sources is allowed for; and
- doses are ALARA.

The human health acceptance criteria to assess the potential impacts from radon gas is the Health Canada guideline for radon in household air of 200 Bq/m^3.

The specific criteria adopted for each scenario are outlined in the Assessment Context section of the PostSA.

The PostSA uses the best available information on the NSDF Project and its surrounding environment to form the basis of the mathematical models developed specifically to represent the system. These have been used to calculate results that can be compared with relevant Canadian criteria and standards, as well as inform on uncertainties and identify the most important aspects of the system. These uncertainties and important aspects are captured using a number of scenarios, which are summarized in the PostSA and within the groupings below:

- Normal Evolution Scenario;
- Disruptive Event Scenarios;
- Defence-in-Depth Cases;
- “What-If” Cases; and
- Sensitivity Analysis Cases.

The **Normal Evolution Scenario** is a description of the most likely, expected, evolution of the ECM and its surrounding environment. The Normal Evolution Scenario accounts for the expected degradation of the engineered barriers over the post-closure phase. It starts immediately following the operations phase, to capture the entire post-closure phase (i.e., institutional control and post-institutional control periods). It is assumed that during the institutional control period (year 2100 to year 2400), the base liner and cover will be functional and no leachate will seep through the base liner. The PostSA estimates doses to humans during the post-closure phase.

Disruptive Event Scenarios are variants on the Normal Evolution Scenario, designed to address uncertainties that have arisen during the definition of scenarios and conceptual models. Each is described with scenario-specific assumptions. The following Disruptive Event Scenarios were assessed in the PostSA:

- **Human Intrusion (Borehole):** This scenario assesses the potential of humans drilling, extracting and examining a core sample from the facility, potentially leading to internal or external exposures.
- **Human Intrusion (House with Basement):** In this scenario, a potential basement is constructed on top of the ECM and excavated soil/waste is spread over the garden area.
- **Enhanced Erosion Case:** This scenario investigates the potential faster erosion of the cap such that wastes are exposed at the ground surface and eroded materials spread downslope in the swamp area between the ECM and Perch Creek. This could be caused by seismic events.
- **Localized Cover Failure:** In this scenario, it is assumed that potential localised high infiltration through a failure in the cap, resulting in earlier bathtubbing of the ECM (relative to the Normal Evolution Scenario).
- **Localized Liner Failure:** This scenario assesses there is increased leaching through a potential failure in the base liner, resulting in delayed bathtubbing of the ECM (relative to the Normal Evolution Scenario).
- **Damage to the Berm:** This scenario assesses potential damage to the berm; the reduced height of the berm results in increased flow of water over the berm during bathtubbing and reduced the water level in the wastes.

In addition to Normal Evolution Scenario and Disruptive Event Scenarios, the PostSA also considers other types of scenarios, including “What-If” Cases, Defence-in-Depth Cases and Sensitivity Analysis Cases.

- “What-If” Cases represent a deliberately extreme set of assumptions that can be used to understand the absolute limits of safety performance. These have been identified as potentially of interest in the same way as other scenarios, but discounted from the main set of assessment calculations on the basis that they are of very low or negligible likelihood. Nevertheless, they inform on the underlying bounds to post-closure safety and, as such, provide valuable perspective. However, due to their very low likelihood they are not included in consideration for the identification and assessment of residual effects.
- Defence-in-Depth Cases are aimed at building confidence in the performance of the NSDF after closure. These cases examine the extent to which the NSDF Project depends on key engineered barriers and what would happen if those barriers were not present. This group of scenarios therefore involves hypothetical combinations in order to analyze the barriers in the system. Each scenario involves a change in one or more parameters related to a particular barrier; by comparing the results to those of the Normal Evolution Scenario, the influence of the barrier is shown.
- Sensitivity Analysis Cases are used to directly examine the effect of important uncertainties in the models and data used to represent the system. As many modelling aspects can in practice be expressed through parameter values, sensitivity cases focus on using alternative parameter value choices. The alternative parameter values that are assigned need not represent specific bounds on uncertainty (as in some cases these cannot easily be established); in other words, the alternative parameters need not necessarily be the ‘highest’ or ‘lowest’ possible values. Rather, they are used to test the effect of uncertainty; for example, if parameter x is increased by a factor of 10, by what factor does the dose increase?

These cases serve to illustrate the importance of facility design features, address uncertainty in model parameters and provide perspective on the limits of safety performance. These scenarios are not relevant for the EIS effects assessment and are therefore not discussed further in this report. In general, the EIS only restates necessary information from the PostSA. Further information on scenarios, receptors, calculations and results in general, is available in the PostSA (Arcadis and Quintessa 2020).

5.8.6.1.1.3 Receptor Selection

Operations and Closure Phases

For normal operations, the dose to the worker is quantitatively assessed. The dose to an off-site receptor (member of the public) is confirmed to be acceptable by meeting the air and water release limits as prescribed in the CRL License Conditions Handbook (CNSC 2019) and by the criteria set out in the Derived Release Limits (DRL) for CNL's Chalk River Laboratories (CNL 2018d). The NSDF Project is designed so that the potential release of radionuclides during normal operation is less than a target of 1% of the corresponding release limits and DRL.

The on-site receptors are workers and include both the NSDF Project worker and a representative CNL employee at a central location on-site. The closest public receptor was chosen to represent the off-site dose. This receptor is the Quebec cottager/resident across the Ottawa River, approximately 3 km from the SSA. Traditionally, cottagers are assumed to spend 8% of their time in the cottage area, for the purposes of dose calculations. CNL received feedback from a nearby cottage resident which indicated that the cottage was being used as a full-time residence. As a result, the cottage resident is treated as having the same occupancy factor as any other Potential Critical Group, which is conservatively assumed to be 100%. Local food and water consumption rates are based on the Canadian Standards Association (CSA) N288.1-14 (CSA Group 2014).

Post-closure Phase

The PostSA identifies two potential exposure groups conceived for the Normal Evolution Scenario:

- Resident/Farmer: A small household (comprising two adults, a child and an infant) above the ECM footprint. The household raises chickens, are assumed to grow a portion of their fruits and vegetables in the garden, as well as raise cattle in the affected swamp area. It is assumed that 100% of the family receptors' occupancy time occurs within the contaminated area. The house does not have a basement, but there is potential exposure from radon-222.
- Hunting/Recreational: This group is represented by a small number of adults and children making hunting and/or recreational use of the area surrounding the ECM, including Perch Creek and the Ottawa River. This group occasionally drinks water from the Perch Creek and eats deer hunted from the CRL site.

The PostSA also assesses other receptors as part of the Sensitivity Analysis Case. Two receptor types were chosen:

- Self Sufficient Indigenous Group: This group represents a group of Indigenous Peoples, including adults and children, using area that surrounds the ECM, including Perch Creek and the Ottawa River, for hunting and gathering. Individuals in this group are assumed to obtain all of their food through hunting and gathering in the area. It is assumed that this group would have increased consumption of fish and wild game. Furthermore, this group is assumed to gather local mushrooms and berries.
- Public Interest Receptor: This group is represented by resident receptors that obtain their drinking and bathing water from the Ottawa River, downstream from the NSDF Project. Specifically, these receptors represent the Sheenboro and Ottawa/Gatineau communities. The inclusion of these receptors was driven by public interest.

There is also a driller receptor in the Human Intrusion (Borehole) scenario and Human Intrusion (House with Basement) scenario. This driller is exposed to waste while drilling or excavating the basement.

The PostSA does not calculate the dose to an on-site worker who performs maintenance on the NSDF Project during the institutional control period. This worker's exposure is bounded by the ECM worker during operations who works directly with low-level waste, before the final cover is installed (which acts as a shield).

Table 5.8.6-5 provides a comparison of the key exposure characteristics of the Normal Evolution Scenario receptors.

Table 5.8.6-5: Receptors and Exposure Characteristics

Receptor Group	Lives On site	External Exposure	Inhalation[a]	Drinks from Deep Well	Drinks from Perch Creek	Drinks from Ottawa River	Grows Food On-site	Grows Food Off-site[b]	Raises Chickens	Raises cattle	Gathers Local Food	Collects Honey	Hunts Local Game	Fishes in Ottawa River	Uses Land for Recreation
Resident/Farmer	✓	✓		✓	✓		✓		✓	✓				✓	✓
Hunter/Recreational		✓			✓							✓	✓	✓	✓
Self Sufficient Indigenous		✓			✓						✓	✓	✓	✓	✓
Public Interest Receptor						✓								✓	

a) Inhalation is assessed for human intrusion scenarios (disruptive event)

b) Off-site receptors who many grow food off site are evaluated as a sensitivity analysis

5.8.6.1.2 Application Case Results

5.8.6.1.2.1 Operations and Closure Phases

This section presents a summary of the estimated radiological dose results for human receptors in the pre-closure phase (i.e., construction, operations and closure) for the Normal Operations. Anticipated Operational Occurrences, Design Basis Accidents and Beyond Design Basis Accidents are considered in Section 7.0 (Accidents and Malfunctions). For further detail on these results, the reader is directed to the SAR (CNL 2020).

The criterion used for public radiological exposure as a result of CRL site operations will be ALARA, and subject to the dose constraint of 0.3 mSv/yr for the public (CNSC 2019).

Normal Operations – On-site (Worker) Doses

Doses to the representative NSDF Project workers for normal operations were calculated and shown in Table 5.8.6-6. The peak calculated dose is to an ECM worker performing the task of macro-encapsulation of drummed wastes and is 10.4 mSv/yr. This dose is below CNL's Action Level of 20 mSv/yr, and represents 20.8% of the 50 mSv/yr limit for Nuclear Energy Workers.

Table 5.8.6-6: Doses to Representative NSDF Project Workers for Normal Operations

NSDF Project Worker Type	Effective Dose per Year (mSv/yr)
WWTP worker	5.21
ECM worker tasks:	
▪ Macro-encapsulation of drummed waste	10.4
▪ Normal ECM work	6.37

mSv/yr = millisieverts per year; WWTP = Wastewater Treatment Plant; ECM = engineered containment mound.

Normal Operations – Off-site (Public) Doses

The nearest off-site receptors are located at the Quebec cottages, approximately 3 km from the CRL site, and Chalk River, approximately 7 km west of the CRL site. The primary dose pathways for the off-site receptor are inhalation of airborne contaminants and ingestion of drinking water. Cloudshine and groundshine of the waste placed in the ECM will have a negligible effect on the off-site receptors due to the separation distance (i.e., closest receptor is approximately 3 km from the CRL site).

The effluent discharge targets for radionuclides are based on Canadian Drinking Water Guidelines with the exception of tritium for which a site-specific target is developed (Section 3.4.2.5.1). During normal operations, only the discharge of treated effluent meeting the effluent discharge targets (CNL 2019c) is expected. Therefore, the off-site receptor ingestion dose consequence will be much lower than the dose constraint of 0.3 mSv/yr for the public.

The off-site receptor inhalation dose consequence is expected to very low based on:

- The air emissions from the WWTP process tanks are a fraction of the CRL site DRLs.
- The off-site receptor inhalation dose rate is much lower than that of the ECM worker who is in direct contact with the waste (i.e., closest off-site receptor is approximately 3 km from the CRL site).

Airborne releases of contaminants during normal operations are expected to occur during:

- waste placement and compaction activities in the ECM;
- filling and draining of WWTP tanks; and
- operation of the WWTP active ventilation.

During ECM operations, dust will be controlled following the *Dust Management Plan* (AECOM 2018a), mitigating the airborne releases. During WWTP operations where there is potential for airborne releases, the active ventilation system is implemented to control the spread of contamination and gaseous effluents are directed through HEPA filters to abate particulate discharges.

The dose consequences to the off-site receptors during normal operations are expected to be much lower than the 0.3 mSv/yr dose constraint thus negligible residual effects are expected on human health from radioactivity associated with the NSDF Project during the operations and closure phase.

5.8.6.1.2.2 Post-Closure Phase

This section presents a summary of the estimated radiological dose results for human receptors in the post-closure phase for the Normal Evolution Scenario and Disruptive Event Scenarios as assessed in the PostSA. For further detail on these results, the reader is directed to the PostSA (Arcadis and Quintessa 2020).

Human health criteria for public radiological dose are as follows:

- The criterion used for public radiological exposure as a result of the Normal Evolution Scenario is that the dose to the public will be ALARA and subject to a dose constraint of 0.3 mSv/yr.
- For Disruptive Event Scenarios, the probability of exposure is considered during the scenario definition process. A regulatory dose limit of 1 mSv/yr is used for radiation exposure of humans for unlikely but credible scenarios. If the calculated dose exceeds 1 mSv/yr, the scenario is examined on a case-by-case basis, taking into account the likelihood and nature of the exposure, conservatism and uncertainty in the assessment and conservatism in the regulatory dose limit.
- Radon-222, given its source as a naturally occurring radioactive material, will be compared against a complementary safety criterion. Predicted radon-222 concentrations for relevant scenarios (i.e., within the house on the disposal facility) will be compared against the Health Canada guideline (Health Canada 2014a) for radon in household air (200 Bq/m^3), as well as against the average Ontario and Canada wide household air concentrations, 38.7 Bq/m^3 and 45.5 Bq/m^3 respectively (CNSC 2011). Furthermore, the annual effective dose in Canada for radon is around 1 mSv (CNSC 2011), and predicted radon doses can be compared to this value.

Normal Evolution Scenario

The highest calculated dose rate to any receptor in the normal evolution scenario is 0.015 mSv/y, which is 20 times lower than the dose constraint of 0.3 mSv/yr. This peak dose is received by the on-site resident/farmer adult. The peak occurs around 4,100 years after closure.

The key radionuclides and pathways for doses to the adult on-site resident/farmer are:

- external irradiation from niobium-94 and thorium-228; and
- ingestion of carbon-14 from crops and beef.

The highest calculated dose rate (0.012 mSv/yr) to the hunter/recreation receptor in the normal evolution scenario is received by the adult. This dose rate is 25 times lower than the dose constraint of 0.3 mSv/yr. The peak occurs around 650 years after closure.

The key radionuclides and pathways for doses to the adult on hunter/recreational receptor are:

- ingestion of carbon-14 from game;
- external irradiation from thorium-228, niobium-94, radium-228, radium-226; and
- ingestion of plutonium-239 from fish.

The low peak dose relative to the dose constraint implies that there are negligible residual effects expected on human health from radioactivity associated with the NSDF Project during the post-closure phase.

Any radon that may accumulate in a house potentially built on top of the NSDF Project in the post-closure phase for the NES will have a maximum concentration of 2.9 Bq/m^3, far below Health Canada guidance level of 200 Bq/m^3. This is also far below average values of radon in Ontario houses 38.7 Bq/m^3. This implies that there are negligible residual effects expected on human health due to radon buildup associated with the NSDF Project.

Receptors of public interest were also assessed. These include residents in Sheenboro and Ottawa-Gatineau drawing water from the Ottawa River. The maximum peak dose for these residents was over 70,000 times lower than the dose constraint.

Additionally, a Self Sufficient Indigenous receptor was assessed in the PostSA. The results for this receptor are discussed in Section 6.6 of this EIS.

Disruptive Event Scenarios

Human Intrusion (Borehole)

The peak annual dose calculated for Human Intrusion (Borehole) is 0.00065 mSv and is received by the driller receptor. This peak dose rate is the highest estimated dose rate within the assessment timeframe and is over 1,500 times lower than the regulatory dose limit of 1 mSv/yr. The peak occurs around 300 years (the end of institutional control) after closure.

The key radionuclides and pathways for doses to the driller are:

- inhalation of americium-241 and its progeny thorium-228 and radium-228 from dust.

The low dose relative to the regulatory dose limit implies there are negligible residual effects expected on human health associated with the NSDF Project for the Human Intrusion Borehole Case.

Human Intrusion (House with Basement)

The peak annual dose calculated for Human Intrusion (House with Basement) is received by the on-site resident/farmer. The calculated peak dose rate is 0.017 mSv/yr, compared to the regulatory dose limit of 1 mSv/yr. This peak dose rate is over 50 times lower than the regulatory dose limit. The peak occurs around 2,900 years after closure.

The key radionuclides and pathways for doses to the on-site resident/farmer adult are:

- ingestion of carbon-14 from beef; and
- external exposure of thorium-228, niobium-94, radium-228, and radium-226 from swamp area.

The low dose relative to the regulatory dose limit implies there are negligible residual effects expected on human health associated with the NSDF Project for the Human Intrusion Basement Case.

Any radon that may accumulate in a house, potentially built on top of the NSDF Project in the post-closure period for the Human Intrusion (House with Basement) will have a maximum concentration of 10.7 Bq/m^3, far below Health Canada guidance level of 200 Bq/m^3. This is also below average values of radon in Ontario houses 38.7 Bq/m^3. This implies that there are negligible residual effects expected on human health due to radon buildup associated with the NSDF Project for the H.I. Basement Case.

Enhanced Erosion Case

The highest peak annual dose rate calculated for the Enhanced Erosion Scenario is 0.14 mSv/yr, compared to a regulatory dose limit of 1 mSv/yr. This peak dose is received by the on-site resident/farmer child receptor. This peak dose rate is 6 times lower than the regulatory dose limit. The peak occurs around 7,650 years after closure.

The key radionuclides and pathways for doses to the on-site resident/farmer child are:

- ingestion of radium-228 from foodstuffs.

The low dose relative to the regulatory dose limit implies there are negligible residual effects expected on human health associated with the NSDF Project for the Enhanced Erosion Scenario.

Localized Cover Failure

The peak annual dose rate calculated for the Localized Cover Failure Scenario is 0.017 mSv/yr, and is received by the on-site resident/farmer adult. This peak dose is over 50 times lower than the regulatory dose limit of 1 mSv/yr. The peak occurs around 2,900 years after closure.

The key radionuclides and pathways for doses to the on-site resident/farmer adult are:

- external irradiation of thorium-228, niobium-94, radium-228, and radium-226 from soil; and
- ingestion of carbon-14 from foodstuffs.

The low dose relative to the regulatory dose limit implies there are negligible residual effects expected on human health associated with the NSDF Project for the Localized Cover Failure Scenario.

Localized Liner Failure

The peak annual dose calculated for the Localized Liner Failure Scenario is estimated to be 0.01 mSv/yr, 100 times lower than the regulatory dose limit of 1 mSv/yr. This peak dose is received by both the on-site resident farmer and hunter receptors. The peaks occur around 2,600 years and 650 years after closure for the on-site resident farmer and hunter receptors respectively.

The key radionuclides and pathways for doses to the on-site resident/farmer adult are:

- External irradiation of thorium-228, niobium-94, radium-228, and radium-226 from soil; and
- Ingestion of carbon-14 from foodstuffs.

The key radionuclides and pathways for doses to the hunter/recreational adult are:

- Ingestion of carbon-14 from game;
- External irradiation of thorium-228, niobium-94, radium228, and radium-226 from soil; and
- Ingestion of plutonium-239 from fish.

The low dose relative to the regulatory dose limit implies there are negligible residual effects expected on human health associated with the NSDF Project for the Localized Liner Failure Scenario.

Damage to the Berm

The peak annual dose rate calculated for the Damage to Berm Scenario is 0.02 mSv/yr, and is received by both the on-site resident/farmer adult and hunter/recreational adult receptors. This peak dose is lower than the annual regulatory dose limit of 1 mSv/yr by 2 orders of magnitude. The peak occurs around 3,600 years and 700 years after closure for the on-site resident farmer and hunter/recreational adult receptors respectively.

The key radionuclides and pathways for doses to the on-site resident/farmer adult are:

- External irradiation of thorium-228, niobium-94, radium228, and radium-226 from soil; and
- Ingestion of carbon-14 from foodstuffs.

The key radionuclides and pathways for doses to the hunter/recreational adult are:

- Ingestion of carbon-14 from game; and
- External irradiation of thorium-228 from soil.

The low dose relative to the regulatory dose limit implies there are negligible residual effects expected on human health associated with the NSDF Project for the Damage to Berm Scenario.

5.8.6.2 Non-radiological Exposure Assessment

5.8.6.2.1 Application Case Methods

The non-radiological exposure assessment considers the ways in which human receptors (introduced in Section 5.8.2) could be exposed to contaminants present in the various environmental media. In general, human receptors may come into contact with contaminants through four primary exposure routes: dermal exposure, incidental ingestion (e.g., of soil), ingestion of contaminated food and inhalation.

This EIS relies upon supporting documents for the prediction and assessment of potential non-radiological effects on human receptors.

5.8.6.2.1.1 Operations and Closure Phases

For the Operations phase of the NSDF Project, the main supporting information is from modelling completed for surface water quality (Section 5.4.2). The non-radiological exposure assessment considered the following two scenarios for the surface water environment (described in Section 5.4.2.6.1.2):

- Scenario 1: This scenario divides the total annual discharge equally between the exfiltration gallery at East Swamp weir and Perch Lake (direct pumping to Perch Lake via transfer line). Scenario 1 was modelled to examine if an exfiltration gallery approach resulted in any measurable decrease in projected Perch Lake concentrations (i.e., some degree of mixing and dilution of WWTP effluent with ambient concentrations anticipated upstream of Perch Lake).
- Scenario 2: This scenario discharges 100% of the total annual discharge directly into Perch Lake at the northeastern shoreline. Scenario 2 was modelled to examine the “worst case” scenario of projected Perch Lake concentrations (i.e., no available mixing nor dilution upstream of Perch Lake).

The two surface water model scenarios were completed for a select group of parameters termed constituents of potential concern (COPCs). Key elements of the COPC selection process included identifying those parameters that were expected to change as a result of the NSDF Project, those with available guidelines and those that were expected to be toxic to aquatic organisms. The ten selected COPCs were aluminum, barium, copper, iron, lead, manganese, phosphorus, selenium, silver, and zinc.

A preliminary screening was completed as shown in Section 5.4.2.6.1.4, wherein predicted concentrations of parameters in untreated effluent were compared to effluent discharge targets. The effluent discharge targets (see Table 3.4.2-3) are generally based on aquatic guidelines from a variety of sources including Canadian Council of Ministers of the Environment (CCME), United States (US) Environmental Protection Agency (EPA), US Department of Energy and others. However, to ensure that human health is adequately protected, predicted concentrations of non-radiological parameters were compared to federal guidelines that are protective of human health. Where federal guidelines were not available, provincial guidelines that are similarly protective of human health were consulted. In the absence of both federal and provincial guidelines, alternate guidelines from other jurisdictions were used. The selected guidelines are described below (see Section 5.8.6.2.1.3).

It is noted that the air quality discipline assessed the predicted non-radiological concentrations in air emissions during the operations phase of the NSDF Project. Predicted concentrations for the Application Case during both construction and operations phases are below applicable air quality guidelines and/or standards with the exception of nitrogen dioxide, that will not meet the 2020 1-hour Canadian Ambient Air Quality Standards (Section 5.2.1.6.2, Table 5.2.1-14). The contributing factor to the high magnitude nitrogen dioxide emissions is the heavy-duty construction equipment and the conservative assumption that all equipment will run simultaneously and continuously during working hours. In reality, individual equipment will be idling or off for varying parts of the workday that can not be predicted but will result in lower emissions than currently estimated. The likelihood that all equipment operates simultaneously for an hour or more along with unfavourable weather conditions to produce the maximum concentrations modelled is very low. With the implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018b) and through the implementation of the *Dust Management Plan* (AECOM 2018a) for the NSDF Project, residual effects from the NSDF Project on air quality are predicted to be not significant. Consequently, non-radiological concentrations in air emissions during the operation phase were not considered for human health.

5.8.6.2.1.2 Post-Closure Phase

For the assessment of human health in the post-closure phase of the NSDF Project, the main supporting document is the PostSA (Arcadis and Quintessa 2020). A general background of the non-radiological methods of the PostSA is provided as follows:

Post-Closure Safety Assessment (PostSA)

The PostSA (Arcadis and Quintessa 2020) analyzes the long-term implications (i.e., during the institutional control and post-institutional control periods) on human health of the NSDF Project.

Evaluating post-closure safety requires projections of the future condition of the NSDF Project and its environment, and how receptors might interact with it. Approaches have been developed to undertake such evaluations, centred on a "system analysis" method. This involves representing the NSDF Project, the facility inventory present and all potentially relevant media, with mathematical models to represent the key processes that may occur (e.g., corrosion of wastes, dissolution into groundwater, uptake by plants). It is essential that the models used are relevant, well-grounded and auditable. This is achieved through a systematic approach to safety

assessment. The international community has developed best practice guidance on the process, which is documented in a report of the IAEA ISAM programme (IAEA 2004) and incorporated into a more recent safety guide (IAEA 2012). This process has been applied internationally since its publication, is consistent with REGDOC-2.11.1 Vol. III (CNSC 2018), and underpins the PostSA analysis. Although this approach has been developed with radiological contaminants in mind, the same principles are considered to be appropriate for non-radiological contaminants and offers consistency in the approach used to assess both contaminant types for the NSDF Project.

The PostSA considers two primary pathways of release of non-radiological contaminants into the environment:

- leachate may be released to soil via overtopping the berm, which can affect human health; and
- leachate may be released through the base liner to groundwater, which can affect human health.

Contaminants released by overtopping the berm will move through the shallow environment by overland flow and interflow resulting in contamination of surface soils. Exposures can arise by external irradiation, inhalation of dust, inadvertent ingestion and consumption of food stuffs grown in the soil, or consumption of animals that have grazed in the contaminated area.

Contaminants released to groundwater beneath the ECM will move through the geological and hydrogeological environment by advection and dispersion and may sorb to sediments. Once in the aquatic environment, there will be further dilution in Perch Creek and then in the Ottawa River. Contaminants may be taken up by aquatic flora and fauna.

It is noted that release of volatiles to air was not considered a primary pathway for non-radiological contaminants given that no volatile non-radiological contaminants have been identified as COPCs.

As noted in Section 3.3.1.3.1, the NSDF Project will follow the guidelines of Ontario's *Regulation 347, General – Waste Management*, thus constraining the non-radiological inventory and limiting the environmental effects in the post-closure phase of the NSDF Project. However, an estimate on the quantity of discrete metals and organics in the NSDF at closure which is comprised of primarily wood, metals and bulk solid wastes. The non-radionuclides explicitly assessed in the PostSA include:

- aluminum;
- copper;
- lead; and
- uranium.

Similar to the radiological dose assessment, six scenarios were considered for the post-closure phase for the non-radiological exposure assessment. These scenarios are described in Section 5.8.6.1.1.2

5.8.6.2.1.3 Guidelines

This section discusses the guidelines that were used to assess the effects from non-radiological elements on human receptors.

Guidelines Used in the Operations Phase

In the operations phase, federal and provincial health-based surface water guidelines were used, as follows.

Federal Guidelines

The federal guidelines include those published by the CCME and Health Canada:

- The Health Canada Guidelines for Canadian Drinking Water Quality are based on health effects, aesthetic effects and operational considerations for drinking water (Health Canada 2014b). Health-based standards are listed as maximum acceptable concentrations and are established based on comprehensive review of known health effects, exposure levels and the availability of treatment and analytical technologies. If no health-based standard was available for a given chemical, then an aesthetic objective or operational guideline was used. Aesthetic objectives (i.e., taste and odour) are established based on whether people will consider the water drinkable. Operational guideline values are established based on levels that may interfere or impair water treatment processes or technology or adversely affect drinking water infrastructure. If health-based guidelines were not available from another source, then the aesthetic/operational values were selected for use in the assessment.

Provincial Guidelines

The provincial guidelines include those published by the Ministry of the Environment, Conservation and Parks:

- The Provincial Water Quality Objectives (PWQOs) are intended to be protective of aquatic life and recreational uses of surface waters (MOEE 1994). The PWQOs represent a desirable level of water quality strived to be maintained in the province. While these objectives are intended for protection of aquatic life, it is considered that they are also protective of human and wildlife health because PWQOs are typically much lower than drinking water guidelines and livestock watering guidelines. Where the PWQOs are explicitly based upon an aquatic endpoint, an alternate health-based guideline from another jurisdiction was selected if available.
- The primary purpose of the Ontario Drinking Water Standards (O. Reg. 169/03) is to protect public health through the provision of safe drinking water. The standards are protective against unsafe concentrations of toxic metals, radioactive substances and disease-causing organisms. Like the drinking water quality standards from Health Canada (i.e., Canadian Drinking Water Quality), Ontario Drinking Water Standards are presented as maximum acceptable concentrations above which there are known or suspected adverse health effects. Standards can also be based on aesthetic objectives, including taste, odour, turbidity and colour, or operational guidelines, including corrosiveness.

Alternate Guidelines

For parameters for which federal and/or provincial guidelines were not health-based (i.e., operational guidelines or aesthetic objectives from Health Canada or based on aquatic life for the PWQOs), alternate guidelines were also considered. Alternate guidelines were sourced from the US EPA. The US EPA provides a similar level of review of the available scientific literature and a similar approach to setting water quality guidelines as Health Canada and Ontario to be protective of human health and the environment. The selected health-based guidelines are shown below in Table 5.8.6-7.

Table 5.8.6-7: Selection of Health-Based Guidelines for Non-Radiological Parameters in Surface Water

Parameter	Federal Guidelines	Provincial Guidelines		Alternate Guidelines
	Health Canada[a] (µg/L)	PWQO[b] (µg/L)	ODWS[c] or GW1[d] (µg/L)	US EPA Tap Water[e,f] (µg/L)
Aluminum	100 (OG)	15	NV	4,000
Barium	1,000	NV	NV	NV
Copper	1,000 (AO)	1	NV	160
Iron	300 (AO)	300	NV	2,800
Lead	10	1	NV	NV
Manganese	120[g]	NV	NV	NV
Phosphorus	NV	NV[h]	NV	NV
Selenium	50	1	NV	NV
Silver	NV	0.1	100	NV
Zinc	5,000 (AO)	30	NV	1,200

Note: Selected health-based guidelines are shown with grey shading.

(a) Health Canada 2014b.

(b) MOEE 1994.

(c) O. Reg.. 169/03.

(d) MOE 2011.

(e) US EPA 2016.

(f) The US EPA Tap Water Regional Screening Levels (RSLs) were derived considering a target Hazard Quotient of 0.1 and Incremental Lifetime Cancer Risk of one in a million. The values presented in this table reflect a target Hazard Quotient of 0.2 (to be consistent with Ontario).

(g) Health Canada 2019.

(h) A PWQO is available for total phosphorus of 10 µg/L, which is based upon algal growth. There are no health-based drinking water guidelines available for phosphorus, as it is generally considered to be non-toxic at environmental concentrations. It is an essential element for human nutrition at upper limit daily intakes of 3 to 4 grams per day (Institute of Medicine 1997).

PWQO = Ontario Provincial Water Quality Objective; ODWS = Ontario Drinking Water Standard; GW1 = Groundwater component value protective of drinking by humans; US EPA = United States Environmental Protection Agency; OG = operational guidelines; AO = aesthetic objective; NV = No Value; µg/L = micrograms per litre.

The selected health-based guidelines are considered to be protective of members of the public (including sensitive receptors such as the very young, elderly, women of child-bearing age and those with pre-existing conditions) that rely on surface water for drinking and bathing. For the purposes of this assessment, it has been assumed that there are no restrictions on members of the public obtaining their potable water from the surface water nodes that may be affected by the NSDF Project during the operations phase. This is a conservative assumption as no water intakes are known to exist in any of the affected waterbodies and none of the areas around the waterbodies are populated.

Guidelines Used in the Post-closure Phase

In the post-closure phase, Environmental Quality Standard (EQS) criteria for groundwater, soil, sediment and surface water were used as guidelines for assessing the potential for adverse effects due to exposure by food chain and/or other pathways. The EQS guideline values, described in the Assessment Context section of the PostSA (Arcadis and Quintessa 2020), are presented as concentrations in environmental media. Consequently, the explicit assessment of the uptake of these substances into biota is not required; for example, exposure via drinking water intake does not need to be calculated if the drinking water concentration is below the EQS. If a contaminant concentration exceeds the EQS in any of the media, these species were further assessed using more detailed, more realistic risk assessment models. The EQS values are based on federal and provincial guideline concentrations for groundwater, surface water, soil and sediment, as follows:

- Guideline concentrations for groundwater, soil and sediment were taken primarily from MOE (2011), since these are the most conservative.
- For surface water, the most conservative guideline concentration values between MOEE (1994) and CCME (2019) were selected.
- For several elements of potential interest, no criteria were provided in MOEE (1994), CCME (2019) or MOE (2011). In these cases, surface water criteria were taken from Sneller et al. (2000), Suter and Tsao (1996), ODEQ (2001) and CCOHS (2009).

5.8.6.2.2 Application Case Results

5.8.6.2.2.1 Operations

The predicted concentrations for the non-radiological COPCs in the discharge from the WWTP were compared to the effluent discharge targets for the NSDF Project and to local ambient water quality at the six water quality nodes (see surface water quality modelling results in Section 5.4.2.6.2). The predicted concentrations of all the parameters measured, with the exception of aluminum, barium, copper, iron, lead, manganese, phosphorus, selenium, silver and zinc, met the effluent discharge criteria at all sampling nodes (while phosphorus concentrations exceeded the effluent limit, phosphorus is considered non-toxic to humans). Concentrations of aluminum, barium, copper, iron, lead, manganese, phosphorus, selenium, silver and zinc exceeded the effluent limits at one or more of the water quality nodes, but were generally at or below local ambient concentrations at these nodes.

Comparison of the predicted concentrations to the selected health-based guidelines is shown in Table 5.8.6-8.

Table 5.8.6-8: Comparison of Health-Based Guidelines to Maximum Predicted Surface Water Concentrations for each Parameter for All Modelled Scenarios and Locations

Parameter	Health-Based Guidelines (µg/L)	Maximum (µg/L)	Scenarios with Exceedances	Locations with Exceedances
Aluminum	4,000	665	None	None
Barium	760	18.8	None	None
Copper	160	8.4	None	None
Iron	2,800	2,867	Scenario 1 Scenario 2	East Swamp weir (local ambient, 95th and max)
Lead	5	5.2	Scenario 1 Scenario 2	Ottawa River (local ambient)
Manganese	120	130	None	Perch Creek weir (local ambient)
Phosphorus	No Value	62	None	None
Selenium	50	1.28	None	None
Silver	100	1.047	None	None
Zinc	5,000	6.59	None	None

µg/L = micrograms per litre.

The predicted concentrations for all modelled parameters for Scenarios 1 and 2 (i.e., operations phase when leaching will be treated at the WWTP prior to discharge) met their respective health-based guidelines with the exception of iron, lead and manganese.

The maximum predicted iron, lead and manganese concentrations at select nodes slightly exceeded their respective health-based guidelines primarily due to existing ambient concentrations.

Considering the conservative assumptions related to the non-radiological concentrations in the waste material and the conservative assumptions in the water quality modelling (Section 5.4.2), and considering that wastes will be required to meet the facility's Waste Acceptance Criteria, risks associated with these parameters and phases are likely negligible. Therefore, with additional information related to water hardness, risks associated with these parameters and phases can be refined.

The peak generation rates of landfill gases occur at the time, 1 year after closure of the ECM (year 51), and the landfill gases and peak generation rates are (AECOM 2018d):

- The total Landfill gases generation rate is 251,700 m^3/yr out of which:
  - Methane generation rate is 125,800 m^3/yr.
  - Carbon dioxide generation rate is 125,800 m^3/yr.

The values stated above are conservative because the rates were determined based on wastes under conditions ideal for the decomposition where all of the organic material in the waste could be completely decomposed. Conditions for the NSDF will not be ideal for waste decomposition as the design and operating practices will result in an in-place waste mass that is too dry to support optimal decomposition.

To address the unlikely event that higher ECM landfill gases generation rates are higher than are currently anticipated, the final cover system design includes landfill gas vents to mitigate against potential future buildup of gas pressures within the ECM after closure.

5.8.6.2.2.2 Post-closure

This section presents results for human health related to non-radiological contaminants for the Normal Evolution Scenario and Disruptive Event Scenarios. Additional details are provided in the PostSA (Arcadis and Quintessa 2020).

Normal Evolution Scenario

During the 10,000-year assessment timeframe of the PostSA, peak concentrations of copper, lead and uranium are below the corresponding environmental quality criteria (EQS) for soil, sediment and water, except for the concentration of lead in groundwater adjacent to the ECM. The concentration of uranium in groundwater is approaching the EQS, and slightly exceeds the EQS for the swamp soils.

Aluminum is a key component of clay minerals in soils and sediments. Therefore, there are not environmental quality standards for aluminum. The peak concentration in groundwater immediately downgradient of the ECM is only slightly elevated above background. However, the concentration is much lower in surface waters. For context, concentrations of aluminum in groundwater and surface water are well below the Health Canada proposed operational guidance value and maximum acceptable concentrations in drinking water (Health Canada 2019). It is noted that these guidance values are not meant for application to environmental concentrations.

Non-radiological contaminants were assessed in the PostSA following a very cautious approach. All non-radiological contaminants were assumed to be readily available for dissolution and leaching upon contact with water, whereas in reality most of the non-radiological inventory will be encased in iron-based matrices. Additionally, as noted in Section 3.3.3.3, the disposal of the remaining small fraction of non-radiological inventory will meet land disposal regulations, which are protective of public health and the environment. Therefore, there are negligible residual effects are expected from non-radiological contaminants associated with the NSDF Project.

Disruptive Event Scenarios

The PostSA model calculates some exceedances for lead, aluminum, copper, and uranium for disruptive events. As discussed for the normal evolution scenario above, the modelling assumptions are conservative, and do not take into account the containment of metal-based matrices or land disposal regulation requirements. Therefore, there are negligible residual effects are expected from non-radiological contaminants associated with the NSDF Project for Disruptive Event scenarios.

5.8.7 Prediction Confidence and Uncertainty

Table 5.8.7-1 describes key uncertainties in assessing residual effects from the NSDF Project on human health and how conservatism in the analysis and assumptions addressed these uncertainties.

Table 5.8.7-1: Uncertainties in the Human Health Assessment

Parameter	Uncertainty	Conservatism and Assumptions
Waste Inventory (radiological)	There is uncertainty with regards to the inventory of radionuclides that have been accumulated over the decades of operation of CRL site, as well as the projected inventory of wastes that will be generated in the future.	▪ Both already accumulated wastes and those that will be generated in the future will have to meet NSDF Waste Acceptance Criteria. ▪ The effect of uncertainty in the radiological inventory is explored in 'Sensitivity Analysis Case - Inventory Sensitivity' for the post-closure phase.
Waste Inventory (non-radiological)	There is uncertainty with regards to the inventory of hazardous wastes (i.e., non-radionuclides) that have been accumulated over the decades of operation of the CRL site, as well as the NSDF Project inventory of hazardous wastes (i.e., non-radionuclides) that will be generated in the future.	▪ Both already accumulated wastes and those that will be generated in the future will have to meet NSDF Waste Acceptance Criteria.
ECM Performance	There is uncertainty with regards to when protective barriers may begin to fail due to erosion or other natural events.	▪ The ECM includes multiple protective barriers in the cover and base liner, designed to isolate the waste even in the event if one or more of the barriers were to fail. ▪ The ECM can be maintained and monitored during the period of institutional control. Any issues identified during ▪ this period can be mitigated. ▪ The PostSA considers two conservative scenarios involving premature failures of the cover and base liner.
Source term	There is uncertainty associated with airborne and waterborne release rates.	▪ Waterborne releases from the WWTP are assumed to contain contaminants at maximum permissible concentrations. This is a bounding assumption; in most cases concentrations will be a minor fraction of maximum permissible concentrations. ▪ Airborne releases from the ECM are based on empirical data for carbon-14 and tritium oxide and on a conservative model for radon-222. ▪ In the PostSA, water release from overtopping the berm is assumed to begin earlier than it would realistically be expected to occur, i.e., it does not account for the time required for the water level in the ECM to rise above the level of the berm. ▪ The generation rate of bulk gases will heavily depend on the nature and quantity of organic and metal wastes, which are currently not well-defined for the ECM. ▪ Accumulation of radon-222 was calculated using an approach that typically overestimates the radon-222 concentrations found in buildings. ▪ Carbon-14-labelled gases are assumed to be released to the surface at the rate they are generated.

Table 5.8.7-1: Uncertainties in the Human Health Assessment

Parameter	Uncertainty	Conservatism and Assumptions
Human habits	It is uncertain that future populations will maintain current habits, consumption rates, and that the location of population centers will not change.	▪ The PostSA (Normal Evolution Scenario) makes conservative assumptions about future land use, using different human receptor groups, such as a resident/farmer household living on the ECM footprint, growing fruits and vegetables, and raising poultry and cattle. ▪ To investigate sensitivity to changes in future human habits and location of potential exposure groups, the PostSA considers scenarios involving borehole drilling, and a house with a basement on the ECM.
Conceptual model	This uncertainty is associated with conceptual model for groundwater flow and potential future effects on it resulting from the climate change.	▪ Current groundwater flow and contaminant transport in Perch Lake area are well understood due to decades of data available for the site. ▪ Groundwater flow model (Golder 2019) was calibrated against the available datasets based on the existing plumes emanating from WMAs and LDAs. ▪ The PostSA includes a Sensitivity Analysis Case where groundwater transit time to Perch Creek is reduced to 5 years (from 7 years in the Normal Evolution Scenario). ▪ Characterization of the site includes 25 test pits, 70 boreholes, and 47 monitoring wells, among other monitoring and testing activities.
Assessment of radiological doses to members of the public	There is uncertainty in modelling parameters used for the assessment of radiological dose to members of the public	▪ In the PostSA, assumptions for dispersion, consumption and intake rate parameters are mainly based on CSA N288.1 (CSA Group 2014). ▪ Conservative values are chosen for occupancy and other human exposure factors in the PostSA. ▪ Estimated radiological doses represent a very minor fraction of the limit.
Leaching and Transport parameters	Parameter uncertainty may lead to underestimation of radiological doses to members of the public and non-human biota	▪ The site characteristics are well understood, owing to many decades of monitoring. ▪ To test the effect of uncertainty in sorption rates, the PostSA includes a Sensitivity Analysis Case where a lower water-soil distribution coefficient (K_d) was assumed. A lower K_d would result in more rapid release and more rapid transport in groundwater.
Effect of Environment on ECM	Performance of the ECM barriers could be impeded by natural events, such as floods, weathering, animal borrowing and fires destroying vegetative cover.	▪ To address uncertainty in the performance of the cover and liner during the post-closure phase, the PostSA examines the effect of accelerated degradation of these barriers (relative to their design life). ▪ Additionally, the PostSA explores the importance of both the cover and liner using two scenarios that assume either the cover or the liner is absent at the time of closure. A third scenario is also included to assess the importance of the berm.

Table 5.8.7-1: Uncertainties in the Human Health Assessment

Parameter	Uncertainty	Conservatism and Assumptions
Modelling Tool uncertainty	Uncertainty associated with conceptual models built within AMBER codes	▪ The models used in the PostSA calculations (e.g., AMBER) have undergone model validation for the relevant pathways and exposure scenarios. ▪ The assessment of long-term safety of the NSDF in the PostSA was undertaken in accordance with Canadian Nuclear Safety Commission REGDOC-2.11.1, Vol. III (CNSC 2018), which states: ▪ *"Due to the uncertainty of predictions made far into the future, the reliability of quantitative predictions diminishes with increasing timescale. The demonstration of safety will rely less on quantitative predictions and more on qualitative arguments as the timescale increases. Long-term quantitative predictions should therefore not be considered as guaranteed impacts, but rather as safety indicators."* ▪ It also states that: ▪ *"uncertainties in the modeling should be addressed by conservatism built into: 1. the assessment model; 2. the scenario design; and 3. parameter choice."* ▪ As documented within this table, modelling uncertainty is addressed with conservatism built into the model, scenario design, and parameters.
Cumulative Effect	Uncertainty associated with the cumulative effect during post-closure, taking into account releases from WMAs and LDAs in the Perch Creek Basin.	▪ Canadian Nuclear Laboratories is developing an appropriate environmental remediation concept for contaminated areas. The decision-making process is based on radiological effects. ▪ It is expected that, if there is any potential to have cumulative effects exceeding safety objectives, then contaminated land from WMAs and LDAs will be removed prior to the NSDF closure.

ECM = engineered containment mound; WMA = Waste Management Area; LDS = Liquid Dispersal Area; PostSA = Post-closure Safety Assessment.

5.8.8 Residual Effects Classification and Determination of Significance

The residual effects analysis methods for the human health assessment are different in some notable ways from those used by other VCs. Specifically, the assessment of potential effects to human health VCs results in the generation of risk factors that inherently consider the geographic extent, duration, frequency and other characteristics of the predicted changes to the environment that may result from NSDF Project activities. As such, these inherent attributes cannot be used to determine environmental significance, as they can with other components. Instead, significance for human health is evaluated based on: (i) the potential magnitude of the response, as indicated by the comparison to dose limits (for radionuclides) or risk benchmark values (for non-radionuclides) and (ii) the degree of conservatism and uncertainty in the analysis.

Results of the radiological dose assessment for the operations phase and post-closure phase indicates that doses to human health VCs are below their respective dose limits or risk benchmark values. In addition, all predicted non-radiological concentrations were less than their selected guidelines or alternate benchmarks. Although uncertainties in the assessment exist (Section 5.8.7), conservatism has been included in the modelling so that residual effects are not greater than predicted. As such, residual effects are not significant for all human health VCs.

5.8.9 Monitoring and Follow-up

Monitoring of environmental media at the CRL site and surrounding area will proceed in alignment with CNL's existing Environmental Monitoring Program. This includes sampling and analysis of surface water, groundwater, sediment, soil, vegetation, ambient air, milk, garden produce, game animals, farm animals and fish (CNL 2018c). Section 5.7.4 provides additional details regarding the scope of these programs for monitoring radioactivity in environmental media. CNL's Environmental Monitoring Program includes assessment of dose to members of the public based on emissions monitoring and measurements in environmental media (CNL 2018c). Additionally, the dose to workers at CRL is monitored and reported to the CNSC annually.

Emissions and effluents from the NSDF Project during the construction, operations and closure phases and institutional control period will be managed in accordance with CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018b). This standard defines the key requirements, responsibilities and processes for the management of radioactive and non-radioactive emissions at the NSDF Project. The NSDF *Environmental Protection Plan* (AECOM 2018e) expands on the regulatory requirements of CSA N288.5 (CSA Group 2011) for the management of these emissions. For example, operational control monitoring will be completed to confirm emission controls and treatment systems are functioning as intended. In addition, effluent monitoring will be completed to verify that emissions meet effluent discharge targets.

The CRL Effluent Verification Monitoring Program will be established for the monitoring of emissions estimated from the NSDF Project. The Effluent Verification Monitoring Program at the NSDF Project site is required to demonstrate compliance with the dose constraint of 0.3 mSv/yr for the public.

Proposed environmental assessment monitoring and follow-up programs for the NSDF Project are documented in Section 11, including activities related to human health:

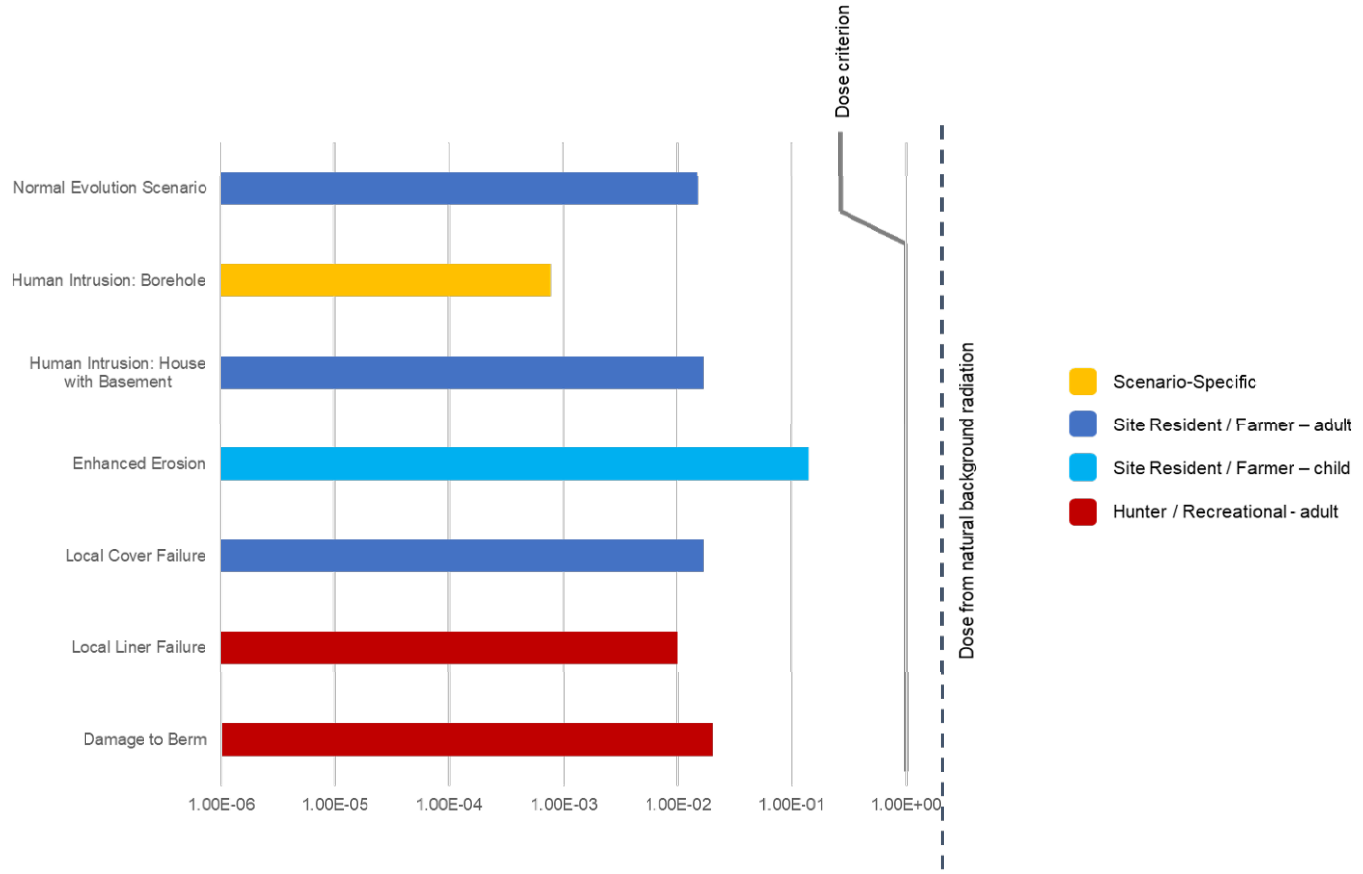
- air quality (i.e., dust) will be monitored at the SSA and air effluent verification monitoring will be performed at the WWTP;
- dust samples collected in the high-volume air sampler during construction and operations will be screened for radioactivity;
- treated effluent from the WWTP, stormwater pond effluent and surrounding surface water quality will be monitored;
- ambient radioactivity will be measured at the SSA; and
- groundwater monitoring will be performed surrounding the ECM, to confirm groundwater quality and detect potential releases of constituents from the ECM containment area.

These monitoring activities will occur during operations, closure and post-closure. The need for and duration of monitoring will be reviewed based on annual review of monitoring data.

5.8.10 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). The human health risk assessment focused on worker and public health. Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future human generations (i.e., incorporates sustainability). The assessment endpoint is the protection of human health. Measurement indicators represent properties of the environment, that when changed, could result in or contribute to an effect on an assessment endpoint. Measurement indicators for the human health assessment include changes in air quality, groundwater quality and surface water quality.

Radiological dose to humans may result from waterborne or airborne emissions from the NSDF Project. Dose to humans from waterborne emissions is calculated during the operations phase, as well as during the post-closure phase for the NSDF Project. The peak calculated doses for all scenarios and sensitivity cases are summarized in Figure 5.8.10-1. The doses are compared against the 0.3 mSv/y dose constraint for the normal evolution scenario, the 1.0 mSv/yr regulatory dose limit for disruptive events, and the average background radiation dose in Canada of 1.8 mSv/yr. For the on-site (worker), the maximum dose during normal operations is calculated to be 10.4 mSv/yr. During the institutional control period, the on-site worker dose is bounded by the operational phase results.



For off-site receptors during the operational phase, there are two radiological dose exposure pathways: airborne and waterborne releases. The effluent discharge targets for radionuclides are based on Canadian Drinking Water Guidelines with the exception of tritium for which a site-specific target is developed (Section 3.4.2.5.1). During normal operations, only the discharge of treated effluent meeting the effluent discharge targets (CNL 2019c), is expected. Therefore, the off-site receptor ingestion dose consequence will be much lower than the dose constraint of 0.3 mSv/yr for the public. Airborne releases of dust are controlled during operations, mitigating airborne releases. The dose consequences to the off-site receptors during normal operations are expected to be negligible and much lower than the 0.3 mSv/yr dose constraint.

During the post-closure phase, the maximum calculated dose during the Normal Evolution Scenario is to the on-site resident/farmer adult, and is 0.015 mSv/y, which is 20 times lower than the annual dose constraint of 0.3 mSv/yr. For Disruptive Events, the maximum dose is 0.14 mSv/yr as a result of the Enhanced Erosion Case, which is 6 times lower than the criterion.

Non-radiological chemicals were screened by comparing concentrations to the federal guidelines that are protective of human health. The predicted concentrations for all modelled parameters for Scenarios 1 and 2 (i.e., operations phase when leachate will be treated at the WWTP prior to discharge) met their respective health-based guidelines. Therefore, there are no anticipated risks to human health due to the modeled non-radiological parameters during the operations phase of the NSDF Project.

Although uncertainties in the assessment exist, conservatism has been included in the modelling so that residual effects are not greater than predicted. As such, residual effects are not significant for all human health VCs during the operations phase and the post-closure phase. Monitoring and follow-up programs are described in Section 5.8.9 and include implementation of the existing Effluent Verification Monitoring Program, Groundwater Monitoring Program and Environmental Monitoring Program, as well as NSDF-specific environmental monitoring activities. These activities will verify effects predictions for human health.

5.9 Land and Resource Use

Section 5.9 of the Environmental Impact Statement (EIS) for the Canadian Nuclear Laboratories (CNL) Near Surface Disposal Facility (NSDF) Project seeks to understand and characterize the potential residual effects of the NSDF Project and previous, existing and reasonably foreseeable developments on land and resource use. The land and resource assessment considers outdoor recreation and tourism, land tenure, and archaeology. Traditional land and resource use by Indigenous Peoples is considered in Section 6.4.

The assessment of effects on land and resources identifies linkages between the NSDF Project activities and current environment, to determine the residual effects of the NSDF Project on land and resource use. Residual effects (i.e., those effects remaining after the implementation of all mitigation) are placed in the context of the cumulative effects of previous, existing and future projects.

5.9.1 Scope of the Assessment

The land and resource use assessment follows the overall environmental assessment approach and methods described in Section 5.1 Environmental Assessment Approach. The assessment is completed following the key steps listed below:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** for the land and resource use assessment (refer to Sections 5.9.2 Valued Components and Section 5.9.3 Assessment Boundaries). The VCs, assessment endpoints and measurement indicators used to assess Project-related changes to the land and resource use are described; along with the spatial and temporal boundaries at which the assessment occurred; and the assessment cases considered.
- **Step 2 – Describe the existing conditions** (refer to Section 5.9.4 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the land and resource use environment. The existing conditions provide a reference to which the effects of the NSDF Project can be compared.
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 5.9.5 Project Interactions and Mitigation). Project components and/or activities with the potential to affect land and resource use are identified and mitigation developed to limit or avoid effects is presented. A pathways analysis is then used to focus further assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated.
- **Step 4 – Present the methods and results of the residual effects analysis**. This step was not required as no primary pathways were identified in the land and resource use assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty.** This step was not required as no primary pathways were identified in the land and resource use assessment.
- **Step 6 – Classify and determine the significance of the predicted residual effects**. This step was not required as no residual adverse effects were identified in the land and resource use assessment.

- **Step 7 – Identifying monitoring and follow-up** required to confirm effects predictions and address uncertainty (refer to Section 5.9.6 Monitoring and Follow-up).
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** of residual effects on land and resource use (refer to Section 5.9.7 Conclusions).

Information and areas of interest raised by stakeholders and Indigenous Peoples during engagement that influenced the scope of the land and resource use assessment are summarized in Table 5.9.1-1. A full record of engagement activities is available in Section 4.3.1. Other general areas of interests and questions raised during the engagement that pertain to the land and resource use assessment (if any) are documented CNL's Indigenous Engagement Report (CNL 2021) and CNL's Stakeholder's Activity Reports (CNL 2017a,b, 2019).

Table 5.9.1-1: Summary of Area of Interest Raised during Engagement Activities that Influenced the Scope of the Land and Resource Use Assessment

Area of Interest	How the Area of Interest Was Included in the Land and Resource Use Assessment
Interest expressed in relation to potential effects on fish and fish harvesting due to concerns of potential contamination or radioactive seepage into Perch Creek, the Ottawa River and other waterbodies from the NSDF Project.	The spatial boundaries of the land use assessment were selected to include consideration of potential effects on water quality and include the aquatics study areas. CNL continues to monitor the aquatic environment extensively, specifically Perch Creek. The NSDF Project has used recent modelling to understand the potential for effects within the Perch Creek and Perch Lake watershed. Existing land use with regards to fishing is described in Section 5.9.4.1.3.2 (outdoor tourism and recreation) and existing traditional land use with regard to fishing is described in Section 6.4.4.1.2.3. Potential effects on these VCs are assessed in Section 5.9.5 and Section 6.4.5. CNL conducts monitoring of fish in the Ottawa River for radioactive contamination as part of its Environmental Monitoring Program. The spatial boundaries for the land use assessment were expanded to include reach of the Ottawa River extending 8 km downstream from CRL site in response to comments received from Indigenous communities and organizations and the public.
Interest expressed in relation to potential effects on recreational activities (i.e., boating and swimming) due to concerns of potential contamination or radioactive seepage into the Ottawa River and other waterbodies from the NSDF Project.	The land use assessment included outdoor tourism and recreation as a VC. The spatial boundaries for the land use assessment include consideration of potential effects to the aquatic environment, and specifically include the aquatics study areas. CNL continues to monitor the aquatic environment extensively. The NSDF Project has used recent modelling to understand the potential for effects within the Perch Creek and Perch Lake watershed. CNL conducts environmental monitoring for tritium and other radionuclides in environmental media including fish from the Ottawa River. Outdoor tourism and recreation are addressed in Section 5.9.4.1.3. The spatial boundaries for the land use assessment were expanded to include reach of the Ottawa River extending 8 km downstream from CRL site in response to comments received from Indigenous communities and organizations and the public.

VC = valued component; EIS = Environmental Impact Statement; SSA = Site Study Area.

The information in Table 5.9.1-1 was used to frame the scope of the assessment and identify VCs (Section 5.9.2). This assessment considers changes in wildlife harvesting and angling, outdoor tourism and recreation opportunities and other resource uses identified during the collection of baseline information at the local and regional scales. CNL has and will continue to meet with interested stakeholders and Indigenous Peoples to receive input on the NSDF Project. The objectives of these meetings are to understand the priorities and interests

of recreational and traditional users and to review potential mitigation to reduce or eliminate the effects of the NSDF Project.

5.9.2 Valued Components

Valued Components (VCs) refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Land and resource use VCs were selected based on the potential for the NSDF Project to interact with these features or activities of the land and resource use environment.

The VCs selected for assessing potential effects on land and resource use conditions are presented in Table 5.9.2-1.

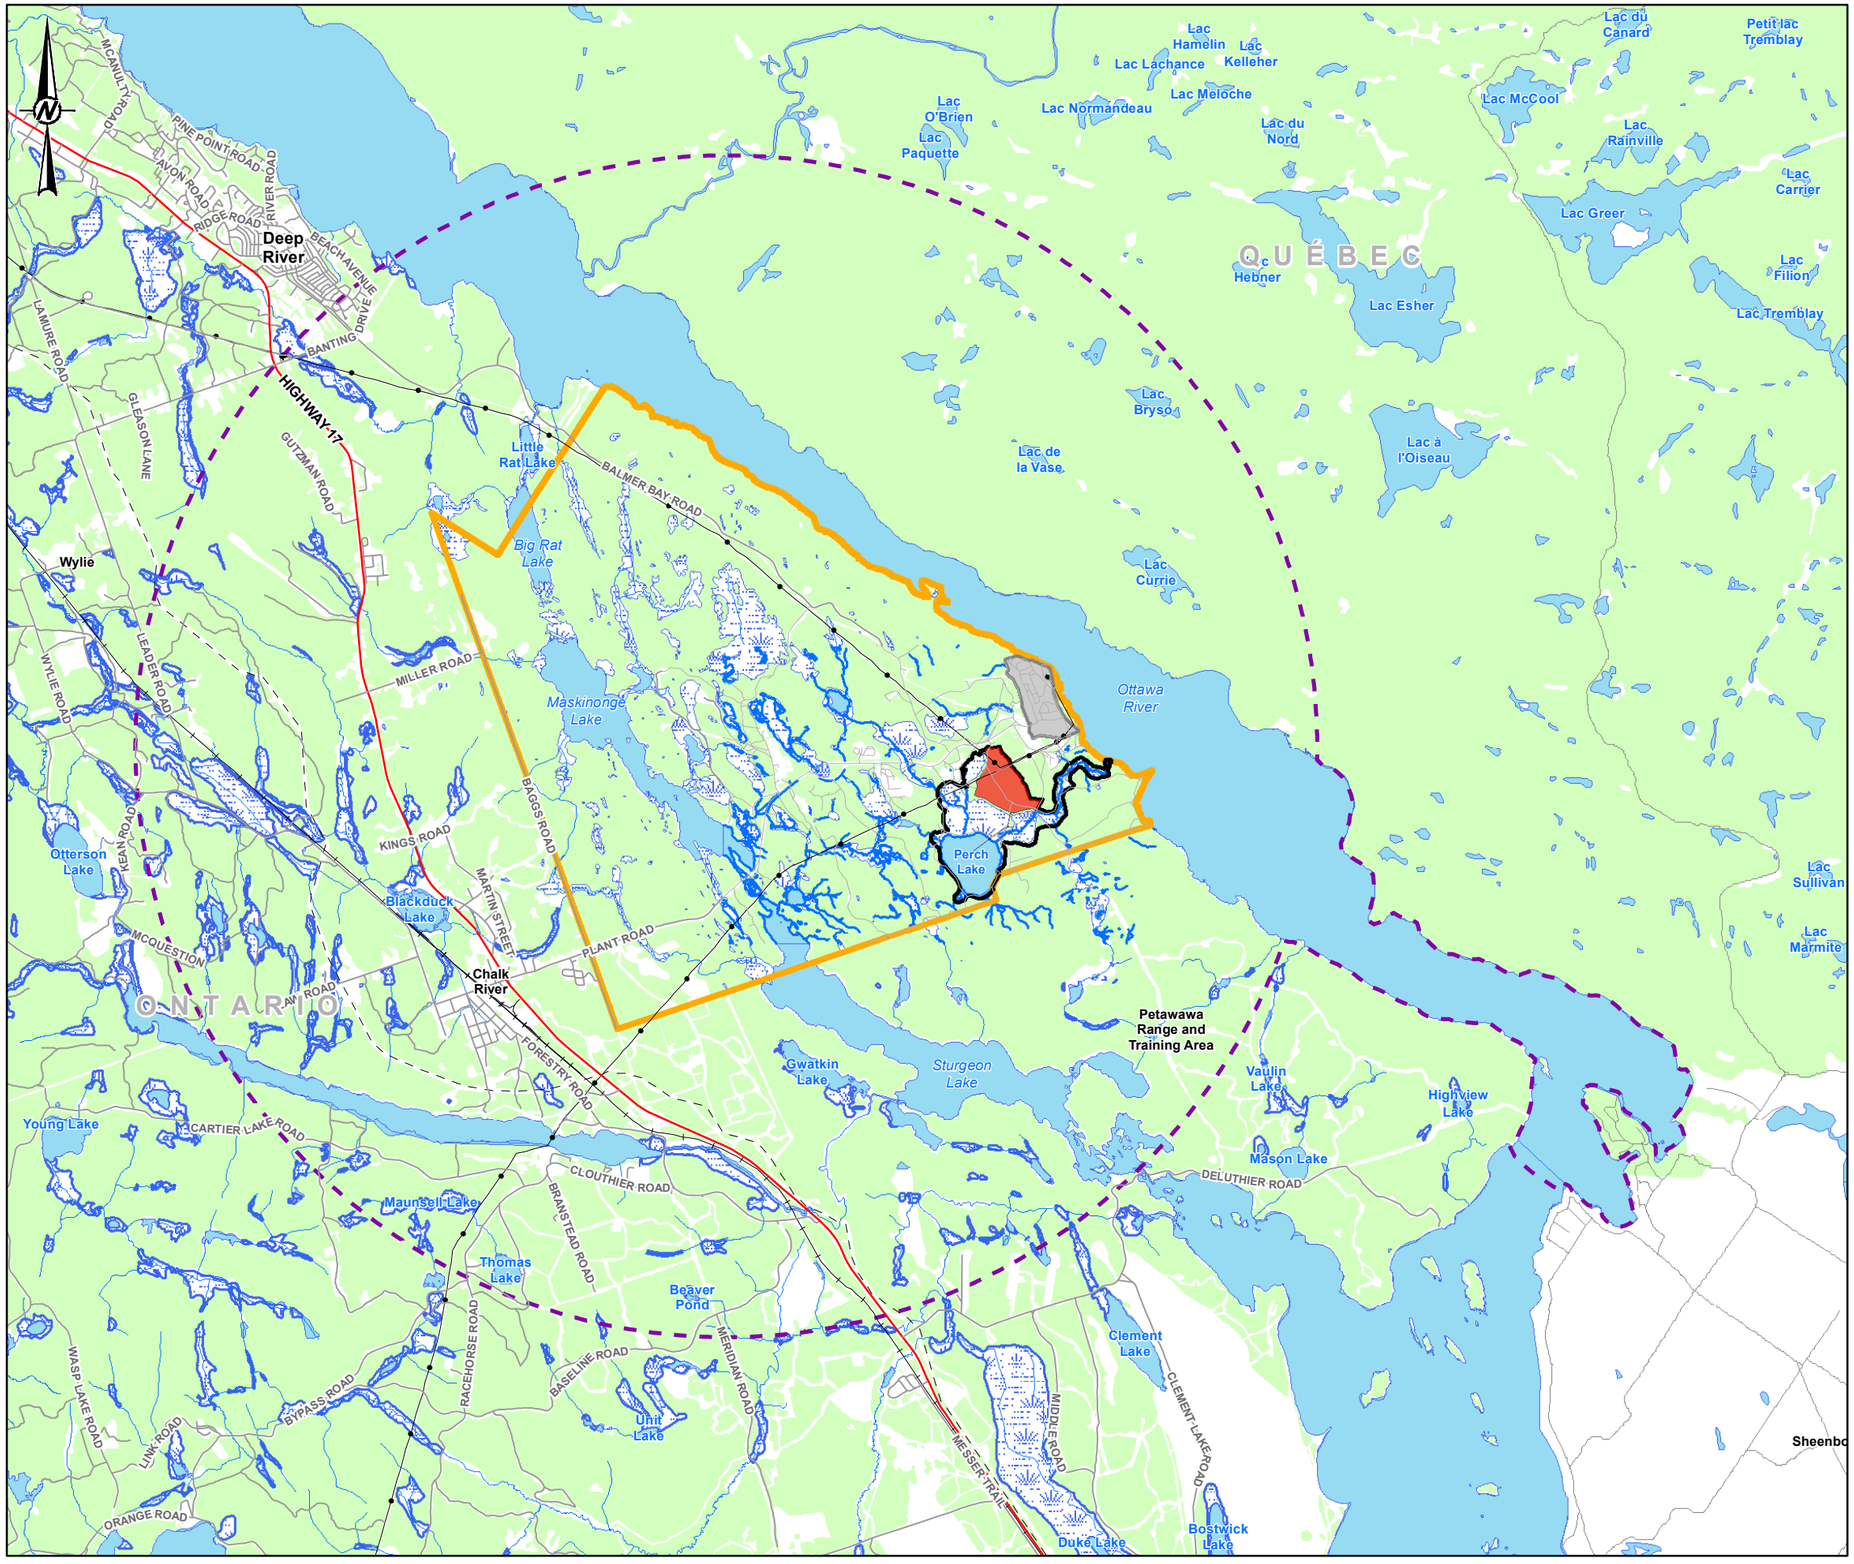
Table 5.9.2-1: Valued Components For The Land And Resource Use Assessment

Valued Component	Rationale for Selection
Land and Resource Tenures and Other Registered Interests	■ Project construction and operation must demonstrate compatibility with existing land use direction as expressed by responsible authorities based on a qualitative comparison of the Project with established land and resource designations in plans, policies and bylaws. ■ Land users and responsible authorities need to understand if the NSDF Project will affect access routes / access to commercial land and resource use areas (e.g., for existing mining, forestry and agriculture). ■ Land users and responsible authorities need to understand if the NSDF Project will affect the availability of commercial land and resource use opportunities.
Outdoor Tourism and Recreation	■ The NSDF Project has the potential to affect access to outdoor tourism and recreational land and resource use opportunities associated with parks and protected areas, fishing, hunting, trapping and non-consumptive tourism and recreation. ■ The NSDF Project has the potential to affect the quality and quantity of outdoor tourism and recreation land use opportunities.
Archaeological Sites	■ Archaeological sites are an important aspect of Indigenous Peoples. Archaeological sites are the focus of the archaeology discipline as archaeological sites are identified and protected by the *Ontario Heritage Act*.

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future generations. Measurement indicators represent properties of the environment and VCs that, when changed, could result in or contribute to an effect on a VC. Measurement indicators can be used to monitor the success of mitigation and management programs. The assessment endpoints and measurement indicators identified for the land and resource use VCs are presented in Table 5.9.2-2.

Table 5.9.2-2: Assessment Endpoints and Measurement Indicators for the Land and Resource Use Assessment

Valued Component	Sub-component	Assessment Endpoints	Measurement Indicators
Land and Resource Tenures and Other Registered Interests	Land use designations	Maintenance of compatibility with federal, provincial, regional and municipal land use designations	▪ Compatibility of the NSDF Project with existing land use designations.
	Mining and aggregates	Continued land and resource use opportunities	▪ Changes in access to land use areas and access routes used for land and resource tenures and other registered interests. ▪ Changes in the availability of tenured land use opportunities and other registered interests.
	Forestry		
	Agriculture		
Outdoor Tourism and Recreation	Parks and protected areas	Continued land and resource use opportunities	▪ Changes in access to outdoor tourism and recreation activities. ▪ Changes in quality and quantity of outdoor tourism and recreation opportunities.
	Fishing		
	Hunting		
	Trapping		
	Non-consumptive tourism and recreation		
Archaeological Sites	Not applicable	Management of cultural and archaeological sites	▪ Number, type and locations of archaeological materials or features that would contribute to an archaeological site and ability to recover archaeological materials or protect archaeological features.



5.9.3 Assessment Boundaries

5.9.3.1 Spatial Boundaries

The spatial boundaries selected for the land and resource use assessment were chosen because they permit a description of existing conditions in sufficient detail to enable potential project-VC interactions and effects to be identified, understood and assessed, including the contribution of the NSDF Project to cumulative effects.
The spatial boundaries selected for the land and resource use assessment are presented on Figure 5.9.3-1 and are described as following.

- **Site Study Area (SSA):** The SSA is the NSDF Project footprint (i.e., where NSDF Project activities would be undertaken, including the NSDF Project's proposed facilities, buildings and infrastructure). The SSA covers an area of approximately 37 ha (Figure 5.9.3-1). The SSA falls within the Chalk River Laboratories (CRL) site boundary.
- **Local Study Area (LSA):** The LSA is selected in consideration of the NSDF Project footprint and the spatial extent of potential direct effects of the NSDF Project on the VCs. The land and resource use LSA corresponds with the combined area of the terrestrial and aquatics LSAs used for the assessment of the groundwater and surface water environment, aquatic biodiversity and terrestrial biodiversity, and covers approximately 226 ha (Figure 5.9.3-1). The aquatics, terrestrial, biophysical LSAs are defined in Sections 5.2 through 5.6. The LSA is defined to capture both direct and indirect effects on the terrestrial and aquatic environments as a result of the NSDF Project (e.g., changes in groundwater and surface water quality, habitat loss and changes in abundance, distribution and disturbances to wildlife and fish) as these effects have the potential to result in subsequent effects on land and resource use. The LSA falls within the CRL site boundary. No land and resource use tenures, outdoor tourism or recreation activities occur within the CRL site boundary.
- **Regional Study Area (RSA):** The RSA is defined as the area within which the potential effects of the NSDF Project may interact with the effects of other existing or reasonably foreseeable developments. The land and resource use RSA is the combined area of the air quality, terrestrial and aquatics RSAs, which have been used for the assessment of the air quality, groundwater, surface water, aquatic and terrestrial environments (Figure 5.9.3-1). The RSA is defined to capture effects on the terrestrial and aquatic environments as a result of the NSDF Project (e.g., habitat loss, sensory disturbance for wildlife and changes to habitat from air quality and surface water quality, changes in groundwater and surface water quality, habitat loss and changes in abundance, distribution and disturbances to wildlife and fish), as these effects have the potential to result in subsequent effects on land and resource use. Therefore, the RSA for land and resource use is a combination of the air quality and aquatic environment RSAs as this is the largest extent of potential cumulative effects on land and resource use. The air quality RSA is defined as an approximate 7.4 kilometre (km) circular radius surrounding the LSA, and the aquatic RSA includes the outlet of Perch Creek to the Ottawa River and extends roughly 8 km downstream in the Ottawa River to Harrington Bay. While there are no land and resource use tenures, or outdoor tourism or recreation activities occurring within the CRL site boundary, there may be some trapping occurring in Garrison Petawawa and in the RSA. The Ottawa River where it overlaps with the RSA boundaries would also most likely be used for some outdoor tourism and recreation.

5.9.3.2 Temporal Boundaries

Temporal boundaries (i.e., project phases) establish the timeframe during which NSDF Project effects are assessed. The temporal boundary represents the timeframe during which project activities are actively occurring, and considers the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a project activity or stressor (which is related to the project phases) plus the time required for the residual effect to be reversed. In some cases, residual effects may be irreversible within the temporal boundaries of the NSDF Project or if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the NSDF Project.

- **Construction phase**: This phase includes site preparation and all activities associated with the construction of the NSDF Project. This phase includes activities such as installing the necessary supporting and/or ancillary facilities and infrastructure to facilitate NSDF Project operations, inactive commissioning and systems testing, and transportation of construction materials. Construction activities are expected take place from 2022 to 2024.
- **Operations phase**: This phase includes all activities associated with waste placement, water management, Wastewater Treatment Plant (WWTP) operations, vehicle movements into and from the SSA and maintenance activities. Operations activities are expected to last approximately 50 years (i.e., 2025 to 2070).
- **Closure phase:** This phase includes activities necessary to complete the installation of the final cover and implementation of long-term monitoring. Closure activities are expected to start in 2070 and continue through to 2100, after which the NSDF Project will transfer into the post-closure phase.
- **Post-closure phase:** This phase has two discrete periods: institutional control and post-institutional control. The institutional control period includes implementation of controls throughout 2100 to 2400 (i.e., 300 years). During institutional control, environmental monitoring will continue to demonstrate compliance with the environmental assessment conditions. Post-institutional control occurs after year 2400 and continues indefinitely.

The temporal boundaries for the land and resource use assessment include consideration of effects of the NSDF Project from construction through to the end of post-closure.

5.9.3.3 Assessment Cases

The assessment cases considered in the in the land and resource use assessment, including the Base Case, Application Case and the Reasonably Foreseeable Development (RFD) Case.

- **Base Case –** This scenario represents existing conditions and characterizes effects from previous and existing developments and activities. The Base Case reflects the effects of existing land and resource uses in the area, such as hunting, fishing, trapping, forestry, agriculture, mining and recreational use. Current effects from the existing CRL facilities and operations are considered part of the Base Case.
- **Application Case –** This scenario represents the effects of the Base Case combined with the predicted effects from the NSDF Project. The Application Case considers effects from the NSDF Project during construction through to post-closure.

- **Reasonably Foreseeable Development (RFD) Case –** This scenario represents the effects of residual adverse effects of the Application case combined with other reasonably foreseeable projects in the land and resource use RSA. Because RFDs will not have any spatial overlap or are likely to positively affect the land and resource use, an RFD Case is not presented as part of this assessment. No cumulative effects with RFDs were identified in Sections 5.5 Aquatic Environment and 5.6 Terrestrial Environment that could potentially introduce indirect effects to land and resource use. Similarly, of the RFDs identified (see Section 8.2), none will result in change in broad land use category, use or access to land outside of the CRL site. As such, potential effects from RFDs are not expected to spatially overlap with potential effects to land and resource use from the NSDF Project.

5.9.4 Description of the Environment

This section describes the setting and characterization for land and resource use, including land and resource tenures, outdoor recreation and tourism, and archaeological sites, as relevant for the assessment of the NSDF Project. It describes the existing conditions (i.e., Base Case) against which potential changes from the NSDF Project are compared and evaluated.

5.9.4.1 Land and Resource Tenures and Outdoor Recreation and Tourism

5.9.4.1.1 Methods

Baseline information was collected from a range of information sources and analyzed to submit a profile for the land and resource use conditions in the LSA and RSA. Baseline information was collected from the following sources:

- regional and local land use Official Plans and Zoning By-laws, as applicable;
- the Ministry of Natural Resources and Forestry's (MNRF) Land Information Ontario (LIO) spatial land use database (MNRF 2016a);
- Natural Resources Canada's (NRCan's) CANVEC spatial land use database;
- municipal and regionally-based outdoor tourism, recreation and economic development webpages and reports;
- information on parks and protected areas available through Ontario Parks and Parks Canada; and
- publicly available wildlife harvesting data available through the MNRF.

5.9.4.1.2 Land and Resource Tenures and Other Registered Interests Results

5.9.4.1.2.1 Land Use Designations

The SSA is located entirely within the CRL site boundary, in the Town of Deep River (a lower-tier municipality), which forms part of Renfrew County (an upper-tier municipality). The SSA is bordered by the remaining CRL site to the north, east and west, the Garrison Petawawa to the south, and the Ottawa River to the southeast. The Town of Laurentian Hills lies adjacent to the CRL site boundary.

County of Renfrew Official Plan

The SSA falls within the County of Renfrew (see Figure 1 in Appendix 5.9-1). Last consolidated in 2014, the 2003 Official Plan for the County of Renfrew sought to manage land use planning for the rural communities within its jurisdiction, but still provided each municipality with the opportunity to develop their own Official Plan if desired (County of Renfrew 2003). The Official Plan addresses land use for ten lower-tier municipalities in the County of Renfrew, but does not include the Town of Deep River (which opted to maintain its own Official Plan). Under Schedule A (Map 1 of 2) of the County of Renfrew Official Plan, the SSA is simply identified as "Non-County Areas"; consequently, the County of Renfrew Official Plan does not apply to the NSDF Project. The NSDF Project is not subject to land use designation provisions or restrictions under the County of Renfrew Official Plan.

Town of Deep River Official Plan

The SSA is located in the Town of Deep River (see Figure 2 in Appendix 5.9-1). The currently approved version of the Official Plan (CRPD 2017) identifies that the presence of the largest nuclear research facility in Canada exerts a dominant influence on the Town of Deep River (CRPD 2017). Section 1.1 of the Official Plan (CRPD 2017) states that the Official Plan applies to lands within the corporate limits of the Town of Deep River, but identifies that the remaining lands are in federal ownership and control in conjunction with Atomic Energy of Canada Limited (CRPD 2017. Consequently, the NSDF Project is not subject to land use designation provisions or restrictions under the Town of Deep River Official Plan.

Town of Laurentian Hills Official Plan

The Town of Laurentian Hills is directly adjacent to the CRL site boundary (see Figure 3 in Appendix 5.9-1). The SSA does not overlap the Town of Laurentian Hills, therefore the NSDF Project is not subject to provisions under the 2010 Official Plan. However, the Land Use Plan Schedule 'A1' still presents and considers the CRL site and consequently, the SSA. In the Schedule A1 land use designation map, the Town of Laurentian Hills identifies the SSA, LSA and RSA as 'Restricted Access Crown Land.'

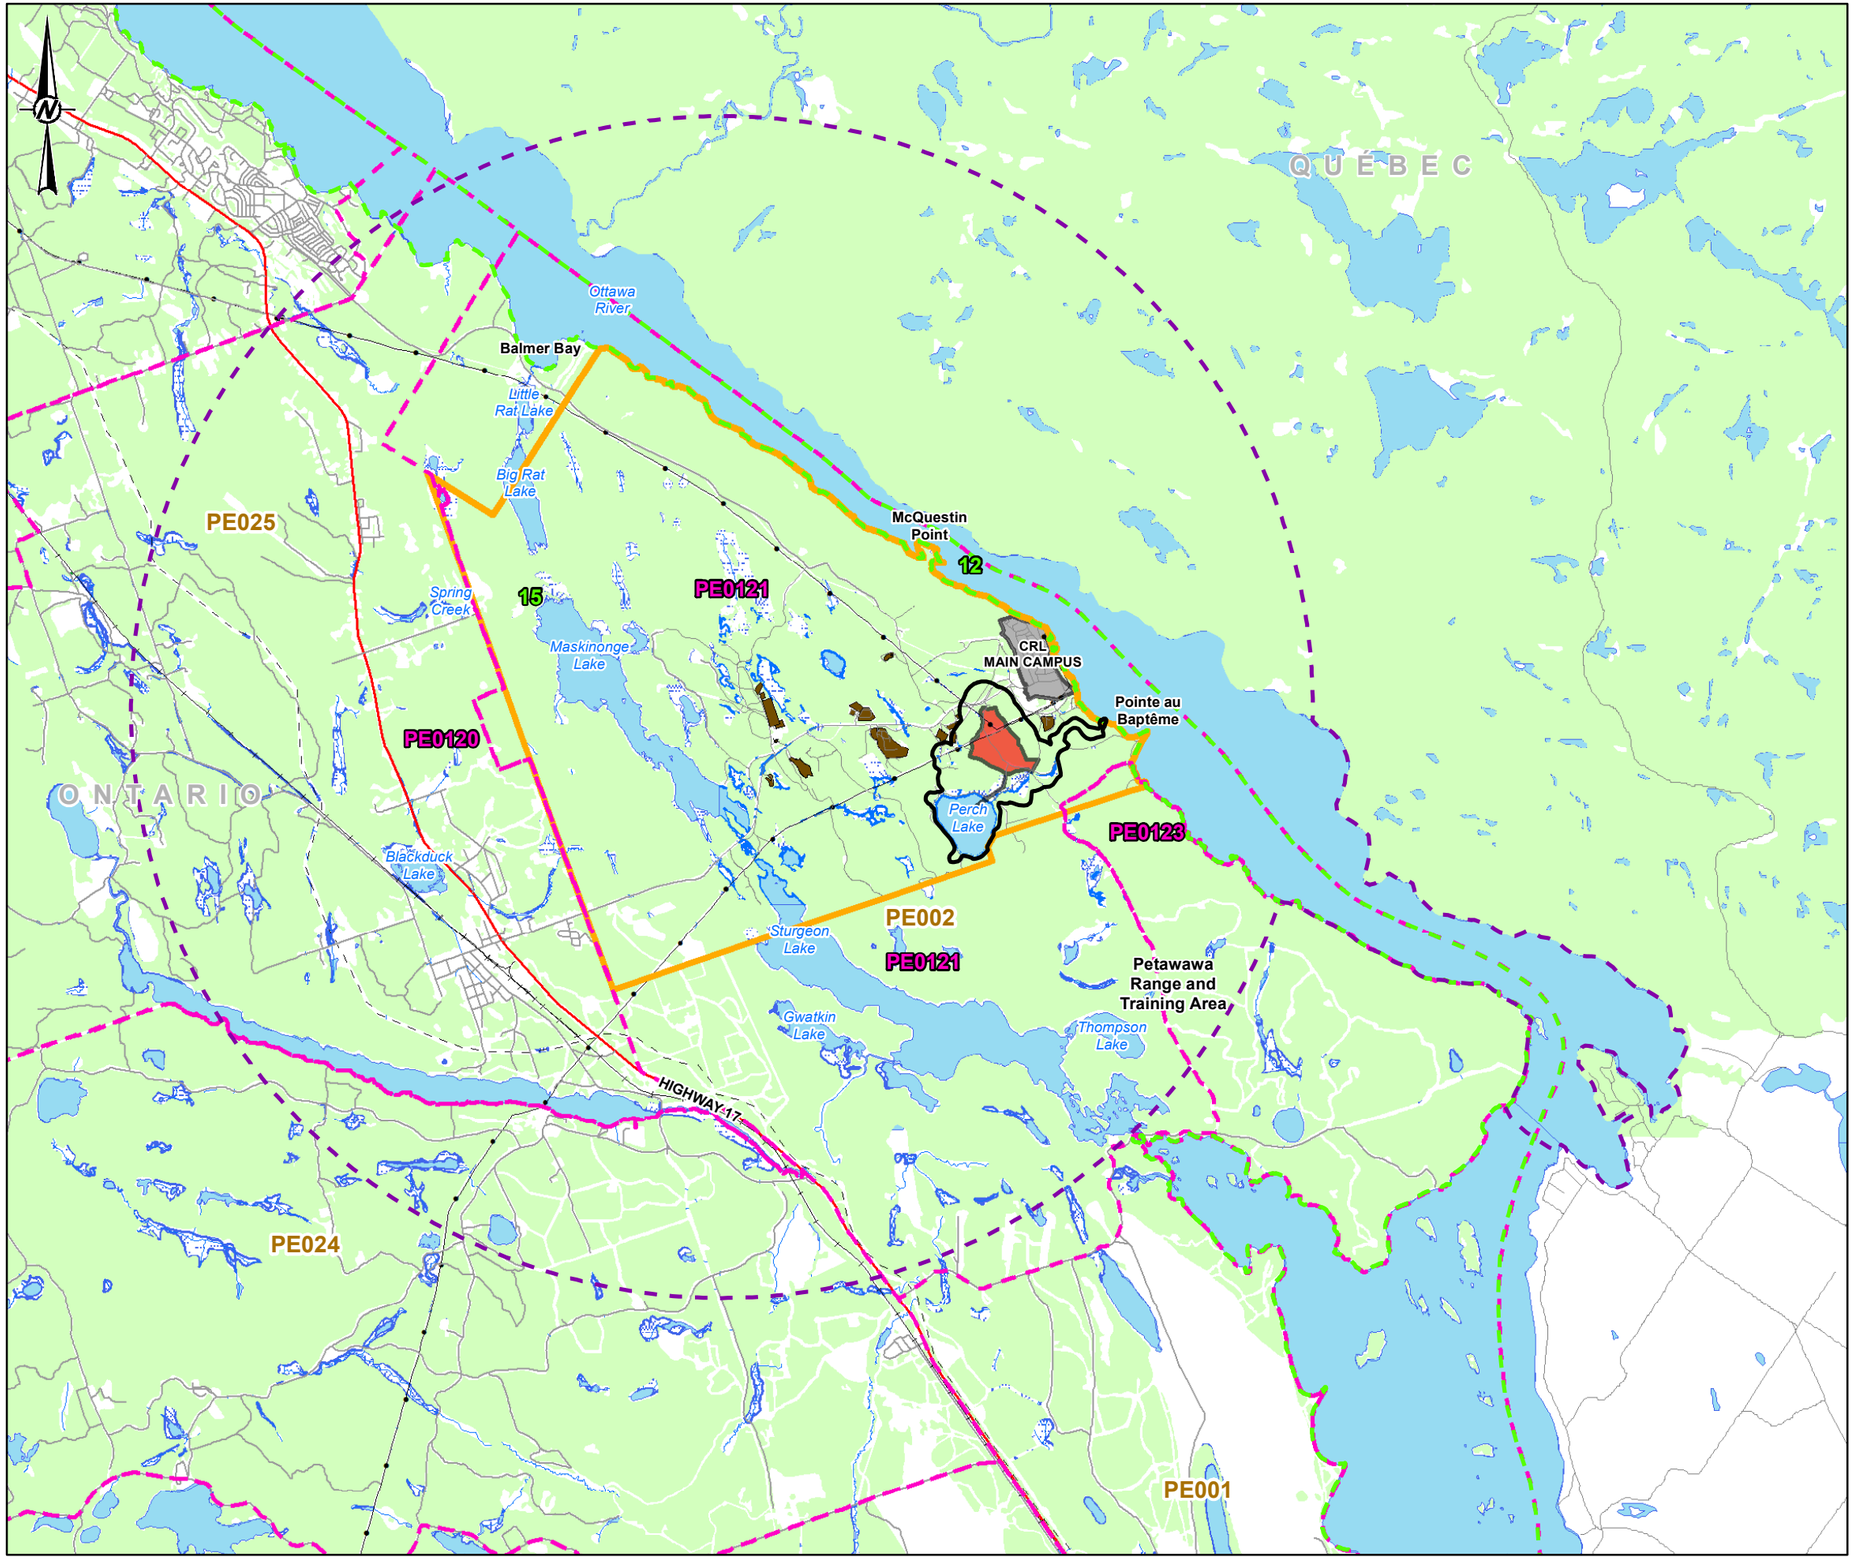
The presence of Crown land is not uncommon in the Town of Laurentian Hills; as identified in Section 2.6 of the Town's Official Plan. A large proportion of the Town's land base (51.8%) is made up of federal/Crown land, which are not subject to municipal land use controls. In accordance with Section 5.12 of the Town's Official Plan:

> "The Municipality recognizes that there are no provisions in the *Planning Act* which binds the Federal Crown in the administration and use of its lands. Section 6 (2) of the *Planning Act* requires the Ministries and agencies of the Ontario government…as set out in Sections 3, 6, 48 and 62 of the *Planning Act*, shall have regard to the Municipality's planning policies and consult with the Municipality before carrying out or authorizing any undertaking considered to affect the Municipality. Council's intent is to ensure that the planning process be applied to changes of use that may arise."
>
> (Town of Laurentian Hills 2010).

Crown Land Designations

The SSA is located in Crown land, subject to federal jurisdiction. According to spatial data sourced from the MNRF LIO database and CNL, the SSA is comprised entirely of Patented Land, External (e.g., lands held in title to other provincial or federal government agencies or sold by the Crown), as is the vast majority of the LSA (Table 5.9.4-1). A negligible 0.1 ha of the LSA and 18.1 ha of the RSA are considered to be unpatented Crown land (i.e., lands that remain under the Crown and have never been transferred to a private owner). The southern portion of the RSA also overlaps 84.6 ha of lands attributed to Garrison Petawawa.

Table 5.9.4-1: Crown Land Designations in the Site Study Area and Regional and Local Study Areas

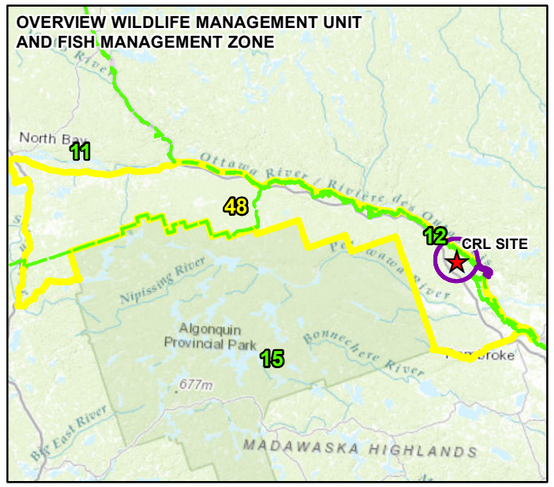


Crown Land Use Category	Description	SSA (ha)	LSA (ha)	RSA (ha)
Unpatented Crown Land	Lands that have never been patented (i.e., transferred to a private owner) by the Crown, or patented lands that have been forfeited back to the Crown.	0.0	0.1	5,814.9
Garrison Petawawa	Garrison Petawawa – approximate boundary	0.0	0.0	4,059.6
Patented Land External (Federal Government)	Lands which have been sold by the Crown. May include lands in title to other provincial or federal government agencies or mining patents.	37.1	225.6	3,861.4

Source: MNRF 2016a.

SSA = site study area; LSA = local study area; RSA = regional study area.

5.9.4.1.2.2 Mining and Aggregates



Aggregate resources are regulated under the Ontario *Aggregate Resources Act* on Crown lands and most private lands (MNR 2012). The MNRF manages aggregate resources in collaboration with the Ministry of Northern Development and Mines and the Ontario Aggregate Resources Corporation. There are no active Authorized Aggregate Sites (i.e., licenced and permitted pits and quarries) in the land and resource use LSA or RSA. The RSA overlaps one Aggregate Designated Area, which prohibits the extraction of aggregates on these private lands without a licence. Aggregate Designated Area boundaries are presented on Figure 5.9.4-1 (MNRF 2016a). There are no existing mine sites, active mining claims, pending mine claims, active dispositions or active withdraws in the LSA or RSA (MNRF 2016a).

5.9.4.1.2.3 Forestry

The MNRF is responsible for the long-term health of Ontario's Crown forests. Where active forestry is desired, the MNRF shares this responsibility with forest product companies through forest management planning guided by the *Crown Forest Sustainability Act, 1994* and the Ontario *Environmental Assessment Act*. Approximately 44% of Ontario's Crown forests are managed forests, divided into forest management units (FMUs; MNRF 2016b).

These FMUs are managed by various Indigenous and non-Indigenous companies through forest management plans. The MNRF requires forest management plans to be developed prior to any forestry activity within these FMUs. The forest management plans determine where and how much harvesting can occur, where roads can be built and how much forest will be renewed. These plans are prepared by registered professional foresters with input from Indigenous Peoples, stakeholders and other members of the public, to ensure sustainability while finding a balance of economic, social and environmental values (MNRF 2016b). The forest management plans are approved for 10-year terms.

The RSA overlaps the Ottawa Valley Forest FMU, licensed to and managed by Ottawa Valley Forest Inc. (MNRF 2016a). The RSA includes small parcels of Crown land to the west of CRL under licence to the Ottawa Valley FMU area and therefore subject to the forest management plan activities mentioned above. There are no agreement forest area or forest processing facilities in the LSA or RSA.

In the western region of the SSA, approximately 2.6 ha of land is still identified as part of the Petawawa Research Forest plantation. The plantation was established in 1956 to determine the resistance of Norway spruce *(Picea abies*) trees to frost and white pine (*Pinus strobus*) weevil. The plantation was abandoned in the 1980s, and personnel with the Petawawa Research Forest have confirmed this plantation is no longer required for research purposes.

A comprehensive Sustainable Forest Management Plan is being developed for the CRL site, with an objective to ensure the long-term retention of trees serving as maternity roosts for bat species.

5.9.4.1.2.4 Agriculture

The NSDF Project is located in a northern region of Ontario, which has a less prominent history of agriculture than southern parts of the province. Consequently, the spatial provincial Agricultural Resource Inventory, which identifies and characterizes agricultural resources in the Province of Ontario, does not extend into the LSA or RSA (Ministry of Agriculture, Food and Rural Affairs 2016). The RSA is restricted to the CRL site and a small portion of the Garrison Petawawa property. Agricultural use of these properties is prohibited due to restricted public access.

5.9.4.1.3 Outdoor Tourism and Recreation Results

This subsection describes the non-traditional outdoor tourism and recreation activities occurring in the land and resource use LSA and RSA (e.g., parks and protected areas, fishing, hunting, trapping and non-consumptive tourism and recreation activities and features), as well as the legislated harvesting and tenure requirements for non-traditional land users. Use of these resources by Indigenous Peoples is addressed in Section 6.4.4.1.2.

5.9.4.1.3.1 Parks and Protected Areas

The LSA and RSA do not overlap any parks and protected areas, including municipal parks, provincial parks, national parks, conservation reserves, non-governmental organizations, Nature Reserves, Natural Heritage System Areas, Significant Ecological Areas, Heritage River Systems or Areas of Natural and Scientific Interest (MNRF 2016a). No Ontario Conservation Authorities maintain jurisdiction over the LSA or RSA, nor do the LSA and RSA overlap any conservation areas (Conservation Ontario 2019).

5.9.4.1.3.2 Fishing

In the Province of Ontario, fishing is managed through fisheries management zones (FMZs) used by the MNRF to establish zone-specific limits and seasons to protect vulnerable fisheries, re-establish fish populations, adjust fishing seasons for different climates and allow more fishing in thriving fishery zones (MNRF 2016c). These are administered under the *Fish and Wildlife Conservation Act, 1997*. The LSA and RSA overlap FMZs 12 and 15, while the SSA only transects FMZ 15.

FMZ 12 is located along the Ontario/Quebec border. It is a large and diverse fishery, valuable for the recreational and tourism-based fishing industries (MNRF 2016d). It represents an important Eastern Ontario fishery for Walleye (*Sander vitreus*), Sauger (*Sander canadensis*), Northern Pike (*Esox Lucius*), Muskellunge (*Esox masquinongy*), Largemouth Bass (*Micropterus salmoides*) and Smallmouth Bass (*Micropterus dolomieu*; MNRF 2016d). It includes the Ontario portions of Lake Temiskaming and the Ottawa River, and the Madawaska and Mississippi Rivers upstream to the first dam (MNRF 2016d). As this FMZ is located on the Ontario/Quebec border, the MNRF has dictated that anglers can fish in the Ontario waters of the Ottawa River and Lake Temiskaming with a resident fishing licence from either Ontario or Quebec (MNRF 2016d).

FMZ 15 is located in central Ontario. This large zone has numerous natural lake and brook trout lakes, a well-developed road network and moderate angling effort, includes fishing opportunities in Algonquin Provincial Park, and represents an important recreational fishery for Lake Trout (*Salvelinus namaycush*), Brook Trout (*Salvelinus fontinalis*), Walleye, Northern Pike and Smallmouth Bass. The FMZ is stocked with Lake Trout and Brook Trout to increase angling opportunities (MNRF 2016e). It extends from Georgian Bay in the west to the Ottawa River in the east (MNRF 2016e).

As with other harvesting activities, the MNRF regulates fishing by establishing permitted seasons and limits in each FMZ. For some species, fishing seasons are open all year, whereas others face more restrictions. These fishing seasons influence levels of fishing activity in the SSA, LSA and RSA as presented in Table 5.9.4-2.

Table 5.9.4-2: Fishing Seasons by Fisheries Management Zone in the Local and Regional Study Areas (2019)

Fish Species	Open Fishing Season	
	FMZ 12	FMZ 15
Walleye and Sauger	January 1 to March 31 and Friday before the third Saturday in May to December 31	January 1 to March 15 and the third Saturday in May to December 31
Largemouth and Smallmouth Bass	Friday before the fourth Saturday in June to November 30	The fourth Saturday in June to November 30
Northern Pike	January 1 to March 31 and Friday before the third Saturday in May to December 31	January 1 to March 31 and the third Saturday in May to December 31
Muskellunge	Friday before the third Saturday in June to December 15	First Saturday in June to December 15
Yellow Perch	Open all year	Open all year
Crappie	Open all year	Open all year
Sunfish	Open all year	Open all year
Brook Trout	Friday before the fourth Saturday in April to September 30	January 1 to September 30
Brown Trout and Rainbow Trout	Friday before the fourth Saturday in April to September 30	Open all year
Lake Trout	Friday before the fourth Saturday in April to September 30	January 1 to September 30
Splake	Friday before the fourth Saturday in April to September 30	Open all year
Atlantic Salmon	Friday before 4th Saturday in April to September 30	Closed all year
Lake Whitefish	Open all year	Open all year
Lake Sturgeon	Closed all year	Closed all year
Channel Catfish	Open all year	Open all year
Pacific Salmon	No information publicly available through the MNRF	Open all year

Source: MNRF 2019a.

The use of live organisms as bait remains common among anglers and bait types vary depending on the species of fish being sought (Kerr 2012). Surveys suggest that almost 80% of Ontario anglers use live bait (e.g., worms, baitfish, frogs and/or crayfish) (Kerr 2012). Ontario anglers can choose to harvest or purchase bait (Kerr 2012). Commercial bait harvesting on Ontario is licenced through bait harvesting areas. Bait harvesters pay approximately $300 per year for the exclusive rights to each bait harvesting area. The land and resource use RSA overlaps six bait harvesting areas (PEO118, PE0119, PE0120, PE0121, PE0123 and PE0124). The SSA and LSA only overlap PE0121 (approximately 37 ha and 226 ha, respectively) (MNRF 2016a). There are no fishing access points identified by the MNRF in the LSA or RSA (MNRF 2016a).

5.9.4.1.3.3 Hunting

The MNRF manages hunting activities in Ontario through 95 regulated wildlife management units (WMUs). Each WMU has customized restrictions for the types of game that can be hunted, open season dates and hunting methods permitted (MNRF 2015). The SSA, LSA and RSA are located within WMU 48.

To effectively balance wildlife populations with the demands of harvesting activities, the MNRF establishes seasonal dates where hunting by local residents and non-residents is permitted in the WMU. Hunting seasons are adjusted every year as necessary. The presentation of baseline conditions focuses on moose (*Alces alces*), white-tailed deer (*Odocoileus virginianus*) and black bear (*Ursus americanus*), three indicator species considered important to recreational hunting in Central and Eastern Ontario. Moose, deer and bear hunting seasons in WMU 48 for residents and non-residents are presented in Table 5.9.4-3.

Table 5.9.4-3: Firearm Hunting Seasons for Resident Hunters in Wildlife Management Unit 48 (2019-2020)

Species	WMU 48	
	Resident Hunters	Non-Resident Hunters
Moose	October 19 to October 25	No Season
Deer	November 4 to November 17	November 4 to November 17
Black Bear	September 1 to November 30	September 1 to November 30

Source: MNRF 2019b.

The MNRF also monitors harvest data to establish sustainable hunting seasons year over year and to assess levels of hunting activity in each WMU. The most recent, publicly available hunter and harvest data for moose in the WMU overlapping the SSA, LSA and RSA is presented in Table 5.9.4-4. In 2017, approximately 1,211 hunters were active in WMU 48 in 2017, harvesting a total of 53 moose.

Table 5.9.4-4: Resident Moose Hunter and Harvest Data for Wildlife Management Unit 48 (2008-2017)

WMU	Year	Estimated Active Resident Moose Hunters	Estimated Total Moose Harvest by Resident Hunters
48	2008	803	26
	2009	1,007	44
	2010	1,059	75
	2011	1,182	54
	2012	1,092	60
	2013	948	53
	2014	1,229	68
	2015	1,100	79
	2016	1,263	59
	2017	1,211	53

Source: MNRF 2018a.

The most recent, publicly available hunter and harvest data for white-tailed deer in WMU 48 is presented in Table 5.9.4-5. The number of resident white-tailed deer hunters active in WMU 48 varied between 2008 and 2017, with a peak of 3,067 licensed hunters active in 2015. The number of deer harvested has declined since 2013 with a peak of 948 deer harvested in 2013 to only 577 deer harvested in 2018 (a decrease of 39%; MNRF 2018b).

Table 5.9.4-5: Resident Deer Hunter and Harvest Data in Wildlife Management Unit 48 (2008-2017)

WMU	Year	Estimated Active Resident Deer Hunters	Estimated Total Deer Harvest by Resident Hunters
48	2008	2,621	767
	2009	2,698	716
	2010	2,010	639
	2011	2,994	775
	2012	3,026	805
	2013	2,862	948
	2014	2,611	825
	2015	3,067	692
	2016	3,030	675
	2017	2,896	577

Source: MNRF 2018b.

The most recent, publicly available hunter and harvest data for bear in WMU 48 is presented in Table 5.9.4-6. The number of bear hunters and bears harvested rose between 2013 and 2016 and then started to decline in 2018. There are no Bear Management Areas[1] or Crown Game Preserves overlapping the SSA, LSA or RSA.

Table 5.9.4-6: Resident and Non-Resident Bear Hunters and Harvests in Wildlife Management Unit 48 (2012 to 2017)

WMU	Year	Resident and Non-Resident Bear Hunters	Bear Harvest
48	2012	464	55
	2013	365	37
	2014	398	78
	2015	567	149
	2016	639	168
	2017	627	109

Source: MNRF 2018c.

[1] Bear Management Areas (BMAs) are areas of Crown land licenced annually to a tourist operator for providing bear hunting services to non-resident clients. Some BMAs can completely surround private or patent land. Bear hunting services can occur on these lands provided that the licenced tourist operator allocated the BMA has obtained permission of the land owner to provide bear hunting services on the property.

5.9.4.1.3.4 Trapping

In the Province of Ontario, trapping is regulated under the *Fish and Wildlife Conservation Act, 1997,* administered by the MNRF (MNRF 2016f). Individuals must hold trapping licences to harvest fur, identifying where each individual can trap, in order to monitor furbearer populations and regulate trapping activities through seasons and harvest quotas (MNRF 2016f). Trapline tenures are gained by obtaining licences from the MNRF, which can be secured by proving Canadian citizenship, holding a valid hunting/fishing Outdoors Card, and successfully completing the MNRF's Fur Harvest, Fur Management and Conservation course (MNRF 2016f). The SSA, LSA and RSA all overlap the active PE002 trapline area. Trapline areas PE025 and PE024 also overlap the western section of the RSA. While trapping is prohibited in the LSA and most areas of the RSA due to restricted public access within the CRL site boundary (see Figure 5.9.4-1)[2], results of consultation and engagement have identified that there may be some limited trapping activities at the southern portion of the RSA, beyond the CRL site boundary, on the Garrison Petawawa property.

5.9.4.1.3.5 Non-consumptive Tourism and Recreation

While tourism and recreation opportunities exist in the County of Renfrew and the Town of Deep River, tourism and recreational opportunities are non-existent in the LSA and very limited in the RSA. According to the MNRF LIO data, there are no formal access points, boat caches (private or commercial), boathouses, club houses, designated camping sites, recreation camps[3], tourism establishment areas[4], potential tourism establishment areas, beaches, golf courses, resting areas, trailheads or Ontario Trail Network trails in the LSA or RSA (MNRF 2016a). There is snowmobile and all-terrain vehicle use, including a trail along the north-western side of the CRL site within the RSA. Potential disturbance through existing traffic noise to people, including tourists and recreational site users, within the RSA is characterized in Section 5.10.4.2.10, with low levels of disturbance identified.

Recreational boaters do traverse the Ottawa River within the RSA. The Pointe au Baptême represents a site of importance not within the footprint of the NSDF Project, but within the RSA on the CRL site. (Figure 5.9.3-1). Recreational boaters on the Ottawa River frequently use Pointe au Baptême as a picnic stop.

[2] It is noted that CNL contracts a trapper for managing nuisance beavers on the CRL site.

[3] A Recreation Camp is a polygon feature that identifies an area used for commercial tourist operations with a focus on outdoor activities other than hunting and fishing (MNRF no date [a]).

[4] A Tourism Establishment Area is a polygon feature that identifies an area containing facilities and services for tourists (MNRF no date [b]).

5.9.4.2 Archaeological Environment

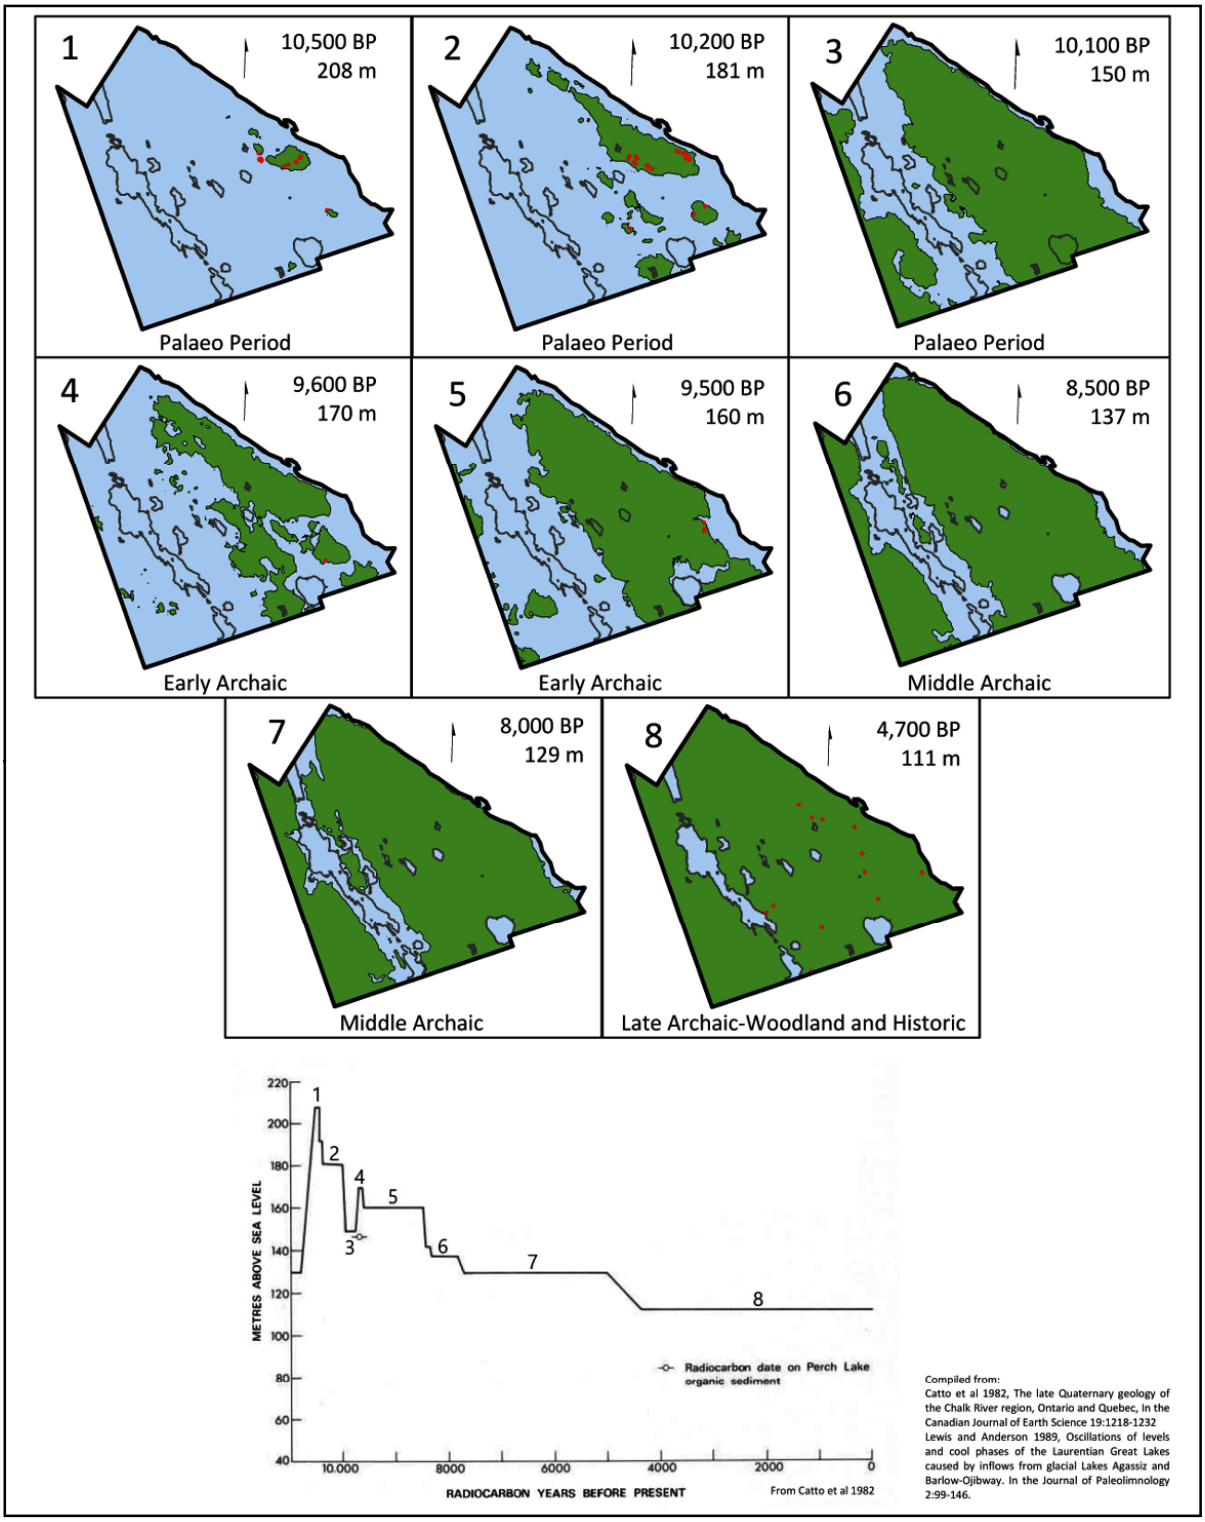
5.9.4.2.1 Archaeological Context

In 2008, CNL developed an Archaeological Master Plan (CNL 2008) that resulted in a formal Cultural Resource Management (CRM) Program at CNL. The CRM Program includes an archaeological potential model which assists in locating areas of archaeological potential and a robust cultural resource inventory of heritage sites. Figure 5.9.4-2 illustrates the archaeological potential for pre-contact deposits within the area. This potential model was created using the principal assumption that proximity-to-water is one of the prime indicators of areas of potential human occupation and land use. During the early postglacial period a sequence of relic shorelines formed as the water level gradually receded. For lengthy periods of time the relic shore stayed at the elevations of 159 m; 170 m; and 180 m above sea level. Archaeological potential exists within 150 m of each former waterline. The proposed footprint for the NSDF Project is located on a fossil island that contains three relic shorelines of the Ancestral Ottawa River. These have been identified as 180 masl, 170 masl, and 159 m masl (see Figure 5.9.4-3; Catto, N.R., et al. 1982, Lewis and Anderson 1989). Using this Archaeological Master Plan, to date the CRM Program at CRL has identified over 50 archeological sites that are registered with the Ontario Ministry of Tourism, Culture and Sport within the CRL site. According to the Borden (1952) system of archaeological site registration (Borden 1952, as cited in Swayze and Cameron 2016, the CRL site is in the CaGi “Borden Block” (a rectangular area, about 13 km by 19 km) that straddles both sides of the Ottawa River. Six archaeological sites were previously recorded within 1 km of the SSA. Each of these sites are described below.

- CaGi-54 South Shore Site is a small early postglacial Pre-Contact Period site discovered on the edge of the D6 115 kV hydro corridor at 181 to 183 metres above sea level (masl) (Swayze 2008, as cited in Swayze and Cameron 2016). Stage 3 test excavations were carried out at CaGi-54 in 2010 to collect a larger artifact sample and to determine the nature and condition of the deposit. Ten 1 m units were excavated and a total of 135 stone tools were recovered. The raw material consists of quartz and metamorphic rock available in the till. No formal artifacts or exotic material occurred. The excavation of an additional 35 test pits determined that the deposit was isolated in the hydro corridor, but it continued for some extent to the north. In terms of cultural affiliation, CaGi-54 is consistent with the Gulf of Main Archaic Tradition (Robinson 1992, as cited in Swayze and Cameron 2016) even though it probably dates to the Palaeo-Indian time period (Swayze 2009; Swayze and McGhee 2011; as cited in Swayze and Cameron 2016).
- CaGi-52 Communications Tower Site is an early postglacial Pre-Contact Period site that was recorded in 2008 during a Stage 2 assessment of the footprint for the communication tower (Swayze 2010, as cited in Swayze and Cameron 2016). A collection of 52 stone artifacts, similar to the artifacts recovered from CaGi-54, was obtained from nine positive Stage 2 test pits, which were expanded into Stage 3 test units. Similar to the South Shore site, CaGi-52 is consistent with the Gulf of Maine Archaic Tradition, even though the 180 m strand it is associated with pre-dates the earliest maritime sites.
- Pole 191 Stack Road Site was recorded during a Stage 2 assessment of wood pole replacements along the D6 115 kV hydro corridor and was assigned the temporary designation Borden Number CaGi-G (Swayze 2012, as cited in Swayze and Cameron 2016). Eleven test pits were excavated around this pole structure and there were three positive results. Test units were excavated around each positive test pit but in total, only nine stone artifacts were discovered. The recovered stone artifacts are consistent with the Gulf of Maine Archaic Tradition.

- CaGi-37 Blimkie Farm Site originally consisted of a two room, two storey log house with stone and cement foundations, three outbuildings and a laneway. Much of this archaeological site has been disturbed by road and fence construction in the area. Artifacts on the surface include mower and sleigh parts, ceramics and glass[5].
- CaGi-40 Parking Lot Site is an Early Archaic site under a new parking lot. It was found in 2007 with assistance of the Stewardship Rangers and the Earthwalkers of Pikwakanagan. The site was along the relic shoreline of the recessional Ancestral Ottawa River.
- CaGi-53 Parking Lot was discovered in 2008. The site consists of expedient stone tools associated with an early postglacial low water event. The deposit was subsequently inundated and buried under riverine sediments, which have affected the condition of the artifacts.

In 1955, the National Research Universal heritage site was discovered in a sand deposit, approximately 3 m above the waterline, near the National Research Universal reactor. The site was not registered with the Borden system and the disposition of the artifacts is uncertain, although some are believed to be stored at the Canadian Museum of History in Ottawa. Bone, pottery sherds and Chert chips were found in an area approximately 15 m by 60 m. Most artifacts were disturbed, although one intact refuse pit was excavated. The pottery was determined to match Middle Woodland (Point Peninsula) activity from approximately 2,000 years ago.



The *Canadian Environmental Assessment Act, 2012* requires a designated project to consider whether changes to the environment caused by project activities will adversely affect cultural heritage resources. Archaeological assessments in Ontario are completed in accordance with the *Standards and Guidelines for Consultant Archaeologists* (the Guidelines; OMTC 2011). These standards and guidelines identify four main stages for completing archaeology assessments. The purpose of the four stages is to:

- discover any archaeological resources on the lands that are being developed;
- determine the degree of cultural heritage value of any archaeological resources found on the property;
- recommend the most appropriate strategies for conserving archaeological sites prior to land development activities; and
- implement recommendations for long-term protection strategies for archaeological sites to be affected by the project, or if protection of the site is not a viable option, conduct archaeological excavation to document the site and remove artifacts before construction begins.

Following the guidance provided in the *Reference Guide on Physical and Cultural Heritage Resources* (The Agency 1996), an archaeological assessment was completed for the NSDF Project (Swayze and Cameron 2016) in accordance with the *Standards and Guidelines for Consultant Archaeologists* (OMTC 2011). This assessment was submitted to the Ministry of Tourism and Culture in 2017 as a condition of licensing, in accordance with the *Ontario Heritage Act*.

[5] During the Stage 2 assessment, the Blimkie Farm archaeological site (CaGi-37) was identified to be within the CRL site. The NSDF Project chose to preserve the site by modifying the footprint boundary. As a result, this site is no longer within 1 km of the current SSA.

Section 5.9.4.2.2 summarizes the findings of the archaeological assessment completed for the NSDF Project, titled Cultural Resource Management At Canadian Nuclear Laboratories, 2016 Stage 1, 2 & 3 Archaeological Assessments At The Near Surface Disposal Facility (NSDF) On Part Of Lots 20-23 Ranges A & B Buchanan Township (Geo.), Renfrew County (Swayze and Cameron 2016), and Stage 4 Archaeological Assessment. Proposed Near Surface Disposal Facility - EMR Site. 232-509213-REPT-003 (Kinickinick Heritage Consulting and Cameron Heritage Consulting Inc. 2018).

5.9.4.2.2 Archaeological Assessment

5.9.4.2.2.1 Methods

Licenced by the Ontario Ministry of Tourism, Culture and Sport (formerly the Ontario Ministry of Tourism and Culture), the consultant archaeologist conducted the Archaeological Assessments in accordance with the Guidelines (OMTC 2011). These standards and guidelines identify four main stages for completing archaeology assessments. The four stages are:

1) Background Study and Property Inspection;

2) Property Assessment;

3) Site-specific Assessment; and

4) Mitigation of development impacts.

CNL contracted Kinickinick Heritage Consulting and Cameron Heritage Consulting to complete the Archaeological Assessment for the NSDF Project. The following sections are based on information provided in the reports prepared by one or both consultants during the four stages of archaeological assessment work.

The majority of the background research that describes the past and present land use and the settlement history was gathered during the Stage 1 and 2 archaeological assessments and can be reviewed in more detail in Cameron 2017, 2018a). Kinickinick and Cameron Heritage Consulting were also retained by CNL to complete a Stage 3 archaeological assessment of CaGi-65 Locations J-L, CaGi-66 Location A-C, and G, CaGi-67 Locations D-F, H and I (Swayze 2017, Cameron 2018b) including additional areas and the subsequent Stage 4 Archaeological Assessment where a controlled removal through excavation and recording of cultural value and interest was documented. Please refer to Cameron and Swayze (2018) for more detail.

All documents, and records were curated at the offices of Kinickinick Heritage Consulting and Cameron Heritage Consulting. All Archaeological Assessment Reports were submitted to the Ontario Ministry of Tourism, Culture and Sport in accordance with the requirements of the Ministry of Tourism, Culture, and Sport's Standards and Guidelines for Constant Archaeologists (MTCS 2011). The artifacts will be curated at the Kinickinick Heritage Consulting storage facility until such time that they can be permanently curated at The Algonquin Way Museum in Pikwakanagan. All of the reports have been made available for review by Indigenous Peoples and stakeholders. Engagement related to archeological assessment with Indigenous Peoples is further discussed in Section 6.2.4.

Stage 1 Assessment

Under the *Standards and Guidelines for Consultant Archaeologists* (OMTC 2011), it is recognized that much of northern Ontario and the Canadian Shield present obstacles to archaeological assessment including less detailed mapping and difficulties of access. The Guidelines (OMTC 2011) make allowances for assessments carried out in these areas where the bedrock is Pre-Cambrian Canadian Shield.

A desktop assessment (Stage 1 Background Study and Property Inspection) was completed to identify areas where potential archaeological resources may exist. The desktop assessment focused on the underlying principles of archaeological resource prediction, particularly of a hunter-gatherer society, including the proximity to water and the association of archaeological sites with certain landforms. The first assumes that human habitation is dependent upon potable water and that economic activity will occur most frequently on the shores of major bodies of water that offer biodiversity and biomass and act as communication and transportation corridors. The second assumes that the physical site and setting of human activity will not occur randomly on the terrain, but

will reflect a choice of soil, drainage and landform that reflect economic decisions. A desktop review of historical geologic maps was completed to identify areas of archaeological potential, in particular, relic shorelines created over the millennia through glaciation.

Stage 2 Assessment

Stage 2 (Property Assessment) begins with test pit surveys completed in areas where archaeological potential was identified during the background study and property inspection (Stage 1). Test pit surveys were completed over the entire property, digging at two intervals: every 5 m within 100 m of each major relic shore and every 10 m within 101 to 150 m above the former waterline.

Test pits were approximately 30 cm by 30 cm in size and were excavated by hand with a shovel and masonry trowel to a depth at least 5 cm into the parent material. Given the shallow nature of the soil, some test pits met this condition at 15 to 20 cm below surface; however, most test pits were excavated to 30 cm depth and frequently as deep as 40 cm. The back dirt was passed through a 6 mm mesh and the screen inspected carefully for artifacts or samples of potential artifacts.

The second phase of Stage 2 involved “infilling” where further excavation was completed at each positive test pit to determine if further inspection of the area was necessary. The procedure consisted of excavating infill test units around the positive test pit, in a “compass rose” pattern, at 2.5 m distance, as well as the excavation of a 1 m by 1 m unit over the discovery spot. The infill excavation methods were identical to that described above for the test pit survey. Artifact samples from infill test pits were tagged and bagged according to date, excavator, sequential number and infill unit location.

Stage 3 Assessment

The Stage 3 component of the Archaeology Assessment is a site-specific assessment and involves controlled surface pick up of material and text unit excavation determining the location and number of significant test pits. To accomplish this, test excavations were carried out wherever five or more artifacts of any kind were recorded during Stage 2, and within any area (i.e., a 10 m by 10 m area). The procedure consisted of establishing a permanent datum at each cluster of positive test pits and superimposing a 1 m grid over the area to be tested. Grid units were then excavated out at 5 m intervals over the prescribed area. An additional 20% of units were then placed at selected areas where artifact concentrations might be expected. These grid units were excavated by hand with a shovel and trowel to at least 5 cm depth into the parent material. The back dirt was passed through a 6 mm screen and the rock samples in it were carefully examined for archaeological material. In accordance with the Guidelines (OMTC 2011), when dealing with Early Archaic archaeological sites, 20% of the back dirt from the grid units was passed through a 3 mm screen to determine if there were any tiny retouch flakes or beads, that could slip through the standards screen.

Stage 4 Assessment

Stage 4 in an Archaeological Assessment involves implementing long-term management strategies for those sites recommended for mitigation in Stage 3. Stage 4 entails either preservation and protection (the preferred choice when possible) or controlled excavation to remove the deposit. Stage 4 controlled excavation entails excavating eight grid units around the significant Stage 3 unit. If any of these exceed 10 artifacts of any kind then 1 m by 1 m units will be excavated around it. The excavations continue until the artifact frequency remains consistently below the threshold.

5.9.4.2.2.2 Results and Recommendations

Stage 1 Assessment

The desktop review (Stage 1 Background Study and Property Inspection) determined that the majority of the SSA had some level of archaeological potential (Figure 4 of Swayze and Cameron 2016). In general, the areas of archaeological potential include:

- within a 150 m buffer above the elevation of a relic shoreline;
- within a 100 m buffer above a major waterbody, such as the shoreline of a lake or river;
- within a 50 m buffer around secondary areas of archaeological interest (e.g., the shorelines of streams, wetlands and intermittent creeks and landforms like lookouts, rock-faces, or sources of suitable rocks for tool manufacture); and
- within a 50 m buffer on each side of historical roads.

Large areas of high archaeological potential were identified due to proximity to relic shorelines or the historical Mattawa Road. The relic shorelines are associated with the drainage of Glacial Lake Algonquin waters through the North Bay Outlet and as successive elevations of the ancestral Mattawa and Ottawa River (Kichi-Sìbì) over several millennia. Relict shorelines of the ancestral Ottawa River (Kichi-Sìbì) within the SSA are located at 180, 170 and 159 masl, at which the elevation of the former sea level stayed for several centuries at a time. Areas of high archaeological potential were identified as 100 m above each relic shoreline. Areas of moderate potential were identified as above 101 to 150 m of each relic shoreline. Low potential terrain within the SSA consists of organic terrain that cannot be tested because of standing water or water saturated soil conditions.

Stage 2 Assessment

Approximately 9,000 test pits have been excavated with only 337 of these identified as positive test pits (approximately 3.7%). The positive test pits above 180 masl were assigned the Borden Number CaGi-65; while those between 170 and 179 were designated CaGi-66; and those between 159 and 169 are designated CaGi-67 (Figure 5 of Swayze and Cameron 2016). In total, approximately 450 artifacts were discovered, usually only one or two artifacts per test pit. During the Stage 2 assessment, the Blimkie Farm archaeological site (CaGi-37, see Section 5.9.4.2.1) was identified to be within the CRL site. The NSDF Project chose to preserve the site by modifying the footprint boundary.

As a result of infill excavations, 117 of the original 337 positive test were determined to be insignificant and are no longer of any heritage concern. However, 53 test pits are now “areas” (10 m by 10 m area) containing more than five artifacts of any kind and warrant test excavation on a grid. Most of these test pits were incorporated into existing test excavation areas, although a few are small 25 m² outliers. The infill excavation added approximately 400 artifacts to the collections.

Stage 3 Assessment

Based on the Stage 2 assessment a total of 68 locations were recommended for Stage 3 site assessment. Results of the Stage 3 assessment identified 19 units that contained cultural heritage value or interest in seven areas of concentration within the boundaries of the NSDF site. None of these areas were able to be avoided and protected and, therefore, all 19 units were recommended for Stage 4 assessment.

Stage 4 Assessment

Stage 4 entails either preservation and protection (the preferred choice when possible) or controlled excavation to remove the deposit.

Within CaGi-65 there were five 1m by 1 m units in three areas of concentration that contained sufficient cultural heritage value or interest to require Stage 4 mitigation. Fieldwork was conducted between August 10 and November 1, 2017. A total of 118 m² were excavated within three areas of concentration within CaGi-65. A total of 2,787 lithic artifacts were recovered and all but 15 were from local sources. The artifacts and their distribution throughout CaGi-65 indicates that this site consists of a general lithic workshop/quarry area.

Within CaGi-66 there were five 1 m by 1 m units in one area of concentration that contained sufficient cultural heritage value or interest to require Stage 4 mitigation. Fieldwork was conducted between October 19 and October 26, 2017. A total of 33 m² was excavated within one area of concentration within CaGi-66. A total of 198 lithic artifacts were recovered and all were from local sources. The artifacts and their distribution throughout CaGi-66 indicates that this site consists of a general lithic workshop/quarry area.

Within CaGi-67 there were nine 1 m by 1 m units in three areas of concentration that contained sufficient cultural heritage value or interest to require Stage 4 mitigation. Fieldwork was conducted between August 10 and November 1, 2017. A total of 130 m² were excavated within three areas of concentration within CaGi-67. A total of 1,978 lithic artifacts were recovered and all but 25 were from local sources. The artifacts and their distribution throughout CaGi-67 indicates that this site consists of a general lithic workshop/quarry area.

Site Analysis and Results

Indicators of an archaeological site's significance and importance include representativeness, site type or function, age, rarity, depositional integrity, preservation of organics, artifact and feature frequency and density, the presence or absence of human remains and burials, and deeply buried archaeological material (OMTC 2011). The cultural heritage and scientific value, as well as the potential value to a community or as a public resource are also considered (OMTC 2011). These criteria are discussed below in terms of how they apply, generally and specifically, to the NSDF Project archaeological material (Swayze and Cameron 2016).

Representativeness (i.e., is this type of site typical or unusual) – In the consultant's opinion, the archaeological materials assessed are typical or representative of small and large diffuse lithic scatters. Given that stone technology creates a great deal of detritus over time, one should not be surprised to find some indication of it anywhere on relic shorelines in this region.

Site Type/Function – The NSDF Project area is situated on a natural landform; a fossil island that contains three relict shorelines of the Ancestral Ottawa River. Given the distribution and concentration of the lithic artifacts along the base of a garnet gneiss bedrock outcrop, the SSA area is considered a lithic workshop/quarry area. Furthermore, there are a considerable number of expedient tools that were recovered, indicating the area was a raw lithic source and processing activities would have taken place.

Age – The association of these sites with the earliest postglacial relict shoreline suggests a geochronological date of 8,500 to 10,500 BP.

Rarity – The early postglacial time period is poorly known everywhere in Ontario, in part because the early postglacial Great Lakes shorelines are now submerged. In the Ottawa Valley, on the other hand, the major shorelines of the ancestral Ottawa River are available for sampling as “relic shorelines” and “fossil islands”. Although systematic survey in the Ottawa Valley is relatively recent, similar lithic scatters were encountered on all the major relic shorelines, where sampled. Although all archaeological deposits are rare phenomena (and older deposits are more rarely preserved than recent ones) sites like those encountered in the SSA, may not be especially rare in this region, only rarely recorded.

Depositional Integrity – Sites with good depositional integrity exhibit buried cultural features (e.g., hearths, pits and post molds) and artifacts remains that are, more-or-less, left as they were. At the excavations on the SSA, however, there were no buried cultural features and no apparent pattern in the horizontal or vertical distribution of the artifacts. The parent material throughout is deep deltaic sand, stony and rocky in places, and “pit and hummock” terrain is common. As a result, there has been considerable surface mixture.

Preservation of Organics – No organic materials or cultural features were observed, which is not surprising given the age of the deposit and the acidic and excessively well-drained nature of the soil. Bones from food remains do not preserve well in such conditions and are rarely preserved in Archaic period sites.

Artifact and Feature Frequency and Density – The frequency and density of artifacts is generally low, with the exception of the concentrations where test excavations are under way. There are no chronologically diagnostic artifacts present. The artifact assemblage consists of expedient or informal tools made from locally available raw material.

Human Remains and Burials – None were observed. One would not expect bones or burials to be preserved in these conditions.

Deeply Buried Archaeological Material – Excavations units are assessed in the upper 10 to 15 cm of soil during the Stage 2 and 3 assessments, and to a depth of 100 cm during Stage 4 assessments. There is a chance that archaeological material may be deeply buried.

The Guidelines present criteria and indicators to evaluate cultural heritage value and interest (OMTC 2011:60-61, Table 3.2). These guidelines are described as follows as to their applicability to the SSA.

Cultural Heritage Value – The archaeological deposits at the SSA provide some information to advance our knowledge of settlement patterns during the early postglacial period and they provide a glimpse into the material culture of the ancestors of modern Indigenous Peoples, specifically the Anishinaabe. Algonquin oral history is based on a concept of the postglacial period and these sites are associated with “fossil islands” (Swayze and Cameron 2016).

Scientific Value – The sites in the vicinity of the NSDF Project have scientific value, because of their rarity and age (Swayze and Cameron 2016). Nevertheless, their scientific value is compromised by: poor depositional integrity, lack of organic artifact and cultural feature preservation, low artifact productivity and absence of diagnostic artifacts. On the other hand, recent advances in lithic artifact study have found that use wear studies of stone tool collections can provide insight into past activities. High magnification surface analysis of stone tools

is now advanced enough that organic residues such as lipids or resins have been found on the stone artifact surfaces and organic samples as small as a single spore have been radiocarbon dated.

Value to a Community – Different communities may perceive the cultural value or interest of an archaeological site in various ways. Thus, it can be expected that Indigenous Peoples would perceive these sites and artifact collections to have cultural value and interest (Swayze and Cameron 2016).

Value as a Public Resource – This refers to the ability of an archaeological resource to enhance the public's understanding and appreciation of Ontario's past. The criteria include potential for public use for education, recreation or tourism and the indicators of a suitable archaeological site are that it can be made accessible to tourists, local residents or school groups, and can be incorporated into local education, recreation or tourism strategies and initiatives. The sites in the vicinity of the NSDF Project have no potential in this respect because Stage 4 protection is not a realistic expectation. However, there may be places in CRL where these kinds of programs could be carried out in partnership with Indigenous Peoples (Swayze and Cameron 2016).

In summary, the archaeological sites encountered in the SSA, may not be especially rare in this region, only rarely recorded. There are no chronologically diagnostic artifacts or human remains or burials present. However, it can be expected that Indigenous Peoples would perceive these sites and artifact collections to have cultural value and interest. Based on the Stage 4 assessment, CaGi-65, CaGi-66 and CaGi-67 have been fully excavated and documented to the extent required under the *Standards and Guidelines for Consultant Archaeologists* (OMTC 2011). No cultural heritage value or interest remains and the locations have been fully documented and the information is preserved for future study; therefore, no further archaeological work was recommended for the NSDF Project.

5.9.5 Project Interactions and Mitigation

5.9.5.1 Methods

This section describes the process by which interactions between NSDF Project components and activities and the land and resource use VCs were identified and evaluated. Potential effects pathways are identified and mitigations have been developed to eliminate and/or reduce potential adverse project effects. A pathways analysis is used to focus the assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential for residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment. As such the "Project Interactions and Mitigation" section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis is to identify the potential effects pathways for all stages of the NSDF Project. The next step in the analysis is the development of environmental design features and mitigation practices that could be incorporated into the NSDF Project to eliminate and/or reduce effects to land and resource use VCs. These measures include environmental design features, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the engineering and environmental teams, combined with input from Project-specific engagement with other interested parties. The design features and/or mitigation activities were selected

considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effect pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments, and the effectiveness of environmental design features and mitigation:

- **No linkage:** The pathway is removed by environmental design features or mitigation such that the NSDF Project would not be expected to result in a measurable environmental change to measurement indicators identified for land and resource use VCs relative to Base Case values, and therefore, would have no residual effects to land and resource use VCs.
- **Secondary pathway:** The pathway could result in a measurable minor change to measurement indicators identified for land and resource use VCs, but would have a negligible residual effect on land and resource use VCs relative to Base Case values and is not expected to contribute cumulatively to other NSDF Project effects or to the effects of other previous, existing or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway:** The pathway is likely to result in an environmental change to measurement indicators identified for land and resource use VCs relative to the Base Case that could contribute to residual effects to socio-economic VCs.

Environmental design features and mitigation that could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects to land and resource use VCs were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to land and resource use VCs through quantitative and qualitative evaluation of the pathway were also not advanced for further assessment. Primary pathways are carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the NSDF Project on land and resource use VCs.

5.9.5.2 Results

The pathways analysis for the land and resource use VCs is presented in Table 5.9.5-1.

Table 5.9.5-1: Pathways Analysis for the Land and Resource Use Valued Components

Project Activity	Valued Component	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Construction, operations, closure, post-closure	Land and Resource Tenures and Other Registered Interests (i.e., land use designations, mining and aggregates, forestry and agriculture.	Change in access to or availability of tenured land use opportunities and other registered interests.	▪ Access to the LSA is restricted; therefore, no mining, aggregate, forestry, or agricultural activity will be affected by the NSDF Project.	No Linkage

Table 5.9.5-1: Pathways Analysis for the Land and Resource Use Valued Components

Project Activity	Valued Component	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Construction and operations, closure, post-closure (institutional control)	Outdoor Tourism and Recreation (i.e., parks and protected areas, fishing, hunting, trapping and non-consumptive tourism and recreation).	Changes in access to or quality and quantity of outdoor tourism and recreation activities (except trapping).	▪ Access to the LSA is restricted; therefore, no parks or protected areas will be affected by the NSDF Project. ▪ Terrestrial effects are limited to the CRL site, which encompasses the LSA and is restricted access; therefore, no hunting activities will be affected by the NSDF Project. ▪ The RSA overlaps the mouth of Perch Creek and a small portion of the Ottawa River where fishing activities may take place. Results of the surface water quality assessment identify there is no residual effect as there are no measurable concentrations of indicator compounds predicted and therefore fishing will not be affected by the NSDF Project.	No Linkage
		Changes in access to or quality and quantity of trapping opportunities	▪ There is trapping identified in the southern portion of the RSA in the Garrison Petawawa property and two trapline areas in the western portion of the RSA. ▪ While terrestrial effects are limited to the CRL site, which is restricted access, CNL will work to consult with the trappers to understand any remaining concerns.	Secondary
Post-closure (post-institutional control)	Outdoor Tourism and Recreation (i.e., fishing, hunting, trapping and non-consumptive tourism and recreation).	Changes in access to or the quality and quantity of outdoor tourism and recreation activities.	▪ Environmental monitoring will be completed as required during the institutional control period for the NSDF Project to confirm that the final cover is functioning as intended.	Secondary

Table 5.9.5-1: Pathways Analysis for the Land and Resource Use Valued Components

Project Activity	Valued Component	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Construction	Archaeological Sites	Ground disturbance from the NSDF Project during construction may cause disturbance or destruction to archaeological sites.	■ Implementation of CNL's Archaeological Master Plan and CRM Program. ■ Should previously undocumented archaeological resources be discovered, CNL will suspend construction immediately and will engage a licensed consultant to carry out archaeological fieldwork, in compliance with Sec. 48 (1) of the Ontario Heritage Act. ■ If any human remains are identified during construction, CNL will immediately notify the police or coroner, and the Registrar of Cemeteries, MTCS, and applicable Indigenous communities or organizations.	No Linkage

RSA = regional study area; CNL = Canadian Nuclear Laboratories; CRM = Cultural Resource Management; CFB = Canadian Forces Base.

5.9.5.2.1 No Linkage Pathways

An interaction may have no linkage to environmental effects if the activity does not occur, or if the interaction is removed by mitigation so that the NSDF Project results in no detectable change in measurement endpoints, and subsequently, no residual effect to land and resource use VCs. The following pathways are anticipated to have no linkage to residual effects to land and resource use VCs, and will not be carried through the residual effects assessment.

- **Change in access to or availability of tenured land use opportunities and other registered interests**
- **Changes in access to or quality and quantity of outdoor tourism and recreation activities (except trapping)**

Although the engagement activities have identified concerns from stakeholders and Indigenous Peoples extending beyond the RSA (Table 5.9.1-1), there is no evidence to suggest that there is potential for the terrestrial environment to be adversely affected by the NSDF Project outside of the CRL site (which encompasses the LSA), as discussed Section 5.6. Further, the RSA overlaps a small portion of the Ottawa River; however, results of the surface water quality assessment identifies no residual effect as there are no measurable concentrations of indicator compounds predicted in the Ottawa River. Therefore, no pathway to affect outdoor tourism/recreation activities or uses of the Ottawa River are identified as a result of the NSDF Project. No biophysical effects are expected beyond the CRL site from project-environment interactions with the atmospheric environment and groundwater. This is reflective of the design of the NSDF Project, which includes multiple barriers of protection against effects on the environment.

Beyond the RSA, a transportation route may affect the experience of recreation users via nuisance effects due to increased truck traffic. Section 5.10.5.2.2 provides a qualitative assessment of noise effects including the transportation route. This assessment determined that the effect of increased traffic on noise levels is considered

to be a slight but discernible change when compared to existing levels of traffic from current employees and operations at CRL. Transportation of site preparation and construction equipment, and construction materials will be scheduled to reduce noise and traffic volumes and limit inconvenience to local residents. As such, this potential project-environment interaction is considered to have a negligible residual effect on quality of life and subsequently not predicted to affect land and resource use.

The health and safety of tenure holders and recreational and tourism land users (except trappers) to actively participate in commercial and recreational land use activities and resource harvesting is not predicted to be affected outside of the CRL site. Further, access to these land use areas and the quality or quantity of these land use areas are not predicted to be affected outside the CRL site, as described below.

The LSA is located entirely within restricted federal lands (i.e., the CRL site). Aside from the operations and activities undertaken by CNL, other land uses of the CRL site are prohibited due to restricted public access. Tenured, registered and outdoor tourism and recreation land uses within the terrestrial and aquatic areas potentially affected by the NSDF Project do not currently exist, in order to protect land users from existing activities in the SSA. The Comprehensive Preliminary Decommissioning Plan (CPDP) for the CRL site recognizes that the CRL site will be maintained under institutional control for at least 300 years. Where the continued land use designation of the LSA during post-closure is as a monitored site with restricted assess, the presence of the NSDF will continue to be aligned, with no pathway to affect other land uses within the SSA.

With respect to changes in access to, or availability of, tenured land use opportunities and other registered interests, although the NSDF Project overlaps the Ottawa Valley Forest FMU, the RSA does not overlap any active agreement forest areas. Moreover, there are no active mine sites, active mining claims, active dispositions or active withdraws in the RSA, nor is there any permitted agricultural use. Consequently, there are no mining, aggregate, or agricultural activities occurring within the RSA that have the potential to be disturbed.

With respect to outdoor tourism and recreation, there are no municipal, provincial or national parks or conservation reserves, Areas of Natural and Scientific Interest or natural heritage systems or tourism establishment areas located within the land and resource use RSA where users' access will be reduced, or where users will face disturbances that could be perceived to reduce the quality of tourism or recreational opportunities. The SSA is comprised of federal lands intended for nuclear-related activities and is not subject to municipal land use plan designations; therefore, there are no predicted NSDF Project effects related to land use planning.

Although the NSDF Project overlaps large FMZ, WMU, trapline and baitfish harvest areas where hunting, trapping and fishing take place, the LSA is located within federal lands with restricted use, where consumptive and non-commercial land and resource use (i.e., outdoor tourism and recreational activities) is prohibited.
The NSDF Project will have no interaction with recreational activities (e.g., boating) taking place on the adjacent Ottawa River, as the NSDF Project will occur within a restricted area. However, the NSDF Project is not predicted to have any terrestrial effects beyond the CRL site, and results of the aquatic environment assessment identify that measurable residual effects on aquatic biodiversity VCs are not predicted as a result of the NSDF Project. Therefore, no effects on land users are expected.

Overall, there are no anticipated residual effects on continued land and resource opportunities. No further assessment or characterization of residual effects is undertaken for the land and resource use VCs.

However, in order to address stakeholder and Indigenous Peoples concerns with regards to perceived risks on the safety and quality of lands and waters currently used for commercial and recreational land and resource use activities, considerations for monitoring and follow-up programs are provided in Section 5.9.6.

- **Ground disturbance from the NSDF Project during construction may cause disturbance or destruction to archaeological sites.**

There are no effects anticipated to archaeological resources as most mitigation for archaeological resources are applied and completed in advance of ground disturbance activities. Further, based on the archaeological assessments completed to date, potential archaeological sites within the SSA have been fully excavated and documented to the extent required under the Standards and Guidelines (OMTC 2011). No cultural heritage value or interest remains and the locations have been fully documented and the information is preserved for future study; therefore, no further archaeological work was recommended for the NSDF Project.

In 2008, CNL developed an Archaeological Master Plan that resulted in a formal CRM Program at CNL. The CRM Program includes an archaeological potential model which assists in locating areas of archaeological potential and a robust cultural resource inventory of heritage sites. To date, the CRM Program at CRL has identified over 50 heritage sites that are registered with the MTCS, within the CRL site. There are six archaeological sites previously recorded within 1 km of SSA, but none are located directly within the NSDF CRL site.

The CRM Program will be used to identify unanticipated archaeological resources and implement adaptive management. The archaeological assessment was submitted to the Minister of Tourism, Culture and Sport as a condition of licensing in accordance with the *Ontario Heritage Act*. Should previously undocumented archaeological resources be discovered, CNL will suspend construction immediately and will engage a licensed consultant to carry out archaeological fieldwork, in compliance with Sec. 48 (1) of the *Ontario Heritage Act*. If any human remains are identified during construction, CNL will immediately notify the police or coroner and the Registrar of Cemeteries, Ministry of Small Business and Consumer Services and Indigenous Peoples. Consequently, this pathway was identified as having no linkage to effects on archaeological resources and is not evaluated further in this assessment.

5.9.5.2.2 Secondary Pathways

Two secondary pathways were identified as having a linkage to the Outdoor Tourism and Recreation VC. These secondary pathways have been identified for changes in access to or quality and quantity of trapping opportunities for land and resource users.

- **Changes in access to or quality and quantity of trapping opportunities**

The results of research identified that there may be a very limited amount of trapping occurring on Garrison Petawawa property. A portion of the RSA extends in to the Garrison Petawawa property and trapline PE002 is located on the Garrison Petawawa property (see Figure 5.9.4-1). Also, two trapline areas (PE025 and PE024) are located in the western portion of the RSA. However, the NSDF Project is not predicted to have any terrestrial effects beyond the CRL site and results of the aquatic biodiversity assessment identified only negligible residual effects on aquatic biodiversity VCs as a result of the NSDF Project. Further, there is a substantial amount of Crown and private land available for trapping outside the CRL site, but in the vicinity of the NSDF Project.

CNL will work with Garrison Petawawa to consult with trappers about their use of the Garrison Petawawa property for trapping activities. CNL will also consult with trappers in the western portion of the RSA to understand

any concerns; however, given the distance from the NSDF Project and that terrestrial effects are limited to the CRL site, no effects to trapping in these areas are anticipated.

No further assessment or characterization of residual effects is undertaken for this VC.

One pathway was identified as having a linkage to the Outdoor Tourism and Recreation VC related to hunting, trapping, fishing and some forms of non-consumptive tourism and recreation during the post-closure (post-institutional control). This secondary pathway has been identified for changes in access to or quality and quantity of these outdoor tourism and recreation activities.

- **Changes in access to in access to or quality and quantity of outdoor tourism and recreation activities**

There are no outdoor tourism and recreation activities occurring presently in either the SSA or LSA, as this is a restricted access area. This restricted access will be maintained until the end of institutional control, after which access within these areas may be re-established. Outdoor tourism and recreation activities likely did occur within the LSA and SSA prior to federal control of the CRL site and may again occur post-institutional control. This represents a potential beneficial change to access for outdoor tourism and recreation activities including hunting, trapping and fishing with access to any resources that may occur at that time. However, given the limited areas of the LSA (226 ha) or SSA (37 ha) that may become accessible, this is anticipated to represent a negligible change to the total area within which outdoor tourism is practiced. Access to fishing areas on the Ottawa River will not be restricted due to the NSDF Project during any project phase.

Quality and quantity of hunting, trapping and fishing consider the health and well-being of users, as well as ecological health. The effect of radiological and non-radiological releases on terrestrial and aquatic biota during the post-closure phase is assessed in the *Post-Closure Safety Assessment* (Arcadis and Quintessa 2020b) and the Ecological Risk Assessment (Arcadis 2020a), summarized in the assessment of effects of ambient radioactivity and ecological health in Section 5.7. No significant residual effects were identified for ambient radioactivity and ecological health during the post-closure phase. As well, the *Post-Closure Safety Assessment* (Arcadis and Quintessa 2020b) models potential effects of radiological and non-radiological releases on human health, using varying scenarios. Section 5.8 reports these findings as part of the assessment of effects to human health. The peak radiological dose for the Normal Evolution Scenario is 20 times lower than the annual dose criterion. The predicted concentrations for all modelled non-radiological chemical contaminants met their respective health-based guidelines.

As no significant residual effects were identified to the health of terrestrial or aquatic biota, or to human health, no change to outdoor tourism and recreation activities during the post-closure phase is anticipated.

5.9.5.2.3 Primary Pathways

No pathways were identified as having a primary linkage to land and resource use VCs. Therefore, the assessment has concluded that no residual effects on land and resource use are anticipated as a result of the NSDF Project. As such, a residual effects analysis and assessment of significance is not required for land and resource use VCs.

5.9.6 Monitoring and Follow-up

As part of CNL's Public Information Program, CNL will continue to engage with local communities, municipalities and Indigenous Peoples, and share the results of the monitoring and follow-up programs recommended for

air quality, surface water quality and groundwater quality data through an accessible format (e.g., NSDF Project website), a recognized best practice used by projects with high levels of perceived risk that may have the potential to alter or reduce land and resource use activity without primary or secondary pathways.

The relevant monitoring and follow-up programs identified above do not directly monitor indicators for land and resource use VCs; rather, monitoring for environmental pathways (i.e., for air quality, surface water quality and groundwater quality) will be implemented to verify effects predictions for land and resource use VCs, and to promote land user comfort around the safety of the LSA, RSA and surrounding areas for land and resource use, outdoor tourism and recreation, and commercial (i.e., tenured) land use activities. Monitoring to verify effects predictions will be on-going during operations, closure and post-closure (institutional control) phases, and the need for and duration of monitoring will be reviewed based on an annual review of monitoring data. This monitoring will be integrated into the CNL Environmental Monitoring Program.

Follow-up programs for archaeological resources are anticipated to be minimal as most mitigation for archaeological resources are applied and completed in advance of ground disturbance activities. Monitoring will be used to identify unanticipated archaeological resources and apply adaptive management through the implementation of the CNL Archaeological Master Plan and Cultural Resource Management Program (AECOM 2018). Should previously undocumented archaeological resources be discovered, CNL will suspend construction immediately and will engage a licensed consultant to carry out archaeological fieldwork, in compliance with Section 48(1) of the *Ontario Heritage Act* (AECOM 2018).

5.9.7 Conclusions

Valued Components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Land and resource use VCs were selected based on the potential for the NSDF Project to interact with the features of the land and resource use environment.

Land and resource VCs selected for this assessment include:

- land and resource tenures and other registered interests (land use designations, mining and aggregates, forestry and agriculture);
- outdoor tourism and recreation (parks and protected areas, fishing, hunting, trapping, non-consumptive tourism and recreation); and
- archaeological sites.

The NSDF Project SSA and LSA are located entirely within the CRL site boundary, on federal lands. Therefore, aside from the operations and activities undertaken by CNL, other land uses of the CRL site are prohibited due to restricted public access, which will continue into institutional control. The lands of the RSA also extend into Garrison Petawawa, other federal lands with restricted public access. As such, there are limited land and resource use tenures, other registered interests, or outdoor tourism and recreational areas occurring within the RSA that have the potential to be disturbed by the NSDF Project. Land users have been identified as potentially trapping in the southern and western portions of the RSA, which overlaps the land and resource use RSA. However, the NSDF Project is not predicted to have any terrestrial effects beyond the CRL site, and results of the aquatic environment assessment identified only negligible residual effects on aquatic biodiversity VCs as a result of the NSDF Project. No pathway to affect quality of life including noise were identified to socio-economic

VCs as a result of the NSDF Project. Access to the Pointe au Baptême site along the Ottawa River will continue to occur and not be restricted because of the NSDF Project. No pathway to affect archaeological resources is identified as most mitigation for archaeological resources are applied and completed in advance of ground disturbance activities. The CRM Program will be used to identify unanticipated archaeological resources and implement adaptive management. Consequently, the NSDF Project is not predicted to have any residual effects to the land and resource VCs.

This page intentionally left blank

5.10 Socio-economic Environment

Section 5.10 of the Environmental Impact Statement (EIS) for the Canadian Nuclear Laboratories (CNL) Near Surface Disposal Facility (NSDF) Project seeks to understand and characterize the potential residual effects of the NSDF Project and previous, existing and reasonably foreseeable developments on the socio-economic environment. Potential effects on human health are described in Section 5.8 and potential effects on archaeology and cultural heritage are described in Section 5.9 Land and Resource Use. This section presents the assessment of socio-economic effects of the NSDF Project.

5.10.1 Scope of the Assessment

The socio-economic assessment follows the overall environmental assessment approach and methods described in Section 5.1 Environmental Assessment Approach. The assessment was completed following the key steps listed below.

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** for the socio-economic assessment (refer to Sections 5.10.2 Valued Components and Section 5.10.3 Assessment Boundaries). The VCs and measurement indicators used to assess Project-related changes to socio-economics are described, along with the spatial and temporal boundaries at which the assessment occurred and the assessment cases considered.
- **Step 2 – Describe the existing conditions** (refer to Section 5.10.4 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current socio-community characteristics, including non-tangible features and the “built” environment. The existing conditions provide a reference to the effects of the NSDF Project can be compared.
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 5.10.5 Project Interactions and Mitigation). Project components and/or activities with the potential to affect socio-economics are identified and mitigation developed to limit or avoid negative effects, or to maximize benefits is presented. A pathways analysis is then used to focus further assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects to socio-economics after incorporating mitigation are carried forward to Step 4 for further analysis and residual effects characterization.
- **Step 4 – Present the methods and results of the residual effects analysis** (refer to Section 5.10.6 Residual Effects Analysis). This section outlines the methods used to predict and characterize residual effects to socio-economics from primary effects pathways. The analysis results are also presented including the characterization of incremental effects from the NSDF Project, as well as cumulative effects of the NSDF Project in combination with other reasonably foreseeable developments (if applicable).

- **Step 5 – Describe the level of certainty and management of uncertainty** (refer to Section 5.10.7 Prediction Confidence and Uncertainty). This purpose of this section is to evaluate the available literature and data used for the assessment, and describe the level of certainty that can be placed on predicted residual effects. This section will also identify how the uncertainty has been managed so that the effects are not underestimated.
- **Step 6 – Classify and determine the significance of the predicted residual effects** (refer to Section 5.10.8 Residual Effects Classification and Determination of Significance). Residual effects predicted from primary pathways are classified using a common set of criteria: direction, magnitude, geographic extent, duration, reversibility, frequency and likelihood. A determination of the significance of the predicted residual effects from NSDF Project for the socio-economics VCs is made.
- **Step 7 – Identifying monitoring and follow-up** required to confirm effects predictions and address uncertainty (refer to Section 5.10.9 Monitoring and Follow-up).
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** of residual effects on socio-economics (refer to Section 5.10.10 Conclusions).

Information and areas of interest raised by the public, communities of interest, and Indigenous Peoples during engagement that influenced the scope of the socio-economic assessment are summarized in Table 5.10.1-1. Other general areas of interest and questions raised during the engagement that pertain to the socio-economics assessment (if any) are documented in CNL's Indigenous Engagement Report (CNL 2021a) and CNL's Stakeholder's Activity Reports (CNL 2017a,b, 2019).

Table 5.10.1-1: Summary of Areas of Interest Raised during Engagement Activities that Influenced the Scope of the Socio economic Assessment

Area of Interest	How the Area of Interest Was Included in the Assessment
Will consideration be given to provide jobs or buy material, such as sand that could be delivered by barge, to the closest full-time residents to the site, in Sheenboro QC?	■ Industries throughout the County of Renfrew and the Ottawa area in Ontario and the Region of Outouais in Quebec, are anticipated to supply the NSDF Project with many of the required goods and services (e.g., manufacturing, wholesale, transport). CNL will competitively procure material and services for the NSDF Project (see Section 5.10.6.2.1). ■ The construction workforce is anticipated to be sourced from firms within the County of Renfrew and the Ottawa area in Ontario and the Region of Outaouais (which includes the Municipality of Sheenboro and City of Gatineau) in Quebec. Canadian Nuclear Laboratories employment opportunities that may arise due to NSDF Project activities will be posted on the vendor portal at www.cnl.ca website (see Section 5.10.6.2.1).

5.10.2 Valued Components

Valued Components (VCs) refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Socio-economic VCs were selected based on the potential for the NSDF Project to interact with the features of the socio-economic environment. The VCs selected for assessing potential effects on socio-economic conditions are presented in Table 5.10.2-1.

Table 5.10.2-1: Valued Components for Socio economic Assessment

Valued Component	Rationale for Selection
Labour Market	▪ Local workforce and communities are interested in long-term employment opportunities that will be generated through the NSDF Project. ▪ Income generation is perceived as a Project benefit by local workforce, businesses and communities.
Economic Development	▪ The NSDF Project will contribute to local and regional economies, through direct procurement, as well as indirect investment in other business activities.
Government Finances	▪ The NSDF Project will generate incremental tax revenues for all levels of government.
Housing and Accommodations	▪ Potential in-migration of workers (and families) for the NSDF Project could increase the demand for permanent housing or temporary accommodations.
Services and Infrastructure	▪ Potential in-migration of workers (and families) for the NSDF Project could increase the demand for community services (i.e., schools, community health, protection and emergency services) and community infrastructure (i.e., water supply and traffic).
Quality of Life	▪ Project activities (i.e., changes in air quality, ambient noise, increases in traffic volume and visual disturbances) could affect worker and local public quality of life[1].
Public Safety	▪ Public safety is a concern near the NSDF Project. Hazards include transport of heavy equipment and supplies to the site and other hazards typical of industrial facilities.

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future generations. Measurement indicators represent properties of the environment and VCs that, when changed, could result in or contribute to an effect on a VC. Measurement indicators can be used to monitor the success of mitigation and management programs. The assessment endpoints and measurement indicators associated with the socio-economic assessment are outlined in Table 5.10.2-2.

[1] See Section 5.8 Human Health for assessment of effects to human health from Project-related changes in ambient radioactivity and non-radiological substances.

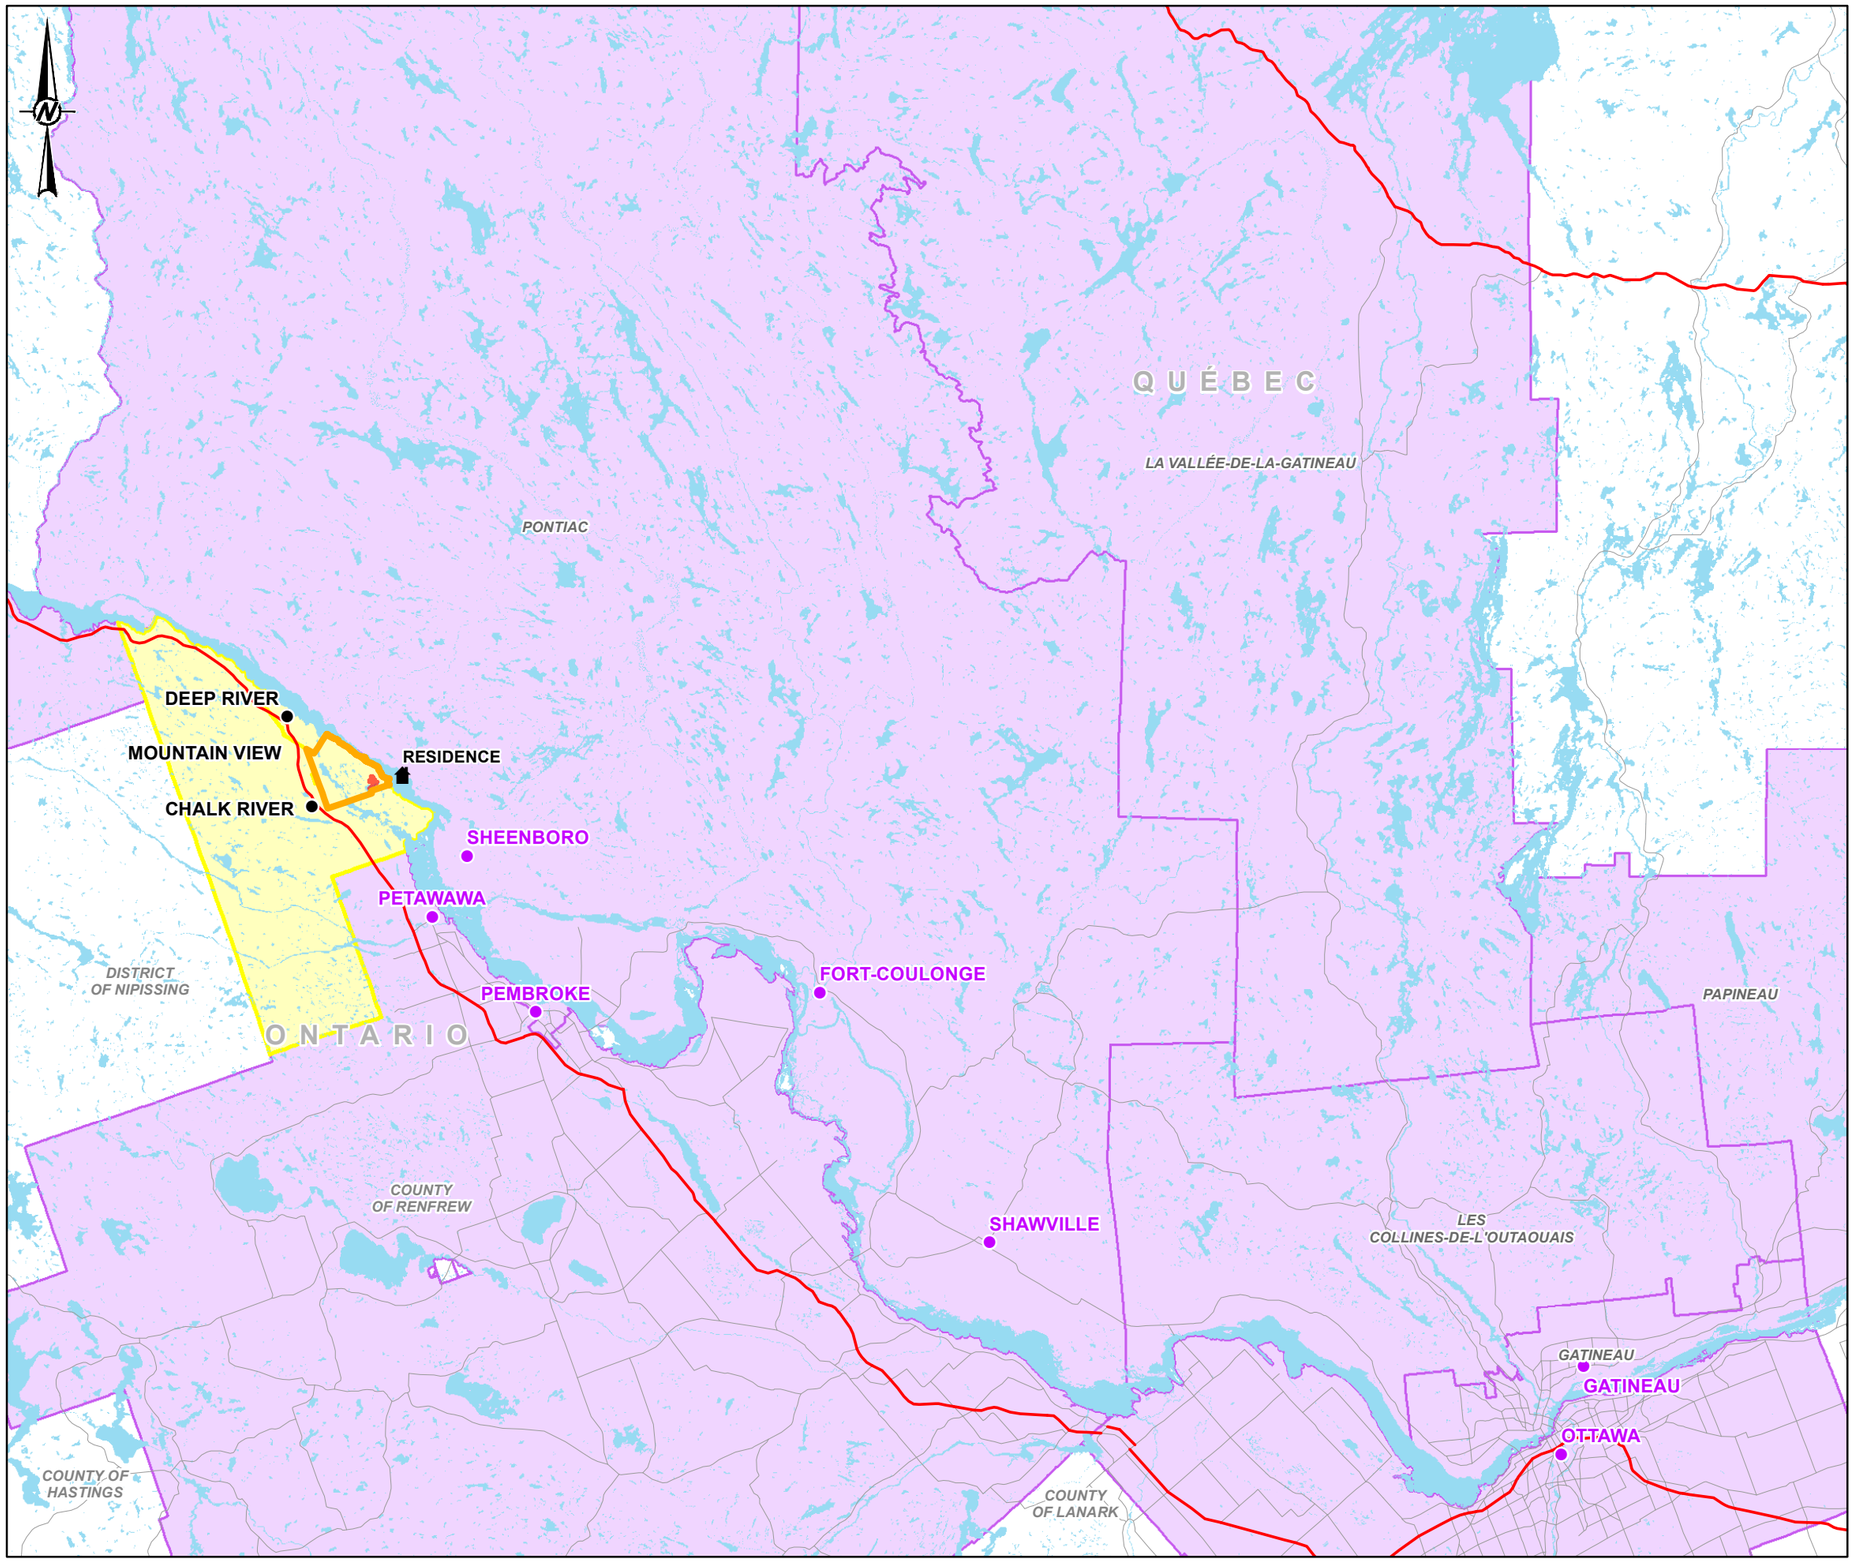
Table 5.10.2-2: Assessment Endpoints and Measurement Indicators for the Socio economic Assessment

Valued Component	Assessment Endpoints	Measurement Indicators
Labour Market	Employment opportunities and income generation	■ Direct, indirect and induced employment ■ Income generation ■ Training and skill development opportunities
Economic Development	Business and economic development opportunities	■ Direct goods and services purchased by types and number of suppliers and their location ■ Indirect supplier industry expenditures and output ■ Induced expenditures and output generated associated with household spending
Government Finances	Contribution to Government finances	■ Government revenue generation
Housing and Accommodations	Housing and accommodation availability	■ Number of residents in local communities ■ Housing demand and supply
Services and Infrastructure	Community services and infrastructure availability and access	■ Education, health, protective and emergency services demand, use and supply
Quality of Life	Contribution to quality of life	■ Quality of Life can be indirectly affected by changes in air quality, ambient noise, increases in traffic volume and visual disturbances (nuisance effects)
Public Safety	Protection of Public	■ Public exposure to physical hazards (note that chemical hazards and potential effects on human health are evaluated in Section 5.7 Ambient Radioactivity and Ecological Health, and Section 5.8 Human Health)

Assessment endpoints and associated measurement indicators for each socio-economic VC are further discussed as following.

- **Labour Market:** The assessment endpoint of continuation of employment opportunities and income generation pertains to the incremental change that the NSDF Project will have on both direct local and regional income through direct employment and purchase of goods and services. It also considers the availability of persons with the required skills to satisfy the NSDF Project's labour needs during all project phases. The assessment endpoint will be influenced by the number of direct construction and operational positions required for the NSDF Project and the average wage/salary levels of these positions. The NSDF Project will also generate employment in goods and services supply (indirect employment) and may possibly lead to a small amount of induced employment from NSDF Project workforce expenditures. Training and skill development opportunities provided by the NSDF Project to the workforce and contractors/suppliers can contribute to the local labour force and local business community's skills and capacity.
- **Economic Development:** The assessment endpoint considers incremental expenditures for procurement requirements created by the NSDF Project and implications to the existing industry and business profile in the regional and local study areas. The measurement indicators used are the types and amount of goods and services required by the NSDF Project, and opportunities provided to local businesses.

- **Government Finances:** The NSDF Project will generate taxes in the form of personal and corporate income taxes, property taxes and various consumption taxes. These fiscal benefits generated by the NSDF Project can be compared to government revenue streams. The assessment endpoint of continuation of government finances will be influenced by the tax generation associated with the NSDF Project.
- **Housing and Accommodations:** Project-related effects on availability of housing and temporary accommodation are driven by potential project-induced changes in the size of local population and population characteristics (i.e., effect of population change on housing supply and demand). New NSDF contract employees (and in some cases their families) may require access to local housing and/or temporary accommodation during the construction phase.
- **Services and Infrastructure:** Project-related effects on availability of community services and infrastructure are driven by potential project-induced changes in the size of local population and population characteristics (i.e., effect of population change on demand of community services and infrastructure). The NSDF Project's effects on services and infrastructure are linked to Project-related direct use of services during construction and operational activities (e.g., transportation network). The NSDF Project's effects are also linked to incremental demand, the available capacity to accommodate additional pressure placed on services due to population growth, the ability of these services to meet the demands of the local population and the potential requirement for additional capital investment in services and infrastructure.
- **Quality of Life:** Project-related effects on quality of life are driven by potential project-induced changes in environment (i.e., changes in air quality, ambient noise, increases in traffic volume and visual disturbances).
- **Public Safety:** The assessment endpoint for public safety addresses concerns related to hazards associated with the NSDF Project site during construction, operations, closure and post-closure activities.



5.10.3 Assessment Boundaries

5.10.3.1 Spatial Boundaries

The spatial boundaries for the socio-economic assessment are defined below. These spatial boundaries were chosen because they permit description of existing conditions in sufficient detail to enable potential VC-project interactions and effects to be identified, understood and assessed, including understanding and assessing the contribution of the NSDF Project to cumulative effects. The spatial boundaries for the socio-economic assessment are presented on Figure 5.10.3-1 and described as follows:

- **Site Study Area (SSA):** The SSA is the NSDF Project footprint (i.e., where NSDF Project activities would be undertaken, including the proposed facilities, buildings and infrastructure).
- **Local Study Area (LSA)**: The LSA is defined as the area within which there is potential for measurable changes to socio-economic VC measurement indicators resulting from the proposed NSDF Project activities. The LSA includes the closest communities to the NSDF Project, specifically the Village of Chalk River located 7 km west of the Chalk River Laboratories (CRL) site, and the Town of Deep River located 9 km northwest of the CRL site (Figure 5.10.3-1). Mountain View, a settlement within the Municipality of Laurentian Hills, lies between Chalk River and Deep River, off Highway 17. Wylie, a settlement that constitutes part of the Municipality of Laurentian Hills, is located 12 km northwest of the NSDF Project, near Mountain View. Wylie and Mountain View were not included in the assessment as data for these settlements are not available due to their small populations.

- **Regional Study Area (RSA): The RSA** is defined as the area within which the potential effects of the NSDF Project may interact with the effects of other existing or reasonably foreseeable developments. The RSA is defined to include the communities of Petawawa and Pembroke located approximately 20 km and 34 km southeast of the CRL site, respectively, as it is anticipated that workforce and business opportunities within these communities may overlap with those required for CNL's Nuclear Power Demonstration (NPD) Closure Project. It is also expected that workforce and business opportunities may be sourced from the City of Ottawa and the Province of Quebec. The RSA therefore includes the City of Ottawa and the Region of Outaouais (Quebec), which encompasses the Pontiac Regional County Municipality (closest regional municipality to the NSDF Project) and the urban centre of Gatineau. Data on Ottawa and Gatineau is included when applicable reflecting the consideration of these areas as sources of labour and materials.

5.10.3.2 Temporal Boundaries

Temporal boundaries (i.e., project phases) establish the timeframe during which NSDF Project effects are assessed. The temporal boundary represents the timeframe during which project activities are actively occurring, and does include the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a project activity or stressor (which is related to the project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the NSDF Project (e.g., residual effect lasts for thousands of years). The following phases were identified for the NSDF Project.

- **Construction phase**: This phase includes site preparation and all activities associated with the construction of the NSDF Project. This phase includes activities such as installing the necessary supporting and/or ancillary facilities and infrastructure to facilitate NSDF Project operations, inactive commissioning and systems testing, and transportation of construction materials. Construction activities are expected take place from 2022 to 2024. The construction phase will require an average of 225 full-time equivalents, with a peak workforce of approximately 300 personnel.
- **Operations phase**: This phase includes all activities associated with waste placement, water management, Wastewater Treatment Plant (WWTP) operations, vehicle movements into and from the NSDF Project site, and maintenance activities. The operations phase is expected to last approximately 50 years (i.e., 2025 to 2070) with an average labour force of 65 full-time equivalents (although this will be adjusted based on operational demand), which is expected to be drawn from the existing CRL workforce.
- **Closure phase:** This phase includes activities necessary to complete the installation of the final cover and implementation of long-term monitoring. Closure activities are expected to start in 2070 and continue through to 2100, after which the NSDF Project will transfer into the post-closure phase.
- **Post-closure phase:** The phase has two discrete periods: institutional control and post-institutional control. The institutional control period includes implementation of controls throughout 2100 to 2400 (i.e., 300 years). During institutional control, environmental monitoring will continue to demonstrate compliance with the environmental assessment conditions. Post-institutional control occurs after year 2400 and continues indefinitely.

For the purposes of the socio-economic assessment, effects during the construction phase are expected to have the greatest magnitude; as such project-related effects are assessed for the construction phase only. Effects to the socio-economic VCs during the operations, closure and post-closure phases are expected to be less than effects predicted during the construction phase of the NSDF Project.

5.10.3.3 Assessment Cases

The assessment cases considered in the socio-economic assessment are the Base Case, the Application Case and the Reasonably Foreseeable Developments Case.

- **Base Case:** This scenario represents existing conditions and characterizes effects from previous and existing developments and activities. The Base Case reflects the effects of existing infrastructure and services in the area, such as forestry, transportation, agricultural, mining, and residential and recreational development. Current effects from the existing CRL facilities and operations are considered part of the Base Case.

- **Application Case:** This scenario represents predictions of the effects of the Base Case combined with the effects that may result from the NSDF Project. The Application Case considers potential effects from the NSDF Project from the construction phase through the post-closure phase. The workforce is the largest during the construction phase, and although the operations phase is expected to last approximately 50 years the operations labor force is expected to be drawn from the existing CRL workforce. As such, the Application Case only considers the construction phase as the bounding phase for socio-economic effects of the NSDF Project.
- **Reasonably Foreseeable Developments (RFD) Case:** This scenario represents the effects of residual adverse effects of the Application case combined with other reasonably foreseeable projects in the socio-economic RSA. Reasonably foreseeable developments in the RSA that are anticipated to overlap with the NSDF Project include new/upgrades to research and development facilities, construction and operation of a small modular reactor, new support infrastructure, on-going decommissioning and environmental remediation activities on the CRL site and the NPD Closure Project. As well, there may be overlap of the construction period with limited construction at the neighbouring Garrison Petawawa. Additional details on these proposed activities are provided in Section 8.0.

5.10.4 Description of the Existing Environment

This section presents an overview of the socio-economic setting as relevant for the assessment of the NSDF Project. It describes the existing conditions (i.e., Base Case) against which potential changes from the NSDF Project are compared and evaluated.

5.10.4.1 Methods

Baseline information was collected from a range of information sources and analyzed to submit a profile for the social and economic conditions in the LSA and RSA. Baseline information was collected from the following sources:

- Statistics Canada census;
- municipal and provincial government websites;
- local service provider websites;
- regional tourism authority sources; and
- email and telephone communications with key informants (e.g., Fire Chiefs).

Existing socio-economic conditions in the LSA and RSA are described, as relevant for the assessment of potential NSDF Project effects on:

- socio-community characteristics (e.g., existing and projected population and demographic data, housing and accommodation, services and infrastructure, and quality of life);
- economic characteristics (e.g., labour market, economic development and government finances); and
- land used by businesses (e.g., existing land developments, outdoor recreation).

5.10.4.2 Results of Socio-community Characteristics

The NSDF Project is located on the CRL site in Renfrew County, approximately 12 km southeast of the Town of Deep River, 9 km northwest of the Garrison Petawawa, and 7 km east of the Village of Chalk River (Figure 5.10.31). The land is characterized by deciduous and coniferous forest and the Ottawa River, which forms the northeastern boundary of the Town of Deep River. The CRL site is located in the Allumette Lake and Lac Coulonge reach of the Ottawa River, which extends approximately 90 km between La Passe and the Des-Joachims hydroelectric dam. The distance from the centre of the NSDF Project site to the closest point on the Ottawa River shoreline is approximately 1.1 km. The following descriptions are based on the most recently available data.

The Village of Chalk River is approximately 7 km southwest across Highway 17. The village is part of the amalgamation of communities that form the Municipality of Laurentian Hills, and is connected directly to the CRL site through Plant Road off Highway 17 (County of Renfrew 2016a). The majority of the population of the Municipality of Laurentian Hills resides in the urban settlement areas of Chalk River, Rolphton and Point Alexander along the Highway 17 corridor (Laurentian Hills 2010).

The Town of Deep River is the largest community near the NSDF Project site, approximately 9 km northwest of the CRL site. Established as a company town for Atomic Energy of Canada Limited in the 1940s, Deep River is the location of the largest nuclear research facility[2] in Canada (CRPD 2017). The Town of Deep River contains the built-up town site, the CRL site and federally-owned forested lands. As the second largest employer in the County of Renfrew, behind the Garrison Petawawa, CNL provides large public-sector employment with above average wages for the area (CRPD 2017). In 2013, CRL employed approximately 2,850 people and Garrison Petawawa employed around 7,000, with base personnel becoming an important source of new residents for the community. The Pembroke Census Agglomeration (CA) is approximately 34 km southeast of the CRL site, and is the largest community and the administrative headquarters of Renfrew County. Pembroke is the largest commercial centre between Ottawa and North Bay and provides many commercial services to local area residents in the Ottawa Valley and surrounding regions (City of Pembroke 2016).

The Region of Outaouais is composed of five regional county municipalities: Gatineau, Papineau, Les Collines-de-l'Outaouais, La Vallee-de-la-Gatineau and Pontiac (Government of Quebec 2017). The largest city in the Region of Outaouais is Gatineau (Government of Quebec 2017). The Municipality of Sheenboro, in the Pontiac Regional County Municipality is the closest municipality to the NSDF Project site in the Province of Quebec. It is located approximately 16 km southeast of Chalk River across the Ottawa River. To travel by road from Chalk River to Sheenboro is approximately 80 km. Sheenboro is a small town of less than 800 citizens with primary industries of logging and farming. Sheenboro is also a popular tourist destination (Municipality of Sheenboro 2011).

[2] All licences for the operation of Chalk River Laboratories were transferred from Atomic Energy of Canada Limited to Canadian Nuclear Laboratories Ltd on November 3, 2014 (CNSC 2017).

5.10.4.2.1 Population, Demographics and Mobility

Between 2011 and 2016, the population in the Town of Deep River (4,109) had a slight decrease (2.0%) while the population in the Municipality of Laurentian Hills (2,961) increased during the same period (5.3%), as shown in Table 5.10.4-1. The Town of Deep River had an almost equal number of males and females, with 2,065 males and 2,040 females in 2016. The Municipality of Laurentian Hills had slightly more males than females, with 1,510 males and 1,450 females (Statistics Canada 2017a,b).

Deep River has a considerably older median age of 47.6 compared to the 41.3 median age of Municipality of Laurentian Hills and 40.4 median age for the province of Ontario (Statistics Canada 2017a,b). The Town of Deep River reported that most retirees remain in the town and replacement workers come from outside the community (CRPD 2017). Both communities experienced greater numbers of intraprovincial migration within the last five years, compared to interprovincial migration, which is likely due to the highly specialized workforce needed for CRL. In 2011, the Town of Deep River and the Village of Chalk River housed the two largest populations of employees from CRL (893 and 190 respectively; County of Renfrew 2011). The skilled workforce required in the nuclear industry is based predominantly in Ontario as most of Canada's nuclear reactors currently in full commercial operation, are in Ontario (NRCan 2016).

The population of Deep River has declined since 1991 when the population was 4,571 (County of Renfrew 2017). Like the aging trends seen in the County of Renfrew and the Province of Ontario, the Town of Deep River is aging as a result of the "baby boom". Between 2001 and 2011, all age categories in the town, except for the under-45 category, increased (Jp2g Consultants 2015a). The highest rate of growth in that period was seen in the 50 to 54 and 55 to 59 age ranges (16.7% and 25.7%), while the under 45 age range decreased (-7.4%).

A greater proportion of the Municipality of Laurentian Hills identified as Indigenous Peoples (13.4%) compared to the Town of Deep River (6.7%). For both communities, this is well above the provincial average (Statistics Canada 2017c). Table 5.10.4-1 presents the population and demographic characteristics of the LSA.

In the RSA, the Petawawa CA[3] had a population of 17,187 and the Pembroke CA[4] had a population of 23,269 in 2011. The population of Petawawa grew by 7.5% between 2011 and 2016. The high rate of population growth in Petawawa is due to increased personnel at Garrison Petawawa, with soldiers returning from missions abroad with the end of active combat in Afghanistan (Butler 2012; Chase 2014). The presence of a large number of military personnel and their families also provides an explanation for the lower median age of 30.8 years, which is lower than the other LSA and RSA communities, and the Province. Similarly, both interprovincial and intraprovincial migration was higher in Petawawa, as military personnel come from across the province and Canada. There is also a relatively high self-identifying Aboriginal[5] population of 8.4% living in Petawawa (Statistics Canada 2017d).

[3] The Petawawa Census Agglomeration (CA) is defined by Statistics Canada as being the Town of Petawawa, Garrison Petawawa, and surrounding areas. Data provided in this report are for the Petawawa CA.

[4] Pembroke Census Agglomeration (CA) is defined by Statistics Canada as being the City of Pembroke and surrounding regions. Data provided in this report are for the Pembroke CA.

[5] Throughout the EIS, the terms Aboriginal, Indigenous, First Nations, and Métis have been used, consistent with the source from which the term is drawn. The source of this information (Statistics Canada 2017d) uses the term Aboriginal.

Pembroke's 3.1% population decline was the third largest population decline in an Ontario urban area between 2011 and 2016 (Norris 2017). In Pembroke, intraprovincial migration was in line with trends seen in Laurentian Hills, Deep River and the Province. There are more women than men in Pembroke, which is common in RSA communities but not LSA communities. Pembroke's 11.1% Aboriginal population is much larger than the provincial average which is inline with communities across the LSA and northern areas of the RSA.

The Region of Outaouais has a population of 382,604 with a median age of 41.2, slightly below the provincial average. The population of the Region of Outaouais has grown 3.6% between 2011 and 2016, slightly above the provincial average of 3.3%. Approximately 5.5% of the population identifies as being of Aboriginal identity, higher than the average for the province which is 2.3%.

Within the Region of Outaouais, the Municipal Region County (MRC) Pontiac has a population of 14,251 and a median age of 50.4, which is higher than both the provincial average (42.5) and that of Outaouais (41.2). The population of MRC Pontiac has remained consistent between 2011 and 2016 with a slight decrease of less than 1%. The proportion of the population in MRC Pontiac identifying as being Aboriginal is approximately 18% which is significantly higher than the average for the province and the Region of Outaouais (Statistics Canada 2017i).

A 2017 paper regarding the economic landscape of MRC Pontiac noted that the area has been in decline for a number of years where youth migrate out of the area due to a lack of a post-secondary school and skilled employment opportunities and an out migration of senior citizens dues to a lack of local facilities and services to meet their needs (Pontiac Regional County Municipality 2017).

The City of Ottawa has a population of 934,243 with a median age of 40.1, slightly below the provincial average. The population of the City of Ottawa has grown 5.8% between 2011 and 2016, above the provincial average of 4.6%. Most of the population growth can be attributed to immigration with almost 32,325 migrants entering City of Ottawa between 2011 and 2016 (Statistics Canada 2017e). Approximately 2.5% of the population identifies as being of Aboriginal identity, lower than the average for Ontario of 2.8%.

Table 5.10.4-1: Population and Demographic Characteristics of the LSA, RSA and the Provinces of Ontario and Quebec

	Municipality of Laurentian Hills	Town of Deep River	Petawawa CA	Pembroke CA	City of Ottawa	Province of Ontario[(a)]	Region of Outaouais	MRC Pontiac	Province of Quebec[(a)]
Total Population 2016	2,961	4,109	17,187	23,269	934,243	13,448,494	382,604	14,251	8,164,361

(a) Data for the provinces of Ontario and Quebec are provided for comparison purposes

CA = Census Agglomeration.

5.10.4.2.2 Education

The population in the LSA are a highly educated and skilled workforce. In 2016, approximately two-fifths (39.9%) of the population of Deep River reported that they had attained a university level education or above, which was higher than the rates for the county and the Province of Ontario (10.1% and 20.9%; Statistics Canada 2017b,c). Approximately a quarter (27.3%) of the population in Deep River reported that they had attained a college or other non-university level certificate or diploma. In the Municipality of Laurentian Hills, approximately one-third (30.5%) had attained a high school certificate as their highest level of educational attainment (Statistics Canada 2017a). In comparison, 11.2% and 5.0% in the Municipality of Laurentian Hills and the Town of Deep River, respectively, had attained an apprenticeship, trades certificate or diploma (Statistics Canada 2017a,b).

In the RSA, approximately 35.2% of the population in Petawawa and 30.2% of the population in Pembroke had a high school certificate or equivalent as their highest level of education achieved. While the percentage of the population with a university degree or equivalent was lower than the provincial average, a larger percentage of people (26.4% in Petawawa CA and 26.3% in Pembroke CA) from these communities had attained a college or non-university certificate or diploma than the provincial average (18.4% in Ontario) (Statistics Canada 2017d,f).

In City of Ottawa, the rate of attaining college, CEGEP or other non-university certificates or diplomas as the highest level of education achieved is 20.0% and the rate of attaining a university certificate or diploma as the highest level of education achieved is greater than the provincial average (37.7% compared to 26.0%; Statistics Canada 2017e).

In the Region of Outaouais, the rate of attaining college, CEGEP or other non-university certificates or diplomas as the highest level of education achieved is slightly more than the provincial average (17.7% compared to 17.6%) and the rate of attaining a university certificate or diploma as the highest level of education achieved is also greater than the provincial average (21.7% compared to 20.5%; Statistics Canada 2017g). Approximately 22.5% of the population of Outaouais has their high school certificate or equivalent as their highest level of education achieved, similar to the provincial average for Quebec (21.5%). In Pontiac, the closest Regional County Municipality to the NSDF Project, 26.7% of the population have completed high school; 20.5% have completed college, CEGEP or other non-university certificate; and 14.1% have completed university at a bachelor level or above as their highest level of education achieved (Statistics Canada 2017i).

5.10.4.2.3 Land Use

The majority of land in the Town of Deep River's municipal boundary is owned by CNL, which falls under federal jurisdiction. Deep River is currently composed of a downtown core (i.e., commercial, institutional, high density residential), including:

- the marina and public waterfront;
- stable residential areas;
- the Highway 17 commercial corridor;
- large-lot estate residential;
- a large open space and parkland network (including the Four Seasons Conservancy trail system); and
- undeveloped areas to the west and east of the developed portion of the Town (Jp2g Consultants 2015a).

With the exception of existing operations and activities undertaken by CNL, other land uses of the CRL site are prohibited due to restricted public access. Limited trapping may occur along the southern portion of the RSA as described in Section 5.9 in the area surrounding the CRL site. The nearest area of notable agriculture and dairy farming is located within the RSA, 15 km southeast on the Quebec side of the Ottawa River and 35 km southeast on the Ontario side.

The Municipality of Laurentian Hills is a sparsely populated area. Outside of the village and hamlet settlement areas, most land within the municipality is rural land (Laurentian Hills 2010). With a population density of 4.6 people per km^2, the majority of residents in the municipality reside along the Highway 17 corridor and along the shoreline of the Ottawa River (Statistics Canada 2017a; Laurentian Hills 2010). A business park of approximately 9.7 ha of vacant lands is located at the southeast end of Chalk River (Laurentian Hills 2010).

Outdoor recreational activities in the Municipality of Laurentian Hills and the Town of Deep River include hiking, biking, snowmobiling and skiing trails as well as swimming, sport fishing and boating along the Ottawa River (Ottawa Valley 2016; Laurentian Hills 2016a). Of particular note is the 400-ha area located east of the Town of Deep River, the Four Seasons Conservation area, which is highly valued by the town's residents for outdoor recreation (Deep River 2013).

In the RSA, both the Municipality of Petawawa and the City of Pembroke are urban centres that are more densely populated than the LSA (Statistics Canada 2017a,b,d,f). The Garrison Petawawa is located in the northwest quadrant of Petawawa's central business district and provides retail services to military personnel and their families. The City of Pembroke is also a services and retail hub to nearby suburbs and communities. In the Region of Outaouais, much of the territory is used for agriculture with beef, dairy, market gardening and small berry production predominant in the region (Government of Quebec 2017). Recreational activities such as cycling and water-based activities take place in communities along the shores of the Ottawa River by residents and tourists from Ontario and Quebec (Petawawa 2016a; Pembroke 2016a; Outaouais Tourism 2017).

The MRC Pontiac is sparsely populated with a population density of 1.1 per km^2 (Statistics Canada 2017i), the majority of the population is found in the southern portion of the region. Further north the landscape is characterized by large open spaces with a number of lakes and rivers. There are few access roads with the main access to the southern portion of the region being via the Chemin du Bois Franc which runs north to south. This area is utilized for outdoor pursuits. Within the region is the ZEC (zone d'exploitation contrôlée) Pontiac, which is a Controlled Exploitation Zone on provincial land managed by a non-profit organization and offers services related to the practice of forest recreations such as fishing, hunting and camping (ZEC Pontiac 2020). The town of Campbell's Bay is the County seat and features a small number of community resources such as shops, churches, recreation facilities and schools.

5.10.4.2.4 Labour Market

The two largest employers within the vicinity of the NSDF Project are Garrison Petawawa and CNL (CRPD 2017). Garrison Petawawa is located in the RSA near the Town of Petawawa and employs nearly 7,000 military and civilian personnel (CRPD 2017). Chalk River Laboratories (i.e., CNL, as operator for the Atomic Energy of Canada Limited's) is the second largest employer in the region. As of May 2019, CRL employed approximately 2,850 employees. In addition, some of the historically larger employers in the region such as the Government of Canada's Petawawa Research Forest, located east of Chalk River between CRL and Garrison Petawawa, have ramped down operations and employment in the region (Forest Research Partnership 2016).

Between 2011 and 2016, the Municipality of Laurentian Hills's unemployment rate increased from 2.6% to 7.3% (Table 5.10.4-2). While this is a large change, it is likely a market correction as the 2016 rate of unemployment is aligned with the Ontario average (Statistics Canada 2017a,c). During the same period, the Town of Deep River's unemployment rate increased slightly (from 5.2% in 2011 to 5.9% in 2016). Based on the most recent data available, the Town of Deep River has a low unemployment rate (5.9%) while the Municipality of Laurentian Hills has a typical unemployment rate (7.3%) compared to the County of Renfrew (7.3%) and the Province of Ontario (7.4%; Statistics Canada 2017a,b,c,j). While the LSA communities' participation rates were slightly lower than the provincial rate, this is likely due to the higher median ages found in the LSA communities, which indicates a larger percentage of retirees present.

Table 5.10.4-2: Select Labour Market Characteristics (2016)

Community	Population Age 15 and Over	In the Labour Force	Employed	Unemployed	Participation Rate (%)	Unemployment Rate (%)
Municipality of Laurentian Hills	2,435	1,505	1,400	110	61.6	7.3
Town of Deep River	3,395	1,865	1,755	110	54.9	5.9
Petawawa CA	12,520	9,285	8,875	405	74.2	4.4
Pembroke CA	18,960	11,120	10,315	810	58.6	7.3
County of Renfrew	82,830	51,230	47,510	3,715	61.1	7.3
City of Ottawa	761,420	513,655	476,540	37,120	67.5	7.2
Province of Ontario[(a)]	11,038,440	7,141,675	6,612,150	529,525	64.7	7.4
Region of Outaouais	309,055	203,860	189,605	14,255	66.0	7.0
MRC Pontiac	11,985	6,295	5,630	660	52.5	10.5
Province of Quebec[(a)]	6,634,280	4,255,500	3,949,325	306,170	64.1	7.2

Source: Statistics Canada 2017a,b,c,d,e,f,h,I,i,j.

(a) Data for the provinces of Ontario and Quebec are provided for comparison purposes.

CA = Census Agglomeration

An economic overview for Deep River found that in 2014, a large proportion (41% or 1,061 out of 2,574 jobs) of the town's employment base was in the professional, scientific and technical services industry, followed by retail, accommodations and food services, and health care and social assistance (Jp2g Consultants 2015a). While the highest growth is anticipated in the service industries, growth in the professional, scientific and technical industries is largely linked to the operations of CNL, its contractors and other businesses that provide services directly to the company. The Town of Deep River strategized that diversification of this industry to other sources of businesses will benefit the local economy and make it more resilient in the event of organizational and operational changes at CNL (Jp2g Consultants 2015a). This is relatively aligned with the current occupations of Deep River's labour force where 32% of the labour force is employed in the professional, scientific or technical service sector (Statistics Canada 2017b).

There is a very limited number of construction firms in the Town of Deep River and Municipality of Laurentian Hills. In 2014, only 38 out of 2,574 jobs (1.5%) in Deep River were in the construction industry (Jp2g Consultants 2015a). The labour force in Deep River and Laurentian Hills also does not contain many construction workers with only 2.4% and 6% of community members employed in construction respectively (Statistics Canada 2017a,b). This is well below the Ontario provincial average of 6.7% (Statistics Canada 2017c). The few construction companies that do operate in the LSA communities focus primarily on home renovation (Yellow Pages 2016a,b).

In Petawawa, the labour force participation rate is higher (74.2%) than the provincial average and the unemployment rate (4.4%) is lower than the provincial average (Statistics Canada 2017c,d). The Garrison Petawawa employees and the population employed through the demand for goods and services spurred by the base, account for high employment levels and low number of job seekers in the community (Statistics Canada 2017d). Pembroke's labour force participation and unemployment indicators (58.6% and 7.3%%) more closely resemble a larger more diversified economy and are similar to those of Renfrew County (61.1% and 7.3%) and the Province of Ontario (64.7% and 7.4%; Statistics Canada 2017c,f,j). Approximately 9% of the available labour force in Pembroke is employed in the construction industry. This is slightly higher than the Ontario provincial average of 6.7% (Statistics Canada 2017c,f). There are 53 construction firms listed in Pembroke Ontario, and include contractors specialized in excavation, industrial buildings and project management (Yellow Pages 2016c). The 2015 Renfrew County labour market planning report identifies that construction is one of the five top industries of growth and identifies that there are 81 registered heavy construction and civil engineering firms in the county. The report also identifies that the number one industry for job seekers to find employment in is the construction industry, followed by retail and customer services/information jobs (Workforce Planning Ontario 2015). This report also identifies speciality trade contractors as the highest absolute employment growth sector between 2013 and 2014 (Workforce Planning Ontario 2015). Many of the speciality trade contractors operate small to medium sized businesses with one large business identified (Workforce Planning Ontario 2015).

In the Region of Outaouais, the labour force participation rate of 66.0% is 1.3% higher than the Ontario provincial average of 64.7%. The unemployment rate is also 0.4% lower than the provincial average of 7.4% in the Region of Outaouais at 7.0% (Statistics Canada 2017g). Public administration employs approximately 21.5% of the workers in the Region of Outaouais and represents the most prevalent form of employment. The employment in public service is well above the provincial rate of 5.8%. Manufacturing accounts for approximately 3.5% of the jobs in the Region of Outaouais which is below the Ontario provincial average of 9.6%. In all other listed industries, the Region of Outaouais is within 3% of the provincial average (Statistics Canada 2017g). Approximately 8.0% of the workforce is employed in the construction sector with 263 building contractors listed within the region (Statistics Canada 2017g; Yellow Pages 2017a).

In the MRC Pontiac, the labour force participation rate is 52.5% which is lower than the average for the province of Quebec (64.1%). The unemployment rate of 10.5% is higher than the provincial average of 7.2%. *Trades, transport and equipment operators and related occupations* is the most common occupation category for the municipality (22.3%) followed by *sales and service occupations* (21.3%) (Statistics Canada 2017i).

In the City of Ottawa, the labour force participation rate of 67.5% is 2.8% higher than the Ontario provincial average of 64.7%. The unemployment rate is also 0.2% lower than the provincial average of 7.4% in the City of Ottawa at 7.2% (Statistics Canada 2017e). Approximately 4.5% of the workforce is employed in the construction sector with 92 building contractors listed within the region (Statistics Canada 2017e; Yellow Pages 2017b).

5.10.4.2.5 Income

Table 5.10.4-3 presents the selected individual and family incomes by income source in the Municipality of Laurentian Hills, the Town of Deep River, Petawawa CA, Pembroke CA, the County of Renfrew and the Province of Ontario in 2015. Median income, average income and median family income in both LSA communities were higher than the Pembroke, County of Renfrew and Province of Ontario (Table 5.10.4-3). The Town of Deep River in particular had a median income ($48,717) that was approximately $15,000 above the provincial median income (Statistics Canada 2017b); this is most likely due to the number of residents who are employed at CRL, or who are retired and in receipt of a company pension. Similarly, Petawawa's high median income is due to a large portion of the population being employed by the military.

The median income in the Region of Outaouais is approximately $4,000 higher than the median income for Quebec. Those who live in the Region of Outaouais also capture approximately 2% more of their income through employment. The Region of Outaouais' higher than provincial average income is likely due to the high proportion of the population in the public administration sector (Government of Quebec 2017). The City of Ottawa had a median income roughly $8,000 higher than the provincial average.

Within the MRC Pontiac, the median income in 2016 was $26,490, which was lower than the provincial average of $32,975. The proportion of residents who receive their income through employment is lower compared to the rest of Quebec (59% compared to 68.4%), consequently the number of people receiving government transfers is higher (24.2% compared to 15.5%) (Statistics Canada 2017i).

Table 5.10.4-3: Selected Individual and Family Income by Income Source (2015)

	Municipality of Laurentian Hills	Town of Deep River	Petawawa CA	Pembroke CA	County of Renfrew	City of Ottawa	Province of Ontario[b]	Region of Outaouais	MRC Pontiac	Province of Quebec[b]
Median Income ($)	44,160	48,717	50,371	32,161	34,237	41,857	33,539	37,195	26,490	32,975
Average Income ($)	48,306	56,009	49,420	41,744	42,424	54,605	47,915	44,868	35,665	42,546
Market Income[a]	88.7%	90.4%	91.8%	83.6%	84.7%	91.4%	88.9%	85.9%	75.8%	84.4%
Employment Income	67.5%	65.2%	81.4%	66.8%	67.4%	72.8%	72.9%	70.3%	59%	68.4%
Government Transfer Payments	11.4%	9.8%	8.1%	16.4%	15.3%	8.6%	11.1%	14.1%	24.2%	15.6%
Median Household Income ($)	79,411	90,321	86,048	61,511	67,421	85,981	74,287	67,230	50,567	59,822

Source: Statistics Canada 2017a,b,c,d,e,g,h,i,j.

a) Market income is the sum of employment income (wages, salaries and commissions, net self-employment income from farm or non-farm unincorporated business and/or professional practice), investment income, private retirement income (retirement pensions, superannuation and annuities, including those from registered retirement savings plans [RRSPs] and registered retirement income funds [RRIFs]) and other money income from market sources during the reference period. It is equivalent to total income minus government transfers. It is also referred to as income before transfers and taxes.

(b) Data for the provinces of Ontario and Quebec are provided for comparison purposes.

CA = Census agglomeration.

5.10.4.2.6 Economic Development

Future economic growth and development opportunities are a key concern for the communities in the LSA and RSA. For instance, the Town of Deep River has identified that they are concerned with the changing demographics (fewer young people and families and a growing senior population) and the perceived difficulty in retaining young people and young families within the community (Jp2g Consultants 2015a). A Strengths-Weaknesses-Opportunities-Threats analysis completed for the Town of Deep River also identified a need to diversify the local economy to reduce dependence on a single employer (Jp2g Consultants 2015a).

Deep River's Strategic Plan aims to promote economic development and in-migration of newcomers to the community through attracting business and people to the community (Deep River 2019). The Town of Deep River established an economic development advisory committee in 2015 with the aim of having an annual economic development forum to bring local business leaders together to attract investment and retain business. In addition, Deep River revised its Official Plan in 2017 to identify new employment lands, set appropriate targets to increase ratio of jobs per population and establish growth plan targets for the community.

The town has developed a population growth target that would see approximately 10% more employees from CNL and Garrison Petawawa living in Deep River by 2036 through employment growth and attracting a higher proportion of existing employees (Jp2g Consultants 2015a). Three strategies for economic development that have been proposed in Deep River are using the community's natural assets to promote sustainable tourism, diversifying the housing stock and developing long-term care services for the elderly (Jp2g Consultants 2015b, 2016).

Similarly, the Municipality of Laurentian Hills are also pursuing economic development opportunities to encourage positive population growth rates than can be achieved by "a significant change in the economic circumstances of the Municipality leading to in-migration" (Laurentian Hills 2010). The municipality has established the Chalk River Business Park where approximately 9.7 ha of land is available for new business and industrial development.

In Petawawa, the military is still driving investment and growth in the economy. The community has, however, identified a need to diversify its economy and attract non-military driven economic development opportunities and have zoned land for industrial and commercial developments (Petawawa 2016b). In 2015, the Government of Canada committed $20 million dollars as investment for Garrison Petawawa to improve infrastructure, including roads and military housing at the Petawawa base, and to help create local jobs in the community of Petawawa (Government of Canada 2015).

The largest sectors operating in Pembroke include health care, retail and manufacturing (including wood product manufacturing). The community is also actively encouraging the growth of new business opportunities and has established an economic development strategy and advisory committee that aims to expand and retain industrial and small business ventures. Several parcels of land have been slated for commercial opportunities, including two business parks (Pembroke 2016b).

The economy of the Region of Outaouais is predominantly based on tourism, forestry, agri-food and government administration (Government of Canada 2014). In the early 1990s, an economic diversification process was initiated which has resulted in the development of the information technology and agri-food sectors (Government of Quebec 2017). The information technology niche that has expanded most over the years has been software engineering (Government of Quebec 2017).

The MRC Pontiac published their strategic plan in 2010 that outlines five key sectors for development and growth: tourism, social, cultural and community, business and industry, forestry and natural environments, agriculture and agri-foods (Pontiac Regional County Municipality 2010). This document identifies tourism as the “cornerstone of economic development”. A survey with Pontiac business owners in 2017 identified that Pontiac businesses and private and public organizations mainly come from the retail trade (14.4%), agriculture, forestry, fishing and hunting (11.8%), and accommodation and food services (9.9%) sectors (Zins Beauchesne et Associés 2017).

5.10.4.2.7 Government Finances

Tax revenues reflect the economic vitality of a community, in terms of business activity, local incomes and property values. Tax expenditures help identify key areas of public service and community need. Recent municipal revenues and expenditures in the LSA are presented in Table 5.10.4-4. The NSDF Project will be located on land owned by Atomic Energy of Canada Limited, a federal Crown corporation. As the land is Crown property, the company makes payments in lieu of taxes to local governments (Government of Canada 2016). Top revenue sources for the communities in the LSA include municipal and property taxation and user charges. Top expenditures were most often related to protection services and environmental services (Table 5.10.4-4). Table 5.10.4-4 presents municipal government expenditures and revenues for LSA and RSA communities in Ontario and Quebec. Information on Sheenboro is presented as it is the closest municipality to the NSDF Project in the Province of Quebec.

Table 5.10.4-4: Government Expenditures and Revenues in the Local Study Area (Years)

Community (Year)	Total Expenditures ($)	Top Expenditure ($)	Total Revenue ($)	Top Revenue Source ($)	End of Year Financial Position[a,b] ($)
Town of Deep River (2013)	10,389,500	Protection Services, Environmental Services, Recreation and Cultural Services	9,343,330	Taxation, user charges, government transfers	▪ Annual Deficit = (1,046,170) ▪ Accumulated Surplus = 21,945,004
Municipality of Laurentian Hills (2014)	3,663,244	Environmental Services, Transportation Services, Protection Services	4,340,609	Property taxes, governments transfers, sewer and water service charges	▪ Annual Surplus = 677,365 ▪ Accumulated Surplus = 10,036,152
Municipality of Petawawa (2014)	18,133,789	Environmental Services, Recreation and Cultural Services, Protection Services	20,533,756	User charges, payments in lieu of taxes, Property taxation, Gas Tax Funding	▪ Annual Surplus = 2,399,967 ▪ Accumulated Surplus = 84,701,438
City of Pembroke (2013)	33,825,939	Protection Services, Environmental Services, Transportation Services, Recreational Services	35,456,823	Taxation and Payments in Lieu, User Charges, Government Transfers	▪ Annual Surplus = 1,630,884 ▪ Accumulated Surplus = 102,919,067
Municipality of Sheenboro (2014)[c]	693,866	Transportation Services, General Administration, Public Security	687,768	Taxation and Grants	▪ Annual Deficit = (6,098) ▪ Accumulated Surplus = 1,629,602

Source: Deep River (2014), Laurentian Hills (2015).

(a) Annual Surplus/Deficit is the difference between Annual Revenue and Expenditures for a given financial year.

(b) Accumulated Surplus/Accumulated Deficit refers to the municipalities overall financial position at the end of the fiscal year.

(c) No taxation records available for the Region of Outaouais, the closest community is being used as a proxy.

5.10.4.2.8 Housing and Accommodations

In the Town of Deep River, there is a relative shortage of medium to high density housing, with single detached homes comprising most of the housing in the town (CRPD 2017; Jp2g Consultants 2015a). The town has identified a need for more varied and smaller housing forms. In 2016, of the 1,825 total private dwellings, 76% were single detached houses, 12% were semi-detached houses, and 12% were units in apartment buildings (Statistics Canada 2017b). The town strategized that broadening the types of tenure and housing available to residents will make the community more attractive to live in. The vacancy rate, as reported by local real estate agents, is reported to be very close to zero (Town of Deep River 2015).

Similarly, most of the housing in the Municipality of Laurentian Hills is also single-detached homes. In 2016, 92% of the 1,190 private dwellings in the municipality were single-detached- homes (Statistics Canada 2017a). Other housing available in the town are 10 semi-detached houses, five row houses, 50 mobile homes and 30 units in an apartment building.

Approximately 70% of the 6,335 houses in Petawawa are single-detached homes. The remaining homes include semi-detached houses (6.8%), row houses (13.8%) and low-rise apartment buildings (8.8%) (Statistics Canada 2017d). In Pembroke, 71.8% of the almost 10,000 housing units in the community are single detached houses. Low storey apartment buildings account for about 16.7% of all available stock, with the rest being made up of semi-detached and row houses (Statistics Canada 2017f). In the Region of Outaouais, approximately 52.4% of the occupied private dwellings are single detached houses (Statistics Canada 2017g). Remaining homes include apartment dwellings (22.2%), movable dwellings (0.3%), semi-detached houses (11%) and row houses (4.5%; Statistics Canada 2017g). In the MRC Pontiac there are 6,205 homes, 88.2% of which are single-detached homes while 2.7% are semi detached houses, 1% are row homes and the remaining houses are low storey apartments or duplexes and mobile homes (Statistics Canada 2017i).

Hotel accommodations are available in the Town of Deep River. There is one hotel and five motels in the Town of Deep River, and there are no hotels in the Municipality of Laurentian Hills (Laurentian Hills 2016b). Ten motels are available for temporary accommodation in Petawawa (Hotel Guides 2016). In the City of Pembroke and the surrounding area, there are approximately 39 temporary accommodations available (Expedia 2016). Hotel accommodations are available at 236 locations in the Region of Outaouais (Expedia 2017).

5.10.4.2.9 Services and Infrastructure

Traffic and Transportation

The major arterial Highway that connects the NSDF Project to the LSA communities and other regions of Ontario is Highway 17. Highway 17 is the longest highway in Ontario, spanning 1,964 km in a southeasterly direction from Kenora to Arnprior, Ontario. In 2016, annual average daily traffic counts found that traffic levels between the Village of Chalk River and Deep River were 7,950 vehicles per day (MTO 2016). Traffic volumes further south along Highway 17 around Petawawa and Pembroke ranged from 7,300 to 8,750 vehicles per day (MTO 2016). Traffic volumes increase beyond Pembroke towards Ottawa.

From Sheenboro, the primary route to the NSDF Project site is travelling along the Chemin de Chapeau Sheenboro Road, Quebec's Highway 148 and Ontario's Highway 17. The distance from Sheenboro to the NSDF Project site is approximately 85 km and is a one-hour travel with normal traffic (Google Maps 2017). Along the preferred route on Highway 17, the traffic volume ranged between 7,100 and 8,750 vehicles per day (MTO 2016). Along the preferred route on Highway 148 traffic levels ranged from 5,900 to 12,300 vehicles per day (MTO 2016). Data is not available for traffic volume on Chemin de Chapeau Sheenboro.

Existing traffic to and from the site was studied by Stantec (CNL 2017c). The morning peak hour inbound traffic was 724 vehicles while the afternoon peak hour outbound traffic was 787 vehicles (CNL 2017c). Overall, the annual average daily traffic count is calculated to be 8,210 at the existing site for eastbound and westbound traffic.

Waste and Water Management

Chalk River Laboratories has solid waste and wastewater facilities on-site that are able to process uncontaminated, contaminated and radioactive waste. On-site waste facilities include landfills for solid waste, such as office garbage and/or waste rock or fill from construction and operation activities. Chalk River Laboratories also collects food waste for disposal at an off-site composting facility. Chalk River Laboratories has on-site wastewater facilities including a septic system and a sewage treatment plant. The NSDF Project facilities also include the development of a WWTP, which will be dedicated to servicing the NSDF Project. There will be a sanitary sewage system at the NSDF Project site. The grey water and sanitary sewage will be transferred by a gravity sewer network to two septic sewage systems; one located on the north end of the site and the second located on the south end of the site.

The Town of Deep River and the Municipality of Laurentian Hills jointly operate the North Renfrew Waste Disposal Site (Baggs Road Landfill) for household waste located just outside of the CRL site. As well, the Town of Deep River operates the Miller's Road Landfill for construction and demolition waste.

Potable water for most of the population in the region is sourced from the Ottawa River. The communities of Deep River, Petawawa and Pembroke each have water treatment plants and receive their water from the Ottawa River. The Village of Chalk River receives its water from Corry Lake, an inland lake located south of Chalk River.

An estimate of the number of residents using groundwater as their source of potable water was determined from a review of database of water supply wells in the province maintained by the Ontario Ministry of the Environment and Climate Change. The review identified 1,902 water wells in the region between Rolphton and Quebec.

Emergency and Protective Services

Fire Services

Chalk River Laboratories has its own full-time fire service that is staffed 24/7 with 40 full time firefighters, up to 6 casual firefighters, and a 10-member Fire Emergency Response Group. The department delivers fire and emergency services utilising 2 pumpers, an aerial, a pumper/tanker and other ancillary vehicles and equipment. The CRL fire department is comprised of a 4-platoon rotational staffing system with 10 firefighters (two officers and eight firefighters) assigned to each platoon and it is structured to provide emergency services with a minimum of eight firefighters on duty at any given time. CRL has established a reciprocal mutual fire aid agreement with fire services in the communities nearest to the NSDF Project site. The community may be able to provide additional resources upon request if they are not committed to an emergency in their own municipality. CNL and the Town of Deep River signed a Fire Protection Service Agreement, effective as of June 1, 2018. CNL Fire Operations now provides a Fire Chief, Deputy Fire Chief, a Fire Prevention Officer, CNL Officer Firefighters, and CNL Firefighters to the Town to an annual maximum of 14,000 personnel hours. This agreement supports a return to 24/7 on-duty coverage in the Deep River fire hall.

As noted, in the LSA, the Town of Deep River and the Municipality of Laurentian Hills have their own fire departments. The Town of Deep River is comprised of a composite fire department utilising full time and volunteer firefighters (approximately 25 members) whereas the Laurentian Hills fire department is solely comprised of approximately 40 volunteer firefighters. No capacity issues such as staffing, equipment or training have been identified in the LSA (Dillon Consulting 2013).

Additionally, CRL has a formal reciprocal mutual fire aid agreement with the Garrison Petawawa fire department and is eligible to request additional firefighters and/or fire apparatus during an emergency. The Garrison Petawawa fire department may be able to provide additional resources upon request if they are not committed to an emergency in their own area.

In the RSA, the Town of Petawawa has a fire department that has two stations serving the community (Petawawa 2016c). The City of Pembroke also has a composite fire department that currently operates out of one station (Pembroke 2016c,d). Pontiac Regional County Municipality, within the Region of Outaouais, contains eighteen municipalities all offering fire services (Pontiac Regional County Municipality 2011).

Emergency Medical Services

Chalk River Laboratories does not have its own emergency medical services. The County of Renfrew Paramedic Services provides paramedic assistance to communities within the County of Renfrew. Every request for paramedic assistance dispatched through the 9-1-1 system or the Community Paramedic Referral Program is responded to by a qualified Paramedic. Of the two LSA communities, only Deep River has an ambulance base. In the RSA, there are ambulance bases in both Petawawa and Pembroke (County of Renfrew 2016b).

In 2016, the County had 133 front-line paramedics, 67 of those were full-time and 66 are part-time paramedics. There are 47 advanced care paramedics and 86 primary care paramedics. The County has a total fleet of 25 ambulances. Seven ambulance vehicles provide 24-hour coverage seven days a week and 10 ambulances provide 12-hour coverage 7 nights per week throughout the county. There is one emergency response vehicle that operates 24 hours per day, 7 days a week and 5 community paramedic response units, operating 12 hours a day, 7 days a week. The average response time for the Renfrew County emergency medical services is approximately 9 minutes.

County representatives note that a challenge they face is that that they serve a large rural county with long distances between communities. There is currently no service agreement in place between the County of Renfrew's emergency medical services and CRL. The County notes that it would be good to have improved interagency operability between different jurisdictions to improve emergency medical services capabilities.
The nearest hospital to the CRL site is the Deep River and District Hospital located in Deep River.
The Deep River and District Hospital offers emergency care, acute inpatient care, diagnostic imagery, laboratory service and physiotherapy (Deep River and District Hospital 2011a). There are sixteen beds within the hospital and one emergency care physician is on-call or on site (Deep River and District Hospital 2011b,c). The nearest full-service hospital to the NSDF Project site is the Pembroke Regional Hospital, located south of Chalk River in the Municipality of Pembroke (Pembroke Regional Hospital 2016).

Protective Services

Chalk River Laboratories has a security service which provides site access control and conventional security to the CRL site. The Deep River Police Service provides policing services to CRL for any criminal charges and/or motor vehicle accidents that happen on site. The Ontario Provincial Police are responsible for policing the Municipality of Laurentian Hills (i.e., Town of Laurentian Hill and Village of Chalk River). The Ontario Provincial Police also patrols Highway 17.

5.10.4.2.10 Quality of Life

This section presents a description of the existing conditions relating to quality of life for residents living within the LSA. For the purposes of environmental assessment, quality of life is assessed as changes in air quality, ambient noise, increases in traffic volume and visual disturbances (nuisance effects).

Baseline air quality conditions in the air emissions LSA are described in Section 5.2.1 (Air Quality). The primary source of sulphur dioxide and nitrogen oxides in the region is the combustion of fossil fuels, including from the operation of stationary sources, as well as from mobile sources such as vehicles and other equipment. Between 2009 and 2013, no exceedances of the 1-hour or 24-hour Ambient Air Quality Objectives for sulphur dioxide and nitrogen oxides were recorded at the Ottawa Downtown monitoring station[6]. Levels of 24-hour particulate matter less than 2.5 microns in diameter that can affect air quality for humans by aggravating existing lung or heart conditions, have not been exceeded at the Petawawa or Ottawa Station.

Existing traffic volumes are described in Infrastructure and Services (Section 5.10.4.2.9). In 2014, there were 107,028 motor vehicles registered in the County of Renfrew. Most accidents occurred on Highway 17, with 515 total collisions (MTO 2014). Within the county, there were higher numbers of total collisions in the more populated urban communities, with the Municipality of Petawawa having 138 collisions and City of Pembroke registering 206 collisions in 2014. The LSA communities had notably lower number of total collisions, with 10 collisions occurring in the Municipality of Laurentian Hills and 14 collisions in the Town of Deep River in 2013 (MTO 2014).

Baseline data on existing traffic levels were collected on public transportation routes (i.e., Plant Road) used to access CNL's CRL site from the Village of Chalk River as part of the NSDF Traffic Study (CNL 2017b). Existing traffic levels along Highway 17 were taken from published MTO 2016 traffic volumes presented in Section 5.10.4.2.9. To understand approximate noise impacts as a result of these traffic levels, published literature for typical traffic flows along different types of roads was used to develop assumptions. Using these assumptions, the results of *Noise Impact Study of CNL NSDF Project Construction-Related Road Traffic on Human Receptors* (Golder 2020) indicate that at the existing traffic levels, the percentage of people classified as "highly annoyed[7]" is 9.7% at a distance of 15 m from Plant Road and 24.7% at a distance of 20 m from Highway 17. The distances of 15 m and 20 m correspond to the minimum distances between the nearest identified noise-sensitive receptor and Plant Road and Highway 17, respectively. At a distance of 60 m, the percentage of people in the community classified as highly annoyed due to existing road traffic is 2.9% on Plant Road and 10.9% on Highway 17 (Golder 2020).

[6] Nitrogen oxides and sulphur dioxide monitoring was not available at the Petawawa station.

[7] High annoyance has been widely used as one way to estimate a community response to noise levels (Health Canada 2017).

5.10.4.2.11 Public Safety

The NSDF Project will be located entirely on the CRL site. The NSDF Project will follow the CRL security requirements, physical security plans, and health and safety programs. Access to the NSDF Project site is exclusively from within the CRL site boundary and access to the CRL site is strictly controlled by security personnel. Section 3.4.4.3 more fully describes access control, security management, and health and safety plans for the NSDF Project.

5.10.5 Project Interactions and Mitigation

5.10.5.1 Methods

This section describes the process by which interactions between NSDF Project components and activities and socio-economic VCs were identified and evaluated. Potential effects pathways are identified and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment. As such, this section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all stages of the NSDF Project. The next step in the analysis was the development of environmental design features and mitigation practices that could be incorporated into the NSDF Project to eliminate and/or reduce effects to socio-economic VCs. Environmental design features included design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the engineering and environmental teams, combined with input from project-specific or regional engagement with other interested parties. The design features and/or mitigation activities were selected considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effects pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments, and the effectiveness of environmental design features and mitigation.

- **No linkage:** The pathway is removed by environmental design features or mitigation such that the NSDF Project would not be expected to result in a measurable environmental change to measurement indicators identified for socio-economic VCs relative to Base Case values, and therefore would have no residual effects to socio-economic VCs.

- **Secondary pathway:** The pathway could result in a measurable minor change to measurement indicators identified for socio-economic VCs, but would have a negligible residual effect on socio-economic VCs relative to Base Case values and is not expected to contribute cumulatively to other NSDF Project effects or to the effects of other previous, existing or reasonably foreseeable developments to cause a significant direct or indirect effect.
- **Primary pathway:** The pathway is likely to result in an environmental change to measurement indicators identified for socio-economic VCs relative to the Base Case that could contribute to residual direct or indirect effects on socio-economic VCs.

Environmental design features and mitigation that have been or could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects to socio-economic VCs were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to socio-economic VCs through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. These effects can be considered either direct or indirect in nature e.g., effects on residents' quality of life may occur as a consequence of an increase in nuisance effects that may occur from increases in noise or dust as a direct result of project works. Primary pathways were carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the NSDF Project on socio-economic VCs (Section 5.10.6).

5.10.5.2 Results

The results of the pathways analysis are summarized in Table 5.10.5-1. Environmental design features and management policies implemented to reduce potential effects are also described.

Table 5.10.5-1: Pathways Analysis for Socio economic Valued Components

Project Activity	Valued Component	Effects Pathways	Project Design Features and Policies	Pathway Assessment
Employment of personnel, procurement of goods and services, and expenditures from the NSDF Project	Labour Force	▪ Direct and indirect employment requirements may affect employment and income with the local and regional study areas. ▪ The NSDF Project may provide contracting and supplier opportunities to Indigenous local and regional businesses.	▪ CNL employment opportunities that may arise due to Project activities will be posted on the vendor portal on www.cnl.ca website. ▪ CNL is working with Indigenous communities on employment and contracting opportunities.	Primary (Potential socio-economic effects are not related to a change from the Project on the environment)
	Economic Development	▪ The NSDF Project may provide contracting and supplier opportunities to local and regional businesses. ▪ The NSDF Project may provide contracting and supplier opportunities to Indigenous local and regional businesses.	▪ CNL will competitively procure material and services for the NSDF Project. ▪ CNL is working with Indigenous communities on employment and contracting opportunities.	Primary (Potential socio-economic effects are not related to a change from the Project on the environment.)
	Government Finances	The NSDF Project may contribute to government finances through the payment of property taxes.	▪ Payment of taxes.	No Linkage
Employment of personnel, use of services and infrastructure for NSDF Project	Housing and Accommodations	The NSDF Project could increase pressure on commercial accommodations.	▪ None	Primary (Potential socio-economic effects are not related to a change from the Project on the environment).
		Changes in housing demand with respect to LSA housing supply and capacity to meet demand.	▪ The construction workforce will be housed in accommodations in the Town of Deep River and the surrounding areas.	No Linkage
	Services and Infrastructure	Changes in demand for community services (health, education, protective and emergency services) with respect to the capacity of LSA services to meet the demand.	▪ Continued implementation and maintenance of compliance with all applicable health and safety standards and CNL's existing environmental, safety and security programs.	Primary (Potential socio-economic effects are not related to a change from the Project on the environment)

Table 5.10.5-1: Pathways Analysis for Socio economic Valued Components

Project Activity	Valued Component	Effects Pathways	Project Design Features and Policies	Pathway Assessment
Employment of personnel, use of services and infrastructure for NSDF Project (cont'd)	Services and Infrastructure (cont'd)	Changes in demand for community infrastructure (e.g., domestic waste management) with respect to capacity of infrastructure to meet demand.	▪ Use of existing waste management infrastructure and facilities on the CRL site where possible. Disposal of materials at appropriate licensed waste management facilities with capacity where off-site disposal of contractor construction waste is required.	Secondary (Potential indirect socio-economic effects could occur as a result of changes not related to the environment).
		The NSDF Project could increase road degradation due to increased traffic volume from the transportation of workers, supplies and equipment.	▪ Coordinate transportation of equipment and materials during construction to avoid peak traffic times to the extent possible.	Primary (Potential socio-economic effects are not related to a change from the Project on the environment)
	Quality of Life	The NSDF Project could affect air quality through the generation of emissions and fugitive dust.	▪ Implementation of CNL's procedure for Management and Monitoring of Emissions, which includes operational control monitoring and verification monitoring. ▪ Implementation of the Dust Management Plan developed for the NSDF Project, which includes appropriate management techniques to control dust generated by the NSDF Project.	Secondary (Potential indirect socio-economic effects could occur as a result of a change from the Project on the environment [i.e., dust])
		The NSDF Project could affect ambient noise levels due to construction traffic.	▪ A maximum of 40 shipments per day will occur during the nighttime period (i.e., 10 pm to 7 am).	Secondary (Potential indirect socio-economic effects could occur as a result of a change from the Project on the environment [i.e., noise])

Table 5.10.5-1: Pathways Analysis for Socio economic Valued Components

Project Activity	Valued Component	Effects Pathways	Project Design Features and Policies	Pathway Assessment
Employment of personnel, use of services and infrastructure for NSDF Project (cont'd)	Quality of Life (cont'd)	The NSDF Project could affect ambient noise levels due to blasting activities.	▪ Blasting activities will be done by a qualified person and in accordance with the Blasting Plan to be developed by the contractor, indicating the type of explosives used and the method of detonation.	Secondary (Potential indirect socio-economic effects could occur as a result of a change from the Project on the environment [i.e., noise])
		The NSDF Project could have a negative effect on visual aesthetics.	▪ The visual effect of the NSDF Project site will be limited as the line of sight will be obscured by hilly topography and the surrounding tree line.	Secondary (Potential indirect socio-economic effects could occur as a result of a change from the Project on the environment [i.e., effects to the visual landscape])
	Public Safety	Public's potential exposure to physical hazards associated with the NSDF Project.	▪ The NSDF Project will follow the CRL security requirements, physical security plans, and health and safety programs.	No Linkage

LSA = Local Study Area.

5.10.5.2.1 No Linkage Pathways

An interaction may have no linkage to environmental effects if the activity does not occur, or if the interaction is removed by mitigation so that the NSDF Project results in no detectable change in measurement endpoints, and subsequently, no residual effect to socio-economic VCs. The following pathways are anticipated to have no linkage to residual effects to socio-economic VCs, and will not be carried through the residual effects assessment in Section 5.10.6.

- **The NSDF Project may contribute to government finances through the payment of property taxes.**

As the NSDF Project will be built on CNL's existing CRL site, which is located on federal land, no additional property taxes are required. Payment in lieu of taxes will continue to be paid to the Town of Deep River. This potential project-environment interaction has therefore been assessed as resulting in no change from existing conditions.

- **Public's potential exposure to physical hazards associated with the NSDF Project.**

The NSDF Project security will follow CRL's site security requirements and physical security plans (Section 3.5.2.7). Access to the NSDF Project site is exclusively from within the CRL site boundary and access to the CRL site is strictly controlled by security personnel. In addition, a security fence will be installed around the entire perimeter of the engineered containment mound to prohibit unauthorized personal from entering, and to limit animal injury and contact during construction and waste placement operations. As well, CNL's Occupational Safety and Health Program is designed to provide for the protection of workers and public health and safety in relation to CNL activities. CNL and its contactors will meet all applicable health and safety legislative requirements. CNL has a Transportation of Dangerous Goods Program that applies to all modes of transport and all locations where CNL is responsible as the consignor (shipper), consignee (receiver), carrier or material owner of dangerous goods off-site. Section 3.5.2 describes access control, security management plans, health and safety programs, and transportation of dangerous goods for the NSDF Project. As security measures to limit access to the NSDF will be put in place, as well as safety measures to protect workers and the public, this potential Project-environment interaction has been assessed as having no linkage to residual effects to public safety.

- **Changes in housing demand with respect to LSA housing supply and capacity to meet demand.**

Residential housing in the LSA is not expected to be affected by the temporary presence of NSDF Project construction workers. NSDF Project employment during the construction phase will be temporary in nature, and filled largely by contractors from the LSA and RSA, although some may also be out of area. Temporary workers from outside of the LSA will be housed in existing accommodations and are not expected to relocate permanently to the LSA due to the temporary nature of employment. Given that no project in-migration is expected and workers will be housed in existing accommodations (e.g., hotels), an increased demand for housing is not expected. As such, this potential Project-environment interaction has therefore been assessed as having no linkage to residual effects to local housing and accommodations.

5.10.5.2.2 Secondary Pathways

In some cases, an interaction may exist, but since the change caused by the NSDF Project is anticipated to be negligible, it has no measurable or detectable effect on socio-economic VCs relative to baseline conditions. The following pathway is expected to be secondary and will not be carried through the residual effects assessment in Section 5.10.6.

- **The NSDF Project could affect air quality through the generation of emissions and fugitive dust.**

The construction and operations phases of the NSDF Project will generate non-radiological air and dust emissions such as carbon monoxide, oxides of sulphur (includes sulphur dioxide), oxides of nitrogen (includes nitrogen dioxide), particulate matter less than 2.5 microns in diameter ($PM_{2.5}$) and suspended particulate matter (SPM). Air emissions can result from the use of fossil fuels in generators, vehicles and machinery. Vehicle exhaust and fugitive dust from unpaved and paved roads is the largest contributor to particulate matter (SPM, PM_{10} and $PM_{2.5}$) during both construction and operations (see Section 5.2.1.6.2).

Mitigation measures to be implemented to limit predicted residual effects from NSDF Project emissions to air quality include meeting Tier 2[8] emission standards for on-site vehicles and equipment engines, use of vehicles that are maintained in good working order and idling of vehicles on site will be limited consistent with CNL's Environmental Protection Program. Dust control will be conducted to support waste placement operations in accordance with the *Dust Management Plan* (AECOM 2018) during loading, transportation, placement and compaction operations. Work areas that have the potential for generating dust will require implementation of dust suppression technique. The primary dust control method will include water spraying or misting techniques (e.g., water trucks). Water application is controlled to avoid generation of free liquids. Fixatives (e.g., chemical suppressant) may also be used for dust control and for use as daily ECM cover. The use of fixatives is reviewed prior to application for potential effects on leachate and surface water runoff generated by the ECM.

Predicted concentrations for the Application Case during both construction and operations phases are below applicable air quality guidelines and/or standards with the exception of nitrogen dioxide, that will not meet the 2020 1-hour CAAQS (Section 5.2.1.6.2, Table 5.2.1-14). The contributing factor to the high magnitude nitrogen dioxide emissions is the heavy-duty construction equipment and the conservative assumption that all equipment will run simultaneously and continuously during working hours. In reality, individual equipment will be idling or off for varying parts of the workday that cannot be predicted but will result in lower emissions than currently estimated. The likelihood that all equipment operates simultaneously for an hour or more along with unfavourable weather conditions to produce the maximum concentrations modelled is very low. With the implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018) and through the implementation of the *Dust Management Plan* (AECOM 2018) for the NSDF Project, the residual effects from the NSDF Project on air quality was predicted to be not significant. Consequently, this potential Project-environment interaction is considered to have a negligible residual effect on quality of life.

[8] These regulations set performance-based emission standards for air pollutants and toxic substances from new off-road diesel engines such as those typically found in construction, mining, farming, and forestry machines. Increasing Tier levels indicate stricter emission standards required at the time of manufacture.

- **The NSDF Project could affect ambient noise levels due to construction traffic.**

Noise propagation will be mitigated by the topography as the NSDF Project is situated on the lower side of the hill adjacent to East Mattawa Road (Figure 3.1.1-1 NSDF Site Layout). Changes in ambient noise levels from activities on the NSDF Project site are not expected to be detected in the LSA communities, due to the distance from the NSDF Project site (i.e., Village of Chalk River is the nearest local community and is located 7 km west of the NSDF site).

Noise-level changes often considered in an environmental assessment include noise-induced sleep disturbance, noise complaints and long-term high annoyance. For the NSDF Project, a qualitative assessment of the acoustic environment was carried out based on the separation distance between the NSDF Project site and the nearest dwelling. In accordance with the Ontario Ministry of Environment, Conservation and Parks guideline NPC 300 (MOE 2013), dwellings include permanent and/or seasonal residences. Communities in the vicinity of the NSDF Project site are shown on Figure 5.10.3-1, which includes the nearest residences on the Quebec side of the Ottawa River, approximately 3 km from the NSDF Project site. Based on this separation distance, a detailed assessment is not typically required by the Ontario Ministry of the Environment and Climate Change. In addition, based on the Health Canada guidance (Health Canada 2011), a less extensive assessment may be warranted if noise levels at all receptors are not expected to result in a change in long-term high annoyance exceeding 6.5%.

The haulage route for transportation of site preparation and construction equipment, and construction materials will be via public roads to the CRL site (e.g., Highway 17 and Plant Road). Plant Road is a two lane paved road, primarily used as a conduit for employee traffic to the CRL site as it is the only access route. As discussed in Section 5.10.4.2, CRL employs approximately 2,850 employees and there are also contractors working on-site and daily deliveries to and from the CRL site. There is a community of approximately 35 buildings on Plant Road, including both residences and businesses, between Highway 17 and the CRL site, with no other types of noise sensitive receptors (i.e., schools, hospitals). There is also traffic associated with a small municipal landfill accessed from a side road just before the CRL site.

The hours of operation for truck transport is typically 6 days per week, with 16-hour days but may vary between 12 and 18 hours per day depending on Project activities. Based on estimates of truck deliveries to the NSDF Project site during the 24-month construction period, it is anticipated there will be approximately an additional 200 shipments per day during the 9-month construction season. This represents an increase of approximately 5% to 6% (assuming each inbound trip results in an outbound trip) over existing traffic volumes on Highway 17 at Deep River. The additional construction personnel requirements are expected to result in an additional 300 inbound and outbound trips to the site daily. It is estimated that there will be 10 trucks per day during operations (i.e., less than 1 truck per hour).

In addition, it is assumed that construction workers will travel to the NSDF Project site from the local commercial accommodations using their own personal vehicles. The transport vehicles will pass through the Town of Chalk River. This level of activity is not expected to result in a change in long-term high annoyance exceeding 6.5%. Similarly, the noise levels associated with these truck movements are not expected to increase day-night noise levels (L_{dn}) above 75 dBA (the level at which noise complaints may include strong appeals to authorities to stop noise [Health Canada 2017]). Transportation of equipment and construction materials will be scheduled during normal business and daylight hours to the greatest extent possible to limit inconvenience to local residents. In addition, notifications of peak traffic periods will be distributed to local residents in the Village of Chalk River. In the noise assessment, it was assumed that up to 40 of the 200 shipments could occur during the nighttime period (i.e., 10 pm to 7 am).

Overall, the increase in transport vehicles is considered negligible in comparison to current traffic levels on the roads (personal vehicle traffic for over 2,000 employees and transport vehicles) to support operation of the CRL site. The change in long-term high annoyance is between 6.2% at 15 m and 2.3% at 60 m along Plant Road and 4.7% at 20 m and 2.7% at 60 m along Highway 17. The effect of increased traffic on noise levels at receptors along Highway 17 and Plant Road is considered to result in a small but noticeable change when compared to existing levels of traffic from current employees and operations at CRL. The predicted change in %HA is less than 6.5% and as such, this potential project-environment interaction is considered to have a negligible residual effect on quality of life. The detailed results of the noise effect study are presented in *Noise Impact Study of CNL NSDF Project Construction-Related Road Traffic on Human Receptors* (Golder 2020).

Canadian Nuclear Laboratories (CNL) is committed to organizational transparency, ensuring that Indigenous Peoples, the general public, local communities, elected and appointed government officials and other industry stakeholders are properly informed about activities carried out at CNL sites. This commitment is met through the company's Public Information Program (CNL 2021b), a communications program that was developed to build public awareness and trust, and to encourage transparent and proactive communication with its various stakeholders. CNL's Public Information Program includes specific communications to stakeholders, public access to information related to routine activities, radiological and non-radiological emissions, and non-routine items or events at the different sites managed by CNL. Accordingly, CNL will notify local communities of the start of NSDF Project construction.

CNL proactively provides information regarding business activities and environmental remediation management projects. Notification is done through email, letter and face-to-face meetings to ensure appropriate distribution of information.

- **The NSDF Project could affect ambient noise levels due to blasting activities.**

Rock blasting will be required to complete site preparation activities for the NSDF Project site. Blasting activities will be done by a qualified person and in accordance with the Blasting Plan to be developed by the contractor, indicating the type of explosives used and the method of detonation. Additional guidance for the NSDF Project blasting limits will be obtained from the Ontario Provincial Standard Specification in the document *OPSS 120 – General Specification for the Use of Explosives* (OPSS 2014). Blasting activities will follow industry standard best management practices and applicable federal regulations, including the *Explosives Act*.

Communities in the vicinity of the NSDF Project site are shown on Figure 5.10.3-1 (i.e., nearest community is the Village of Chalk River located 7 km away), which includes the nearest residences on the Quebec side of the Ottawa River, approximately 3 km from the NSDF Project site. Given this distance from the site, noise and vibrations from blasting activities are not anticipated to be noticeable to these residents. Blasting activities would be completed during the construction phase only and would be infrequent for a short period of time. In addition, blasting noise and vibrations will be mitigated by the topography as the NSDF Project site is situated on the lower side of the hill adjacent to East Mattawa Road. Overall, the infrequent and short-term blasting activities are considered to have a negligible residual effect on quality of life of local residents.

- **The NSDF Project could have a negative effect on visual aesthetics.**

The visual effect of the NSDF Project site will be limited, as the line of sight will be obscured by hilly topography and the surrounding tree line. The NSDF Project is not expected to be visible to the local public.

- **The NSDF Project could change demand for community infrastructure (e.g., domestic waste management) with respect to capacity of infrastructure to meet demand**

All of the waste that arises as a result of the construction, operations and closure phases will be safely managed and in accordance with CNL's Waste Management Program. The CNL Waste Management Program prescribes that management of solid waste at CNL-operated sites is completed in a safe and environmentally responsible manner that meets or exceeds applicable regulations and standards, and limits current and future environmental effects and liabilities. Facilities and activities within these sites are planned, developed and operated or conducted in a manner that reduces both the volume and the level of hazard of all wastes that are generated during the entire life cycle of the facility or activity. Under the Waste Management Program, wastes are managed in accordance with CNL's Management of Solid Waste and Management of Liquid Waste documents, and CNL's Waste Generation and Handling Standards.

Conventional waste generated during the construction and operations phases will comprise of consumables and sanitary waste. Conventional (non-radiological) waste generated from the NSDF Project during construction will be managed by the contractor. Types of consumables include non-reusable/recyclable construction materials and other regular waste generated at an industrial work site. Each contractor on site will be responsible for their own housekeeping and waste handling/disposal. Standard mitigation will be implemented for storage of conventional waste at the site (e.g., collection and storage in appropriate wildlife-resistant containers), prior to disposal at landfill, which may include off site licenced waste management facilities with capacity to accept it. Construction materials will be reused or recycled, if possible.

Hazardous (non-radiological) materials generated during the construction and operations phases will be typical of those generated for construction of large industrial facilities and will include solvents, chemicals, cleaners, aerosol cans, compressed gases, oils and lubricants. These materials will be managed, including storage, use and disposal, in compliance with applicable legislation, codes and CNL's Waste Generation and Handling Standards. Once collected by a licensed hazardous waste disposal company, these wastes will be transferred off site to licensed waste management facilities for treatment and/or disposal.

During site preparation and construction, waste management includes managing conventional wastes that are generated as part of the work activities. Any radioactive waste that is generated during site preparation and construction activities will be separated and managed according to existing procedures established for all CNL operated sites, which are consistent with applicable regulations.

Grey water and sanitary sewage generated at the NSDF Project site will be managed on the NSDF Project site. The grey water and sanitary sewage will be transferred by a gravity sewer network to two septic sewage systems; one located on the north end of the site and the second located on the south end of the site.

The NSDF Project is expected to require the use of off site waste management facilities including in the nearby communities of Deep River and Chalk River only for contractor-generated non-radiological wastes during construction, as there is existing infrastructure and facilities available on CNL's existing CRL site for other types of waste and infrastructure needs. As a limited amount of construction waste may potentially need to be disposed of at licenced waste management sites with capacity to accept it, this waste disposal activity is considered to have a negligible residual effect on availability of services and infrastructure.

5.10.5.2.3 Primary Pathways

The primary pathways listed below were identified as having a residual effect on socio-economic VCs and have been carried forward to the residual effects analysis. These pathways relate to changes in the socio-economic environment from the NSDF Project and are not indirect effects related to changes in the environment.

- **direct and indirect employment requirements may affect employment and income within the local and regional study areas;**
- **the NSDF Project will extend contracting and supplier opportunities to local, regional and Indigenous businesses;**
- **the NSDF Project could increase pressure on commercial accommodations;**
- **changes in demand for community services (health, education, protective and emergency services) with respect to the capacity of LSA services to meet the demand; and**
- **the NSDF Project could increase road degradation due to increased traffic volume from the transportation of workers, supplies and equipment.**

5.10.6 Residual Effects Analysis

5.10.6.1 Methods

This section builds on the environmental assessment approach outlined in Section 5.1 and will describe the specific methods used to predict changes to socio-economic VCs and assess the residual effects. Residual effects will be evaluated for the Application Case and RFD Case. Only primary pathways identified in Section 5.10.5 Project Interactions and Mitigation are included in the residual effects analysis.

5.10.6.2 Application Case Results

This section describes the residual effects of the NSDF Project on the socio-economic VCs for primary pathways (Table 5.10.5-1). The section also describes the appropriate mitigations for each effect and characterizes the residual effect from the NSDF Project after mitigations have been applied.

5.10.6.2.1 Labour Market and Economic Development

The NSDF Project is expected to be constructed between 2022 and 2024. The key surface structures that will be constructed for the NSDF Project are the engineered containment mound, WWTP, access roads and support facilities and infrastructure. The construction phase will require an average of 225 full-time equivalents, with a peak workforce of approximately 300 personnel. The labour force is expected to be variable depending on the number of parallel activities being performed. Limited maintenance and inspection will occur in off-shift hours. Labour force requirements during the operations, closure and post-closure phases are expected to be less than requirements for the construction phase. Given the nature of the NSDF Project construction activities, it is expected that the construction workforce will be sourced from both local public firms and Indigenous firms within the LSA and RSA (throughout the County of Renfrew and the Ottawa area in Ontario and the Region of Outouais in Quebec). CNL employment opportunities that may arise due to NSDF Project activities will be posted on the vendor portal on the www.cnl.ca website.

Industries in the RSA (throughout the County of Renfrew and the Ottawa area in Ontario and the Region of Outouais in Quebec) are anticipated to supply the NSDF Project with many of the required goods and services (e.g., manufacturing, wholesale, transport). Economic opportunities arising from the NSDF Project will be extended to Indigenous companies. The construction workforce will, therefore, either already live in the RSA or may come from out of area and require temporary residence in the Town of Deep River, the Municipality of Petawawa and the City of Pembroke. The potential exists for a modest increase of expensed meals and accommodations due to the construction workforce which has a peak employment of 300 workers, who may seek to temporarily reside in the LSA and RSA during the construction phase.

Overall, the NSDF Project may result in small positive effects to local Indigenous Peoples through potential contracting or employment opportunities. Indigenous People have expressed an interest in potential opportunities and CNL will continue to engage with Indigenous Peoples on potential employment and contracting opportunities for the NSDF Project.

5.10.6.2.2 Service and Infrastructure

Transportation and Traffic

The haulage route for transportation of site preparation and construction equipment and construction materials will be via public roads to the CRL site (e.g., Highway 17). Transportation of equipment and materials during construction will be scheduled to avoid peak traffic times where possible, to minimize contribution to peak noise and traffic volumes, and limit inconvenience to local residents. Construction materials (e.g., processed granular materials and gravel, geosynthetic products and clay) will be transported to the NSDF Project site using standard highway haul vehicles. It is estimated that there will be approximately 200 trucks per day during construction (based on a construction season of 9 months) and 10 trucks per day during operations. This results in approximately 15 trucks per hour during construction and less than 1 truck per hour during operations for the daytime period. In addition, it is assumed that construction workers will travel to the NSDF Project site from the local commercial accommodations using their own personal vehicles. Within the CRL site, transport of site preparation and construction equipment and construction materials to the NSDF Project site will be by the Plant Road, which leads to the main site access road. This increase in traffic from the transportation of workers, supplies and equipment for the NSDF Project is expected to result in degradation of public transportation infrastructure.

Emergency and Protective Services

Emergency and protective services at CRL rely on CRL's own internal capacity as the first responder to incidents at the NSDF Project site. For more serious incidents, CRL may rely on the County of Renfrew and the Town of Deep River, respectively. As there are no mutual aid agreements in place beyond those related to fire protection services, the NSDF Project may potentially increase demand for emergency and protective services in neighbouring municipalities or in the County due to the need to respond to project-related incidents.

During all phases of the NSDF Project, several strategies will be in place to reduce the likelihood of an incident occurring and to avoid the requirement for community emergency services. Additional mitigation includes operating in compliance with all applicable federal and provincial health and safety standards and CNL's existing Health, Safety, Security and Environmental programs (Section 3.5.2).

5.10.6.2.3 Housing and Accommodations

It is anticipated that the out-of-area construction workforce will be housed in hotels in the Town of Deep River, Municipality of Petawawa, City of Pembroke and the Ottawa Valley (i.e., LSA and RSA in Ontario). This use may slightly increase the demand on commercial accommodations (i.e., hotels) within the RSA during the construction phase of the Project.

5.10.6.3 Reasonably Foreseeable Development Case Results

This section describes the residual effects of the NSDF Project on the socio-economic VCs in consideration of other reasonably foreseeable developments that may overlap spatially and temporally with the NSDF Project. Reasonably foreseeable developments in the RSA that are anticipated to overlap with the NSDF Project include new/upgrades to research and development facilities, construction and operations of the SMR, new support infrastructure and on-going decommissioning and environmental remediation activities on the CRL site and the NPD Closure Project. As well, there may be overlap of the Construction Phase with limited construction at neighbouring Garrison Petawawa. The following sub-sections describes the predicted cumulative residual effects for the RFD Case.

5.10.6.3.1 Labour Market and Economic Development

Atomic Energy of Canada Limited and the Government of Canada are investing $1.2 billion for new and renewed science and site support infrastructure in order to revitalize the CRL site. Over the period 2016 to 2026, CNL is decommissioning more than 100 buildings and structures to make room for new, renovated and repurposed facilities to transform the site into a world-class, nuclear science and technology campus. CNL has consulted with local companies to inform them of revitalization program, CNL's contracting strategy and procurement processes. On-going decommissioning and environmental remediation activities on the CRL site are focusing on early reduction of liabilities. CNL is performing most of the decommissioning activities to gain efficiencies and reduce risks associated with redundant, high-hazard facilities (CNL 2017d). This approach supports the acceptance and adaptation of site-wide program controls to enable an accelerated decommissioning schedule. Additionally, development of a core team and capabilities will reduce incidents and costs, particularly those associated with multiple subcontractors trying to perform multiple scopes of work on congested site amid other on-going work (CNL 2017d). International decommissioning experience gained on multiple sites has demonstrated that the development of a trained and experienced workforce with flexibility to move between buildings as conditions require, is a key step in safely accelerating decommissioning activities.

CNL is planning new nuclear research facilities and support buildings to revitalize the CRL site. The revitalization of the CRL site is planned to occur over the 10-year period 2016-2026. The workforce required for site revitalization activities at any point is expected to be maintain a similar rate to the workforce on-site supporting those activities at present, captured as part of existing conditions. This workforce is anticipated to be approximately equal to that required for the construction of the NSDF Project. CNL will continue to provide updated information to interested contractors and suppliers on work packages as they develop. Nonetheless, the business prospective of the NSDF Project has motivated prospective contractors to engage local and Indigenous companies. A specific new research and development project announced in 2019 is the proposal by Global First Power to build and operate a small modular reactor at the CRL site. Based on the small scale of the development, labour resources for construction will be small compared to that required for the NSDF Project and negligible compared to on-going CRL site operations.

CNL's proposed NPD Closure Project is expected to be executed over a two-year period from 2022 to 2024. It will employ an average of 40 people (approximately 30 existing CNL employees and 10 external contractors). External contractors that may be sourced from the LSA and RSA communities, with possibly some specialized contractors coming from Ottawa and beyond. The peak workforce is expected to be approximately 340 workers in RFD Case (300 peak workforce for the NSDF Project and approximately 40-person workforce for the NPD Closure Project).

Decommissioning of eight buildings, renovation of three and construction of a new 9,900 m facility for the Royal Dragoons planned within the built-up area at Garrison Petawawa (approximately 10 km south of the SSA) in 2020 to 2021 may require labour resources for construction from within the RSA.

Given the size of the labour force in the LSA and RSA in 2016 of approximately 3,370 and 791,985 respectively, with an unemployment rate of 6.6% for both the LSA and RSA (Statistics Canada 2017a,b,f,g), it is not expected that local labour will be constrained in consideration of the demand for labour from the RFD Case.

5.10.6.3.2 Services and Infrastructure

Transportation and Traffic

It is anticipated that there will be additional traffic associated with an estimated average of 225 full time equivalent workers commuting to and from the CRL site each day for the NSDF Project. CNL is planning new nuclear research facilities and support buildings to revitalize the CRL site. The revitalization of the CRL site is planned to occur over the 10-year period 2016-2026. The workforce required for site revitalization activities at any point is expected to be maintain a similar rate to the workforce on-site supporting those activities at present, captured as part of traffic monitoring to characterize existing conditions. This workforce is anticipated to be approximately equal to that required for the construction of the NSDF Project. On-going decommissioning and environmental remediation activities on the CRL site will primarily be completed by CNL employees.

Traffic generated for construction and operations of the SMR, as well as for limited construction at Garrison Petawawa will be small compared to that required for NSDF and negligible compared to on-going CRL site operations.

The NPD Closure Project is not expected to require regular transportation to and from the CRL site. The NPD Closure Project is projected to increase traffic on local roads including Highway 17 by approximately 70 trips per day delivering materials, personnel and services to the CNL NPD site (approximately 30 trips a day for raw materials and 40 trips per day for personnel travel).

Overall, if there is temporal overlap of the NSDF Project, NPD Closure Project and the CNL site revitalization projects, this could result in an average additional 265 workers (225 for the NSDF Project and 40 for the NPD Closure Project) commuting in the region, with approximately 225 of these additional workers commuting to the CRL site. As well, based on estimates of truck deliveries to the NSDF Project site during the 24-month construction period, approximately 200 shipments per day are anticipated during the nine-month construction season.

In consideration of the increased traffic from the NSDF Project and applicable RFD Projects, and the annual average daily traffic levels in the LSA and RSA, which range from 6,700 to 12,300 vehicles per day, the cumulative effects of traffic from the RFD Case may slightly increase traffic levels during the morning and evening commutes.

The increase in traffic from the transportation of workers, supplies and equipment for the NSDF Project and applicable RFD projects is expected to result in degradation of public transportation infrastructure.
The incremental increase in traffic expected from applicable RFD Projects is small, when considered with the NSDF Project during construction.

Emergency and Protective Services

Emergency and protective services at CRL generally rely on CRL's own internal capacity. For medical emergencies, trained CNL personnel will conduct initial evaluation and assistance, and will request external EMS, as required. Chalk River Laboratories' existing emergency and protective services at the CRL site are expected to be sufficient for the NSDF Project, construction and operations of the SMR, on-going decommissioning and revitalization projects. Existing emergency and protective services around the NPD site are also expected to be sufficient for the NPD Closure project activities. There may be a potential increase in demand for emergency and protective services in the LSA and RSA communities, as well as the County of Renfrew, due to the need to support more serious project-related incidents (e.g., incidents requiring hospitalization). However, the predicted residual effect is expected to be limited due to the size of the workforces at any one time for the RFD projects.

5.10.6.3.3 Housing and Accommodation

Similar to the NSDF Project, it is expected that a portion of the RFD project workforce would come from the LSA and RSA and, therefore, already be residents of the area and not require temporary accommodation. In addition, not all of the RFD projects would occur at the same time. For example, the NPD Closure Project is anticipated to occur over a two-year period from 2022 to 2024 whereas revitalization and decommissioning activities at the CRL site will occur progressively over the 10-year period 2016 to 2026. The construction of the SMR may overlap with the construction of the NSDF Project; however, based on the small scale of the development, labour resources for construction will be small compared to that required for the NSDF Project. Based on the small scale of the development and short timeline for construction, labour requiring temporary accommodation will be small compared to that required for the NSDF Project. Limited construction at neighboring Garrison Petawawa is planned in between 2020 and 2021. When considered with the NSDF Project temporary accommodation requirements, and the availability of hotels, motels and other accommodation in the LSA and RSA, it is not expected that the combined effects of the RFD projects will place considerable constraints on temporary accommodation in LSA and/or RSA communities.

5.10.7 Prediction Confidence and Uncertainty

Predictions of the NSDF Project's effects on socio-economics carry an element of uncertainty because many factors will affect the future, including how individuals' choices will affect their personal and community circumstances. For example, the proportion of workers who live in the local communities may continue to be the same, but it is also possible that more workers will choose to live elsewhere and commute into the area for their work shift. The NSDF Project's effects will also be influenced by economic conditions and broad factors affecting societal change within the communities affected by the NSDF Project.

Confidence in the prediction of the effects of the NSDF Project on the socio-economics of the local communities is based on a number of assumptions of future conditions, including the following:

- workers' skill requirements will be similar to those existing at CRL;
- working conditions (e.g., shift schedules) will be the same;
- most workers at the NSDF Project during the operations phase will be employed by CRL; and
- employees will continue to live in the same communities.

The confidence in the effects assessment for socio-economics is considered to be moderate.

A second key source of uncertainty is related to the RFD Case and the contribution to residual effects from the CRL site revitalization outlined in the Site Master Plan. Although specific contractor opportunities and supplier requirements are unknown at this time; there is uncertainty in the combined effects for the RFD Case. However, it is expected that effects from these activities will largely be positive.

Mitigation proposed in the assessment is based on accepted and proven best management practices that are well-understood and have been applied to numerous construction projects throughout Canada. Uncertainty in the assessment has been reduced by making conservative assumptions, planned implementation of known effective mitigation and monitoring, and available adaptive management measures to address unforeseen circumstances should they arise.

Certainty of the predicted effects for commercial accommodation is high, given the effectiveness of the mitigation to be implemented and knowledge of the NSDF Project design and schedule. However, events that may require emergency and protective services are difficult to predict. Mitigation regarding best practices and emergency response are reliably effective and have been or are currently being used pursuant to the *Nuclear Safety and Control Act* and CNL's existing Health, Safety, Security and Environmental programs (Section 3.5.2).

5.10.8 Residual Effects Classification and Determination of Significance

This section classifies the residual effects from cumulative changes to measurement indicators for the Application Case and presents a determination of significance for each socio-economic VC that was predicted to be affected by a primary pathway. Although the positive and neutral residual effects associated with the NSDF Project are reported in this section, they are not assessed for significance.

5.10.8.1 Residual Effects Classification

Effects from adverse residual changes to measurement indicators were classified using a categorical scale and common words to facilitate the determination of significance. The purpose of categorical classification is to provide definitions that permit a clear, thorough and unambiguous classification of residual effects such that reviewers and readers can follow and apply the logic used in the assessment and reach the same classification for a given residual effect.

All primary pathways affecting each measurement indicator were combined for the residual effects classification such that one classification is provided for each measurement indicator. Changes to measurement indicators are classified for each VC, for the Application Case. The classification is based on the residual effects analysis provided in Section 5.10.6.

Magnitude, geographic extent and duration are the principal factors considered to predict significance (Table 5.10.8-1). Magnitude refers to the degree of change in the measurement indicator. Magnitude may be low, moderate or high. Economic effects were assigned magnitude qualitatively based on levels of concern, analysis of the existing economic environment and projected future changes as they affect economic sustainability. Geographic extent refers to the area affected and is categorized into three scales: local, regional and beyond regional. Local effects are those confined to the communities in the LSA. Regional effects include the LSA, but do not extend beyond the RSA. Beyond regional refers to effects that extend beyond the region and throughout the province of Ontario or even farther. Duration is defined as the amount of time from the beginning of an effect when the effect on a VC has ended or dissipated to the point of not being detectable and is expressed relative to project phases.

Direction indicates whether an effect is considered negative (i.e., less favourable) or positive (i.e., beneficial). While the focus of the effects assessment is to predict whether the development is likely to cause significant adverse effects on the environment or cause public concern, the positive and neutral changes associated with the NSDF Project are reported. Some effects may have both positive and negative dimensions. For example, although increased income from employment can increase spending in local communities, there is also a cost associated with the management of an out of area workforce by municipalities and infrastructure and service providers.

Table 5.10.8-1: Assessment Criteria for Classifying Predicted Residual Adverse Effects to the Socio-economic Valued Components

Direction	Magnitude	Geographic Extent	Duration
Positive: An improvement over Base Case values or conditions. **Neutral:** No change to measurement indicators over Base Case values or conditions. **Negative:** A less favourable change to measurement indicators relative to Base Case values or conditions.	**Negligible:** No discernible change is expected from Base Case values or conditions. **Low:** A slight, but discernible change to measurement indicators from Base Case conditions, but within the capacity of the system. **Moderate:** The change to measurement indicators is detectable, but still remains within historical system capacity or market capacity for response. **High:** The change to measurement indicators is beyond historical norms or existing system or market capacity for effective response.	**Local:** The change to the measurement indicator will not extend beyond communities in the LSA. **Regional:** The change to the measurement indicator will affect the Regional Study Area and LSA (where the changes are more widespread, but still detectable). **Beyond Regional:** The change to measurement indicators will extend beyond the RSA into other areas of the Province.	**Short-term:** The change to measurement indicators occurs during construction, but ends before the end of construction; or occurs during active closure stage only, but ends before final closure. **Medium-term:** The change to measurement indicators occurs throughout operations phase and ends before or near the end of the operations phase. **Long-term:** The change to measurement indicators will extend beyond the operational life of the NSDF Project.

LSA = local study area; RSA = regional study area.

Some of the criteria used to determine significance in other sections of the EIS have limited or no application to the socio-economic assessment and include the following criteria.

- **Frequency** refers to number of times an effect is expected to occur over a given period. Although there are isolated exceptions, most economic effects are experienced continuously and are cumulative (i.e., they interact and are directed and shaped by the broader continuously evolving economic environment). Thus, frequency generally is not deemed an applicable criterion for the socio-economic assessment.
- **Reversibility** is defined as the probability and time required to return to a state that is similar to baseline or comparable to similar environments not affected by the NSDF Project. Socio-economic effects associated with a project are typically part of an on-going process of interdependent economic, social and cultural changes extending into the future, which generally cannot be reversed to return to the pre-development conditions. For example, although most employment will come to end at retirement, job experience and training will have enhanced capacity of individuals to find other employment, with lifelong implications (i.e., the employment effect will not be reversed fully).
- **Likelihood** of the predicted NSDF Project effects are all assumed to be high (i.e., occurring) if the NSDF Project proceeds for the purpose of the assessment.

5.10.8.2 Determination of Significance

The classification of primary pathways and the associated predicted changes in measurement indicators provide the foundation for determining the significance of effects from the NSDF Project on the socio-economic VCs. Effect criteria of magnitude, duration and geographical extent are discussed in the context of the changes to the socio-economic measurement indicators from the NSDF Project to the existing environment. As previously mentioned, positive and neutral residual effects associated with the NSDF Project are not assessed for significance.

For socio-economic VCs, an adverse effect was considered significant if it was predicted to have an effect of high magnitude at the local, regional or provincial geographic extent with a long-term duration. When considering a high magnitude rating, an adverse socio-economic effect was considered significant if the effect was predicted to result in the capacity of the system being exceeded on an on-going and consistent basis and the system is unlikely to be able to respond in a timely manner. As part of the determination of significance, confidence in the assessment identified in Section 5.10.7 was considered for each VC.

5.10.8.2.1 Labour Market and Economic Development

Residual effects from the NSDF Project on the labour market and economic development are predicted to be positive. The effects are predicted to be local, regional and beyond regional as is expected that the construction workforce will be sourced from the LSA, RSA which includes the County of Renfrew and the Ottawa area in Ontario and the Region of Outouais in Quebec. The effect is considered medium-term (i.e., during the construction and operations phases).

An increase in procurement of goods and services from local and regional contractors and businesses is expected during the NSDF Project construction (i.e., positive effect). Procurement of construction goods and services is expected to be regional due to the lack of suitable construction firms and associated industries in the LSA. The construction workforce is expected to reside temporarily in the Town of Deep River, the Municipality of Petawawa and City of Pembroke; therefore, the increase in meals and accommodations during construction is expected to be low relative to the size of the local economy, local in geographic extent and short-term in duration (Table 5.10.8-2).

Table 5.10.8-2: Evaluation of Predicted Residual Effects on Labour Market and Economic Development for the Application Case

Indicators	Direction	Magnitude	Geographic Extent	Duration	Significance
Employment opportunities and income generation	Positive	Low	Local to Beyond Regional	Medium-term	Not applicable (significance is not determined for positive effects)

The predicted residual effect of the NSDF Project, in combination with the RFD projects, are expected to result in a detectable increase in labour requirements; therefore, the magnitude of the cumulative residual effect on employment opportunities is predicted to be moderate in magnitude, local to beyond regional in geographic extent and medium-term in duration (Table 5.10.8-3).

Table 5.10.8-3: Evaluation of Predicted Residual Effects on Labour Market and Economic Development for the RFD Case

Indicators	Direction	Magnitude	Geographic Extent	Duration	Significance
Employment opportunities and income generation	Positive	Moderate	Local to Beyond Regional	Medium-term	Not applicable (significance is not determined for positive effects)

5.10.8.2.2 Housing and Accommodations

There may be limited amounts of increased pressure on commercial accommodations during construction of the NSDF Project. The predicted residual effect of construction activities on the availability of commercial accommodations can be positive for business owners and the local economy for increasing accommodation rates, or can be negative in direction because it has the potential to reduce availability of temporary accommodation during periods of high demand, such as peak tourism periods. Given the available hotel capacity in the Town of Deep River, Municipality of Petawawa and City of Pembroke (one hotel and five motels in Deep River and additional hotels in the Municipality of Petawawa and City of Pembroke) and the expected peak construction workforce of 300 personnel, the NSDF Project is expected to have a slight, but discernible effect on commercial accommodation availability (i.e., low magnitude). Overall, the negative residual effect of the NSDF Project on commercial accommodation availability is determined to be not significant (Table 5.10.8-4).

Table 5.10.8-4: Evaluation of Predicted Residual Effects on Commercial Accommodations for the Application Case

Indicators	Direction	Magnitude	Geographic Extent	Duration	Significance
Increased pressure on commercial accommodations	Positive and Negative	Low	Local to Regional	Short-term	▪ Not Significant (where direction is negative) ▪ Not applicable (where direction is positive, as significance is not determined for positive effects)

When considered with the NSDF Project temporary accommodation requirements, and the availability of hotels, motels and other accommodation in the LSA and RSA, it is not expected that the combined effects of the RFD projects will place considerable benefit to or constraints on temporary accommodation in LSA and/or RSA communities. Therefore, the cumulative residual effect on commercial accommodation availability from the NSDF Project combined with the RFD projects is predicted to be of low magnitude, local to regional in extent and medium-term in duration. Overall, the negative cumulative residual effect on commercial accommodation availability is predicted to be not significant for the RFD Case (Table 5.10.8-5).

Table 5.10.8-5: Evaluation of Predicted Residual Effects on Commercial Accommodations for the RFD Case

Indicators	Direction	Magnitude	Geographic Extent	Duration	Significance
Increased pressure on commercial accommodations	Positive or Negative	Low	Local to Regional	Medium-term	▪ Not Significant (where direction is negative) ▪ Not applicable (where direction is positive, as significance is not determined for positive effects)

5.10.8.2.3 Service and Infrastructure

Transportation and Traffic

Increased road degradation due to increased traffic volume on highways and local roads used to access the NSDF Project is predicted during construction. The predicted residual effect of construction activities on highways and local roads used to access the NSDF Project is negative in direction because the increase of traffic for the NSDF Project will place increased pressure on road infrastructure in the LSA and RSA. It is considered short-term in duration because the measurable increase in traffic volume will occur only during NSDF Project construction. The effect of increased traffic on road conditions is considered to be a slight but discernible change (i.e., low magnitude) when compared to existing levels of traffic from current employees and operations at CRL. The effect is considered beyond regional as traffic is expected to come from outside the RSA on Plant Road and Highway 17. Overall, the NSDF Project's residual effect on transportation and traffic is determined to be not significant (Table 5.10.8-6).

Table 5.10.8-6: Evaluation of Predicted Residual Effects on Transportation and Traffic for the Application Case

Indicators	Direction	Magnitude	Geographic Extent	Duration	Significance
Increased road degradation due to increased traffic volume from the transportation of workers, supplies and equipment.	Negative	Low	Beyond Regional	Short-term	Not Significant

In consideration of the increased traffic from the NSDF Project, and the average annual daily traffic levels in the LSA and RSA, the cumulative effects of traffic from the RFD Case may slightly increase traffic levels during the morning and evening commutes. There is a small incremental increase in traffic expected from applicable RFD Projects. The increased levels of traffic from the RFD projects are considered to be low in magnitude when considered with the effects of the NSDF Project. Increased traffic for the RFD Case is expected to occur beyond regional and medium-term in duration. Overall, the cumulative residual effect of road degradation due to increased traffic volume on transportation and traffic is predicted to be not significant for the RFD Case (Table 5.10.8-7).

Table 5.10.8-7: Evaluation of Predicted Residual Effects on Transportation and Traffic for the RFD Case

Indicators	Direction	Magnitude	Geographic Extent	Duration	Significance
Increased road degradation due to increased traffic volume from the transportation of workers, supplies and equipment.	Negative	Low	Beyond Regional	Medium-term	Not Significant

Emergency Services

The NSDF Project will have a residual effect on the demand for emergency services during the construction and operations phases. The predicted residual effect of the NSDF Project on the provision of emergency services is negative in direction because of the potential increased demand on a limited service. The effect is regional in extent because emergency services operate at a regional level in the LSA and RSA. A minor incident could result in personal injury requiring minimal emergency medical care, while a major incident could result in the need for substantial emergency medical care.

While the risk of a major incident is low and made even less likely by CRL's internal capacity and project-related mitigations, accidents by their very nature are unpredictable, as are their outcomes. The added demand associated with the NSDF Project will not lead to unmanageable service requirements or delivery due to the excess of capacity generally. Therefore, the NSDF Project's residual effect on emergency services is assessed to be of negligible to moderate magnitude. Due to the nature of the NSDF Project, the predicted residual effect is considered long-term as the risk of project-related accidents could occur during the construction, operations and closure phases. The NSDF Project's residual effect on emergency services is determined to be not significant (Table 5.10.8-8).

The predicted residual effect of construction activities on the provision of protective services is negative in direction because of the potential increased demand on a limited service. As with demand for emergency services, it is not known with any certainty whether or not the NSDF Project will bring about increased demand for protective services. Regular, planned construction activities are not expected to place demand on police services in the LSA or RSA. As all workers are expected to abide by CNL's environmental, safety and security policies and programs, the magnitude of this effect on service provision is considered to be negligible as it is expected that the protective services in the LSA would have sufficient capacity to respond to the incident. As this effect will persist only through construction, and would likely be felt in communities where the construction workforce will reside, it is considered short-term and regional in extent as workers may reside outside of the LSA in the Municipality of Petawawa and City of Pembroke. The NSDF Project's residual effect on protective services is determined to be not significant (Table 5.10.8-8).

Table 5.10.8-8: Evaluation of Predicted Residual Effects on Emergency Services on the Application Case

Indicators	Direction	Magnitude	Geographic Extent	Duration	Significance
Increased demand for emergency services	Negative	Negligible to Moderate	Regional	Short-term to Long-term	Not Significant
Increased demand for protective services	Negative	Negligible	Regional	Short-term	Not Significant

The demand for emergency services will continue to depend on the occurrence and severity of an accident, which is unplanned by its nature. In consideration of the RFD projects, the demand for emergency services will be negative in direction, negligible to moderate in magnitude and regional in geographic extent. As the revitalization and decommissioning activities of the CRL site are for a 10-year period and operations at the SMR are planned for 20 years, the duration of the cumulative residual effect is predicated to be medium-term. The cumulative residual effect on emergency services for the RFD case determined to be not significant (Table 5.10.8-9).

The predicted cumulative residual effect of the RFD case on protective services is assessed to be negative in direction and negligible in magnitude due to the small workforce and implementation of CNL's environmental, safety and security policy and programs. The effect will be regional in geographic extent and short-term in duration, only taking place during the construction phase of the NSDF Project. The cumulative residual effect on protective services in consideration of the RFD case is determined to be not significant (Table 5.10.8-9).

Table 5.10.8-9: Evaluation of Predicted Residual Effects on Emergency Services on the RFD Case

Indicators	Direction	Magnitude	Geographic Extent	Duration	Significance
Increased demand for emergency services	Negative	Negligible to Moderate	Regional	Medium-term	Not Significant
Increased demand for protective services	Negative	Negligible	Regional	Short-term	Not Significant

5.10.9 Monitoring and Follow-up

Monitoring and follow-up programs are not specifically identified for socio-economics; rather, monitoring for environmental pathways (i.e., for air quality, water quality and groundwater quality) will be implemented to verify effects predictions. This monitoring will be on-going during the construction, operations and closure phases and the need for and duration of monitoring will be reviewed based annual review of monitoring data. This monitoring will be integrated into the CNL Environmental Monitoring Program.

Recognizing people's interest in understanding and participating in decisions that affect them, CNL will proactively seek, engage and support meaningful discussion on issues and opportunities related to the NSDF Project as part of the Public Information Program (PIP, CNL 2021b), which can be found on the CNL website (www.CNL.ca). The PIP includes specific communications to stakeholders and public access to information related to routine activities as well as new projects such as the NSDF Project. These measures are meant to mitigate questions and complaints regarding CNL activities, as well as ensure community input is sought, received and action is taken to respond to these inputs.

The PIP also provides a platform for the public to voice their concerns related to NSDF Project activities and for CNL to address and develop resolutions to these concerns; the process includes:

- Corporate Communications receives issues and concerns through the formal feedback submission on the CNL website (https://www.cnl.ca/contact us), emails (communications@cnl.ca), phone calls (1-800-364-6989), and social media platforms (e.g., Facebook and Twitter);
- All NSDF Project-related issues and concerns (including complaints about noise disturbances) received are forwarded to the NSDF Project for resolution;

- The NSDF Project address and resolve concerns about the NSDF Project on a case-by-case basis and resolution may include further mitigation of NSDF site activities;
- Throughout this process, CNL will maintain two-way dialogue between the stakeholder and the NSDF team until the issue is resolved; and
- All inquiries are tracked and resolution or responses are recorded once completed.

CNL will continually evaluate both the process and the outcome of the on-going engagement and communication activities to address and manage issues as they arise. The level and nature of engagement with the communities will depend on feedback received.

As part of the Environmental Assessment Monitoring and Follow-up Program, with respect to the noise assessment, a traffic count study will be completed along Highway 17 and Plant Road as a pre-construction activity. Traffic counts will be obtained along both; Highway 17 and Plant Road to establish an Annual Average Daily Traffic (AADT) count in accordance with accepted practices and will consider traffic by type. The study will consider Highway 17 north and south of Plant Road and will include precise study location maps. Average hourly distribution will be established for Highway 17 and Plant Road that will allow for the establishment of daytime and nighttime traffic levels. The gathered traffic count data will be used to verify the noise modelling result, and if required, additional mitigation will be implemented.

5.10.10 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Socio-economic VCs were selected based on the potential for the NSDF Project to interact with the features of the socio-economic environment, and consist of:

- labour market;
- economic development;
- government finances;
- housing and accommodations;
- services and infrastructure;
- quality of life; and
- public safety.

Residual effects from activities that occur during the construction phase have been identified as the primary linkage to potentially affect socio-economic VCs. During the construction phase, NSDF Project activities will result in residual effects from direct and indirect employment requirements, contracting and supplier opportunities, increased pressure on commercial accommodations, changes in demand for community services and increased degradation of public transportation roads. A summary of the predicated residual effects for socio-economics, including associated mitigation, are provided in Table 5.10.10-1. Examples of mitigation practices implemented to limit predicted residual effects to socio-economic VCs include:

- continued implementation and maintenance of compliance with all applicable health and safety standards and CNL's existing environmental, safety and security programs;
- continued implementation of CNL's procedure for *Management and Monitoring of Emissions*, which includes operational control monitoring and verification monitoring;
- implementation of the Dust Management Plan developed for the NSDF Project, which includes appropriate management techniques to control dust generated by the NSDF Project; and
- Coordinate transportation of equipment and materials during construction to avoid peak traffic times to the extent possible.

Recognizing people's interest in understanding and participating in decisions that affect them, CNL will proactively seek, engage and support meaningful discussion on issues and opportunities related to the NSDF Project as part of the PIP. CNL will continually evaluate both the process and the outcome of the on-going engagement and communication activities to address and manage issues as they arise.

Table 5.10.10-1 summarizes negative residual project and cumulative effects increased pressure on commercial accommodations, changes in demand for community services and increased degradation of public transportation roads. With the implementation of appropriate mitigation, residual effects of the NSDF Project on socio-economic VCs are predicted to be not significant. The NSDF Project may result in positive benefits to the labour market and economic development through potential contracting or employment opportunities, including potential benefits to commercial accommodation providers.

Table 5.10.10-1: Summary of Predicted Residual Effects for Socio economics Valued Components

Valued Components	Assessment Endpoint	Residual Effects	Project Phase Residual Effect Occurs	Contributing Project Activity	Proposed Mitigation	Significance	
						Application Case	RFD Case
Labor Market	Continuation of employment opportunities and income generation.	Direct and indirect employment requirements may affect employment and income with the local and regional study areas.	Construction	Employment of personnel, procurement of goods and services, and expenditures from the NSDF Project.	Canadian Nuclear Laboratories (CNL) employment opportunities that may arise due to project activities will be posted on the vendor portal on www.cnl.ca website.	Positive residual effect, therefore, significance is not determined.	Positive residual effect, therefore, significance is not determined.
Economic Development	Continuation of business and economic development.	The NSDF Project may provide contracting and supplier opportunities to local and regional businesses.	Construction	Employment of personnel, procurement of goods and services, and expenditures from the NSDF Project.	The NSDF Projects will competitively procure material and services local and regional communities.	Positive Residual Effect, therefore, significance is not determined.	Positive Residual Effect, therefore, significance is not determined.
Housing and Accommodations	Maintenance of commercial accommodation availability.	The NSDF Project could increase pressure on commercial accommodations.	Construction	Employment of personnel, use of services and infrastructure for NSDF Project.	None	Not significant (where negative in direction) Positive Residual Effect; therefore, significance is not determined (where positive in direction)	Not significant (where negative in direction) Positive Residual Effect; therefore, significance is not determined (where positive in direction)

Table 5.10.10-1: Summary of Predicted Residual Effects for Socio economics Valued Components

Valued Components	Assessment Endpoint	Residual Effects	Project Phase Residual Effect Occurs	Contributing Project Activity	Proposed Mitigation	Significance	
						Application Case	RFD Case
Services and Infrastructure	Maintenance of community services and infrastructure availability and access.	Increased road degradation due to increased traffic volume from the transportation of workers, supplies and equipment.	Construction	Employment of personnel, use of services and infrastructure for NSDF Project.	Coordinate transportation of equipment and materials during construction to avoid peak traffic times to the extent possible.	Not significant	Not significant
		Changes in demand for community services (health, education, protective and emergency services) with respect to the capacity of LSA services to meet the demand.	All NSDF Project Phases	Employment of personnel, use of services and infrastructure for NSDF Project.	Continued implementation and maintenance of compliance with all applicable health and safety standards and CNL's existing environmental, safety and security programs.	Not significant	Not significant

RFD = Reasonably Foreseeable Developments; LSA = local study area.

6.0 INDIGENOUS INTERESTS

6.1 Introduction

Canadian Nuclear Laboratories (CNL) has prepared this standalone section on Indigenous interests with respect to the Near Surface Disposal Facility (NSDF) for the disposal of solid, low-level radioactive waste at Chalk River Laboratories (CRL) – the NSDF Project. This is a new section that was not present in the 2017 Draft version of the NSDF Environmental Impact Statement (EIS) and is intended to consolidate and summarize the areas of assessment relevant to Indigenous Peoples into one single section.

This section of the EIS is divided into seven major subsections, each of which are described below:

- **Section 6.1 – Introduction:** This section outlines the structure of Section 6 and generally describes how CNL is working with Indigenous Peoples to include their interests in the NSDF Project environmental assessment.
- **Section 6.2 – Indigenous Engagement:** This section describes Indigenous engagement by community or organization, summarizes key interests and concerns of Indigenous community or organization, how CNL is addressing the interest/concern, how CNL has verified with the applicable Indigenous community or organization that the interest/concern is resolved, and identification of next steps. This section is an updated version of the former Section 4.3.2 “Aboriginal Engagement” of the 2017 Draft EIS. This section documents all the engagement with Indigenous Peoples on the NSDF Project that has occurred. CNL is committed to facilitating opportunities for Indigenous Peoples to continue to be involved in the NSDF Environmental Assessment Process and onward. CNL is working with engaged communities and organizations to develop a mutual path forward in verifying feedback and addressing interests and concerns.
- **Section 6.3 – Valued Components:** This section describes Indigenous specific Valued Components (VCs). It also describes how comments from Indigenous Peoples on VCs are addressed in the VC selection.
- **Section 6.4 – Traditional Land and Resource Use:** This section describes the assessment process for traditional land and resource use and more specifically the scope of the assessment, valued components, assessment boundaries, existing conditions, and potential project interactions and mitigation for traditional land and resource use. This section incorporates information on known traditional land and resource use that has come from existing studies (e.g., publically available information and datasets), studies specific to the NSDF Project, and through project specific engagement with regards to Indigenous communities and organizations.
- **Section 6.5 – Indigenous Health and Indigenous Receptor:** This section describes the Self Sufficient Indigenous Group receptor selected as part the NSDF Post-Closure Safety Assessment (Arcadis and Quintessa 2020b) to assess potential future effects of the NSDF Project on Indigenous Peoples’ future interactions with the environment around the proposed facility.
- **Section 6.6 – CNL’s Long-Term Relationship with Indigenous Peoples:** This section describes CNL’s long-term approach to working with Indigenous Peoples.

This section is supported by a technical supporting document to this EIS, CNL’s Indigenous Engagement Report (IER), which was recently updated in 2021 (CNL 2021a). The IER was prepared in accordance with CNSC’s *REGDOC-3.2.2 Indigenous Engagement* (CNSC 2019). The IER outlines CNL’s approach to Indigenous engagement to support the environmental assessment process for the planned NSDF Project. The IER is a more

detailed version of Section 6 that provides details of CNL's engagement activities for the NSDF Project – which are summarized and incorporated in this EIS – and remains a living document that will continue to be updated.

In accordance with *REGDOC-3.2.2*, the scope of the IER includes:

- identification of Indigenous Peoples (identified through consultation with the CNSC);
- Indigenous engagement activities that have taken place up to the date of writing and a proposed schedule for interim reporting on these activities to the CNSC; and
- the plan on how CNL has and will continue to engage with Indigenous Peoples.

CNL also enhanced the scope of the IER by adding the following:

- a section demonstrating compliance with regulatory requirements;
- an enhanced summary of each identified Indigenous community or organization to demonstrate CNL's understanding of the historical, legal, socio-economic, traditional use and other characteristics, including documenting (where available) their interests in the Ottawa Valley and in the vicinity of the NSDF Project;
- a section providing a discussion and summary of the engagement results;
- a section on Valued Components pertaining to Indigenous Peoples;
- a summary of the assessment of the impact of the NSDF Project on traditional land and resource use;
- a summary of the assessment of the impact of the NSDF Project on Indigenous socio-economic interests;
- a section on Indigenous health and the development of an Indigenous receptor; and
- a section describing CNL's approach to long-term relationships with Indigenous Peoples.

With these enhancements, CNL has a more comprehensive document with respect to Indigenous Peoples and provides information in a single report that supports Section 6 of this EIS.

After the filing of the EIS, CNL will continue to engage with Indigenous Peoples both about the NSDF Project and also more broadly about the CRL site and other projects. CNL is working towards developing long-term relationships with Indigenous Peoples that have traditional territories and modern day interests near its operations. CNL recognizes that such relationships may take a long time to form but believes this is consistent with the Government of Canada's approach to reconciliation. CNL is working closely with Atomic Energy of Canada Limited (AECL) regarding Indigenous Peoples interests with whom AECL is engaging. Engagement with regard to Indigenous interests has demonstrated that Indigenous Peoples are also interested in fostering such long-term relationships with CNL and AECL. As the parties involved see their relationships as evolving and beyond the scope of a single regulatory project such as the NSDF Project.

Discussions regarding long-term relationships and on specific aspects of projects, such as the NSDF Project, will be on-going up until and after the CNSC Commission Hearing on the NSDF Project. Because of the on-going nature of these discussions and relationships, CNL intends to provide a revised IER as part of the Commission Member Document package for the CNSC Commission Hearing on the NSDF Project. The revised IER will document the on-going engagement, discussions and negotiations with Indigenous Peoples that are relevant both corporately and specific to the NSDF Project.

6.2 Indigenous Engagement

This section summarizes CNL's Indigenous engagement objectives, the methods adopted to meet these objectives, the Indigenous communities and organizations that CNL has identified, engagement activities that have been undertaken as of May 2021, feedback received as of May 2021, and future engagement activities. As of May 2021, CNL has verified (or attempted to verify) a path forward and next steps with the identified Indigenous communities and organizations, including formulating commitments to address outstanding interests and concerns.

6.2.1 Objectives

As part of its corporate, environmental and social responsibility, CNL recognizes and encourages the on-going engagement of Indigenous communities through the course of its environmental assessment process for the NSDF Project. Through its engagement activities, CNL seeks to inform communities while building awareness and understanding of NSDF Project activities. CNL communicates with community members on the potential effects of NSDF Project activities on the environment and on Indigenous and/or treaty rights including rights to trap, hunt, fish, gather or conduct cultural ceremonies.

Regulatory requirements related to these activities are summarized in Section 2 of the IER (CNL 2020). The *Canadian Environmental Assessment Act, 2012* (CEAA 2012) provides a clear description of the environmental effects on Indigenous Peoples that are to be taken into account. The CNSC *REGDOC-3.2.2* (CNSC 2019) provides more detailed information and sets out the "requirements and guidance for licensees" with respect to engagement. It also provides procedural direction for licensees:

> *Licensees shall conduct a review to consider whether the activity described in their licence application requesting authorization from the Commission:*
>
> - *could result in impacts to the environment; and*
> - *could adversely impact an Indigenous group's potential or established Indigenous and/or treaty rights, such as the ability to hunt, trap, fish, gather or conduct ceremonies" (CNSC 2019).*

As the CNSC *REGDOC-3.2.2* provides specific requirements and guidance on consideration of rights and activities (i.e., hunt, trap, fish, gather or conduct ceremonies) results of CNL's engagement are specifically addressed in the IER and this EIS. Section 6 of the IER describes traditional land and resource use, based on existing and available information.

Additional CNSC requirements that are to be addressed or considered with respect to Indigenous Peoples are found in Appendix A.3.8 of the CNSC *REGDOC-2.9.1 Environmental Protection: Environmental Principles, Assessments and Protection Measures* (CNSC 2017) and the CNSC's *Generic Guidelines for the Preparation of an Environmental Impact Statement* (Generic EIS Guidelines; CNSC 2016a). These requirements are included in Table 2-1 of the IER. Key requirements identified in Table 2-1 of the IER, as summarized below, generally relate to identifying community perspectives and/or information associated with:

- NSDF Project components and related activities;
- effects assessment, including Valued Components (VCs) identified for the NSDF Project, spatial and temporal boundaries for the assessment, and adverse impacts to potential or established Indigenous and/or Treaty rights;

- potential positive or negative effects of the NSDF Project on the natural environment, community socio-economic conditions/elements, community health and diet, traditional land and resource use (e.g., hunting, trapping, fishing and gathering), and physical and/or cultural heritage features;
- proposed mitigation measures in the EIS with respect to potential effects, including those potential impacts on Indigenous and/or Treaty rights;
- Indigenous treaties and outstanding or ongoing claims associated with the CRL site;
- traditional Indigenous knowledge associated with the CRL site; and
- the NSDF Project Indigenous engagement process.

On March 8, 2017, the CNSC released a Record of Decision addressing expectations on the scope of factors to be assessed in the environmental assessments of three CNL designated projects under CEAA 2012. Included in these three was the NSDF Project. Pursuant to Section 19 of CEAA 2012, the CNSC determined the project scope for the environmental assessment must include the factors mandated in paragraphs 19(1) (a) to (h) of CEAA 2012, with no additional factors. The Record of Decision also set out that the environmental assessment must consider the CNSC's Generic EIS Guidelines (CNSC 2016a) with respect to information and requirements for identifying VCs and spatial and temporal boundaries, and engaging Indigenous Peoples and the public on these key points. See Appendix A of the IER for a copy of the Record of Decision.

CNL's Indigenous engagement objectives include:

1) initiating and maintaining two-way communication channels between CNL and Indigenous communities to determine the best methods for communicating Project information and to provide opportunities for Indigenous Peoples to provide input on Project considerations including: design, the EIS process, and assessment of impacts;
2) developing meaningful, user-friendly information and communication products geared for the public and Indigenous communities, and providing accessible and current information on Project activities;
3) demonstrating CNL's long-term commitment and approach to safe and responsible management of AECL's radioactive waste and decommissioning liabilities;
4) informing and educating Indigenous communities about nuclear decommissioning, environmental remediation and radioactive waste management;
5) using engagement to further the development of long-term relationships with Indigenous communities; and
6) meeting all regulatory-based communication and engagement requirements.

To meet these objectives, CNL has developed specific strategies to increase the effectiveness of the engagement program so that Indigenous engagement requirements for the NSDF Project are met. These strategies include:

- presenting information in a format that is easily understood through a variety of communications channels using targeted key messaging;
- engaging technical experts to communicate information in various formats;
- accomplishing all required activities in a timely manner; and
- providing various means for Indigenous communities and organizations to access information.

6.2.2 Identified Indigenous Communities and Organizations

A proposed list of Indigenous communities and organizations with a potential interest in the NSDF Project was identified by CNL and included in the IER. Identification of communities was based on consultation with the CNSC and through the use of publicly available sources of information including:

- Indigenous community and organization websites;
- the Aboriginal and Treaty Rights Information System (Government of Canada and INAC 2016); and
- Crown Indigenous Relations and Northern Affairs Canada First Nation community profiles.

The proposed list was based on the identified potential or established Indigenous or treaty rights of Indigenous communities in the vicinity of the NSDF Project and is provided in Table 6.2.2-1 along with a brief rationale for inclusion. The inclusion of specific communities considers the nature of the established and/or claimed rights and potential effects on those rights caused by the proposed NSDF Project based on a preliminary assessment of existing and available information. As such, the working list is subject to change based on information and dialogue with the identified Indigenous communities and organizations.

Table 6.2.2-1: Identified Indigenous Communities and Organizations

Indigenous Communities (by representative organization) and/or Organizations Location	Identification Rationale
▪ Algonquins of Ontario, comprising 10 Algonquin communities: ▪ Antoine Algonquin First Nation ▪ Algonquins of Pikwakanagan First Nation ▪ Algonquin Nation Kijicho Manito Madaouskarini ▪ Bonnechere Algonquin First Nation ▪ Algonquins of Greater Golden Lake First Nation ▪ Mattawa-North Bay Algonquin First Nation ▪ Ottawa Algonquin First Nation ▪ Shabot Obaadjiwan First Nation (Shabot Lake) ▪ Snimikobi (Ardoch) (Beaver Creek) Algonquin First Nation ▪ Whitney and Area Algonquins	▪ The CRL site is located within the vicinity of known traditional territory; there are AOO communities located close to the NSDF Project site. ▪ The NSDF Project site directly overlaps and is within the unceded AOO Settlement Area where Algonquins from various communities exercise Aboriginal rights and interests. ▪ Accepted for negotiations with Self-Government ▪ Framework Agreement (Signed) ▪ Established CNL relationship (member of CNL's Environmental Stewardship Council [ESC](a))
Algonquins of Pikwakanagan First Nation (included as part of the AOO but also separately identified)	▪ Historic relationship with AECL and CNL ▪ Closest First Nation to the CRL site ▪ The CRL site is located within the vicinity of known traditional territory ▪ Accepted for negotiations with Self-Government ▪ Framework Agreement (Signed) ▪ Established CNL relationship (member of CNL's ESC(a))

Table 6.2.2-1: Identified Indigenous Communities and Organizations

Indigenous Communities (by representative organization) and/or Organizations Location	Identification Rationale
Algonquin Anishinabeg Nation Tribal Council (AANTC) (two of its member communities): ▪ Kebaowek First Nation (formerly known as Eagle Village First Nation) ▪ Kitigan Zibi Anishinabeg First Nation	▪ The CRL site is located within the vicinity of known traditional territory ▪ Assertion of rights
Métis Nation of Ontario (MNO) (community councils representing the Project location): ▪ MNO North Bay ▪ MNO Mattawa Métis ▪ MNO Sudbury via the Mattawa/Lake Nipissing Traditional Territory Consultation Committee	▪ Assertion of rights in the vicinity of NSDF Project ▪ Established CNL relationship (member of ESC)[(a)] ▪ Historic Métis community identified at Mattawa
Williams Treaties First Nations, composed of seven First Nations: ▪ Alderville First Nation (Mississaugas) ▪ Beausoleil First Nation (Chippewas) ▪ Chippewas of Georgina Island First Nation ▪ Chippewas of Rama First Nation ▪ Curve Lake First Nation (Mississaugas) ▪ Hiawatha First Nation (Mississaugas) ▪ Mississaugas of Scugog Island First Nation	▪ Historical treaty, CRL site is located within lands covered by one of the Williams Treaties
Anishinabek Nation (formerly known as Union of Ontario Indians), which advocates for 40 member First Nations, 7 of which are included and noted above (i.e., Alderville First Nation, Beausoleil First Nation, Chippewas of Georgina Island First Nation, Chippewas of Rama First Nation, Curve Lake First Nation, Mississaugas of Scugog Island First Nation and Algonquins of Pikwakanagan First Nation).	▪ Umbrella organization that has members with potentially affected rights
Algonquin Nation Secretariat (ANS), which represent three First Nation communities in Quebec: Timiskaming First Nation, the Algonquins of Barriere Lake, and Wolf Lake First Nation	▪ Umbrella organization that has members with potentially affected rights

a) Note that CNL has established an Environmental Stewardship Council (ESC) for the CRL site. The function of the council is to provide opportunity for face-to-face meetings and to build an enhanced working relationship through effective two-way dialogue with a representative membership of community opinions. Of the communities represented by the Algonquins of Ontario, only the Algonquins of Pikwakanagan hold a seat on the ESC. The Métis Nation of Ontario also holds a seat on the ESC.

The IER provides background information on these communities and/or representative organizations with a potential interest in the NSDF Project and includes, where possible, reference to individual community's elected council, geographic location, population, and associations or memberships. The IER will be updated as these communities and organizations provide additional information as the NSDF Project progresses. The information summarized in this EIS reflects a summary information available to CNL as of May 2021. As of May 2021, CNL has undertaken a verification process (as outlined in Section 6.2.4) with the identified Indigenous communities and organizations or have made on-going attempts to engage. CNL utilized all available information from June 2016 to May 2021 to conduct this verification and be in a position to finalize the EIS and submit to the Responsible Authority for the next steps in the EA process. Although the opportunity still exists for the Indigenous communities and organizations to continue involvement, the on-going updates will be incorporated in to the IER as the living document.

As noted in the Record of Decision referenced in Section 6.2.1, funding was offered by the CNSC to assist Indigenous Peoples to participate in the NSDF Project, review of the licence application, and the processes for the CNSC Commission Hearing on the NSDF Project. Following consideration of applications (to date) by Indigenous Peoples for funding, participant funding was allocated to the Algonquins of Ontario (AOO), Algonquins of Pikwakanagan First Nation (AOPFN), Métis Nation of Ontario (MNO) and the Algonquin Anishinabeg Nation Tribal Council (AANTC). Further information on the participant funding process is provided in the CNSC Participant Funding Program, which is available on the CNSC's Project webpage (CNSC 2016b).

CNL has considered and provided capacity funding to specific Indigenous communities and organizations to further their ability to participate in the environmental assessment process.

6.2.3 Engagement Methods

Section 6.2.4 describes the engagement that CNL has undertaken with the identified Indigenous communities and organizations (as outlined in Section 6.2.2): Algonquins of Ontario (AOO); Algonquins of Pikwakanagan First Nation (AOPFN); Métis Nation of Ontario (MNO); Algonquin Anishinabeg Tribal Council (AANTC); Kitigan Zibi Anishinabeg First Nation; Keboawek First Nation, Williams Treaties First Nations (WTFN); Anishinabek Nation; Algonquin Nation Secretariat and, Mohawks of the Bay of Quinte First Nation. It should be noted that the Mohawks of the Bay of Quinte are not identified on CNL's engagement list (Table 6.2.2-1) but have provided correspondence on the NSDF Project.

Various engagement methods were designed to communicate information to and solicit input from identified Indigenous communities and organizations, while fulfilling CNL's corporate and regulatory objectives. The methods CNL has utilized to date, or plans to undertake, are highly diverse and vary based on expressed community need and desired methods. This includes general information activities, focused community meetings and workshops and long-term relationship building activities. In Section 6.2.4, these activities are described for each community but, in general, the methods are summarized in Table 6.2.3-1. Project-specific examples are included however, as noted above, long-term relationship building engagements and funding were also a key activity. CNL recognizes a mutual desire to establish long-term relationship agreements to help facilitate many aspects both related and unrelated to projects such as NSDF. Although CNL may have various projects over time, it is important to both the communities and CNL that these relationships endure, grow and respond to future activities.

In March 2020, the COVID-19 pandemic impacted in-person engagement activities. CNL has adapted to the restrictions providing online platforms for virtual meetings, workshops, webinars, project updates and open houses. CNL remains committed to ensure engagement activities are ongoing and in alignment with current pandemic restrictions.

Table 6.2.3-1: Project-specific Engagement Methods

Engagement Method	Example Activities

Project Specific Agreements and Long-Term Relationship Meetings and Negotiations	▪ Project-specific Agreements (i.e., separate Memoranda of Understanding (MOUs) entered into with the AOO and the MNO as well as the AOPFN):
	  ▪ Provision of funding to assist in resource capacity development; and
	  ▪ Capacity assistance and building, as appropriate, such as basic costs to support meetings such as hall rental or production of print materials, in-kind access to the technical expertise of CNL staff, reimbursement for some expenses to participate in engagement activities such as site visits, tours.
	▪ Broader CRL site long-term relationship agreements with CNL (not specific to only the NSDF Project)

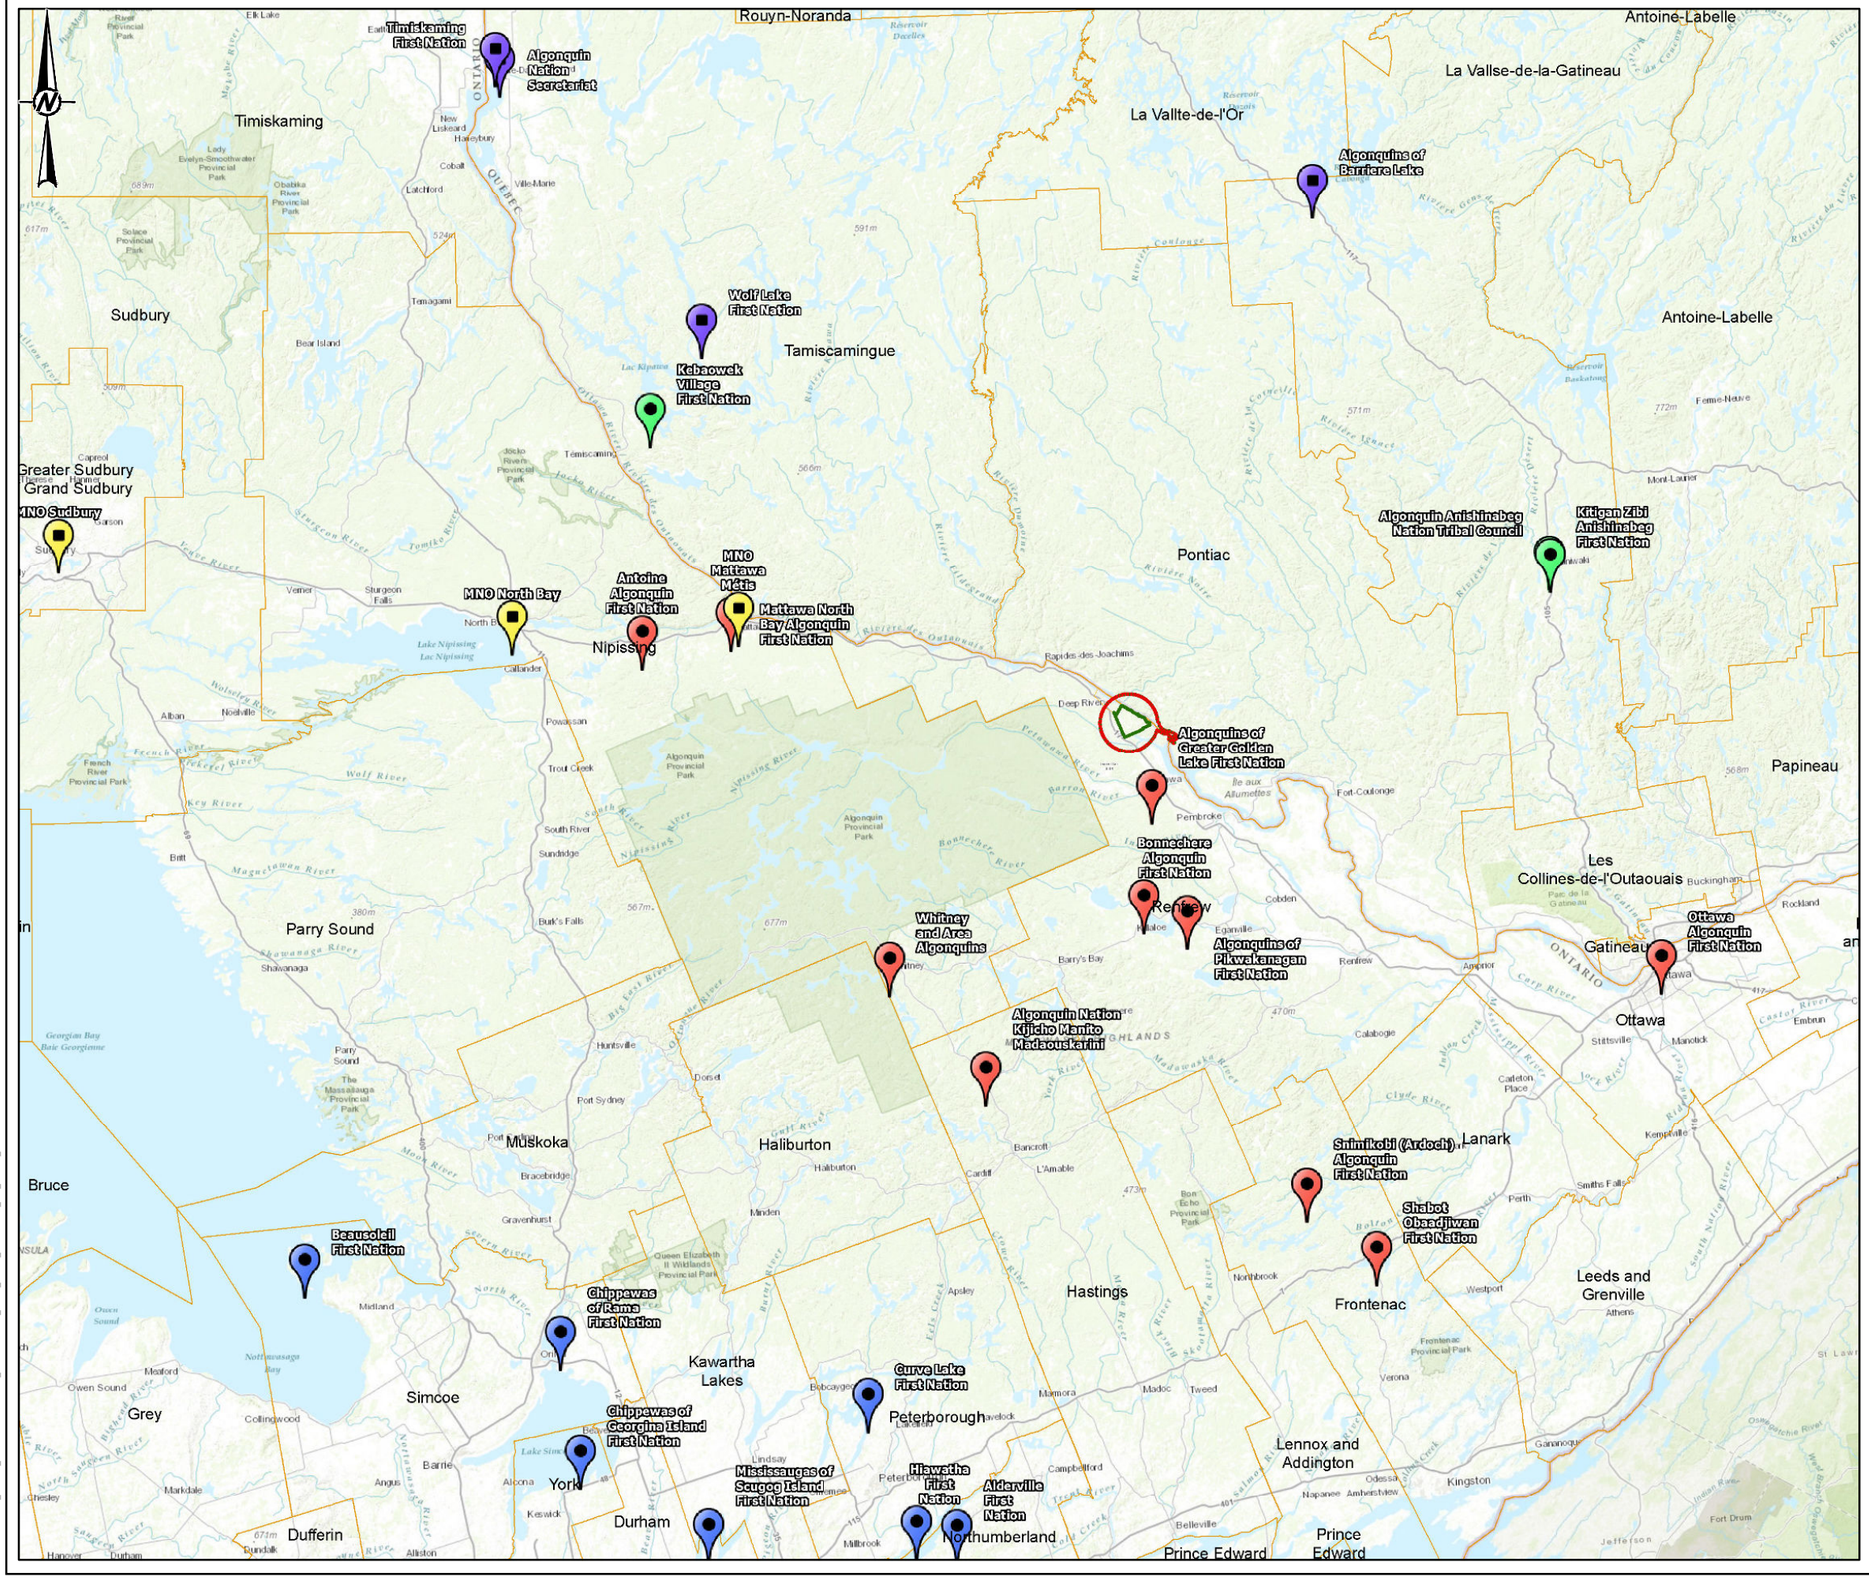
Technical Assistance and Contribution Agreements	▪ Contribution Agreements entered into with the AOPFN and under development with Curve Lake First Nation ▪ Provision of funding to assist in technical review of CNL produced studies ▪ Provision of funding for Indigenous led studies ▪ Peer review studies and engagements with Indigenous organization consultants and staff ▪ Work plan development to formalize engagement processes with communities and/or organization representatives
Project Specific Meetings and Workshops	▪ Meetings/workshops with Indigenous community and/or organization representatives to discuss the NSDF Project and potential effects ▪ Community meetings/open houses ▪ Presentations to Indigenous communities and/or organization representatives upon request ▪ Targeted community initiatives ▪ Workshop attendance and cultural awareness training ▪ Technical meetings, upon request, to provide interested communities and/or organization representatives an opportunity to discuss more detailed technical information concerning the NSDF Project
Specific Communications Activities	▪ Letters to Indigenous communities and/or organization representatives (accompanied by follow-up calls) ▪ Email correspondence and/or phone calls with Indigenous communities and/or organization representatives ▪ Distributing the IER to Indigenous communities and/or organization representatives ▪ Distributing copies of maps, technical studies or reports upon request ▪ Webinars and online meetings with Indigenous communities and organizations

Table 6.2.3-1: Project-specific Engagement Methods

Engagement Method	Example Activities
General Communications Activities	▪ NSDF Project notifications and newspaper advertisements ▪ ESC meetings (for ESC member communities) ▪ Public information sessions, including display materials and handouts ▪ Media notifications/releases ▪ Webpage content ▪ Site visits and participation in National Indigenous Day ▪ Participation and presentation at Indigenous Youth Summit ▪ NSDF Project site visits and benchmarking tours

6.2.4 Engagement

6.2.4.1 Introduction



Formal notification of the NSDF Project in the form of a letter was sent to all identified Indigenous Peoples communities and organizations on July 15, 2016. The letter provided information about the NSDF Project and provided mechanisms for comments and/or questions. Follow-up outreach (i.e., phone contact) was conducted with recipients to confirm receipt of the NSDF Project information and to ascertain the best means for on-going contact.

Engagement activities have varied and are at the discretion of the various communities and subject to community availability. Table 6.2.4-1 provides a summary of engagement activities that have continued through to May 2021 in preparation of the EIS. As the NSDF Project and environmental assessment process progresses, the IER will be updated and maintained as a living document going forward capturing any additional engagement activities undertaken and progress made on engagement issues.

There is crossover in several instances in engagement activities between the NSDF Project and CNL's NPD Closure Project given the proximity and relative timelines of each project. As such, engagement that addresses both projects are also noted here so as to report on the discussions in their original context. Examples of correspondence and meeting materials are provided in the appendices of the IER and all records of meeting presentations are kept and can be provided upon request.

The list of Indigenous communities and organizations included in Table 6.2.2-1 are described in this section of the EIS and in more detail in Chapter 3 of the IER. These sections also describe the rationale for the inclusion of the various communities. Figure 6.2.4-1 below shows the home location (Reserve or office) of these various communities in relation to the NSDF site.

Table 6.2.4-1 below quantitatively describes and summarizes the various Indigenous engagement activities undertaken for the NSDF Project. The table is intended to demonstrate two key points:

- CNL has utilized a wide assortment of engagement tools on the consultation spectrum ranging from basic communications to two-way formal and informal dialogues to detailed studies, funding and investigation and finally to the consideration of long-term relationship agreements. The consultation activities in the columns reflect the increasing degree of engagement.
- CNL has reached out to all the Indigenous communities and organizations on the list below in the manner as demonstrated and has indicated that it is willing to engage with any Indigenous community or organization that responds back. At the same time, CNL has “deeply” engaged with those Indigenous communities and organizations that live and practice traditional activities in closest proximity to the NSDF site.

[1] CNL notes that the number of meetings includes Long-Term Relationship Agreement meetings.

[2] All Indigenous communities and organizations listed in Table 6.2.4-1 were provided the 2019 revised Draft EIS. This column identifies those that CNL has received confirmation from that a review of this draft had been conducted.

This page intentionally left blank

Table 6.2.4-1 generally demonstrates that more and deeper engagement has occurred with Indigenous communities and organizations that are generally located closer to the NSDF site, have populations living closer to the NSDF site, and, as identified by the communities and organizations themselves, have larger numbers of individuals practicing traditional activities near the NSDF site.

Outlined in the remainder of Section 6.2.4 is a summary of engagement that CNL has undertaken with each identified Indigenous community and organization that CNL has engaged with. Section 6.2.4 is a summary of the engagement and the reader is encouraged to review the IER for more detail on engagement with each Indigenous community and organization. Chapter 3 of the IER describes each community in detail and Chapter 4 of the IER describes the engagement in detail.

In the Appendices of the IER (i.e., each Indigenous community and organization has a dedicated appendix) are detailed five-column tables labelled as “Tables of Interests and Concerns of Each Indigenous Community/Organization” (Tables of Interests). These tables were developed for the final revision of the EIS and are intended to describe in more detail the substance and stage of engagement with each Indigenous community and organization on their various interests and concerns raised. These Tables of Interests in the IER identify the specific comments that have been formally submitted to the CNSC and CEAA or identify that the concerns and comments have been raised directly to CNL.

Engagement with individual Indigenous communities and organizations are not all at the same stage. Some Indigenous communities and organizations became engaged early on with NSDF, often on highly specific topics while other communities have only more recently shown an interest in the NSDF Project. As well, some communities may have engaged early on in some interests and concerns but only more recently with others. As such, CNL has had significant discourse and formal exchange of comments and responses to some communities on some interests and concerns with results having been incorporated into the EIS while with other communities the engagement is not as advanced. With all Indigenous communities and organizations, in addition to seeking the information on Indigenous interests required by the CNSC and CEAA, 2012, CNL developed and adapted its engagement activities with each Indigenous community or organization according to the unique interests, information needs and concerns of each. The Tables of Interests have been organized and presented to describe the stage of engagement with each community and organization on each interest and concern.

The Tables of Interests from the IER are summarized in this section. With each Indigenous community and organization, CNL has briefly described the Indigenous community or organization and then described the engagement according to the following headings.

- **Engagement.** This sub-section summarizes the engagement CNL has had with the Indigenous community or organization.
- **Feedback.** This sub-section describes the specific topics of interest or concern each Indigenous community or organization has identified formally in writing and/or verbally to CNL. Each bullet point represents a general theme identified by each Indigenous community or organization.
- **Summary Discussion of Interest or Concern.** Within each bullet CNL has generally described the interest or concern as raised and also discussed in summary form its response to the interest and discussions on the topic. This feedback section directly corresponds to Columns 2 (Key Interests and Concerns) and 3 (How CNL is addressing the Feedback/Concern) in the Tables of Interests.

- **Verification.** The purpose of the verification section is to describe the status of each interest or concern with each community (as of May 2021).
  - Where Indigenous communities or organizations submitted formal comments on the 2017 Draft EIS, CNL has responded to those comments and provided written responses to the respective Indigenous community or organization also indicating where changes to the EIS have been made. In some cases, the interest or concern raised has been resolved. However, there may be circumstances where there is a difference in opinion and/or the Indigenous community or organization have not confirmed that the response by CNL is deemed acceptable, even though multiple attempts have been made to perform verification.
  - CNL also notes that the NSDF Project has directly received submissions or comments from specific Indigenous communities and organizations, including comments on the 2019 revised Draft EIS and the 2020 Final EIS. CNL has provided written responses to the Indigenous communities and organizations, indicating where changes have been incorporated in the EIS.
  - CNL has also responded in writing to questions received during presentations when a response in writing was requested by the Indigenous community or organization.
  - CNL requested feedback from all identified Indigenous communities and organizations on assumptions CNL had made in the EIS with respect to traditional land use around the CRL site. CNL has incorporated information from traditional land use and knowledge studies that have been completed by the AOO, the AOPFN and MNO and verified with these organizations and community the studies were reflected adequately in this EIS.
  - CNL has provided a summary of commitments CNL has made to the Indigenous community or organization during NSDF Project engagements, to seek confirmation from the respective Indigenous community and organization.
- **Next Steps.** This sub-section describes where CNL is as of May 2021 with each Indigenous community or organization and how it plans to address outstanding interests or concerns. CNL is aware that some interests and concerns go beyond the scope of the NSDF Project or there remain a difference of opinion on certain concerns. As such, CNL is attempting to listen, respond to and, if possible, address all interests and concerns raised. “Next Steps” is the last column in the Tables of Interest.

CNL has also developed a system to generally describe where each Indigenous community/organization is in the engagement and verification process/steps. The verification process is similar to the above points but is described below.

- **Process Step #1 –** Receive Formal Comments on the Project Description or 2017 Draft EIS from Indigenous community or organization.
- **Process Step #2 –** Share the 2019 revised Draft EIS and offer to meet and discuss how comments were incorporated:
  - 2 (a) If offer accepted, draft responses to comments on 2017 Draft EIS prior to the meeting (e-mail and/or registered letter); and

  - 2 (b) If no response, share draft responses to comments on 2017 Draft EIS and offer again to meet and discuss (e-mail, registered mail, follow-up by phone).

- **Process Step #3 –** Acknowledgement and possibly feedback from Indigenous community or organization. CNL incorporates any feedback received by revising responses.
- **Process Step #4 –** Share revised draft responses to comments for confirmation by Indigenous community or organization.
- **Process Step #5 –** Finalize EIS.

Where each Indigenous community or organization is in the above process is described below within each Verification sub-heading.

6.2.4.2 Algonquins of Ontario (AOO)

The Algonquins of Ontario (AOO) is an organized collective of Algonquin communities assembled to enable a unified approach to reaching a settlement over a comprehensive land claim including an area of over 3.6 million hectares (ha) within the Ottawa River and Mattawa River watersheds in eastern Ontario (AOO, 2020b). The area that is the subject of the Algonquin Land Claim in Ontario includes the National Capital Region, all of Renfrew County and most of Algonquin Park. The AOO is comprised of ten Algonquin communities located within the Ottawa Valley: Antoine Algonquin First Nation; Algonquins of Pikwakanagan First Nation; Algonquin Nation Kijicho-Manito Madaouskarini; Bonnechere Algonquin First Nation; Algonquins of Greater Golden Lake First Nation; Mattawa/North Bay Algonquin First Nation; Ottawa Algonquin First Nation; Shabot Obaadjiwan First Nation; Snimikobi (Ardoch) (Beaver Creek) Algonquin First Nation; and, Whitney Area Algonquins. Sixteen Algonquin Negotiation Representatives (ANRs), serving three-year terms represent these communities. The ANRs are comprised of the Algonquins of Pikwakanagan First Nation Chief and Council (six Councillors) along with one representative from each of the other Algonquin communities listed above. The CRL property is located within unceded AOO Settlement Area. The AOO has indicated to CNL that the AOO have Aboriginal rights and title throughout the unceded AOO Settlement Area, including the CRL site. This land claim is currently under negotiation by the Algonquins of Ontario and the Governments of Canada and Ontario.

A fuller description of the AOO can be found in Chapter 3 of the IER.

In 2018, the AOO, AECL and CNL signed a tri-partite Memorandum of Understanding (MOU) to guide dialogue between the parties on matters of mutual interest. More specifically the MOU was intended to be a vehicle to work towards the development of a Long-Term Relationship Agreement amongst the parties. The MOU identified the need for both a Technical Group to deal with the NPD project and a Long-Term Relationship Group that would advance a Long-Term Relationship Agreement amongst the parties. The MOU broadly identified potential topic areas for the Long-Term Relationship Agreement. Over 2019, through 2020 and into 2021, the AOO, AECL and CNL developed a Terms of Reference and work plan for the Long-Term Relationship Agreement. The Long-Term Relationship Agreement is intended to cover the interests of all three parties with respect to both the CRL and NPD sites as well as other further projects and/or initiatives across the unceded AOO Settlement Area. The Long-Term Relationship Agreement discussions are relevant to NSDF as it is expected that certain project specific initiatives and commitments will be implemented or realized under the agreement. While the AOO decided to initially focus its interests on the Long-Term Relationship Agreement and the NPD project, more recently the AOO has reviewed the NSDF Project draft 2020 Final EIS as a result of capacity provided by CNL.

6.2.4.2.1 Engagement

Table 6.2.4-2 below summarizes AOO engagement and Appendix J.1 of the IER provides a detailed record of engagement activities that have occurred with AOO on the NSDF Project and/or Long-Term Relationship Agreement.

Table 6.2.4-2: Algonquins of Ontario (AOO) Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings*, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Algonquins of Ontario	14	69	17	Yes	42	2019	MOU	Yes (AKLUS)	Yes (2020 Final EIS, as well as Sections 6.2 and 6.4 of the 2021 Final EIS)	Yes

The complete table is located in Section 6.2.4.1.
* CNL notes that the number of meetings includes Long-Term Relationship Agreement meetings.

CNL first reached out to representatives with the AOO in June 2016, after receiving a copy of the AOO's comments on the 2016 Project Description for the NSDF Project, with an invitation to meet and discuss the NSDF Project. Engagement activities with the AOO commenced in August 2016 after receipt of the CNL NSDF Project introductory letter sent in July 2016.

In August 2016, CNL hosted AOO Consultation Office and Technical staff for an information session at the CRL site as well a tour of the two proposed NSDF Project location sites. Activities later in 2016 included discussions on archaeological liaison participation at the proposed NSDF site as well as sharing documents of interest to the AOO, which included biodiversity reports, archaeological information and topographical maps of the CRL site.

In March 2017, CNL shared the NSDF Project 2017 Draft EIS and encouraged the AOO to participate in the public and Indigenous comment period followed by a meeting with the AOO Consultation staff and the Algonquin Negotiation Representatives (ANR) to discuss future engagements on the NSDF Project. CNL also hosted the ANRs to the CRL site for a tour in April and June 2017 which included the proposed NSDF site and a discussion on a work plan. The AOO did not submit comments on the NSDF Project 2017 Draft EIS through the environmental assessment process.

In June 2017, an information session for AOO community members was held in Pembroke, ON, which included a project overview as well as an opportunity for one-on-one discussions with NSDF Project technical staff. Over 8,000 AOO community members were sent the invitation by mail and approximately 15 were in attendance. All questions were verbally addressed at the open house. In late 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning. CNL did not receive any feedback from the AOO on this report.

CNL and the AOO started discussions on developing a Memorandum of Understanding (MOU) in early 2018, which included multiple meetings and email correspondence resulting in a signed MOU in July 2018. The MOU set the platform for AOO, AECL and CNL to enter into discussions on a Long-Term Relationship Agreement. Long-term relationship agreement meetings continue with signing estimated in 2021.

Throughout 2018 and 2019, CNL evolved project engagements to meet Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. The AOO received invitations to all engagement activities and have been in attendance at select events to date.

Upon request, the NSDF Project provided an update to the AOO's Planning and Environmental Working Group in December 2019 which included a summary of how Indigenous Peoples key interests were addressed and the introduction of the new Indigenous Interests section in the 2019 revised Draft EIS. All questions were verbally addressed at the meeting.

In December 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with the AOO and encouraged community input for the final revision. In May 2020, CNL provided AOO with a follow-up letter on the 2019 revised Draft EIS and IER for discussion and verification of the AOO's comments on the 2016 Project Description. The letter also contained an invitation to meet and discuss the AOO's specific interests and concerns with respect to the NSDF Project. The AOO responded in July 2020 that they only had capacity funding for a review of the Final EIS and EA Report stage and requested additional capacity funding from CNL to undertake a

review of the 2019 Draft EIS. The AOO later clarified (via email correspondence in October 2020) that in the AOO's initial review of the 2017 Draft EIS they understood that the NSDF Project would enable the CRL site revitalization through improved environmental management of Government of Canada legacy waste liabilities, and the decommissioning of outdated infrastructure at the CRL property and other business locations. However, the 2019 revised Draft EIS recognized the advent of small modular reactors (SMRs) thus resulting in CNL updating the Reasonably Foreseeable Development (RFD) case and the cumulative effects assessment thus altering the AOO's consideration of impacts on rights and interests. Thus changing the AOO's level of interest in the NSDF Project and the AOO now desired to review the most recent version of the EIS. Although the AOO intended to review the 2019 revised Draft EIS, capacity funding arrangements were not confirmed until late 2020. As a result, AOO and CNL agreed that the AOO would complete a technical review of the 2020 Final EIS given its forthcoming availability.

CNL continued to provide bi-monthly webinar updates throughout 2020, including an email invitation to participate in the NSDF Virtual Open House (VOH) from October 12 to 25, 2020. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions.

In December 2020, CNL sent the AOO notification of the submission of the 2020 Final EIS to the CNSC and the availability of the document online. The AOO shared with CNL a preliminary technical report of the AOO's review of the 2020 Final EIS in January 2021. In February 2021, CNL sent the AOO a letter addressing at a high level some of the AOO interests and concerns identified within the preliminary technical report, indicating individual comments and recommendations would be responded to by CNL once the AOO's report was finalized. In early March 2021, the technical review was approved by the ANRs and the AOO shared the final report with CNL. In mid-March 2021, CNL provided the AOO with draft responses to the individual comments and recommendations from the AOO's technical review of the 2020 Final EIS. CNL proposed commitments as next steps for any outstanding interests and concerns as well as extended an invitation to meet and discuss.

Separately, CNL along with the CNSC, provided supplemental funding to the AOO to support an Algonquin Knowledge and Land Use Study (AKLUS) which commenced in 2019. CNL provided a NSDF Project overview presentation in June 2019 at the Algonquin Knowledge and Land Use Study Workshop in Deep River, ON. All questions were answered verbally at the workshop. In December 2020, the AOO shared the final results of the AKLUS with CNL which included both general and site-specific recommendations for CNL to address the potential impacts of the proposed NSDF Project on Algonquin interests. The AOO indicated that there is an expectation that CNL would provide written responses to each of the enclosed comments and recommendations. In February 2021, CNL provided written responses to each of the comments and recommendations which had accompanied the AOO AKLUS. CNL proposed commitments as next steps for any outstanding interests and concerns as well as extended an invitation to meet and discuss. Additionally, since it was necessary for the NSDF Project to make revisions to the EIS in order to meet CNSC staff expectations from the review of the 2020 Final EIS; CNL took the opportunity to acknowledge and incorporate summaries of the AOO AKLUS into Section 6.4 of the Final EIS. In February 2021, recognizing the AKLUS is proprietary information to the AOO, CNL shared the revisions of Section 6.4 with the AOO and received written feedback which has been incorporated into the Final EIS.

In February 2021, the AOO suggested and CNL agreed to (as well as provided capacity for) an Issues and Resolution Workshop which would be an integrated discussion of the outstanding interests and concerns from both the AOO technical review of the 2020 Final EIS and the comments and recommendations which had accompanied the AOO AKLUS. During the workshop in April 2021, the AOO representatives made it clear that

from AOO's perspective there are outstanding information requests and reviews that are still in progress. CNL has provided additional information in April 2021 and pending the AOO's review, the AOO will report back on whether the information provided resolves the respective outstanding interests or if additional commitments are required to address the concern. This has been deemed acceptable to both parties, AOO has received sufficient capacity to participate in the now very extensive and mature NSDF Project environmental assessment process. CNL has captured any outstanding interests which are in progress or not resolved within Section 6.2.4.2.3 below. CNL notes that the IER will be a living document that will include any updates related to the progress of the outstanding interests prior to the Commission Hearing process.

In March 2021, CNL shared a link (via email) with AOO to the draft Environmental Assessment Follow-Up Monitoring Program (EAFMP) for the proposed NSDF Project for review. CNL included a request for input and ideas for NSDF follow-up monitoring as well as an invitation to meet and discuss the draft NSDF EAFMP. CNL also advised of potential focus group workshops, for AOO participation, on various aspects of the EAFMP in the late spring/early summer 2021 timeframe.

In May 2021, CNL sent a letter to the AOO providing a summary of commitments intended to support the resubmittal of the NSDF Project Final EIS. The list of commitments was reflective of the resolution status and next steps which had been agreed to by both CNL and AOO during the Issues and Resolution Workshop as well as subsequent emails and discussions in April 2021. CNL indicated that the commitments list is an evergreen list and has asked for a response if there were any concerns regarding the commitments list. In late-May a meeting that included the CNSC, CNL, AECL and the AOO was held with the objective to discuss proposed measures and/or commitments to address potential impacts to AOO's Indigenous Rights as identified in the CNSC's Rights Impact Assessment. At the meeting the AOO indicated they were generally satisfied with the engagement by CNL to date and in agreement with the summary of commitments CNL had provided.

6.2.4.2.2 Feedback

The AOO provided feedback on the 2016 Project Description however did not provide formal comment on the 2017 Draft EIS, for the reasons previously mentioned. However, CNL has received feedback from the AOO technical review of the 2020 Final EIS as well as the comments and recommendations which had accompanied the AOO AKLUS.

Appendix J.2 of the IER provides a Table of Interests for AOO interests and concerns and CNL responses. The table also identifies and links the interests and concerns with formally submitted comments made through the environmental assessment process.

The topics in the Table of Interests are briefly summarized below.

- **Long-Term Relationship Agreement**. The AOO requested that CNL and AECL enter into negotiations with the AOO to establish a LTRA, to address consultation and engagement, economic opportunities, future land uses, and environmental and cultural heritage stewardship and monitoring.
- **Acknowledgement that CRL is in the Unceded Algonquin Settlement Area**. During the review of the 2016 Project Description, the AOO made the request that a statement be placed in the NSDF Project Description acknowledging CRL is in the unceded Algonquin Settlement Area.
- **Impact on Rights.** The AOO have expressed concern about the historical cumulative effects of the CRL site as well as raised concerns with respect to the NSDF Project's potential impacts on Algonquin rights.

- **Engagement**. During the review of the 2016 Project Description, the AOO requested that all ten AOO communities be included in the engagement process as well as was concerned about the flow of information from CNL to the Algonquins.
- **Independent Oversight.** The AOO requested opportunities for involvement and participation in the oversight for the NSDF Project.
- **Protection of the Kichi-Sìbì (Ottawa River).** The AOO expressed that the protection of the Ottawa River is of extremely high priority to AOO.
- **Protection of the Flora and Fauna**. The AOO expressed the importance of flora and fauna to their communities and general awareness of biological studies.
- **Archaeological Assessment.** The AOO stated the significance of archaeological resources within their claim area as well as commented the description of the archaeological assessment within the EIS is missing critical details from the AOO's perspective. The AOO also requested to be meaningfully engaged in the development of the NSDF Project's cultural heritage protection plan.
- **Environmental and Cultural Heritage Stewardship and Monitoring**. The AOO expressed concerns with respect to cultural, environmental and rights impacts as well as requested a role in the design and implementation of future environmental and cultural heritage stewardship and monitoring, both NSDF Project and site-wide CRL monitoring.
- **Algonquin Knowledge and Land Use**. The AOO identified the need for Algonquin knowledge to be incorporated into the EIS and requested funding for an AKLUS. Within the AKLUS report the participants expressed concerns with, but not limited to, impacts to traditional land and resource use and cultural heritage.
- **Valued Components**. Through engagement activities and correspondence, the AOO indicated interest in specific Valued Components.
- **Socio-economic**. Participants of the AKLUS indicated a strong interest in obtaining more socio-economic benefits from the NSDF Project and CNL in general. In the review of the 2020 Final EIS, the AOO commented that there are gaps in the socio-economic VCs and associated assessment. The AOO's concern is CNL does not acknowledge the linkages between ecological, human health and socio-economics as inter-connected impacts on the AOO.
- **Human Health**. The AOO commented that traditional food quality be used to assess protection of human health, requested support for an AOO-driven traditional foods study and requested additional details to demonstrate the conservatism of the human health risk assessment.
- **End State/Closure Plan.** The AOO request that the CNL explicitly commit to requiring their input and approval prior to ceasing monitoring activities on site.

6.2.4.2.3 Summary Discussion of Interests and Concerns

As previously indicated this Summary Discussion of Interests and Concerns is taken from the Tables of Interest that appear in Appendix J.2 of the IER. The discussion of the interests and concerns below is CNL's understanding based on written submissions and oral discussions with the AOO. CNL has made its best efforts to

document the position the AOO has taken on each interest/concern while acknowledging that the AOO may articulate the perspective somewhat differently.

Long-Term Relationship Agreement

The AOO requested that CNL and AECL enter into negotiations with the AOO to establish a LTRA, to address consultation and engagement, economic opportunities, future land uses, and environmental and cultural heritage stewardship and monitoring. The AOO has expressed that while the meetings to advance the LTRA were critical to advance the framework for ongoing collaboration, these meetings do not fully address NSDF Project-specific impacts. As previously indicated, the AOO, AECL and CNL have undertaken steps towards a LTRA that is intended to cover all AECL/CNL activities in the unceded AOO Settlement Area. AECL, AOO and CNL see the LTRA as a way to address site wide concerns and interests at CRL that go beyond the scope of the NSDF Project.

The LTRA will also allow for a more broad-based platform for all three parties to discuss solutions such as AOO involvement rather than just participating specifically in NSDF Project environmental monitoring. Several meetings have focused on the development of the LTRA and as of May 2021, it is nearing completion. CNL considers this concern outside the scope of the NSDF Project and is addressed as the development of the LTRA is underway.

Acknowledgement that CRL is in the Unceded Algonquin Settlement Area

During the review of the 2016 Project Description, the AOO made the request that a statement be placed in the NSDF Project Description acknowledging CRL is in the unceded AOO Settlement Area. CNL fully acknowledges that CRL is located in the unceded Algonquin Settlement Areas. The requested statement is included in in Section 6.2.4 and 6.4.4.1.2 of the Final EIS. The acknowledgement statement has been slightly revised based on AOO interventions at the CRL site license hearing as well as AOO feedback during their review of the 2020 Final EIS. CNL considers that the concern has been addressed with revisions to the Project Description and the EIS.

Impact on Rights

The AOO has expressed concern about the historical cumulative effects of the CRL site. This concern regarding historical impacts is not specific to the NSDF Project and is related to overall CRL site operations. As the landowner, AECL is engaging with Indigenous communities and organizations alongside CNSC and CNL to build meaningful and productive relationships.

The AOO also expressed concerns with respect to the NSDF Project's potential impacts on Algonquin rights. CNL has communicated to the AOO that as it is CNL's opinion there are no traditional land uses determined to be affected by the proposed project (a finding that AOO disagrees as noted in the AOO's review of the 2020 Final EIS). As there are no traditional land uses determined to be affected by the proposed project, CNL is of the view that Algonquin rights will not be impacted by the NSDF Project activities. CNL acknowledges the AOO disagree with this conclusion and contend through their review of the 2020 Final EIS there are project specific activities that may directly impact traditional land uses and Aboriginal rights and interests beyond the CRL site. Thus this concern will remain unresolved between CNL and the AOO. Determination as to whether the proposed project has impacts on Aboriginal and Treaty rights remains with the CNSC as the representative of the Crown.

Engagement

During the review of the 2016 Project Description, the AOO requested that all ten AOO communities be included in the engagement process as well as was concerned about the flow of information from CNL to the Algonquins.

CNL has moved forward by engaging with the entire AOO organization. All ten AOO communities are identified in Section 6.2.2 the EIS and they are more extensively described in Section 3.3 of the IER. Since 2016, CNL has carried out extensive engagement with the AOO, implemented a Memorandum of Understanding (MOU), and carried out engagement activities and Long-Term Relationship Agreement (LTRA) discussions with the AOO in the form that the AOO has requested. CNL considers this concern addressed as CNL has engaged with AOO and all ten AOO communities.

Independent Oversight

The AOO requested that opportunities for Algonquin participation, review and engagement in Project oversight within the context of the information provided are specified in commitments from the NSDF Project and executed as part of the LTRA. CNL has provided clarification on how the CNSC provides independent regulatory oversight for nuclear facilities within Canada. CNL considers this concern addressed in regulatory requirements. CNL has offered involvement and participation opportunities to the AOO through a number of commitments, which include but are not limited to: engagement and technical review of EAFMP, engagement in the SFMP and co-development of a number of NSDF Project plans.

Protection of the Kichi-Sìbì (Ottawa River)

On a number of occasions, the AOO expressed that the protection of the Kichi-Sìbì (Ottawa River) is of extremely high priority to AOO. Participants in the AKLUS identified concerns with respect to loss of connection and use of lands and water, the proximity of the NSDF Project to the Kichi-Sìbì (Ottawa River), the potential for contamination of the waterways, plants and animals as well as the bioaccumulation of contaminants in fish species.

CNL recognizes that the AOO highly value the Kichi-Sìbì (Ottawa River) and CNL has had made its best efforts to communicate to the AOO how the proposed NSDF Project is designed to protect the Ottawa River. Engagement efforts have occurred with AOO community members and the AOO staff and their consultants. CNL has provided clarification and technical evidence to support CNL's assertion that NSDF is designed to protect the Ottawa River. CNL views the NSDF proposal as an improvement over the current environmental conditions at the CRL site. CNL has updated the EIS to include information from technical supporting documents and continues to discuss the protection of the Ottawa River with AOO.

In response to these concerns, CNL has increased the RSA for surface water (Section 5.4.2.3.1), aquatic environment (Section 5.5.3.1), land and resource use (Section 5.9.3.1), ecological health (Section 5.7.3.1), and human health (Section 5.9.3.1) to extend 8 km downstream of the CRL site within the Ottawa River. This represents a significant expansion from the RSA used in the 2017 Draft EIS which was limited to the mouth of Perch Creek relative to the Ottawa River. Furthermore Section 8.3.3 of the Final EIS summarizes the cumulative effects on the surface water environment. It concludes that residual effects on Ottawa River water quality are determined to be negligible during operations and post-closure phases and may result in a net benefit due to remediation of legacy waste storage areas at the CRL site.

CNL considers this concern is addressed as CNL has demonstrated how the NSDF will ensure protection of the Ottawa River during multiple engagement activities with AOO. CNL acknowledges the AOO's connection with the land and water. CNL also acknowledges that from AOO's perspective, there remain outstanding information requests and reviews with respect to the protection of Kichi-Sìbì (Ottawa River) which are currently in progress. CNL has made the draft EAFMP available to AOO for technical review and input (March 2021).

Protection of Flora and Fauna

On a number of occasions the AOO expressed the importance of flora and fauna to their communities and general awareness of biological studies. Participants in the AKLUS identified concerns with respect to loss of connection and use of lands and water, the potential for contamination of the waterways, plants and animals, the bioaccumulation of contaminants in fish species, impacts to species at risk as well as concerns about the safety of harvesting and consuming harvested foods. In the AOO's technical review of the 2020 Final EIS, the AOO provided comments regarding assessment endpoints, protection of fish and fish habitat as well as protection of species at risk.

Engagement efforts have occurred with AOO community members and the AOO staff and their consultants. CNL has provided clarification and technical evidence to support CNL's assertion that the NSDF is designed to protect fish, wildlife, and plant species during as well as ensure there is sufficient habitat for these species continues to be available. CNL views the NSDF proposal as an improvement over the current environmental conditions at the CRL site. CNL has updated the EIS to include information from technical supporting documents and continues to discuss the protection of the environment with AOO.

The RSA for Traditional Land and Resource Use (Section 6.4.3.1 of the Final EIS) was selected as the combined area of the air quality, terrestrial, and aquatic assessments' RSAs (Figure 6.4.3-1). The RSA is defined to capture and evaluate residual environmental effects as a result of the NSDF Project because these may, in turn, affect traditional land and resource use (e.g., habitat loss, sensory disturbance for wildlife and changes to habitat from air quality and surface water quality, changes in groundwater and surface water quality, changes in species abundance, distribution, and disturbance to terrestrial and aquatic biota). The NSDF Project is not predicted to have any terrestrial effects beyond the CRL site, and results of the aquatic environment assessment identified only negligible residual effects on aquatic biodiversity valued components as a result of the NSDF Project. Species at risk were also a consideration of NSDF site selection as well the NSDF Project has proposed a SFMP as an off-set to habitat loss and offered the AOO involvement in its development.

CNL acknowledges that from AOO's perspective there remain outstanding information requests and reviews with respect to the protection of fish and fish habitat, as well as protection of species at risk, that are currently in progress. This includes AOO's concern with respect to adequacy of baseline values for radioactivity in fish within Perch Lake as well as the adequacy of assessment endpoints that measure the impacts of NSDF Project activities on fish health. CNL has provided the additional information with the next step for the AOO to complete their review and report back on whether the information provided resolves the respective outstanding concern or if additional commitments are required to address the concern. CNL recognizes the AOO's connection with land and water thus has made the draft EAFMP available to AOO for technical review and input (March 2021).

Archaeological Assessment

The AOO stated the significance of archaeological resources within their claim area as well as commented that the description of the archaeological assessment within the EIS is missing critical details from the AOO's perspective. The AOO also requested to be meaningfully engaged in the development of the NSDF Project's cultural protection plan.

CNL has considered the proximity to archaeological sites as part of the site selection process (Section 2.5.5 of Final EIS). CNL has also facilitated Algonquin involvement in archaeological work at the CRL site generally and NSDF specifically. CNL has made several revisions suggested by the AOO in various sections of the EIS to clarify

the archaeological assessments, although these changes do not have an impact on the conclusions of the assessment. No further archaeological work is required on NSDF and CNL has in place a chance find procedure as part of its cultural monitoring program in the event an artefact is discovered during construction. CNL considers this concern is addressed as CNL has incorporated the suggested revisions as well as involved Algonquins in the NSDF archaeological work. CNL considers AOO's general archaeology concerns have also been addressed with development of the LTRA. Additionally, CNL is committed to co-developing a project specific cultural and heritage protection plan (CHPP) with the AOO prior to finalizing the NSDF Project construction work control documents.

Environmental and Cultural Heritage Stewardship and Monitoring

The AOO expressed concerns with respect to cultural impacts as well as requested a role in the design and implementation of future environmental and cultural heritage stewardship and monitoring, both NSDF Project specific and CRL site-wide monitoring. CNL has agreed with AOO's request to be involved in future stewardship and monitoring activities – both at a NSDF Project and CRL site level. AECL, AOO and CNL see the LTRA as a way to address site wide concerns and interests at CRL that go beyond the scope of the NSDF Project. The LTRA will also allow for a more broad-based platform for all three parties to discuss solutions such as AOO involvement in environmental and cultural heritage stewardship and monitoring rather than just participating specifically in NSDF Project monitoring. Additionally, CNL has made the draft EAFMP available to AOO for technical review and input (March 2021). CNL is committed to co-developing a project specific cultural and heritage protection plan (CHPP) with the AOO prior to finalizing the NSDF Project construction work control documents.

Algonquin Knowledge and Land Use

The AOO identified the need for Algonquin knowledge to be incorporated into the EIS and requested funding of which both CNSC and CNL have provided financial capacity to the AOO to undertake it. The study was completed in December 2020. The findings of the AOO AKLUS have been incorporated into the Final EIS including a summary of the AOO AKLUS in Section 6.4.

Culturally significant sites for the AOO were identified within the AKLUS such as Pointe Au Baptême and Oiseau Rock. CNL has clarified with the AOO that Pointe Au Baptême and Oiseau Rock are not within the NSDF Project footprint thus they would not be impacted by the NSDF Project. Furthermore, these sites are not within CRL site thus CNL does not restrict access to these culturally significant sites.

Participants in the AKLUS identified concerns with respect to loss of connection and use of lands and water, the proximity of the NSDF Project to the Kichi-Sìbì (Ottawa River), concerns about the safety of harvesting and consuming harvested foods, changes to accessing important Algonquin cultural sites and the risk of NSDF Project activity impacts to ancestral values. In response CNL has assumed within the EIS traditional uses do occur adjacent and near to the CRL site, whether on the Ottawa River or on accessible private lands outside the restricted/fenced area or provincial crown land outside the restricted/fenced area. CNL has concluded that the NSDF Project is not expected to affect the traditional land and resource uses because the NSDF Project is located on CRL property on federal lands that are inaccessible to the public where traditional use is not permitted. Furthermore, CNL does not anticipate any off-site effects from the NSDF Project that would affect traditional land use and resource VCs (Section 6.4.6 of the Final EIS). The AOO is not in agreement with this conclusion thus this concern will remain unresolved between CNL and AOO. As noted below under human health, the AOO's perspective is there remain outstanding information requests and reviews with respect to the protection of human health that are currently in progress.

CNL acknowledges that from the AOO's perspective, existing concerns and/or perceptions have the potential to be further exacerbated by the NSDF Project if there are not adequate monitoring, transparent communication and outreach with AOO and Algonquins. CNL recognizes that some Algonquins have concerns or perceptions with respect to performing traditional activities close to the CRL site. Although these concerns are not specific to the NSDF Project, CNL acknowledges its role as providing education opportunities and undertaking communications with Algonquin people to alleviate such concerns and fears. As such CNL believes that the LTRA will provide an enhanced platform to carry out such communications.

Valued Components

Through engagement activities and correspondence, the AOO indicated interest in specific VCs. Within the AKLUS report the participants identified a number of features in proximity to the NSDF Project including habitat for wildlife habitat for wildlife, vegetation species, cultural sites, water travel routes and wildlife and harvesting and fishing areas. CNL has incorporated the AOO's feedback into the Final EIS reflecting the Algonquin VCs of cultural significance into Section 6.3.2 as well as reflected inputs from the AOO AKLUS in Section 6.4. With respect to the VCs indicated by the AOO, some were not found in the EIS previously and some were represented by species that CNL was already evaluating as VCs. Table 6.3.2-1 of the Final EIS highlights how valued components identified by AOO are represented by the species that are evaluated in the NSDF Project EIS. CNL considers the concern addressed due to the NSDF Project's approach to selecting and assessing VCs. CNL recognizes the ongoing need to communicate about the NSDF Project thus remains committed to work collaboratively with AOO to avoid and mitigate impacts to VCs identified by AOO.

Socio-Economic

Participants of the AKLUS indicated a strong interest in obtaining more economic benefits from the NSDF Project and CNL in general. CNL is committed to working with the AOO to identify barriers for accessing economic opportunities from the NSDF Project, mitigation of those barriers and ways to monitor the degree to which Algonquins are able to take advantage of benefits of the NSDF Project.

In the AOO technical review of the 2020 Final EIS, the AOO commented that there are gaps in the socio-economic VCs and associated assessment. The AOO's concern is CNL does not acknowledge the linkages between ecological, human health, well-being and socio-economics as inter-connected impacts on the AOO. CNL does appreciate the holistic perspective that the AOO takes to this concern and acknowledges the validity of as a general perspective. However, CNL is of the opinion it has assessed accurately all of the pathways associated with the NSDF Project compliant with CEAA 2012. Since there were no off-site ecological effects predicted as a result of the NSDF Project (e.g., as in the case for terrestrial and aquatic environment as well as ambient radioactivity) there are then no pathway linkages to socio-economic VCs and thus further assessment is not required.

CNL acknowledges the AOO's viewpoint is that the EIS remains inadequate in assessing and addressing impacts to Algonquin health, wellbeing and socio-economics, and in turn has not adequately conveyed the full range and depth of impacts to AOO's Section 35 Aboriginal rights and interests. The AOO has indicated what the AOO is requesting is consistent with the new provisions and commitments under the *Impact Assessment Act*, but beyond the scope of CEAA 2012. The AOO further assert that the consideration of impacts to rights and interests supersedes the scope of CEAA 2012's socio-economic assessment. This concern will remain unresolved between CNL and AOO.

Human Health

The AOO commented that traditional food quality be used to assess protection of human health, requested support for an AOO-driven traditional foods study and requested additional details to demonstrate the conservatism of the human health risk assessment. The assessment of radioactivity in fish and terrestrial foodstuff are covered in Section 5.7.4.9 and 5.7.4.10 of the Final EIS respectively, as well as carried into Section 5.8 as measurement indicators. In response to the AOO's request for a traditional foods study, CNL is committed to providing capacity to the AOO to undertake a country foods survey. CNL will utilize the results of the country foods study to verify project assumptions.

Although CNL provided direct responses to the AOO's request for CNL to confirm the conservatism of the human health risk assessment, CNL acknowledges that from AOO's perspective there remain outstanding information requests and reviews with respect to human health that are currently in progress. This includes AOO's concern that the self sufficient Indigenous receptor does not account for all possible cumulative situations as well the AOO has requested additional details in order to make a determination whether the risk assessment modelling for the self sufficient Indigenous receptor also includes infants, toddlers and women. CNL has provided the additional information with the next step for the AOO to complete their review and report back on whether the information provided resolves the respective outstanding concern or if additional commitments are required to address the concern.

End State/Closure Plan

The AOO requested that the CNL explicitly commit to requiring their input and approval prior to ceasing monitoring activities on site. An initial Closure Plan has been developed but intended to be an evolutionary document that continues to be refined throughout the life (construction, operations) of the NSDF Project. CNL considers this concern addressed as CNL is committed to engaging the AOO in future planning for the closure of NSDF, including input on the timing and circumstances for cessation of monitoring activities. CNL will engage and collaborate with AOO during updates of the NSDF Closure Plan which will occur approximately every five years.

6.2.4.2.4 Verification

The AOO submitted written comments on the 2016 Project Description which CNL has addressed and verified with the AOO through their review of the 2020 Final EIS. Although the AOO did not submit written comments on the 2017 and 2019 Draft EIS, the AOO did submit written comments on the 2020 Final EIS directly to CNL. CNL has responded in detail to each of the AOO comments and received written feedback from the AOO on CNL's responses. Many of the comments were addressed from the AOO's perspective however some were considered still in progress and some were considered as unresolved. CNL notes that for the comments that are in progress, CNL and AOO are working together to resolve and have agreed upon a path forward. CNL also notes that a number of the comments unresolved are related to the Rights Impact Assessment being conducted by the CNSC or a request outside the scope of CEAA 2012. CNL has incorporated the AOO feedback to finalize the EIS thus CNL is of the opinion that it is at Process Step 5 of the CNL Verification Process with the AOO.

CNL has also received and incorporated the AOO AKLUS into the Final EIS, including a summary of the AOO ALKUS in Section 6.4. The AOO have reviewed and provided input into Section 6.4 of the Final EIS to verify that the AOO AKLUS on the NSDF Project has been appropriately represented. The findings of the AOO AKLUS confirmed CNL's previous assumptions and conservative approach that traditional activities were occurring in proximity to the CRL site, but not on the CRL site.

In May 2021, CNL sent a letter to the AOO providing a summary of commitments intended to support the resubmittal of the NSDF Project Final EIS. The list of commitments was reflective of the resolution status and next steps which had been agreed to by both CNL and AOO during the Issues and Resolution Workshop in April 2021. CNL indicated that the commitments list is a living document that may evolve as collaboration during the environmental assessment process continues and is considered the master list of next steps agreed to between AOO and CNL. In late May 2021, the AOO commitment list was reviewed in a meeting with AOO, CNL, CNSC and CNL, where the commitment list was verified by AOO.

6.2.4.2.5 Next Steps

CNL's commitments within the "Next Steps" column of the Table of Interest in Appendix J.2 of the IER, are reflective of the feedback CNL has received to date in the EA process from the AOO's technical review of the 2020 Final EIS, the AOO AKLUS as well as the AOO comments and recommendations which accompanied the AKLUS. CNL acknowledges from the AOO's perspective there are outstanding information requests and reviews that are still in progress. CNL has provided additional information and pending the AOO's review, the AOO will report back on whether the information provided resolves the respective outstanding concern or if additional commitments are required to address the concern. The IER, as a living document, will include any updates related to the progress of these next steps prior to the Commission Hearing process.

CNL recognizes that AOO involvement in the development of the EAFMP and in future long-term monitoring programs is a key area of ongoing interest. As well, CNL is committed to working with Algonquin harvesters on understanding there are no risks to traditional uses adjacent to the Chalk River site.

AOO and CNL, along with AECL, have started preliminary discussions about entering into a longer-term co-operation or relationship agreement, more broadly related to the CRL site.

6.2.4.3 Algonquins of Pikwakanagan First Nation (AOPFN)

The Algonquins of Pikwakanagan First Nation's primary residential reserve is located in the Ottawa Valley on the southeast shore of Golden Lake where it flows in to the Bonnechere River, in Renfrew County, Ontario. Pikwakanagan has a total registered population of slightly under 3,000 with the majority living off-reserve. The Reserve was established through a Crown patent in 1873 following several petitions from the community, formerly known as Golden Lake Indian Reserve No. 39. The Algonquins of Pikwakanagan First Nation have linguistic traditions in the Algonquin language. The First Nation is governed by an elected council comprised of a Chief and six councillors. The AOPFN is a sovereign entity that retains title to the land and resources of the AOO claim area and although the Algonquin Land Claim is currently being negotiated through the AOO, the AOPFN upholds the sacred responsibility to the land, is an independently governed, First Nation with Aboriginal rights associated with that standing. A fuller description of the AOPFN can be found in Section 3 of the IER.

CNL and AECL had been engaging with the AOO until 2020 when the AOPFN identified that the proper channel for engagement by CNL on the NSDF Project was through the AOPFN Consultation Coordinator, and the AOPFN needed to be engaged as an independent First Nation as engagement for this and all other CNL related projects and activities. This required CNL and AECL to consult the AOPFN separately from the AOO to address the AOPFN request for deep meaningful engagement with its members during the environmental assessment process. CNL notes that correspondence from the AOPFN in 2017 indicating interest in the NSDF Project was not received by CNL.

Prior to the AOPFN request for direct engagement, a representative of the AOPFN has been a member of CNL's Environmental Stewardship Council (ESC) since October 2006, the establishment of ESC. The AOPFN, as part of

the AOO for the negotiations of the Algonquin Land Claim, have participated in some of the engagement activities documented in the AOO section including during the development of LTRA.

6.2.4.3.1 Engagement

Table 6.2.4-3 below summarizes engagement with the AOPFN and Appendix K.1 of the IER provides a detailed record of engagement activities that have occurred with the AOPFN on the NSDF Project.

Table 6.2.4-3: Algonquins of Pikwakanagan First Nation (AOPFN) Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings*, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Algonquins of Pikwakanagan First Nation (part of the AOO)	19	118	17	—	38	2019	Contribution Agreement (CA), MOU in progress	Yes (3 – AKLUS, Culture and Rights complete; Diet and Harvest in progress)	Yes (as well as Sections 6.2 and 6.4 of the 2021 Final EIS)	Yes

The complete table is located in Section 6.2.4.1.
* CNL notes that the number of meetings includes Long-term Relationship Agreement meetings.

The Algonquins of Pikwakanagan First Nation (AOPFN) were introduced to the proposed project prior to the formal submission of the Project Description for the NSDF. In December 2015, CNL hosted the AOPFN to the CRL site which included a tour and a presentation where the proposed NSDF Project was introduced within the context of a larger vision of the contractor company under the new Government-Owned Contractor-Operated (Go-Co) model.

In July 2016, CNL sent the AOPFN a letter to formally introduce the proposed NSDF Project which included a request for community input on any potential adverse impacts from project activities followed by a secondary letter in November 2016 which inquired about the AOPFN asserted rights and traditional activities. The AOPFN sent a letter to CNL in January 2017 acknowledging receipt of letters and advised of negotiations with the federal and provincial government on the settlement of their land claim and the interest in meeting later in 2017. CNL followed-up on the AOPFN meeting request from the January 2017 letter and were informed in June 2017 that the AOPFN did not want to meet at this time and that ANRs were involved through the AOO engagement activities. It should be noted that since this initial exchange with the AOPFN, it has come to CNL's attention that the AOPFN did not have a full understanding of the processes in the environmental assessment or resources/capacity to provide responses and/or comments until the AOPFN became resourced with a Consultation Coordinator.

In early 2017, CNL also shared the 2017 Draft EIS and encouraged the AOPFN to participate in the public and Indigenous environmental assessment comment period and in June 2017 the AOPFN ANRs participated in a meeting with the AOO Consultation staff and the ANRs to discuss future engagements on the NSDF Project. CNL also hosted the ANRs to the CRL site for a tour which included the proposed NSDF site (several AOPFN ANRs joined this event). The AOPFN did not submit comments on the NSDF 2017 Draft EIS through the environmental assessment process. In late 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning. CNL did not receive any feedback from the AOPFN on this report.

Throughout 2018 and 2019, the AOPFN ANRs continued participation through the AOO engagement activities. During this time, CNL evolved project engagements to meet Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. The AOPFN received invitations to all engagement activities and have been in attendance at select events to date. In late 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the Indigenous Engagement Report (IER) with the AOPFN and encouraged community input for the final revision.

In March 2020, CNL received a letter from the AOPFN inviting the NSDF Project to provide a project overview/update at a community meeting in April 2020. This meeting was postponed one week later due to the COVID-19 pandemic. After receiving the March 2020 letter, discussions commenced between the AOPFN and CNL on the AOPFN's intent to review the 2019 revised Draft EIS and interest in AOPFN specific engagement. During these discussions, it was determined that a letter sent from the AOPFN to the CNL President and CEO in December 2017 was never received. This letter was resent via email to Environmental Remediation (ERM) Stakeholder Relations in April 2020. The 2017 letter indicated interest in NSDF Project activities as well as CNL procurement and corporate activities.

In May 2020, CNL sent a letter to the AOPFN following up on recent AOO communications (which involved the AOPFN) and made inquiries for AOPFN specific information. A response from the AOPFN Chief was received

immediately indicating interest in AOPFN specific engagement and a LTRA with CNL/AECL. The Chief also acknowledged upcoming engagement activities with respect to the NSDF Project. In late May 2020, CNL received comments from the AOPFN on the NSDF 2019 revised Draft EIS. After receipt of the comments, CNL initiated discussions with the AOPFN on establishing a NSDF Project specific contribution agreement to ensure support of AOPFN's participation in the environmental assessment process. Contribution agreement meetings started in early June 2020 and a contribution agreement was signed in September 2020. The contribution agreement includes funding for AOPFN-led studies as well as for meetings/discussions on the AOPFN's review of the AKLUS, review of NSDF Project documents and engagements leading up to the CNSC Commission Hearing on the NSDF Project. Revisions to the contribution agreement were agreed to between the AOPFN and CNL in December 2020 to accommodate additional capacity for the review of the 2019 revised Draft EIS.

Upon signing of the contribution agreement, Working Group meetings started in September 2020 and the AOPFN Advisory Committee (AAC) meetings started in October 2020. The introductory meeting between CNL representatives and the AAC occurred virtually which included a general overview of CNL and the CRL site in addition to an overview of the NSDF Project. Questions were answered throughout the CNL presentation. A subsequent meeting was planned for January 2021 however this time the intent was to be an in-person (following all COVID protocols) in Pikwakanagan, ON. As a result of the lockdown measures put in place by the provincial government at the end of December 2020, the in-person meeting of the AAC and CNL representatives had to be deferred until safe to proceed. As of May 2021 there have been 15 Working Group meetings and one AAC meeting.

In October 2020, CNL responded in detail to each of the AOPFN comments on the 2019 revised Draft EIS. CNL and the AOPFN had two Working Group meetings that month to discuss the AOPFN comments in detail to ensure CNL's understanding of the context and support preparation of comprehensive responses.

In October 2020, CNL received the AOPFN's Nation-specific report on the Algonquin AKLUS which included general mitigation and accommodation measures to apply to the NSDF Project in response to study participant concerns. In November 2020, CNL acknowledged receipt of the AKLUS report but due to the timing of receipt (i.e., 2020 Final EIS submission to CNSC was imminent), CNL committed to including the AOPFN study results within future revisions of the NSDF IER which would support the Commission Hearing. However, in January 2021 CNL received feedback from the CNSC making it necessary for CNL to revise the 2020 Final EIS thus CNL took the opportunity to acknowledge and incorporate summaries of the AOPFN AKLUS into Section 6.4 of the Final EIS. In February 2021, recognizing the AKLUS is proprietary information of the AOPFN, CNL shared the revisions of Section 6.4 of the EIS with the AOPFN. At the request of the AOPFN, CNL also shared Section 6.2 of the EIS for transparency of how the AOPFN interests and concerns would be represented in the Final EIS. In March 2021, CNL received written feedback on both Section 6.2 and Section 6.4 of the EIS from the AOPFN, which was discussed at a Working Group meeting, and subsequently incorporated into the Final EIS.

CNL continued to provide bi-monthly webinar updates throughout 2020, including an email invitation to participate in the NSDF Project Virtual Open House (VOH) from October 12 to 25, 2020. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions.

In January 2021, CNL received a letter from the AOPFN enclosing implications of the AKLUS for the NSDF Project. Key comment themes on the study and recommendations for next steps included: adequacy of traditional land use assessment for the AOPFN in the project EIS, limitations of the AKLUS for the NSDF Project, implications and key findings of the AKLUS Study for the NSDF Project and the AOPFN supported recommendations from the AKLUS for the NSDF Project. In January and early February 2021, two Working Group meetings occurred to discuss the AKLUS implications where the AOPFN provided their perspectives of the AKLUS and its implications and limitations of the study in context of the ongoing environmental assessment for the NSDF Project, demonstrating the linkages to the AOPFN recommendations and expectations should the project proceed. The AOPFN identified that the findings of the AKLUS suggest that there are impact pathways from the NSDF Project on the AOPFN traditional land and resources use and culture that have either not been integrated into the EIS or inadequately assessed as to their likelihood and magnitude. A preliminary list of commitments intended to address the AOPFN recommendations and expectations was proposed by CNL for the AOPFN consideration. At these meetings CNL's proposed commitments were also categorized as either NSDF Project specific or at a CRL site level.

In late January 2021, CNL provided the AOPFN with updated responses to the AOPFN comments on the 2019 revised Draft EIS which were reflective of the discussions from the October 2020 Working Group meetings. The AOPFN provided written feedback to CNL responses in February 2021. In February and March 2021, seven Working Group meetings occurred to discuss and finalize CNL's responses to the AOPFN comments on the 2019 revised Draft EIS as well as reach an agreement on the next steps and CNL commitments to the AOPFN, should the project proceed. The next steps and summary of CNL commitments were reflective of feedback CNL received from the AOPFN on the 2019 revised Draft EIS, participant concerns documented in the AKLUS, the AOPFN's perspective of the AKLUS implications for the NSDF Project and general AOPFN engagements.

In late March 2021, CNL sent a letter to the AOPFN providing a summary of commitments intended to support the resubmittal of the NSDF Project Final EIS. CNL indicated that the commitments list is a living document that may evolve as collaboration during the environmental assessment process continues. In early April 2021, the AOPFN provided a letter of acknowledgement that the summary of commitments provided by CNL was an accurate summation of CNL's commitments. This acknowledgement from the AOPFN is not indicative of the AOPFN support for the NSDF Project, but that there is a reasonable path forward and the parties have agreed to the next steps. The AOPFN recognized progress at the Working Group level, but also flagged outstanding concerns:

> "Certain commitments, particularly those related to the concepts of "Willing Host" and AOPFN expectations that AOPFN will have the right of free, prior and informed consent prior to any additional radioactive waste being brought into AOPFN territory, remain outstanding." (AOPFN letter to CNL of April 6, 2021)

As of the issuance of the Final EIS in May 2021, these two concerns have yet to be resolved between CNL and the AOPFN.

CNL also incorporated feedback from the AOPFN on, and issued the final responses to the AOPFN comments on the 2019 revised Draft EIS in April 2021.

In May 2021, the AOPFN sent CNL, AECL and CNSC a confidential copy of the final report of the Culture and Rights Study related to the NSDF Project. The AOPFN identified that this will be a valuable resource for considering Project-specific and cumulative effects on culture and rights of the AOPFN members. CNL notes that the AOPFN Culture and Rights study results have not be integrated into the Final EIS.

In January 2021, the AOPFN requested the CNSC consider an extension to the current timelines for the environmental assessment of the NSDF Project due to the limitations of the COVID pandemic for in-person meetings and technological and connectivity challenges within their community. In response CNL provided some technological capacity to assist the AAC engagements with both the NSDF and NPD Closure Projects.

As of May 2021, the AOPFN and CNL are continuing to meet regarding implementation of the NSDF-specific AOPFN requested commitments, and toward the development of revisions to the Project-specific Contribution Agreement for high priority actions that require capacity support moving forward in developing project-specific relationship policies, plans and programs between the AOPFN and CNL. Discussions on a CRL site level MOU have also commenced between CNL, AECL and the AOPFN which have progressed substantially with six meetings to date.

6.2.4.3.2 Feedback

Since the AOPFN's 2017 letter asking for direct engagement in the NSDF environmental assessment was not received by CNL until May 2020, CNL understood that the AOPFN feedback was being provided through the AOO. In late May 2020, the AOPFN provided a separate submission on their interests and concerns to CNL, CNSC and AECL, based on their review of the 2019 revised Draft EIS. In addition to the AOPFN review of the 2019 revised Draft EIS, the feedback below is also reflective of the AOPFN AKLUS as well as the AOPFN's additional perspectives and emphasis on the study. CNL notes that the AOPFN Culture and Rights study results received in May 2021 have not been integrated into the Final EIS.

Appendix K.2 of the IER provides a Table of Interests for AOPFN interests and concerns and CNL responses. The table also identifies and links the interests and concerns with formally submitted comments made through the environmental assessment process.

The topics in the Table of Interests are briefly summarized below:

- **Historical Impacts**. The AOPFN expressed concern about the historical and existing cumulative effects of the CRL site and how they interact with impacts from the NSDF Project.
- **Engagement**. The AOPFN inquired about crown engagement, the management structure at CNL and the potential for a long-term relationship agreement with CNL.
- **Alternative Means Assessment**. The AOPFN commented that the approach to alternative means assessment did not meet best or acceptable practice for projects, including for example that it did not utilize criteria from the Major Project Assessment Standard of the First Nations Major Projects Coalition (2019). The AOPFN also raised concerns direct from a community member that a request to move the NSDF further from the Ottawa River was not followed up on in a meaningful way.
- **Traditional Land and Resource Use and Cultural Impacts**. The AOPFN identified the need for traditional knowledge to be incorporated into the EIS. The AOPFN raised concerns with potential project effects on traditional land and resource use as well as requested a role in the future cultural heritage stewardship and monitoring of the CRL site. Additionally, the AOPFN requested the opportunity for a pre-construction inventory of the NSDF Project site.
- **Project Description and Study Areas**. The AOPFN questioned whether the study area for the project incorporated all the necessary project infrastructure and activity including areas of increased traffic and haul routes, the main concern being for wildlife-vehicle collisions.

- **Environmental Monitoring**. The AOPFN have requested involvement in both project and CRL site-wide monitoring, including specifically support for the development of an independent AOPFN guardian program for the NSDF Project, and involvement of AOPFN guardians in multiple aspects of follow up monitoring for the NSDF Project.
- **End State/Closure Plan**. The AOPFN expressed an interest in opportunities for planning and review of end state and land use goals for the CRL facility and for the development of a closure plan for NSDF.
- **Risk Communication**. The AOPFN expressed concerns with how risks are communicated and the use of plain language with respect to the NSDF Project, and expressed that in order to improve communication, capacity for an AOPFN Communications Coordinator, country foods monitoring, and an Indigenous-driven risk communications strategy for the NSDF Project are necessary.
- **Independent Oversight.** The AOPFN raised questions about Indigenous involvement in independent oversight of the CRL site.
- **Valued Components.** The AOPFN had a series of comments related to VCs and CNL's use of indicator species.
- **Environmental Assessment Methodology and Process Issues**. The AOPFN expressed concern about the way in which residual effects assessment was conducted, including whether there was any role for Indigenous Peoples in the assessment of effects or determination of significance or related significance thresholds.
- **Loss of Wildlife Habitat.** The AOPFN expressed concern with respect to the potential project effects on wildlife habitat (e.g., Blanding's Turtle, moose, white-tailed deer and bald eagle) and requested involvement in developing project-specific measures for the protection of monz (moose) and wawashkeshi (white-tailed deer) and their habitat.
- **Impacts on Rights**. The AOPFN raised questions as to the NSDF Project's potential impacts on rights, indicating that the AOPFN does not agree with the characterization by CNL that the NSDF Project will have no impacts on the AOPFN rights, and also concerns that the cumulative effects context – a critical consideration in rights impact assessment – for rights was not characterized by CNL prior to making this assertion. The AOPFN has also raised concerns that with the creation of a permanent radioactive waste disposal facility at the CRL site, the existing fears, stigma and alienation associated with the CRL site may continue further into the future.
- **Socio-economic**. The AOPFN has indicated a strong interest in obtaining more economic benefits from the NSDF Project and CNL-operated, AECL-owned operations in the AOPFN territory in general.
- **Health**. The AOPFN considered the health assessment to be inadequate from an Indigenous determinants of health perspective.
- **Willing Host and Importation of Radioactive Waste.** The AOPFN requested commitment to a "willing host" requirement from the AOPFN for NSDF and any future projects proposed at the CRL site. The AOPFN also raised concerns about how much waste will come in from other sites, noting that the AOPFN has nuclear project principles that cannot be reconciled with importation of wastes, and requested CNL not import radioactive wastes for disposal at NSDF without the AOPFN's free, prior and informed consent.

6.2.4.3.3 Summary Discussion of Interests and Concerns

As previously indicated this Summary Discussion of Interests and Concerns is taken from the Tables of Interest that appear in Appendix K.2 of the IER. The discussion of the interests and concerns below is CNL's understanding based on written submissions and oral discussions with the AOPFN, and is followed in each instance by CNL's perspective on and commitments made in relation to the issue, which may not be shared by the AOPFN. CNL has made its best efforts to document the position the AOPFN has taken on each interest/concern while acknowledging that the AOPFN may articulate the perspective somewhat differently.

Historical Impacts

The AOPFN expressed concern about the historical and existing cumulative effects of the CRL site and how they interact with impacts from the NSDF Project. This concern is not specific to the NSDF Project and is related to the overall CRL site operations. Historical and CRL site-wide concerns are being discussed with the AOPFN, CNL and AECL separately.

Engagement

Until the May 2020 letter from the AOPFN, CNL was not aware that the AOPFN wanted to be engaged separately and not through the AOO office. After receipt of the comments on the 2019 revised Draft EIS, CNL initiated discussions with the AOPFN to establish a NSDF Project specific contribution agreement to ensure support of the AOPFN's participation in the environmental assessment process. CNL considers this concern resolved since the participation of both the AOPFN and CNL in the Working Group have resulted in an increased level of engagement which CNL is committed to continuing as the EA proceeds. Additionally, CNL has committed to providing funding to continue NSDF Project activities with the AOPFN, including the Working Group as an interface for project engagement, pending a successful regulatory decision.

CNL considers the balance of concerns within this issue not specific to the NSDF Project since it was with respect to CRL site wide planning. The AOPFN, AECL and CNL have begun discussions towards a Long-term Relationship Agreement (LTRA) which is meant to identify areas of mutual benefit, enable communications and engagement, and address broader AOPFN interests related to AECL and CNL activities. The agreement will include provisions for the AOPFN involvement in environmental and cultural stewardship and monitoring.

Concerns raised with respect to Crown engagement were directed to CNSC and AECL.

Alternative Means Assessment

The AOPFN commented that the approach to alternative means assessment did not meet best or acceptable practice for the involvement of Indigenous Peoples, noting for example that it did not utilize criteria from the Major Project Assessment Standard of the First Nations Major Projects Coalition. CNL provided clarification that the Major Project Assessment Standard identified was developed after the commencement of the NSDF environmental assessment thus was not available at the time the NSDF Project alternative means assessment was performed. The NSDF EIS was prepared following guidance from the Canadian Environmental Assessment Agency (CEAA 2012). CNL considers this concern to be addressed as the alternative means assessment was prepared in accordance with CEAA 2012 and the project has demonstrated how public and Indigenous feedback during the development of the EIS expanded the alternative means assessment in the Final EIS. The AOPFN continues to raise consistent concerns in particular about the location of the NSDF in proximity to the Kichi-Sìbì (Ottawa River).

Although the AOPFN were provided opportunities to provide input on the alternative means assessment during the development of the EIS, CNL acknowledges that how feedback was integrated may not be clear to the AOPFN community members. Thus, CNL has committed to providing capacity for an AOPFN employed Communication Specialist to work with CNL on project communications for the AOPFN members.

Traditional Land and Resource Use and Cultural Impacts

With respect to the AOPFN's concerns on incorporating traditional knowledge into the EIS, the CNSC and CNL provided capacity for the AOPFN AKLUS which was completed in October 2020. Since it was necessary for the NSDF Project to make revisions to the 2020 Final EIS in early 2021, CNL has used the opportunity to incorporate the findings of the AOPFN AKLUS report into the Final EIS.

CNL has assumed within the EIS that traditional uses do occur adjacent and near to the CRL site, whether on the Ottawa River or on accessible private lands outside the restricted/fenced area or provincial crown land outside the restricted/fenced area. CNL has concluded that the NSDF Project is not expected to affect the traditional land and resource uses because the NSDF Project is located on CRL property on federal lands that are inaccessible to the public and where traditional use is not permitted. Furthermore, CNL does not anticipate any off-site effects from the NSDF Project that would affect traditional land use and resource VCs (Section 6.4.6 of the Final EIS). CNL recognizes that the AOPFN's AKLUS and subsequent analysis, including inputs from the AAC, disagrees with this finding, in part on the basis of the AOPFN members' sense of safety on the land (fears of contamination real or perceived). In addition, the AOPFN has flagged concerns about the NSDF Project creating a longer-term impact at the CRL site, through the building of a permanent radioactive waste disposal facility. CNL does recognize its obligation to continue to work with Indigenous communities in addressing such concerns thus through the Working Group, CNL and the AOPFN have agreed that the perceptions of safety and willingness to harvest within the proximity of the NSDF Project can be addressed by an Indigenous-driven country foods monitoring program and Risk Communication Strategy for the NSDF Project which is discussed below under Risk Communication. CNL acknowledges the AOPFN has requested involvement in country foods monitoring program, which is not specific to the NSDF Project and has been designated for discussions under the long-term relationship agreement.

Culturally significant sites and features for the AOPFN were identified within the AKLUS such as Pointe Au Baptême (which CNL does not restrict access to), undocumented archaeological resources or areas of significance, eagle feathers and culturally significant species. CNL considers this concern resolved as CNL is committed to co-developing a project specific cultural and heritage protection plan (CHPP) with the AOPFN prior to finalizing the NSDF Project construction work control documents. This plan will include protocols and procedures for notification and providing recovered features of interest to the AOPFN (e.g., eagle feathers, artefacts). Furthermore, CNL is committed to and assisting the AOPFN with a pre-construction inventory of the NSDF Project LSA which would allow the AOPFN to identify the presence of any culturally valued indicator species.

Project Description and Study Areas

The AOPFN questioned whether the study area for the NSDF Project incorporated all the necessary project infrastructure and activities including areas of increased traffic and haul routes, the main concern being wildlife-vehicle collisions. CNL has appropriately determined the study area, including all traffic and haul routes, and assessed the impact of traffic activities due to the NSDF on terrestrial animals in Section 5.6. With the application of the proposed mitigation measures, the small increase in vehicle traffic that may occur during NSDF construction, operations and closure are not expected to result in a significant adverse residual effect on the terrestrial environment. CNL considers this concern resolved as CNL already reports vehicle wildlife collisions on an annual basis and has committed to work with the AOPFN to develop project-related thresholds as part of the AOPFN's technical review of the EAFMP.

Environmental Monitoring

The AOPFN have requested involvement in both project specific and CRL site wide environmental monitoring. At present, there is no specific Indigenous-led monitoring program at the CRL site. The AOPFN involvement in the CRL site environmental monitoring program is a CRL site level concern. Specific to the NSDF Project, CNL is willing to involve all Indigenous communities who have interest in the NSDF Project environmental monitoring and have shared the draft EAFMP with the AOPFN for technical review. The EAFMP will not be finalized until after an EA decision is rendered by the CNSC, thus there remains opportunity for direct involvement in its development and implementation. CNL considers this concern resolved as CNL is committed to develop with the AOPFN a practical, meaningful role for the AOPFN in the NSDF monitoring program, and support Indigenous knowledge monitoring in relation to the NSDF Project. This includes financial support from CNL for the development and implementation of an AOPFN Guardian Program, as it relates to the NSDF Project.

End State/Closure

The AOPFN expressed an interest in opportunities for planning and review of end state and land use goals for the CRL facility and for the development of a closure plan for NSDF. The AOPFN involvement in the CRL site wide end state and land use planning is a CRL site level concern. As noted in Section 5.9 of the Final EIS, the existing condition of restricted access to the CRL site would continue into the institutional control period for the NSDF footprint. An initial Closure Plan has been developed but intended to be an evolutionary document that continues to be refined throughout the life (construction, operations) of the NSDF Project. CNL considers this concern resolved as CNL is committed to engaging the AOPFN in future planning for the closure of NSDF, including input on restoration or rehabilitation of the facility footprint. CNL will engage and collaborate with the AOPFN during updates of the NSDF Closure Plan which will occur approximately every five years.

Risk Communication

The AOPFN expressed concerns with how risks are communicated and the use of plain language with respect to the NSDF Project, and expressed that in order to improve communication, capacity for an AOPFN Communications Coordinator, country foods monitoring, and an Indigenous-driven Risk Communications Strategy for the NSDF Project are necessary. CNL acknowledges that the AOPFN members in proximity to the CRL site have expressed concerns with respect to the perceptions that their harvesters have with regarding contamination associated with the CRL site. The AOPFN have indicated that these perceptions can lead harvesters to: avoiding particular areas; feelings of alienation from particular lands; and/or consuming less traditional foods than they normally would in particular areas. Engagement with Indigenous Peoples and their traditional knowledge and land

use studies do not demonstrate that complete avoidance is occurring, but concerns of safety and risk are prevalent as evidenced by their reluctance to harvest country foods, fish, water and vegetation adjacent to and beyond the CRL site.

CNL does recognize its obligation to continue to work with Indigenous communities in addressing such concerns. Thus, through the Working Group, CNL and the AOPFN have agreed that the perceptions of safety and willingness to harvest within the proximity of the NSDF Project can be addressed by the Indigenous-driven Risk Communication Strategy for the NSDF Project. Development of such a strategy will be facilitated by an integration of CNL's commitments including capacity for an AOPFN Communications Coordinator and engagement in the development of the NSDF Project EAFMP as well as the implementation of an AOPFN Guardian Program. CNL also recognizes that future updates of the AKLUS will continually inform the EAFMP as well as demonstrate effectiveness of an Indigenous-drive Risk Communication Strategy for the NSDF Project thus has committed capacity for future updates of the AKLUS. CNL acknowledges the AOPFN has requested involvement in country foods monitoring program, which is not specific to the NSDF Project and has been designated for discussions under the long-term relationship agreement.

Independent Oversight

The AOPFN raised questions about Indigenous involvement in independent oversight of the CRL site. CNL has provided clarification on how the CNSC provides independent regulatory oversight for nuclear facilities within Canada. CNL considers this concern addressed in regulatory requirements. Furthermore, CNL has committed financial support for the development and implementation of an AOPFN Guardian Program, as it relates to the NSDF Project, thus addressing certain aspects of the AOPFN's concerns for an independent oversight body.

Valued Components

The AOPFN had a series of comments related to VCs and CNL's use of indicator species. CNL has provided a detailed response on its VCs and rationale for them and discussed the topic with the AOPFN. CNL considers the concern addressed due to the NSDF Project's approach to selecting and assessing VCs. However, CNL is committed to exploring with the AOPFN potential practical, meaningful role for the AOPFN in the NDSF EAFMP. As such CNL will provide the AOPFN with a co-development role in identifying adaptive management triggers/thresholds and responses in relation to valued components relation to the AOPFN rights and interests, which would be built into the EAFMP. Furthermore, CNL is committed to and assisting the AOPFN with a pre-construction inventory of the NSDF Project LSA which would allow the AOPFN to identify the presence of any culturally valued indicator species.

Environmental Assessment Methodology and Process Issues

The AOPFN expressed concern about the way in which residual effects assessment was conducted, including whether there was any role for Indigenous Peoples in the assessment of effects or determination of significance or related significance thresholds. CNL considers this concern addressed since the approach used in the NSDF EIS to classify residual environmental effects on VCs followed the Generic EIS Guidelines. However, CNL is committed to exploring with the AOPFN potential practical, meaningful role for the AOPFN in the NDSF EAFMP. As such, CNL will provide the AOPFN with a co-development role in identifying adaptive management triggers/thresholds and responses in relation to valued components related to the AOPFN rights and interests, which would be built into the EAFMP.

Loss of Wildlife Habitat

The AOPFN expressed concern with respect to the potential project effects on wildlife habitat (e.g., Blanding's Turtle, moose, white-tailed deer, bald eagle) and requested involvement in developing project-specific measures for the protection of monz (moose) and wawashkeshi (white-tailed deer). Specifically, the AOPFN desire project mitigation measures that result in no net loss of important wildlife habitat. CNL considers this concern addressed since the Blanding's Turtle Road Mortality Mitigation Plan includes offsets to the loss of critical habitat that will be more effective for the CRL site conditions (i.e., increasing habitat connectivity and provide adequate nest mounds). CNL has committed to offset the loss of forested area and habitat with a CRL site wide Sustainable Forest Management Plan (SFMP) as well as offered the AOPFN involvement in the SFMP development. This proposed offset will contribute to no net loss of habitat by the NSDF Project as well as will benefit the large mammal population within the Algonquin territory. CNL will also consider support for offsets at off-site locations brought forward by the AOPFN, which are commensurate with the wildlife habitat impacts associated with the NSDF Project. In addition, CNL is committed to co-developing with the AOPFN additional mitigation measures to include within the NSDF Project Environmental Protection Plan.

Impacts on Rights

The AOPFN raised questions as to the NSDF Project's potential impacts on rights, specifically indicating that CNL's assertions re: rights impacts have not been adequately grounded in a proper rights impact assessment (which is ongoing between the AOPFN and the CNSC). CNL has communicated to the AOPFN that as it is CNL's opinion there are no traditional land uses determined to be affected by the proposed project (a finding that the AOPFN's AKLUS and subsequent analysis, including inputs from the AAC, disagrees with). The AOPFN has also raised concerns that with the creation of a permanent radioactive waste disposal facility at the CRL site, the existing fears, stigma and alienation associated with the CRL site may continue further into the future. As it is CNL's determination that there are no traditional land uses affected by the proposed project, CNL is of the view that Algonquin rights will not be impacted by the NSDF Project activities. CNL acknowledges the AOPFN disagrees with this conclusion and contend through their review of the 2019 revised Draft EIS there are project specific activities that may directly impact traditional land uses and Aboriginal rights and interests. The AOPFN has provided CNL with a copy of the NSDF-specific Culture and Rights Study in May 2021. The implications of the Culture and Rights Study will be subject of further discussion at the Project-specific Working Group level, as the parties develop implementation tools related to commitments made by CNL to increase the role for the AOPFN in monitoring and adaptive management of the NSDF Project, should it proceed. Determination as to whether the proposed project has impacts on Aboriginal and Treaty rights remains with the CNSC as the representative of the Crown.

Socio-economic

The AOPFN has indicated a strong interest in obtaining more economic benefits from the NSDF Project and CNL generally. CNL considers this concern resolved since CNL is committed to working with the AOPFN to identify barriers for accessing economic opportunities from the NSDF Project, mitigation of those barriers and ways to monitor the degree to which the AOPFN members are able to take advantage of benefits of the NSDF Project. Economic opportunities for the AOPFN community members are also considered by the AOPFN and CNL to be a CRL site level concern and will be included as part of the long-term relationship discussions.

Health

The AOPFN considered the health assessment to be inadequate from an Indigenous determinants of health perspective. CNL has removed any reference to the lifestyle survey from the EIS as this survey was not specific to only Indigenous Peoples. CNL notes for the Post-Closure Safety Assessment, a conservative hunter/gatherer self-sufficient Indigenous receptor, was included. This receptor was assumed to be an Indigenous person (including adults and children) who obtained all their food through hunting and gathering in the area. It was also assumed that this person would have increased consumption of fish and wild game and would also consume local mushrooms and berries. CNL considers this concern resolved since CNL is committed to use the results of the Harvest and Diet Study to verify the assumptions within the Post-Closure Safety Assessments were in fact conservative for the NSDF Project (i.e., modelling of self sufficient Indigenous receptor).

While CNL maintains that human health has been conservatively assessed for Indigenous groups within the Final EIS, CNL acknowledges that the AOPFN disagrees on the basis that there are other determinants of health important to the AOPFN including the avoidance of consuming traditional foods. Thus, similar to the path forward for the Traditional Land and Resource concerns, the perceptions and willingness to consume traditional foods can be addressed by an Indigenous-driven Risk Communication Strategy for the NSDF Project. In addition to the commitments mentioned above, CNL acknowledges the AOPFN have identified the key role that a country foods monitoring program would play in mitigating the AOPFN member concerns. The country foods monitoring is not specific to the NSDF Project and is related to the overall CRL site operations.

Willing Host and Importation of Radioactive Waste

The AOPFN has identified that it wishes for CNL to respect any “Willing Host” or other free, prior and informed consent decision made by the AOPFN in relation to the proposed NSDF, flagging in particular that this would be the creation of a permanent radioactive waste disposal facility on the AOPFN territory. The AOPFN has also raised concerns about how much waste will be received from other AECL sites. The AOPFN has noted their nuclear project principles that cannot be reconciled with importation of wastes, and requested CNL not import radioactive wastes for disposal in the NSDF without the AOPFN’s free, prior and informed consent.

CNL has an obligation to address federal nuclear liabilities and carry out activities which support the goal of responsibly managing radioactive waste. It is not possible for CNL to commit to "willing host" as a requirement for the NSDF Project to proceed given the NSDF Project is critical to the environmental clean-up mission and will result in a general improvement of the current environmental conditions at the CRL site.

The transportation of off-site waste to the CRL site is not specific to the NSDF Project and is an existing activity. Consolidation of AECL-owned low-level waste is reflective of the intention to minimize the number of waste repositories required to manage federal liabilities. CNL receives radioactive waste from Canadian universities and hospitals that is generated from diagnostic procedures or cancer treatments thus of the benefit to Canadians.

Any request for commitments with respect to future CNL projects at the CRL site is outside the scope of the NSDF environmental assessment. With respect to the NSDF Project, CNL is committed to achieving understanding and support from the AOPFN as part of the NSDF Project engagement. Where there are differences of opinion or concerns that need to be addressed, CNL is willing to explore mitigation measures and formulate commitments with the AOPFN with the intention of trying to remove or lessen the concern. To this end, CNL is committed to continued discussions with the AOPFN on the NSDF Project prior to the Commission Hearing. CNL considers this concern in progress as CNL’s commitments to the AOPFN with respect to the NSDF Project, for the AOPFN

support, is reflective of the AOPFN's communicated principles and requirements. CNL acknowledges it must demonstrate progress in implementation of the commitments the AOPFN have identified as high priority to its community.

6.2.4.3.4 Verification

The AOPFN did not submit written comments on the 2016 Project Description or the 2017 Draft EIS in the formal environmental assessment process, however the AOPFN did submit written comments on the 2019 revised Draft EIS directly to CNL. CNL has responded in detail to each of the AOPFN comments and received written feedback from the AOPFN on CNL's responses. CNL does not want to imply that the AOPFN is fully accepting of all of CNL's responses but that it is has reviewed and acknowledged them. CNL is of the opinion that it is at Process Step 5 of the CNL Verification Process with the AOPFN.

The AOPFN have reviewed and provided input on Section 6.4 of the Final EIS to verify that the AOPFN AKLUS findings were accurately integrated into the description of environment. However, the AOPFN has noted that other aspects of the AOPFN AKLUS are not adequately reflected in Section 6.4, which in the end is CNL's assessment of the NSDF Project effects on traditional land and resource use. Issues of remaining concerns for the AOPFN regarding Section 6.4 include the lack of integration of risk perception and sensory changes on harvesters as impact pathways, the use of a biophysical proxy approach to assessing impacts on traditional use by AOPFN harvesters, and disagreement with the overall finding by CNL of no anticipated residual impacts on traditional land and resource use from the Project. CNL encourages the AOPFN to identify these remaining issues in its written submission to the Commission, and will continue to work with the AOPFN on improving understanding of effects of the Project, should it proceed.

The findings of the AOPFN AKLUS confirmed CNL's previous assumptions and conservative approach that traditional activities were occurring within proximity to the CRL site but not on the CRL site (due to existing access restrictions).

In late March 2021, CNL sent a letter to the AOPFN providing a summary of commitments intended to support the resubmittal of the NSDF Project Final EIS. The list of commitments was reflective of the resolution status and next steps which had been agreed to by both CNL and the AOPFN during Working Group meetings. CNL indicated that the commitments list is a living document that may evolve as collaboration during the environmental assessment process continues. In early April, the AOPFN provided a letter of acknowledgement that the summary of commitments provided by CNL was an accurate summation of CNL's commitments. This acknowledgement from the AOPFN is not indicative of the AOPFN support for the NSDF Project, but that there is a reasonable path forward and both parties have agreed to the next steps.

6.2.4.3.5 Next Steps

The NSDF Project developed a commitments list within the structure of the existing Working Group and is committed to continuing the existing Working Group, with funding for the AOPFNs involvement, into the planning, construction and operations phase of the NSDF Project, should it proceed. CNL's commitments within the "Next Steps" column of the Table of Interest in Appendix K.2 of the IER, are also reflective of the feedback CNL has received to date in the EA process from the AOPFN's review of the 2019 revised Draft EIS, the AOPFN AKLUS, the AOPFN's perspectives on the AKLUS and the implications for the NSDF Project, as well as general the AOPFN engagements including the Working Group meetings.

CNL recognizes there are outstanding concerns with the AOPFN, including but not limited to differences of opinion on the likelihood of adverse effects on culture, traditional use and the AOPFN rights from the Project, whether or not CNL will respect “Willing Host” or other free, prior and informed consent decisions by the AOPFN, and the importation of radioactive materials from off-site for disposal at NSDF, should it proceed. The CNL commitments reflect resolution status and next steps which have been agreed to by both CNL and the AOPFN through Working Group discussions. The IER, as a living document, will include any updates related to the progress of these next steps prior to the Commission Hearing process.

CNL recognizes that the AOPFN involvement in the development of the EAFMP and in future long-term monitoring programs is a key area of ongoing interest. As well, CNL is committed to working with the AOPFN members and harvesters on understanding there are no risks to traditional uses adjacent to the Chalk River site.

The AOPFN and CNL, along with AECL, have started preliminary discussions about entering into a longer-term co-operation or relationship agreement, more broadly related to the CRL site.

6.2.4.4 Métis Nation of Ontario (MNO)

The Métis Nation of Ontario (MNO) was formed in 1993 to represent communities and individuals recognized by the Métis Nation within Ontario and works to represent the rights, interests and collective aspirations of Métis people and communities throughout the province. The MNO identifies a registry of over 20,000 Métis citizens (MNO, 2020d). Members of the MNO Mattawa/Lake Nipissing Métis Traditional Territory Consultation Committee and MNO Lands, Resources and Consultation Branch have participated in CNL’s Indigenous Engagement Program for the Project. A fuller description of the MNO can be found in Chapter 3 of the IER.

The MNO and CNL have signed a MOU along with a Reciprocal Funding Agreement for the NSDF and NPD projects that has allowed the MNO enhanced participation in the NSDF Project. The MOU is with the MNO and more specifically the Mattawa/Lake Nipissing Traditional Territory Consultation Committee which includes the Sudbury Métis Council, the North Bay Métis Council and the Mattawa Métis Council which represent the regional rights-bearing Métis community. A representative of the MNO has been a member of CNL’s ESC since March 2012.

The summarized objectives of the MOU include: to establish, in relation to the Projects, a mutually beneficial, cooperative, productive and on-going working relationship; provide a process for CNL to engage with the local and regional Métis communities, address any potential effects and discuss necessary mitigation measures; enhance the ability of the MNO to participate in the environmental assessment processes for the NSDF Project. The MOU also indicates the intention of both parties to pursue a longer-term relationship between CNL and the MNO.

CNL therefore provided funding to the MNO to assist them in enhanced engagement, specific funding for technical studies, VC workshop, and funds to allow staff to co-ordinate activities and work with CNL. The MNO have focused their technical reviews on three specific topics: Métis rights and interests, archaeology and protection of water. The MNO also carried out a comprehensive traditional knowledge and land study funded by the CNSC.

6.2.4.4.1 Engagement

Table 6.2.4-4 below summarizes MNO engagement and Appendix L.1 of the IER provides a detailed record of engagement activities that have occurred with MNO on the NSDF Project.

Table 6.2.4-4: Métis Nation of Ontario (MNO) Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings*, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Métis Nation of Ontario (MNO)	15	72	17	Yes	16	2017 & 2019	MOU	TKLUS	Yes (and 2020 Final EIS)	Yes

The complete table is located in Section 6.2.4.1.

* CNL notes that the number of meetings includes Long-Term Relationship Agreement meetings.

CNL first reached out directly to the MNO in June 2016 to hold a teleconference with MNO representatives to introduce the proposed NSDF Project and enable preliminary discussion. This meeting was followed up by a letter in July 2016. This letter included a request for community input on any potential adverse impacts from project activities.

Later in July 2016, a meeting between the MNO Mattawa/Lake Nipissing Traditional Territory Consultation Committee and CNL was held to share an overview with a wider group of MNO representatives. After these initial contacts, there was some follow-up, including a letter sent from CNL to the MNO in December 2016, which made inquiries about MNO asserted rights and traditional activities. CNL did not receive a response from the MNO.

In early 2017 CNL shared the 2017 Draft EIS and encouraged the MNO to participate in the public and Indigenous environmental assessment comment period. Following this, the MNO sent a letter to CNL in July 2017 sharing information to CNL on Métis rights, the need for consultation, and confirmation that the MNO Mattawa/ Lake Nipissing Traditional Territory Consultation Committee. CNL responded to this letter with a letter in August 2017 sharing CNL interest in developing a plan or agreement for engagement between CNL and the MNO. The MNO provided comments on the 2017 Draft EIS through the formal environmental assessment process. In the fall of 2017, there were numerous correspondence between CNL and the MNO and a meeting was held in Sudbury in September. This meeting was hosted by the MNO and CNL shared information on environmental monitoring, environmental assessments, a project overview, and the environmental assessment process. In late 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning.

The next meeting between the MNO and CNL was held in March 2018 and focused on the development of a Memorandum of Understanding (MOU) to create a framework for relationship building between CNL and the MNO. This MOU set the platform for MNO, AECL and CNL to enter into discussions on a Long-Term Relationship Agreement (LRTA). Long-term relationship agreement meetings continue with signing estimated in fall 2020. Another aspect of particular importance relating to the MOU was the provision of capacity to undertake a Traditional Knowledge and Land Use Study (TKLUS). This was jointly funded by CNL, through the MOU, and the CNSC through Public Participant Funding. Information sharing occurred in follow-up to the March 2018 meeting. Further correspondence between the MNO and CNL occurred in 2018 culminating in a meeting and site visit in June 2018 and the signing of the MOU in December 2018.

Throughout 2018 and 2019, CNL evolved project engagements to meet Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. The MNO received invitations to all engagement activities and have been in attendance at select events to date.

In February 2019, the MNO shared the TKLUS, which gave insight into the traditional land and resource use of the MNO citizens in the region. This TKLUS has helped inform the recent revisions to the EIS. Following the receipt of the TKLUS, in April 2019, the MNO and CNL met to review the draft dispositions to the MNO comments on the 2017 Draft EIS. The MNO and CNL met again in North Bay for a two-part meeting in late 2019. The first part (morning) involved discussions with the MNO Mattawa/Lake Nipissing Traditional Territory Consultation Committee Councillors. The second part (evening) consisted of a community information session for MNO citizens. This information session included a presentation by project representatives and the opportunity for questioning. In November 2019, the MNO sent a formal letter detailing the MNO response to CNL’s draft

dispositions of the MNO comments on the 2017 Draft EIS. This included verification on whether the MNO accepted CNL's dispositions or whether they required further information. In late 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with the MNO. In October 2020, CNL requested verification from MNO regarding text proposed for the Final EIS regarding the results of the TKLUS. MNO provided modified wording, which was incorporated in to the Final EIS.

Early in 2020, CNL hosted the MNO at the Port Hope and Port Granby sites for a benchmarking trip to view near surface waste facilities there. Then, in February 2020, the MNO sent CNL a letter providing positive feedback on the 2019 revised Draft EIS, as well as detailed comments that required response from the NSDF Project team.

In May 2020, CNL provided MNO with NSDF Project responses to MNO comments on the 2017 Draft EIS. This letter also requested feedback on assumptions CNL had made in the EIS with respect to land use around the CRL site with regards to traditional use, values and interests and potential impacts on rights related to the NSDF Project. In August 2020, CNL received a response to the May 2020 letter. This letter acknowledged that a large number of the 2017 Draft EIS comments have been addressed but reiterated the importance of MNO engagement in the follow-up monitoring program. The letter also included an updated comment and response table, indicating no further comment or required further clarification from the NSDF team. Comments that require further clarification were related to the follow-up monitoring program.

An MNO site tour of the NSDF Project site was being planned for the fall of 2020, which was postponed indefinitely due to the COVID-19 pandemic.

CNL continued to provide bi-monthly webinar updates throughout 2020, including an email invitation to participate in the NSDF Virtual Open House (VOH) from October 12 to 25, 2020. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions.

In December 2020, CNL and the MNO met virtually for a discussion on CNL's updated response to an outstanding comment with respect to transportation noise and traffic volumes having the potential to interfere with traditional land use, as well as an overview presentation on NSDF, radiation and waste management, environmental monitoring at CRL and details of the NSDF Follow-up Monitoring Plan. Discussions also included how the MNO can be involved with monitoring at the CRL site. As a follow up to this meeting, CNL and MNO met in February 2021 to discuss MNO's involvement in a long-term monitoring program at the CRL site, not specific only to the NSDF Project, but part of a long-term relationship agreement.

In February 2021, CNL sent a letter to the MNO providing an update on the status of the NSDF environmental assessment, as well as to provide a summary of commitments that CNL had previously made to the MNO during NSDF Project engagements. CNL indicated that the commitments list is an evergreen list and has asked for a response by March 1, 2021 if there were any concerns regarding the commitments list. In early March 2021, the MNO sent a letter which included an updated comment and response table, based on their review 2020 Final EIS, identifying the status of EIS comments (i.e., no further comment, partially accepted, unresolved). The letter did not provide any feedback or comments on the summary of CNL commitments made to the MNO that were sent in February 2021. Based on the feedback provided from the MNO to CNL on their review of the 2020 Final EIS, CNL contacted the MNO to verbally confirm comments would be addressed and/or incorporated into the summary of CNL commitments made to the MNO. In mid-March, in response to the letter earlier that month from the MNO, CNL provided responses to the MNO comments as well as an updated summary of commitments from CNL. CNL requested a response by March 22, 2021 if the MNO had concerns regarding the updated summary of

commitments. In late-March a meeting that included the CNSC, CNL, AECL and the MNO was held with the objective to discuss proposed measures and/or commitments to address potential impacts to MNO's Indigenous Rights as identified in the CNSC's Rights Impact Assessment. At the meeting the MNO indicated they were generally satisfied with the engagement by CNL to date and in agreement with the summary of commitments CNL had provided.

In March 2021, CNL shared a link (via email) with the MNO to the draft EAFMP for the proposed NSDF Project for review. CNL included a request for input and ideas for NSDF follow-up monitoring as well as an invitation to meet and discuss the draft NSDF EAFMP. CNL also advised of potential focus group workshops, for MNO participation, on various aspects of the EAFMP in the late spring/early summer 2021 timeframe.

While not specific to the NSDF Project, meetings aimed at developing an LTRA between CNL, AECL and the MNO for the CRL site commenced virtually in the summer of 2020.

6.2.4.4.2 Feedback

The MNO and CNL have had extensive engagement on the NSDF Project. Through a variety of engagement forums including technical reviews and workshops the MNO has raised a number of interests, concerns and questions that were initially based on their review of the 2017 Draft EIS but re-iterated in subsequent technical comments on the 2019 revised Draft EIS and 2020 Final EIS.

Appendix L.2 of the IER provides a Table of Interests for MNO expressed interests and concerns and CNL responses and also identifies and links the interests and concerns with formally submitted comments made through the environmental assessment process.

The topics in the Table of Interests are briefly summarized below:

- **Engagement.** Early in the engagement process the MNO expressed concern about lack of capacity to be involved in the NSDF Project.
- **Long-Term Relationship Building.** Both the MNO and CNL have indicated an interest in developing a longer-term relationship.
- **Métis Rights and Interests and Traditional Uses.** The MNO requested capacity assistance to more deeply understand potential impact of the NSDF Project on Métis Rights and Interests including traditional uses.
- **Valued Components.** The MNO expressed concern about incorporation of its interests into VCs for the NSDF Project.
- **EIS Section Specific Concerns.** Very early on in the NSDF Project, the MNO raised concerns that MNO interests were not described more fulsomely throughout the 2017 Draft EIS.
- **EIS General Concerns.** The MNO generated a large number of comments based on the review of the 2017 Draft EIS.
- **Archaeology/Cultural Sites.** The MNO expressed some initial concern about the archaeological work, Métis cultural interests and the Pointe Au Baptême site.
- **Indigenous Health.** Initially, the MNO in their review raised some concerns about the human health assessment and more specifically about whether consumption of country foods were comparable to Métis levels.

- **Future Involvement in Environmental Monitoring.** The MNO has expressed interest in better understanding the environmental program and monitoring at the CRL site and participating in any future monitoring.
- **Environmental Effects, Mitigation and Monitoring.** With the 2017 Draft EIS, the MNO expressed some concerns with the environmental effects description and proposed mitigation and monitoring.

6.2.4.4.3 Summary Discussion of Interests and Concerns

As previously indicated this Summary Discussion of Interests and Concerns is taken from the Tables of Interest that appear in Appendix L.2 of the IER. The discussion of the interests and concerns below is CNL's understanding based on written submissions and oral discussions with the MNO. CNL has made its best efforts to document the position the MNO has taken on each interest/concern while acknowledging that the MNO may articulate the perspective somewhat differently.

Engagement

Early in the engagement process the MNO expressed concern about lack of capacity to be involved in the NSDF Project. For the NSDF Project, CNL considers this concern was addressed through the signing of the MOU and Reciprocal Funding Arrangement. CNL is also providing further capacity to the MNO for additional costs not covered by the participant funding the MNO is receiving from the CNSC for review of the Final EIS and participation in a Commission Hearing.

Long-Term Relationship Building

Both the MNO and CNL indicated an interest in developing a longer-term relationship. This is not an NSDF specific concern but is rather intended to be for CRL site wide activities. The MNO and CNL have had preliminary discussions on a long-term relationship that would support a mutually beneficial working relationship with CNL, for collaboration on environmental monitoring, education, economic inclusion and cultural support.

Métis Rights and Interests and Traditional Land Uses

The MNO requested capacity assistance to more deeply understand the potential impact of the NSDF Project on Métis Rights and Interests including traditional land uses. CNL provided the MNO with capacity funding through the MOU for engagement and to assist in the technical review of various studies.

CNL has undertaken engagement with MNO to better understand Métis Rights and Interests and Traditional Uses. The EIS was revised to include the Métis Nation of Ontario (MNO), MNO North Bay, MNO Mattawa Métis, and MNO Sudbury via the Mattawa/Lake Nipissing Traditional Territory Consultation Committee (Table 6.2.2-1).

CNL has communicated that the NSDF Project would not impact on any Métis traditional use because the CRL site is inaccessible to the public and there are no off-site effects predicted as a result of the NSDF Project. MNO has indicated that it remains concerned that perceptions about the CRL site that lead to avoidance strategies by its citizens can represent an impact on their traditional use and therefore harvesting rights. The MNO has also indicated that collaborative environmental monitoring with traditional land users should be undertaken to assure them the land and their rights have not been adversely impacted by the NSDF Project.

CNL will continue working with MNO citizens on understanding there are no risks to adjacent to the Chalk River site and no impact traditional uses as a result of the NSDF Project. Canadian Nuclear Laboratories (CNL) recognizes this is an important issue for MNO and will continue to work them and their harvesters in the future. CNL has also indicated that it is willing to involve the MNO in its future monitoring programs both for NSDF and more broadly related to CRL site.

Valued Components

The MNO expressed concern about incorporation of its interests into VCs for the NSDF Project. CNL considers this concern addressed since CNL provided funding for an MNO VC workshop and report and consulted with the MNO on how their particular VC interests were considered and incorporated into the VCs for the NSDF Project. In the 2020 February letter, MNO notes that reasonable effort by CNL to incorporate and consider the information brought forward by MNO in the 2017 Draft EIS review, the TKLUS and the VC appendix, MNO further states there was adequate synthesis of the TKLUS information into Section 6 of the EIS.

EIS Specific and General Concerns

The MNO identified 52 general and specific technical concerns associated with the 2017 Draft EIS. CNL provided funding to the MNO through the MOU to review the EIS including the retention of technical experts. The comments from the MNO varied from points that required basic clarifications to technical comments on topics such as water quality, archaeology, air emissions/dust, fish and fish habitat, ambient radioactivity, noise, waste management, and biology. Over the course of several meetings (2018 – 2021) and through a number of exchanges of comments and responses, CNL has worked with the MNO to address these concerns which included revisions to the EIS. Additionally, the MNO has requested review of a number of plans associated with the construction and operations of the NSDF. A number of documents have been provided to MNO already. Some documents will only be finalized closer to commencement of construction and operations. CNL is committed to providing documents requested to the MNO.

Environmental Effects, Mitigation and Monitoring

In MNO's comments on the 2017 Draft EIS, the MNO expressed some concerns with the environmental effects description and proposed mitigation and monitoring. Through engagement sessions and in response to direct comments, CNL has worked with the MNO to address concerns with the description of environmental effects and proposed mitigation and monitoring measures. CNL is of the opinion that it has addressed all of the MNO's comments and questions. CNL provided an overview presentation on the future Environmental Assessment Follow-Up Monitoring Program (EAFMP) in December 2020. CNL is willing to involve all interested Indigenous communities in the NSDF Environmental Assessment Follow-up Monitoring Program (EAFMP) and is committed to discussing this further with MNO.

Archaeology/Cultural Sites

The MNO expressed some initial concern about the archaeological work, Métis cultural interests and the Pointe Au Baptême site. CNL provided capacity assistance through the MOU to allow the MNO to undertake a peer review of the archaeological work. CNL also took MNO staff and councillors on a visit to the archaeological fieldwork at the NSDF site and to ask questions of the project archaeologist. CNL has also explained that the Pointe Au Baptême site is not located on CRL property (publicly accessible from the Ottawa River) and will not be impacted by the proposed NSDF Project.

The MNO questioned the methodology followed by the heritage consultant, however CNL is of the opinion the consultant followed standards and guidelines in place at the time of the study.

Should previously undocumented archaeological resources be discovered on the NSDF Project site, CNL will suspend construction immediately and will engage a licensed consultant to carry out archaeological fieldwork, in compliance with Sec. 48 (1) of the Ontario *Heritage Act*. If any human remains are identified during construction, CNL will immediately notify the police or coroner and the Registrar of Cemeteries, Ministry of Small Business and Consumer Services, and Indigenous communities or organizations (Section 6.4.4.2.1 of Final EIS).

Indigenous Health

In MNO comments on the 2017 Draft EIS, the MNO raised some concerns about the human health assessment and more specifically about whether consumption of country foods was comparable to Métis harvesters. CNL provided a response to MNO outlining how the self sufficient Indigenous receptor was incorporated into the Post-Closure Safety Assessment. In a February 2020 MNO letter, the use of the self sufficient Indigenous receptor for potential radiological and non-radiological exposure was noted by MNO as a positive change to the 2019 revised Draft EIS, stating "*This consideration may provide the MNO with some assurance of ongoing safety of the Project which is a key component of perceptive based effects*.".

Future Involvement in Monitoring and Protection at NSDF

The MNO has expressed strong interest in better understanding the environmental program and monitoring at the CRL site and participating in any future monitoring for both the NSDF Project and site-wide. CNL considers this concern addressed since CNL is willing to involve the MNO in its future monitoring programs both for NSDF and site-wide. In 2020 and early 2021, the MNO and CNL had two meetings on future monitoring for both the NSDF and Chalk River Laboratories. CNL has agreed that future discussions on site-wide monitoring should occur as part of long-term relationship discussions.

6.2.4.4.4 Verification

The MNO and CNL have been deeply engaged since the signing of an MOU in 2018. The MNO and CNL have had extensive communications on their submissions and how the 2019 revised Draft EIS incorporated MNO input and findings from their TKLUS and VC workshop. MNO's consultants have reviewed CNL's materials and responses. The MNO provided an acceptance letter in 2020 of the majority CNL's responses. CNL does not want to imply that the MNO is fully accepting of all of CNL's responses but that it is has reviewed and acknowledged them. CNL is of the opinion that it is at Process Step 5 of the CNL Verification Process with the MNO.

CNL notes that additional technical comments were received by the MNO consultant in 2019, 2020 and 2021. CNL provided technical responses to the technical comments from 2019 and to date have not received feedback from MNO on these responses. MNO has acknowledged CNL's effort to incorporate concerns into 2019 revised Draft EIS (received 2020 February and 2020 August), along with additional comments for consideration. In March 2021, CNL received feedback from MNO on the incorporation of MNO input into the 2020 Final EIS. Many comments were closed with no further comment, some were considered partially addressed and some were considered unresolved. CNL notes that a number of the comments partially or unresolved were related to the Rights Impact Assessment being conducted by the Canadian Nuclear Safety Commission. CNL responded in March 2021 to all comments on the Final EIS, indicating proposed next steps and commitments where necessary.

In February and March 2021 CNL sent a letter to the MNO providing an update on the status of the NSDF environmental assessment, as well as to provide a summary of commitments that CNL has made to the MNO in order to address any outstanding interests or concerns. CNL indicated that the commitments list is a living document that may evolve as collaboration during the environmental assessment process continues and is considered the master list of next steps agreed to between MNO and CNL. In late March 2021, the MNO commitment list was reviewed in a meeting with MNO, CNL, CNSC and CNL, where the commitment list was verified by MNO.

6.2.4.4.5 Next Steps

CNL remains committed to ongoing engagement with the MNO. CNL recognizes that MNO involvement in the development of the EAFMP and in future long-term monitoring programs is an area of ongoing interest. As well, CNL is committed to working with MNO citizens and harvesters on understanding there are no risks to traditional uses adjacent to the CRL site.

MNO and CNL, along with AECL have started preliminary discussions about entering into a longer-term co-operation or relationship agreement, more broadly related to the CRL site.

6.2.4.5 Algonquin Anishinabeg Nation Tribal Council (AANTC)

The Algonquin Anishinabeg Nation (AAN), also referred to as the Algonquins of Western Quebec, or Algonquin Anishinabeg Nation Tribal Council (AANTC) was voluntarily established in 1992. Its purpose was to provide representation in land claim development and negotiation for member nations. Traditional territories claimed include the Ottawa River valley. At its inception, it comprised five member nations: Kebaowek First Nation (formerly known as Eagle Village) First Nation, Lac Simon First Nation, Abitibiwinni First Nation, Kitigan Zibi Anishinabeg First Nation, and Long Point First Nation (Winneway). Later two other communities joined the AANTC. A fuller description of the AANTC can be found in Chapter 3 of the IER.

6.2.4.5.1 Engagement

Table 6.2.4-5 below summarizes AANTC engagement and Appendix M.1 of the IER provides a detailed record of engagement activities that have occurred with the AANTC on the NSDF Project.

Table 6.2.4-5: Algonquin Anishinabeg Nation Tribal Council (AANTC) Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Algonquin Anishinabeg Nation Tribal Council (AANTC)	12	44	17	Yes	3	2017 & 2019	In progress	—	Yes	—

* The complete table is located in Section 6.2.4.1.

In July 2016, CNL sent the AATNC a letter to introduce the proposed NSDF Project which included a request for community input on any potential adverse impacts from project activities followed by a secondary letter in November 2016, which inquired about AANTC asserted rights and traditional activities. CNL did not receive a response from the AANTC.

In early 2017 CNL shared the NSDF Project 2017 Draft EIS and encouraged the AANTC to participate in the public and Indigenous environmental assessment comment period. In response the AATNC and CNL met in April 2017 to discuss the NSDF Project and gain feedback from AANTC leadership. The AANTC provided comments on the 2017 Draft EIS through the formal environmental assessment process. In late 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning. CNL did not receive any feedback from the AANTC on this report.

Throughout 2018 and 2019, CNL evolved project engagements to meet Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. CNL invited AANTC to all engagement activities and the AANTC Director attended an event in April 2019. At that engagement event a tentative meeting date of May 2019 between CNL and the AANTC was discussed. In preparation for the meeting CNL sent the draft dispositions to the formal EIS comments submitted by the AANTC to review prior to meeting. The AANTC did not commit to a meeting date and did not provide feedback on CNL's draft dispositions to their formal EIS comments. In late 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with the AANTC and encouraged community input for the final revision.

In early 2020, CNL followed-up to determine a suitable meeting time to discuss CNL's draft dispositions to the AANTC formal comments on the 2017 Draft EIS. The AANTC inquired about NSDF Project timelines as well as the environmental assessment deadlines, which CNL provided. In April 2020, CNL provided updated draft dispositions to AANTC formal comments based on the 2019 revised Draft EIS and reiterated the importance of meeting to discuss comments and responses. In early May 2020, CNL sent a letter to AANTC following up on the dispositions that were sent and included links to the 2019 revised Draft EIS as well as inquiries for specific AANTC information to assist validate assumptions CNL made in the EIS. Following the letter, AANTC indicated they would be reviewing the 2019 revised draft EIS and requested a hard copy of the 2019 revised Draft EIS. In late May 2020, AANTC requested several NSDF technical support documents as well as clarification on inquiries about content in the 2019 revised Draft EIS. CNL provided the clarification to the inquiries and mailed the technical support documents to the AANTC consultant. In June 2020, CNL received follow-up comments on the 2019 revised Draft EIS from AANTC. The additional comments requested details of the NSDF follow-up monitoring plans which CNL acknowledged and advised were still under development therefore a response would be sent upon completion. In July 2020, CNL received an email from AANTC consultant indicating that the full review of the 2019 revised Draft EIS was complete and was with AANTC for review and approval. As of May 2021, CNL has not received this report so cannot complete verification that AANTC's concerns from the 2017 Draft EIS have been addressed.

CNL initiated discussions with AANTC in late May 2020 to establish a NSDF Project specific contribution agreement to ensure support of AANTC's participation in the environmental assessment process. Contribution agreement meetings started in early June 2020. The contribution agreement was to include meetings/discussions on AANTC comments received on the 2017 Draft EIS as well as engagement leading up to the CNSC

Commission Hearing on the NSDF Project. In August 2020, AANTC updated CNL that they were looking into retaining a biologist and would be able to provide a better idea of capacity support required, in the contribution agreement, once this resource was secured.

In May 2020, the AANTC and Kebaowek First Nation submitted a letter to the Government of Canada outlining interests and concerns that included the NSDF Project: Letter from AANTC May 14 2020. In August 2020, the AANTC and Kebaowek First Nation submitted a second letter to the Minister of Natural Resources outlining similar concerns: Letter from AANTC August 26 2020. In September 2020, the AANTC informed CNL that they would refrain from future meetings with CNL until a response from the Minister of Natural Resources addressing their requests was received. In November 2020, the Minister of Natural Resources responded to AANTC and Kebaowek First Nation acknowledging the Chalk River environmental assessment projects: Letter from Minister November 5 2020. Also in November 2020, the CNSC responded to the AANTC and Kebaowek First Nation: Letter from CNSC November 25 2020. In January 2021, Kebaowek First Nation and AANTC submitted a third letter to the Minister of Natural Resources indicating the need to meet to discuss Indigenous consultation and engagement for the Chalk River nuclear assessment projects. While many of these concerns are related to the Government of Canada, CNL is interested in meaningful engagement with AANTC and Kebaowek First Nation on the NSDF Project.

In August 2020, CNL received 17 more questions and document requests from the AANTC consultant. CNL provided the requested documents and indicated the comment responses would follow. CNL provided responses to the AANTC in September 2020. In October 2020, CNL received a list of information requests related to surface water quality, aquatic ecosystem health and future monitoring from the AANTC consultant on behalf of the AANTC biologist. CNL acknowledged receipt and indicated the draft follow-up monitoring program was under development and a response would be sent upon completion.

In October 2020, CNL sent a letter to the AANTC highlighting the remaining opportunities to provide further input or feedback on the NSDF Project, as well as an invitation to meet one-on-one with AANTC to provide NSDF Project updates. AANTC did not provide a response. CNL continued to provide bi-monthly webinar updates throughout 2020, including an email invitation to participate in the NSDF Virtual Open House (VOH) from October 12 to 25, 2020. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions.

In December 2020, CNL sent AANTC notification of the submission of the 2020 Final EIS to the CNSC and the availability of the document online. AANTC did not provide a response.

In February 2021, CNL provided responses to the AANTC biologist information request from October 2020 as well as responses to the comments from June 2020 pertaining to the draft follow-up monitoring program.

In February 2021, CNL sent a letter to the AANTC providing an update on the status of the NSDF Project environmental assessment, as well as to provide a summary of commitments that CNL had previously made to the AANTC during NSDF Project engagements. CNL indicated that the commitments list is an evergreen list and has asked for a response by March 1, 2021 if there were any concerns regarding the commitments list. AANTC did not provide a response.

In March 2021, CNL shared a link (via email) with the AANTC to the draft EAFMP for the proposed NSDF Project for review. CNL included a request for input and ideas for NSDF follow-up monitoring as well as an invitation to meet and discuss the draft NSDF EAFMP. CNL also advised of potential focus group workshops, for AANTC

participation, on various aspects of the EAFMP in the late spring/early summer 2021 timeframe. The AANTC consultant requested eight documents referenced in the draft EAFMP, CNL sent six of the requested documents and indicated the other two were pre-construction documents and were not available at this time.

Although a number of correspondence exchanges with AANTC consultants have occurred through the fall of 2020 and into early 2021, the AANTC have not responded directly to CNL's engagement attempts since September 2020.

6.2.4.5.2 Feedback

Appendix M.2 of the IER provides a Table of Interests for AANTC interests and concerns and CNL responses and also identifies and links the interests and concerns with formally submitted comments made through the environmental assessment process.

The topics in the Table of Interests are briefly summarized below:

- **Alternative Means.** In their review of the 2017 EIS, the AANTC identified concerns with the alternative means assessment.
- **Protection of Water Resources.** In their review of the 2017 Draft EIS, the AANTC identified a concern with the location of the NSDF in close proximity to the Ottawa River and potential impacts on it.
- **Facility Design – Engineered Containment Mound**. In response to the 2017 Draft EIS, the AANTC identified concerns associated with the engineered containment mound.
- **EIS availability in both official languages.** The AANTC requested that the EIS be in English and French.
- **Valued Components.** In their response to the 2017 Draft EIS the AANTC expressed concern that the VCs lacked consideration of potential adverse impacts of the NDSF Project relative to Indigenous Peoples' interests, concerns, conceptions, etc.
- **Environmental Effects – Aquatic Environment**. In response to the 2017 Draft EIS, AANTC felt that the EIS was incomplete and expressed concern about the gaps in the draft document concerning aquatic biota.
- **Cumulative Effects.** In their review of the 2017 Draft EIS, the AANTC did not think cumulative effects had been considered.
- **Assessment of the Effects of the Environment on the NSDF Project.** In their review of the 2017 Draft EIS, the AANTC expressed general concerns about the assessment of extreme environmental events on the NSDF Project.
- **Remediation of Contaminated Areas at the CRL site.** In their review of the 2017 Draft EIS, the AANTC expressed the importance of remediating contaminated areas at the CRL site.
- **Technical Support to Review the EIS.** Both the CNL and AANTC initiated discussions to establish a NSDF Project specific contribution agreement to ensure support of the AANTC's participation in the environmental assessment process.
- **Future Involvement in Monitoring.** In a June 2020 letter the AANTC has expressed interest in better understanding the environmental program and monitoring at the CRL site.

- **Socio-economic.** The AANTC indicated a general interest about procurement or contracting opportunities at the CRL site.

6.2.4.5.3 Summary Discussion of Interests and Concerns

As previously indicated this Summary Discussion of Interests and Concerns is taken from the Tables of Interest that appear in Appendix M.2 of the IER. The discussion of the interests and concerns below is CNL's understanding based on written submissions and oral discussions with the AANTC. CNL has made its best efforts to document the position the AANTC has taken on each interest/concern while acknowledging that the AANTC may articulate the perspective somewhat differently.

Alternative Means

In their review of the 2017 Draft EIS, the AANTC identified concerns with respect to the alternative means assessment. The alternative means assessment was expanded considerably in the 2019 revised Draft EIS in order to incorporate concerns and interests expressed by the public and Indigenous communities and organizations in their review of the 2017 Draft EIS (Section 2.5). CNL responded to the AANTC comment and provided further opportunities discuss CNL's response on multiple occasions. The AANTC consultant reviewed the 2019 revised Draft EIS and no further comments were provided on alternative means. CNL considers this concern to be addressed by the revisions to the EIS.

Protection of Water Resources

In their review of the 2017 Draft EIS, the AANTC identified a concern with the location of the NSDF in close proximity to the Ottawa River and the potential impacts on the Ottawa River the NSDF Project may have. The concern about the proximity of the proposed project to the Ottawa River and its importance to AANTC member communities has been reiterated by the AANTC in meetings and communications. CNL has clarified that the possibility of a location further away from the Ottawa River was considered in the site selection process and that the proposed EMR site was located on a bedrock ridge that naturally forces the water away from the Ottawa River. The site selection process discussion was expanded in Section 2.5.5. CNL responded to the AANTC comment and provided further opportunities discuss CNL's response on multiple occasions. The AANTC consultant reviewed the 2019 revised Draft EIS and noted many positive improvements regarding protection of water resources and requested further clarification on the follow-up monitoring program. CNL considers this concern to be addressed by revisions to the EIS however recognizes this will likely be an ongoing area of interest for the AANTC thus CNL remains committed to ongoing technical discussions with AANTC consultants if requested as an outcome of their review of CNL's dispositions, and more generally with the AANTC.

Facility Design – Engineered Containment Mound

In their review of the 2017 Draft EIS, AANTC identified concerns associated with the engineered containment mound (ECM) design and requested more information in the EIS. Additional details with respect to the overall design of the ECM have been included in the EIS (see Section 3.4.1.4), clarifying the ECM is designed with a number of engineered barriers to provide multiple layers of safety to support the long-term containment and isolation requirements. CNL responded to the AANTC comment and provided further opportunities discuss CNL's response on multiple occasions. The AANTC consultant reviewed the 2019 revised Draft EIS and no further comments were provided on the facility design. CNL considers this concern to be addressed by the revisions to the EIS.

EIS Availability in Both Official Languages

The AANTC requested that the EIS be available in both official languages. Subsequently CNL has made the 2017 Draft EIS, the 2019 revised Draft EIS as well as the Final EIS available on the project website in both French and English. Furthermore, CNL's draft responses to AANTC comments were provided to AANTC in both official languages. CNL has not received any further feedback from AANTC regarding this concern. CNL considers this concern to be addressed. CNL remains committed to ongoing engagement with the AANTC, with simultaneous interpretation to accommodate meetings in English and French.

Valued Components

In their review of the 2017 Draft EIS, the AANTC expressed concern that the assessment lacks consideration of potential adverse impacts of the NDSF Project relative to Indigenous Peoples' interests, concerns, conceptions, in particular inclusion of the moose, beaver and waterfowl as VCs. In response the EIS now contains a new section (Section 6) to consolidate all Indigenous interests and summarize major areas of assessment relevant to Indigenous Peoples. Furthermore, CNL has requested information from the AANTC on several occasions to ensure their interests and concerns with respect to the NSDF Project, as well as traditional uses within proximity of the NSDF Project, were taken into consideration. CNL has had no response from the AANTC from these requests. The AANTC consultant reviewed the 2019 revised Draft EIS and no further comments were provided on VCs. The discussion of VCs in this EIS, includes the moose, beaver and waterfowl, which were identified by AANTC of importance in their comments on the 2017 Draft EIS. CNL considers this concern to be addressed by the revisions to the EIS but CNL remains available for discussions dedicated to project selected VCs and the link to VCs identified by the AANTC.

Environmental Effects – Aquatic Environment

In their review of the 2017 Draft EIS, the AANTC considered that the EIS was incomplete and expressed concern about gaps with respect to aquatic biota, surface and groundwater, the Waste Water Treatment Plant (WWTP) and future monitoring. The EIS has been revised to address the AANTC concerns related to the EIS discrepancies identified, in particular those related to residual effects of the NSDF Project on aquatic biodiversity (Section 5.5) as well has provided requested technical supporting documents for AANTC consultant technical review. CNL responded to the AANTC comment and provided further opportunities to discuss CNL's response on multiple occasions. The AANTC consultant reviewed the 2019 revised Draft EIS and noted positive improvements regarding protection of wetlands indicating more confidence that baseline monitoring and mapping has been completed. CNL considers this concern to be addressed by revisions to the EIS but CNL remains committed to ongoing technical discussions with AANTC if requested. Furthermore, CNL is willing to involve all interested Indigenous communities including the AANTC in the NSDF Environmental Assessment Follow-up Monitoring Program (EAFMP).

Cumulative Effects

In their review of the 2017 Draft EIS, the AANTC identified concerns that cumulative effects of decommissioning and remediation activities at the CRL site had not been considered. CNL responded that cumulative effects of CRL site decommissioning and remediation activities are evaluated in Section 8. The cumulative effects assessment was performed by environmental component and summarized in Section 8.3. The conclusion of the assessment notes that Decommissioning and remediation activities are predicted to have a positive effect on groundwater and surface water quality at the CRL site. CNL responded to the AANTC comment and provided

further opportunities discuss CNL's response on multiple occasions. The AANTC consultant reviewed the 2019 revised Draft EIS and no further comments were provided on cumulative effects. CNL considers this concern to be addressed by the revisions to the EIS.

Assessment of the Effects of the Environment on the Project

In their review of the 2017 Draft EIS, the AANTC identified general concerns about the assessment of extreme environmental events on the NSDF Project. CNL responded that the revised Section 10 of the EIS describes adverse effects of extreme environmental events. Due to the recognized long timeframe of the NSDF Project as a permanent disposal facility for low-level waste, the EIS describes and assesses the magnitude and severity of natural hazards such as extreme weather, flooding (Ottawa River), tornados, forest fires, seismic events and glaciation. CNL responded to the AANTC comment and provided further opportunities discuss CNL's response on multiple occasions. The AANTC consultant reviewed the 2019 revised Draft EIS and no further comments were provided on extreme environmental events. CNL considers this concern to be addressed by the revisions to the EIS.

Remediation of Contaminated Areas at the CRL site

In their review of the 2017 Draft EIS, the AANTC identified concerns about the current contamination at the CRL site. CNL has responded that the NSDF is required in order for environmental remediation of the CRL site to proceed. CNL responded to the AANTC comment and provided further opportunities to discuss CNL's response on multiple occasions. Concerns with respect to the current contamination and environmental monitoring is a CRL site level concern and not specific to the NSDF Project.

Technical Support to Review the EIS

Both the CNL and AANTC initiated discussions to establish a NSDF Project specific contribution agreement to ensure support of the AANTC's participation in the environmental assessment process. Although CNL attempted further correspondence on the concern with the AANTC, in September 2020 AANTC informed CNL that they would not be willing to meet again until the latest letter sent to the Minister receives a response and requests are met. CNL will continue to follow-up with the AANTC on provision of capacity through a contribution agreement.

Future Involvement in Monitoring

During the review of the 2019 revised Draft EIS, the AANTC consultant expressed interest in better understanding the environmental monitoring program being proposed for the NSDF Project. The EAFMP will not be finalized until after an EA decision is rendered by the CNSC, thus there remains opportunity for direct involvement in its development and implementation. CNL reiterated a willingness to collaborate and engage with AANTC on environmental monitoring activities specific to the NSDF Project and provided the draft EAFMP to AANTC consultants for review. CNL considers an interest in the CRL site environmental monitoring a CRL site level concern and not specific to the NSDF Project.

Socio-economic

The AANTC through general discussions expressed an interest in procurement or contracting opportunities. In its services agreement with the NSDF Construction services contract, CNL has required use of local and Indigenous suppliers. CNL has provided information and is willing to follow-up further with the AANTC at their request. CNL considers interests in economic opportunities a CRL site level concern and not specific to the NSDF Project.

6.2.4.5.4 Verification

CNL has provided draft responses to the AANTC formal comments on the 2017 Draft EIS in May 2019 and then again in April 2020, as well as attempted to engage with the AANTC to discuss CNL's responses on multiple occasions through a variety of means (i.e., emails, letters, telephone, webinars, and meetings). In May 2020, a letter to AANTC also included inquiries for specific information to assist validate assumptions CNL made in the EIS with respect to traditional activities occurring within proximity to the NSDF Project. CNL did not receive a response to these questions.

CNL has made several efforts at co-ordinating a meeting with the AANTC in 2019 and 2020 but has been unable to have a meeting date confirmed.

The AANTC consultant reviewed the 2019 revised Draft EIS and acknowledged positive improvements since the 2017 Draft EIS. The AANTC consultant indicated that the review was complete and a report was with the AANTC for review and approval. As of May 2021, CNL has not received this report or any responses to letters so cannot complete verification the AANTC's concerns from the 2017 Draft EIS have been addressed. CNL is of the opinion that it is at Process Step 3 of the CNL Verification Process with the AANTC (i.e., acknowledgement).

AANTC consultants have submitted additional technical comments and information requests to CNL on the 2019 revised Draft EIS which CNL has responded to and offered to meet and discuss. In CNL's opinion these recent comments do not change the conclusions of this EIS and are not new concerns or interests. Many of the comments are related to the NSDF EAFMP which will not be finalized until an environmental assessment decision is rendered thus there remains opportunity for involvement.

CNL has provided the AANTC with the summary of commitments that CNL had previously made to the AANTC during NSDF Project engagements and requested a response if there were any concerns regarding the commitment list. AANTC has not provided a response.

Although a number of correspondence exchanges with AANTC consultants have occurred, the AANTC have not responded directly to any of CNL's engagement attempts since September 2020.

6.2.4.5.5 Next Steps

Although CNL attempted further correspondence on their concerns, the AANTC has informed CNL that they would not be willing to meet again until the latest letter (January 2021) sent to the Minister receives a response and requests are met.

CNL remains committed to ongoing engagement with the AANTC. CNL recognizes that the protection of water resources, including the Ottawa River, will likely be an ongoing area of interest for the AANTC thus CNL remains committed to ongoing technical discussions with AANTC consultants if requested as an outcome of their review of CNL's dispositions, and more generally with the AANTC. Furthermore, CNL is willing to involve the AANTC in the NSDF EAFMP and would be pleased to discuss the concern further.

CNL will also continue to follow-up with the AANTC on provision of capacity through a contribution agreement.

6.2.4.6 Kitigan Zibi Anishinabeg First Nation

The Kitigan Zibi Anishinabeg First Nation (also known also as the River Desert Band or Maniwaki) is one of the nine currently federally recognized Algonquin communities in Quebec. The community resides on reserve lands which were founded in 1851. The main Reserve is situated to the south-west of the borders of Maniwaki in the Outaouais region of Quebec, on the west bank of the Gatineau River. Kitigan Zibi Anishinabeg First Nation has a

total registered population of 3,500. A fuller description of the Kitigan Zibi Anishinabeg First Nation can be found in Chapter 3 of the IER.

6.2.4.6.1 Engagement

Table 6.2.4-6 below summarizes Kitigan Zibi Anishinabeg First Nation engagement and Appendix N.1 of the IER provides a detailed record of engagement activities that have occurred with the Kitigan Zibi Anishinabeg First Nation on the NSDF Project.

Table 6.2.4-6: Kitigan Zibi Anishinabeg First Nation Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Kitigan Zibi Anishinabeg First Nation	8	16	16	Yes	3	—	—	—	—	—

* The complete table is located in Section 6.2.4.1.

In July 2016, CNL sent Kitigan Zibi Anishinabeg First Nation a letter to introduce the proposed NSDF Project, which included a request for community input on any potential adverse impacts from project activities followed by a secondary letter in November 2016 which inquired about Kitigan Zibi Anishinabeg First Nation asserted rights and traditional activities. While Kitigan Zibi Anishinabeg First Nation provided comments on the Project Description for the NSDF Project through the formal environmental assessment process, CNL did not receive a response from the First Nation on the 2016 CNL letters.

In early 2017, CNL shared the 2017 Draft EIS and encouraged Kitigan Zibi Anishinabeg First Nation to participate in the public and Indigenous environmental assessment comment period and in response the AATNC (which included Kitigan Zibi Anishinabeg First Nation) and CNL met in 2017 April to discuss the NSDF Project and gain feedback from AANTC leadership. In May 2017, CNL met with Kitigan Zibi Anishinabeg First Nation Council in Maniwaki, Quebec to discuss the NSDF Project and the comments submitted on the NSDF Project Description. Following this meeting, CNL hosted Kitigan Zibi Anishinabeg First Nation environmental staff for a CRL site visit in July 2017, which included a tour of the proposed NSDF site and an opportunity to provide feedback on the NSDF Project, which included feedback on species at risk. Kitigan Zibi Anishinabeg First Nation provided comments on the 2017 Draft EIS through the formal environmental assessment process. In late 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning. CNL did not receive any feedback from Kitigan Zibi Anishinabeg First Nation on this report.

Throughout 2018 and 2019, CNL evolved project engagements to gather Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. Kitigan Zibi Anishinabeg First Nation received invitations to all engagement activities and have been in attendance at select events to date.

In December 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with Kitigan Zibi Anishinabeg First Nation and encouraged community input for the final revision as well as the opportunity to meet one-on-one to discuss their comments submitted on the 2017 Draft EIS.

In May 2020, CNL sent a letter to Kitigan Zibi Anishinabeg First Nation which included draft dispositions to their comments on the 2017 Draft EIS, links to the 2019 revised Draft EIS as well as inquiries for Kitigan Zibi Anishinabeg First Nation specific information in order for CNL to verify assumptions with respect to traditional activities in proximity to the NSDF Project. CNL initiated discussions with the AANTC in late May 2020 to establish a NSDF Project specific contribution agreement to ensure support of the AANTC's participation in the environmental assessment process. The initial contribution agreement meeting with the AANTC was in June 2020 and the AANTC informed CNL that Kitigan Zibi Anishinabeg First Nation would be involved in contribution agreement discussions, but they were not in attendance at this meeting.

Although a number of correspondence exchanges with AANTC consultants have occurred through the fall of 2020 and into early 2021, the Kitigan Zibi Anishinabeg First Nation have not responded directly to any of CNL's engagement attempts since September 2020.

In October 2020, CNL sent a letter to the Kitigan Zibi Anishinabeg First Nation highlighting the remaining opportunities to provide further input or feedback on the NSDF Project as well as an invitation to meet one-on-one with the Kitigan Zibi Anishinabeg First Nation to provide NSDF Project updates. Kitigan Zibi Anishinabeg First Nation did not provide a response. CNL continued to provide bi-monthly webinar updates throughout 2020,

including an email invitation to participate in the NSDF Virtual Open House (VOH) from October 12 to 25, 2020. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions.

In December 2020, CNL sent the Kitigan Zibi Anishinabeg First Nation notification of the submission of the 2020 Final EIS to the CNSC and the availability of the document online. Kitigan Zibi Anishinabeg First Nation did not provide a response.

In February 2021, CNL sent a letter to the Kitigan Zibi Anishinabeg First Nation providing an update on the status of the NSDF environmental assessment, as well as to provide a summary of commitments that CNL had previously made to the Kitigan Zibi Anishinabeg First Nation during NSDF Project engagements. CNL indicated that the commitments list is an evergreen list and has asked for a response by March 1, 2021 if there were any concerns regarding the commitments list. Kitigan Zibi Anishinabeg First Nation did not provide a response.

In March 2021, CNL shared a link (via email) with Kitigan Zibi Anishinabeg First Nation to the draft EAFMP for the proposed NSDF Project for review. CNL included a request for input and ideas for NSDF follow-up monitoring as well as an invitation to meet and discuss the draft NSDF Project EAFMP. CNL also advised of potential focus group workshops, for Kitigan Zibi Anishinabeg First Nation participation, on various aspects of the EAFMP in the late spring/early summer 2021 timeframe. As of May 2021, the Kitigan Zibi Anishinabeg First Nation has not provided an acknowledgement.

6.2.4.6.2 Feedback

Appendix N.2 of the IER provides a Table of Interests for Kitigan Zibi Anishinabeg First Nation interests and concerns and CNL responses. The table also identifies and links the interests and concerns with formally submitted comments made through the environmental assessment process.

The topics in the Table of Interests are briefly summarized below. Some of these interests and concerns were raised verbally by Kitigan Zibi Anishinabeg First Nation in meetings.

- **Protection of the Environment. -** Kitigan Zibi Anishinabeg First Nation representatives expressed general concerns with the NSDF Project and protection of the environment, in particular the Ottawa River.
- **Biological Concerns** – **Turtles and specifically Blanding's Turtles**. Kitigan Zibi Anishinabeg First Nation representatives had specific concerns about Blanding's Turtles and their protection.
- **Socio-economic.** A Kitigan Zibi Anishinabeg First Nation representative through general discussions expressed an interest in procurement and general employment opportunities.

6.2.4.6.3 Summary Discussion of Interests and Concerns

As previously indicated this Summary Discussion of Interests and Concerns is taken from the Tables of Interest that appear in Appendix N.2 of the IER. The discussion of the interests and concerns below is CNL's understanding based on written submissions and oral discussions with the Kitigan Zibi Anishinabeg First Nation. CNL has made its best efforts to document the position the Kitigan Zibi Anishinabeg First Nation has taken on each interest/concern while acknowledging that the Kitigan Zibi Anishinabeg First Nation may articulate the perspective somewhat differently.

Protection of the Environment

Kitigan Zibi Anishinabeg First Nation representatives expressed general concerns with the NSDF Project and protection of the environment, in particular the Ottawa River. CNL responded to the Kitigan Zibi Anishinabeg First Nation formal comments and provided further opportunities discuss CNL's response on multiple occasions, however Kitigan Zibi Anishinabeg First Nation has been unresponsive. CNL considers this concern to be addressed by revisions to the EIS but CNL remains committed to ongoing technical discussions with Kitigan Zibi Anishinabeg First Nation if requested.

Biological Concerns – Turtles and specifically Blanding's Turtles

Kitigan Zibi Anishinabeg First Nation representatives had specific concerns about Blanding's Turtles and their protection. This concern was expressed at the May 2017 meeting and was part of the reason for the visit to the CRL site in July 2017. The 2019 revised Draft EIS demonstrates that with the mitigation measures committed to by CNL, effects from the NSDF Project will not jeopardize the survival of the Blanding's turtle population within the region of the NSDF Project (Section 5.6.8). CNL considers this concern to be addressed by the discussions at the July 2017 site visit along with the information CNL provided on its work on research and proposed measures in the EIS to mitigate the NSDF Project effects on Blanding's turtles.

Socio-economic

A Kitigan Zibi Anishinabeg First Nation representative through general discussions expressed an interest in procurement and general employment opportunities. In its services agreement with the NSDF construction services contract, CNL has required use of local and indigenous suppliers. CNL has provided information and is willing to follow-up further with the Kitigan Zibi Anishinabeg First Nation at their request. CNL considers interests in economic opportunities a CRL site level concern and not specific to the NSDF Project.

6.2.4.6.4 Verification

In December 2019, CNL sent the Kitigan Zibi Anishinabeg First Nation notification of the online posting of the 2019 revised Draft EIS and the updated Indigenous Engagement Report (IER) for review and offered to meet one-on-one to provide updates and discuss how their comments were incorporated. The Kitigan Zibi Anishinabeg First Nation did not provide a response.

In May 2020, CNL sent a letter to Kitigan Zibi Anishinabeg First Nation which included draft dispositions to their comments on the 2017 Draft EIS and also included inquiries for specific information to assist validate assumptions CNL made in the EIS including those with respect to traditional activities occurring within proximity to the NSDF Project. CNL has not yet received a response to this letter.

CNL has attempted to engage with the Kitigan Zibi Anishinabeg First Nation to discuss CNL's responses on multiple occasions through a variety of means (i.e., emails, letters, telephone, webinars, meetings), however the Kitigan Zibi Anishinabeg First Nation remain unresponsive. Thus CNL is of the opinion that it is at Process Step 2b of the CNL Verification Process with Kitigan Zibi Anishinabeg First Nation. CNL cannot complete the verification that the Kitigan Zibi Anishinabeg First Nation concerns have been addressed until they engage.

CNL has provided the Kitigan Zibi Anishinabeg First Nation with the summary of commitments that has made to the Kitigan Zibi Anishinabeg First Nation during NSDF Project engagements and requested a response if there were any concerns regarding the commitment list. Kitigan Zibi Anishinabeg First Nation has not provided a response.

6.2.4.6.5 Next Steps

CNL acknowledges that Kitigan Zibi Anishinabeg First Nation may have more comments on the NSDF Project going forward and CNL will continue engagement with Kitigan Zibi Anishinabeg First Nation to provide notifications of NSDF Project activities. As previously identified, Kitigan Zibi Anishinabeg First Nation is a member of the AANTC and the AANTC indicated that Kitigan Zibi Anishinabeg First Nation will be involved in the AANTC contribution agreement meetings.

6.2.4.7 Kebaowek First Nation

Kebaowek First Nation is one of the nine currently federally recognized Algonquin communities in Quebec. The reserve is situated on the shore of Lake Kipawa to the northeast of Témiscaming, Quebec. Based on discussions in June 2020, a Kebaowek representative has indicated that their community has traditional territory as far south as the Mattawa area.

6.2.4.7.1 Engagement

Table 6.2.4-7 below summarizes Kebaowek First Nation engagement and Appendix O.1 of the IER provides a detailed record of engagement activities that have occurred with Kebaowek First Nation on the NSDF Project.

Table 6.2.4-7: Kebaowek First Nation Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Kebaowek First Nation (formerly known as Eagle Village First Nation)	11	10	16	No	2	—		—	—	—

* The complete table is located in Section 6.2.4.1.

In July 2016, CNL sent Kebaowek First Nation a letter to introduce the proposed NSDF Project, which included a request for community input on any potential adverse impacts from project activities followed by a secondary letter in November 2016 which inquired about Kebaowek First Nation asserted rights and traditional activities. CNL did not receive a response from the Kebaowek First Nation.

In early 2017, CNL shared the 2017 Draft EIS and encouraged Kebaowek First Nation to participate in the public and Indigenous environmental assessment comment period and in response the AANTC (which included Kebaowek First Nation) and CNL met in April 2017 to discuss the NSDF Project and gain feedback from AANTC leadership. Kebaowek First Nation did not submit comments on the NSDF 2017 Draft EIS through the environmental assessment process. In late 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning. CNL did not receive any feedback from Kebaowek First Nation on this report.

Throughout 2018 and 2019, CNL evolved project engagements to meet Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. Kebaowek First Nation received invitations to all engagement activities and have not attended any events to date.

In December 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with Kebaowek First Nation and encouraged community input for the final revision.

In May 2020, CNL sent a letter following up on the 2019 revised Draft EIS, the IER as well as inquiries for Kebaowek First Nation specific information to verify CNL assumptions about traditional activities within proximity of the NSDF Project. CNL initiated discussions with the AANTC in late May to establish an NSDF Project specific contribution agreement to ensure support of the AANTC's participation in the environmental assessment process. The initial contribution agreement meeting with the AANTC was in 2020 June and Kebaowek First Nation were in attendance. The AANTC informed CNL that Kebaowek First Nation would be involved in contribution agreement discussions and Kebaowek First Nation indicated their specific interest in the NSDF Project.

In May 2020, the AANTC and Kebaowek First Nation submitted a letter to the Government of Canada outlining interests and concerns that included the NSDF Project: Letter from AANTC May 14 2020. In August 2020, the AANTC and Kebaowek First Nation submitted a second letter to the Minister of Natural Resources outlining similar concerns: Letter from AANTC August 26 2020. In September 2020, the AANTC informed CNL that they would not be willing to meet again until the latest letter sent to the Minister receives a response and requests are met. In November 2020, the Minister of Natural Resources responded to the AANTC and Kebaowek First Nation acknowledging the Chalk River Environmental Assessment projects: Letter from Minister November 5 2020. Also in November 2020, the Canadian Nuclear Safety Commission (CNSC) responded to the AANTC and Kebaowek First Nation: Letter from CNSC November 25 2020. In January 2021, AANTC and Kebaowek First Nation submitted a third letter to the Minister of Natural Resources indicating the need to meet to discuss Indigenous consultation and engagement for the Chalk River nuclear assessment projects. While many of these concerns are related to the Government of Canada, CNL is interested in meaningful engagement with the AANTC and Kebaowek First Nation on the NSDF Project.

Although a number of correspondence exchanges with AANTC consultants have occurred through the fall of 2020 and into early 2021, the Kebaowek First Nation have not responded directly to any of CNL's engagement attempts since September 2020.

In October 2020 CNL sent a letter to the Kebaowek First Nation highlighting the remaining opportunities to provide further input or feedback on the NSDF Project as well as an invitation to meet one-on-one with the Kebaowek First Nation to provide NSDF Project updates. Kebaowek First Nation did not provide a response. CNL continued to provide bi-monthly webinar updates throughout 2020, including an email invitation to participate in the NSDF Virtual Open House (VOH) from October 12 to 25, 2020. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions.

In December 2020, CNL sent the Kebaowek First Nation notification of the submission of the 2020 Final EIS to the CNSC and the availability of the document online. Kebaowek First Nation did not provide a response.

In February 2021 CNL sent a letter to the Kebaowek First Nation providing an update on the status of the NSDF environmental assessment, as well as to provide a summary of commitments that CNL had previously made to the Kebaowek First Nation during NSDF Project engagements. CNL indicated that the commitments list is an evergreen list and has asked for a response by March 1, 2021 if there were any concerns regarding the commitments list. Kebaowek First Nation did not provide a response.

In March 2021, CNL shared a link (via email) with Kebaowek First Nation to the draft EAFMP for the proposed NSDF Project for review. CNL included a request for input and ideas for NSDF follow-up monitoring as well as an invitation to meet and discuss the draft NSDF EAFMP. CNL also advised of potential focus group workshops, for Kebaowek First Nation participation, on various aspects of the EAFMP in the late spring/early summer 2021 timeframe. As of May 2021, the Kebaowek First Nation has not provided an acknowledgement.

6.2.4.7.2 Feedback

Kebaowek First Nation has not submitted any written comments on the NSDF Project Description or the 2017 and 2019 Draft versions of the EIS. However, based on the 2020 letter submitted by Kebaowek First Nation to the Government of Canada.

The topics in the Table of Interests are briefly summarized below:

- **Environmental Assessment Process.** Concern was raised regarding the continued use of CEAA 2012 for the NSDF Project.
- **Consultation and Engagement.** Kebaowek First Nation indicated that they were looking for an opportunity for meaningful Indigenous participation.

6.2.4.7.3 Summary Discussion of Interests and Concerns

As previously indicated this Summary Discussion of Interests and Concerns is taken from the Tables of Interest that appear in Appendix O.2 of the IER. The discussion of the interests and concerns below is CNL's understanding based on written submissions and oral discussions with the Kebaowek First Nation. CNL has made its best efforts to document the position the Kebaowek First Nation has taken on each interest/concern while acknowledging that the Kebaowek First Nation may articulate the perspective somewhat differently.

Environmental Assessment Process

The Kebaowek First Nation raised concern with the continued application of CEAA 2012 for the NSDF Project rather than the new *Impact Assessment Act* (IAA). This concern was directed to the Government of Canada and the Minister of Natural Resources and CNSC both provided a response. CNL considers this concern addressed by the provisions within the IAA legislation.

Consultation and Engagement

The Kebaowek First Nation expressed a concern for the need to have meaningful Indigenous participation. CNL initiated discussions with the AANTC (including Kebaowek First Nation) in late May 2020 to establish a NSDF Project specific contribution agreement to ensure support of the AATNC's participation in the environmental assessment process. CNL has provided opportunities to the Kebaowek First Nation to engage in a discussion with CNL about the NSDF Project on multiple occasions, however Kebaowek First Nation has been unresponsive. CNL considers this concern has been addressed by CNL's multiple attempts to engage the Kebaowek First Nation through a variety of means.

6.2.4.7.4 Verification

Kebaowek First Nation has not submitted any written comments on the NSDF Project Description or the 2017 and 2019 Draft EIS. The only feedback received to date has been a letter directed to the Government of Canada. CNL has provided opportunities for engagement opportunities to Kebaowek First Nation and kept them informed about the NSDF Project status.

CNL has sought to validate assumptions CNL made in the EIS including those with respect to traditional activities that may be occurring within proximity to the NSDF Project, however the Kebaowek First Nation has not provided a response.

CNL has provided the Kebaowek First Nation with the summary of commitments that CNL has made to the Kebaowek First Nation during NSDF Project engagements and requested a response if there were any concerns regarding the commitment list. Kebaowek First Nation has not provided a response.

6.2.4.7.5 Next Steps

As previously identified, Kebaowek First Nation is a member of the AANTC and the AANTC indicated that Kebaowek First Nation will be involved in the AANTC contribution agreement meetings. CNL will continue to follow-up with the Kebaowek First Nation on engagement opportunities and about any outstanding interests and concerns.

6.2.4.8 Williams Treaties First Nations (WTFN)

The Williams Treaties First Nations (WTFN) are the Chippewas of Beausoleil, Georgina Island and Rama, and the Mississaugas of Alderville, Curve Lake, Hiawatha and Scugog Island. These seven First Nations are signatories to various 18th and 19th century treaties that covered lands in different parts of south central Ontario. In 1923, the Chippewas and Mississaugas signed the Williams Treaties, which included one large tract of land between Lake Huron and the Ottawa River bounded on the north by the Mattawa River-Lake Nipissing and French Line and on the south by earlier concluded treaties. A fuller description of the WTFN communities can be found in Chapter 3 of the IER.

6.2.4.8.1 WTFN Process Coordinator Engagement

Table 6.2.4-8 below summarizes WTFN Process Coordinator engagement and Appendix P.1 of the IER provides a detailed record of engagement activities that have occurred with the WTFN Process Coordinator on the NSDF Project. CNL originally contacted the WTFN Process Co-ordinator at the request of a couple of the Williams Treaties First Nation communities. In 2020, CNL was made aware that this position did not co-ordinate any engagements on behalf of these communities and CNL discontinued contacting this individual.

Table 6.2.4-8: Williams Treaties First Nations (WTFN) Process Coordinator Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Williams Treaties First Nations (WTFN) Process Coordinator	2	7	10	—	—	—	—	—	—	—

* The complete table is located in Section 6.2.4.1.

Based on an email from the Chippewas of Rama First Nation advising CNL that the November 2016 CNL letter was sent to the WTFN Process Coordinator for review, CNL sent email correspondence in late 2016 – early 2017 to the Process Coordinator to inquire about whether the WTFN (collectively) were interested in engaging with CNL on the NSDF Project. CNL did not receive a response.

In March 2017, CNL shared the 2017 Draft EIS and encouraged WTFN communities to participate in the public and Indigenous environmental assessment comment period. Hiawatha First Nations provided formal comments on the 2017 Draft EIS through the environmental assessment process. In late 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning. CNL did not receive feedback from any WTFN communities on this report.

Throughout 2018 and 2019, CNL evolved project engagements to meet Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. The WTFN Process Coordinator received invitations to all engagement activities and did not attend any events. In late 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with WTFN communities and encouraged community input for the final revision.

In February 2020, CNL once again reached out to the WTFN Process Coordinator to inquire about whether the WTFN as a whole were interested in engaging with CNL on the NSDF Project. CNL did not receive a response. As of March 2020, CNL was informed that all engagement activities should be done through each community consultation coordinator/liaison, which is described in further detail below.

6.2.4.8.1.1 Next Steps

CNL is of the opinion that it has addressed all of the WTFN communities concerns and comments to date, however more engagement is planned with these communities and CNL will continue to work with WTFN communities (collectively) or on an individual community basis. CNL will also continue to provide notifications of NSDF Project activities to WTFN communities until otherwise instructed.

6.2.4.8.2 Alderville First Nation Engagement

Table 6.2.4-9 below summarizes Alderville First Nation engagement and Appendix Q.1 of the IER provides a detailed record of engagement activities that have occurred with Alderville First Nation on the NSDF Project.

Table 6.2.4-9: Alderville First Nation Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Alderville First Nation	6	33	16	—	2	—	—	—	—	—

* The complete table is located in Section 6.2.4.1.

In July 2016, CNL sent Alderville First Nation a letter to introduce the proposed NSDF Project which included a request for community input on any potential adverse impacts from project activities followed by a secondary letter in November 2016 which inquired about Alderville First Nation asserted rights and traditional activities. CNL did not receive a response from Alderville First Nation.

In early 2017 CNL shared the 2017 Draft EIS and encouraged Alderville First Nation to participate in the public and Indigenous environmental assessment comment period. Alderville First Nation did not provide comments on the 2017 Draft EIS through the environmental assessment process. In late 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning. CNL did not receive any feedback from Alderville First Nation on this report.

Throughout 2018 and 2019, CNL evolved project engagements to meet Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. Alderville First Nation received invitations to all engagement activities and have been in attendance at select events to date. In late 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with Alderville First Nation and encouraged community input for the final revision.

In March 2020, CNL followed up with Alderville First Nation on the 2019 December notification of the 2019 revised Draft EIS. This email follow-up included the Alderville First Nation consultation representative as indicated by the CNSC. In April 2020, CNL sent an invitation to WTFN communities to an interactive webinar to provide an overview of the NSDF Project as well as an opportunity for questions. Alderville First Nation participated in the April 29, 2020 webinar. Actions from the webinar resulted in the distribution of the “NSDF – Responsible Water Management” video and NSDF Stage 4 Archaeological Assessment online links to all WTFN consultation representatives, as well as a request for a future webinar on the NSDF baseliner system and responsible water management. The webinar on the NSDF baseliner system and responsible water management was held on June 30, 2020 and August 26, 2020 on the NSDF cover system and Waste Water Treatment Plan (WWTP), respectively. Alderville First Nation declined participation in both webinars.

In May 2020, CNL sent a follow-up letter to the Alderville First Nation regarding the 2019 revised Draft EIS, IER input as well as a request to learn more about Alderville First Nation and any asserted rights, interests or activities members might undertake in the local or regional study areas in proximity to the NSDF Project. A follow-up email was sent in May 2020 and to date CNL has not received a response.

In October 2020, CNL sent a letter highlighting the remaining opportunities to provide further input or feedback on the NSDF Project within the formal context of the environmental assessment. Alderville First Nation can provide formal input through the comment period after the EA report is prepared as well as participation in the CNSC hearing. Additionally, the letter once again encouraged community input for the IER. CNL did not receive a response from Alderville First Nation. CNL continued to provide bi-monthly webinar updates throughout 2020, including an email invitation to participate in the NSDF Virtual Open House (VOH) from October 12 to 25, 2020. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions.

In early December 2020, CNL sent a notification of the submission of the 2020 Final EIS to the CNSC and links to access the EIS online.

In early 2021, Curve Lake First Nation indicated interest in a CNL monthly update meeting. CNL extended the meeting invitation to all WTFN and encouraged participation. These meetings will provide all WTFN communities with monthly updates as well as an opportunity to ask questions and share feedback on CNL activities. The monthly meetings will take place the last Wednesday of each month.

In February 2021, CNL sent a letter to Alderville First Nation providing an update on the status of the NSDF environmental assessment, as well as to provide a summary of commitments that CNL had previously made to Alderville First Nation during NSDF Project engagements. CNL indicated that the commitments list is an evergreen list and has asked for a response by March 1, 2021 if there were any concerns regarding the commitments list. Alderville First Nation did not provide a response.

In March 2021, CNL shared a link (via email) with Alderville First Nation to the draft EAFMP for the proposed NSDF Project for review. CNL included a request for input and ideas for NSDF follow-up monitoring as well as an invitation to meet and discuss the draft NSDF EAFMP. CNL also advised of potential focus group workshops, for Alderville First Nation participation, on various aspects of the EAFMP in the late spring/early summer 2021 timeframe. As of May 2021, the Alderville First Nation has not provided an acknowledgement.

The first monthly update on CNL's environmental remediation projects was held on March 31, 2021 and included an overview on CNL and AECL as well as a discussion on WTFN preferences for the monthly meeting format and future meeting topics and/or topics important to WTFN communities. Alderville First Nation did not participate. The second monthly update on CNL's environmental remediation projects was held on April 28, 2021 and included an update on the NSDF Project and NPD Closure Project, as well as Port Hope Area Initiative (PHAI) activities in Port Hope and Port Granby. Alderville First Nation attended this meeting.

6.2.4.8.2.1 Feedback

Alderville First Nation has not submitted any written comments on the NSDF Project Description or the 2017 or 2019 revised Draft EIS. However, based on verbal comments during the April 2020 webinar with some of the communities of WTFN, the following interest/concern was identified verbally by Alderville First Nation.

- **Protection of the Environment:** interest was expressed on how the environment and biological species can be protected.

6.2.4.8.2.2 Summary Discussion of Interests and Concerns

As previously indicated this Summary Discussion of Interests and Concerns is taken from the Tables of Interest that appear in Appendix Q.2 of the IER. The discussion of the interests and concerns below is CNL's understanding based oral discussions with the Alderville First Nation. CNL has made its best efforts to document the position the Alderville First Nation has taken on each interest/concern while acknowledging that the Alderville First Nation may articulate the perspective somewhat differently.

Protection of the Environment

In April 2020, CNL provided an overview of the NSDF Project and measures to protect the environment as part of a presentation to the WTFN communities. More specifically this interactive webinar discussion and presentation shared information on the following key areas: an overview of the NSDF Project components and timeline, the EA process, the site location, archaeology, interests heard about the NSDF Project from communities of the WTFN, ensuring protection of the Ottawa River, spatial boundaries to the assessment area, monitoring and the effects assessment. The webinar also asked WTFNs to provide any information they have concerning their interests near

NSDF on traditional uses, cultural sites, and concerns about the NSDF Project. These questions were re-iterated in letters sent in May 2020. A WTFN/CNL action list was created.

Two follow-up webinars were provided to WTFNs on the topics they indicated an interest in specifically on water management and the baseliner system and on the NSDF cover system and wastewater treatment plan. Alderville FN declined participation in those events but were sent all materials related to the webinars.

CNL considers this concern is addressed as CNL has demonstrated how the NSDF will ensure protection of the Ottawa River during webinar activities offered to Alderville First Nation. However, CNL acknowledges the protection of the environment is likely to be an ongoing concern from Alderville First Nation thus CNL has made the draft EAFMP available to Alderville First Nation for technical review and input (March 2021).

6.2.4.8.2.3 Verification

Alderville First Nation has not submitted any written comments on the NSDF Project Description or the 2017 and 2019 Draft EIS. The only feedback received from Alderville First Nation was verbal for which CNL provided additional information in the form of webinars and technical documents. CNL reached out to confirm with Alderville First Nation if their concern was addressed however CNL received no written response. CNL has provided opportunities for engagement opportunities to Alderville First Nation and kept them informed about the NSDF Project status.

CNL has sought to validate assumptions CNL made in the EIS including those with respect to traditional activities that may be occurring within proximity to the NSDF Project, however the Alderville First Nation has not provided a response.

CNL has provided the Alderville First Nation with the summary of commitments that CNL has made to the Alderville First Nation during NSDF Project engagements and requested a response if there were any concerns regarding the commitment list. Alderville First Nation has not provided a response.

6.2.4.8.2.4 Next Steps

CNL will continue to follow-up with Alderville First Nation on engagement opportunities and any emerging interests and concerns unless otherwise instructed.

6.2.4.8.3 Beausoleil First Nation Engagement

Table 6.2.4-10 below summarizes Beausoleil First Nation engagement and Appendix R.1 of the IER provides a detailed record of engagement activities that have occurred with Beausoleil First Nation on the NSDF Project.

Table 6.2.4-10: Beausoleil First Nation Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 Revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Beausoleil First Nation	6	32	16	—	—	—	—	—	—	—

* The complete table is located in Section 6.2.4.1.

In July 2016, CNL sent Beausoleil First Nation a letter to introduce the proposed NSDF Project which included a request for community input on any potential adverse impacts from project activities followed by a secondary letter in November 2016, which inquired about Beausoleil First Nation asserted rights and traditional activities. CNL did not receive a response from Beausoleil First Nation.

In early 2017 CNL shared the 2017 Draft EIS and encouraged Beausoleil First Nation to participate in the public and Indigenous environmental assessment comment period. Beausoleil First Nation did not provide comments on the 2017 Draft EIS through the environmental assessment process. In late 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning. CNL did not receive any feedback from Beausoleil First Nation on this report.

Throughout 2018 and 2019, CNL evolved project engagements to meet Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. Beausoleil First Nation received invitations to all engagement activities and have not attended any events to date. In late 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with Beausoleil First Nation and encouraged community input for the final revision.

In March 2020, CNL followed up with Beausoleil First Nation on the December 2019 notification of the 2019 revised Draft EIS. This email follow-up included the Beausoleil First Nation consultation representative as indicated by the CNSC. In April 2020, CNL sent an invitation to WTFN communities to an interactive webinar to provide an overview of the NSDF Project as well as an opportunity for questions. Beausoleil First Nation declined participation in the April 29, 2020 webinar. CNL sent a copy of the presentation and an invitation to meet one-on-one. Actions from the webinar resulted in the distribution of the NSDF – Responsible Water Management video and NSDF Stage 4 Archaeological Assessment online links to all WTFN consultation representatives, as well a request for a future webinar on the NSDF baseliner system and responsible water management. The webinar on the NSDF baseliner system and responsible water management was held on June 30, 2020, as well as August 26, 2020 on the NSDF cover system and Waste Water Treatment Plan (WWTP). Beausoleil First Nation declined participation in both webinars.

In May 2020, CNL sent a follow-up letter to the Beausoleil First Nation regarding the 2019 revised Draft EIS, IER input as well as a request to learn more about Beausoleil First Nation and any asserted rights, interests or activities members might undertake in the local or regional study areas in proximity to the NSDF Project. A follow-up email was sent in May 2020 and to date CNL has not received a response.

In October 2020, CNL sent a letter highlighting the remaining opportunities to provide further input or feedback on the NSDF Project within the formal context of the EA. Beausoleil First Nation can provide formal input through the comment period after the EA report is prepared as well as participation in the CNSC hearing. Additionally, the letter once again encouraged community input for the IER. CNL did not receive a response from Beausoleil First Nation. CNL continued to provide bi-monthly webinar updates throughout 2020, including an email invitation to participate in the NSDF Virtual Open House (VOH) from October 12 – 25, 2020. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions.

In early December 2020, CNL sent a notification of the submission of the 2020 Final EIS to the CNSC and links to access the EIS online.

In early 2021, Curve Lake First Nation indicated interest in a CNL monthly update meeting. CNL extended the meeting invitation to all WTFN and encouraged participation. These meetings will provide WTFN communities with monthly updates as well as an opportunity to ask questions and share feedback on CNL activities. The monthly meetings will take place the last Wednesday of each month with the first meeting on March 31, 2021.

In February 2021, CNL sent a letter to Beausoleil First Nation providing an update on the status of the NSDF environmental assessment, as well as to provide a summary of commitments that CNL had previously made to Beausoleil First Nation during NSDF Project engagements. CNL indicated that the commitments list is an evergreen list and has asked for a response by March 1, 2021 if there were any concerns regarding the commitments list. Beausoleil First Nation did not provide a response.

In March 2021, CNL shared a link (via email) with Beausoleil First Nation to the draft Environmental Assessment Follow-Up Monitoring Program (EAFMP) for the proposed NSDF Project for review. CNL included a request for input and ideas for NSDF follow-up monitoring as well as an invitation to meet and discuss the draft NSDF EAFMP. CNL also advised of potential focus group workshops, for Beausoleil First Nation participation, on various aspects of the EAFMP in the late spring/early summer 2021 timeframe. As of May 2021, the Beausoleil First Nation has not provided an acknowledgement.

The first monthly update on CNL's environmental remediation projects was held on March 31, 2021 and included an overview on CNL and AECL as well as a discussion on WTFN preferences for the monthly meeting format and future meeting topics and/or topics important to WTFN communities. Beausoleil First Nation did not participate. The second monthly update on CNL's environmental remediation projects was held on April 28, 2021 and included an update on the NSDF Project and NPD Closure Project, as well as Port Hope Area Initiative (PHAI) activities in Port Hope and Port Granby. Beausoleil First Nation did not participate.

6.2.4.8.3.1 Feedback

Beausoleil First Nation has not submitted any written comments on the NSDF Project Description or 2017 and 2019 Draft EIS, or provided any comments verbally.

6.2.4.8.3.2 Summary of Interests and Concerns

Beausoleil First Nation has not submitted any written comments nor provided any verbal comments on the NSDF Project. As such, CNL is not aware of any interests and concerns.

6.2.4.8.3.3 Verification

Beausoleil First Nation has not submitted any written comments nor provided any verbal feedback on the NSDF Project. As such, no feedback was received for which CNL can seek to verify with the Beausoleil First Nation to determine if Beausoleil First Nation interests or concerns have been addressed.

CNL has provided opportunities for engagement opportunities to Beausoleil First Nation and kept them informed about the NSDF Project status.

CNL has sought to validate assumptions CNL made in the EIS including those with respect to traditional activities that may be occurring within proximity to the NSDF Project, however the Beausoleil First Nation has not provided a response.

CNL has provided the Beausoleil First Nation with the summary of commitments that CNL has made to the Beausoleil First Nation during NSDF Project engagements and requested a response if there were any concerns regarding the commitment list. Beausoleil First Nation has not provided a response.

6.2.4.8.3.4 Next Steps

CNL will continue to follow-up with Beausoleil First Nation on engagement opportunities and any emerging interests and concerns unless otherwise instructed.

6.2.4.8.4 Chippewas of Georgina Island First Nation Engagement

Table 6.2.4-11 below summarizes Georgina Island engagement and Appendix S.1 of the IER provides a detailed record of engagement activities that have occurred with Chippewas of Georgina Island on the NSDF Project.

Table 6.2.4-11: Chippewas of Georgina Island First Nation Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Chippewas of Georgina Island First Nation	6	34	16	—	—	—	—	—	—	—

* The complete table is located in Section 6.2.4.1.

In July 2016, CNL sent Georgina Island First Nation a letter to introduce the proposed NSDF Project, which included a request for community input on any potential adverse impacts from project activities followed by a secondary letter in November 2016 which inquired about Georgina Island First Nation asserted rights and traditional activities. CNL did not receive a response from Georgina Island First Nation.

In early 2017 CNL shared the 2017 Draft EIS and encouraged Georgina Island First Nation to participate in the public and Indigenous environmental assessment comment period. Georgina Island First Nation did not provide comments on the 2017 Draft EIS through the environmental assessment process. In late 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning. CNL did not receive any feedback from Georgina Island First Nation on this report.

Throughout 2018 and 2019, CNL evolved project engagements to meet Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. Georgina Island First Nation received invitations to all engagement activities and have not attended any events to date. In late 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with Georgina Island First Nation and encouraged community input for the final revision.

In March 2020, CNL followed up with Georgina Island First Nation on the December 2019 notification of the 2019 revised Draft EIS. This email follow-up included the Georgina Island First Nation consultation representative as indicated by the CNSC. In April 2020, CNL sent an invitation to WTFN communities to an interactive webinar to provide an overview of the NSDF Project as well as an opportunity for questions. Georgina Island did not participate in the April 29, 2020 webinar – CNL sent a copy of the presentation and an invitation to meet one-on-one. Actions from the webinar resulted in the distribution of the NSDF – Responsible Water Management video and NSDF Stage 4 Archaeological Assessment online links to all WTFN consultation representatives, as well as a request for a future webinar on the NSDF baseliner system and responsible water management. The webinar on the NSDF baseliner system and responsible water management was held on June 30, 2020, as well as August 26, 2020 on the NSDF cover system and Waste Water Treatment Plan (WWTP). Georgina Island First Nation declined participation in both webinars.

In May 2020, CNL sent a follow-up letter to the Georgina Island First Nation regarding the 2019 revised Draft EIS, IER input as well as a request to learn more about Georgina Island First Nation and any asserted rights, interests or activities members might undertake in the local or regional study areas in proximity to the NSDF Project. A follow-up email was sent in May 2020 and to date CNL has not received a response.

In October 2020, CNL sent a letter highlighting the remaining opportunities to provide further input or feedback on the NSDF Project within the formal context of the EA. Georgina Island First Nation can provide formal input through the comment period after the EA report is prepared as well as participation in the CNSC hearing. Additionally, the letter once again encouraged community input for the IER. CNL did not receive a response from Georgina Island First Nation. CNL continued to provide bi-monthly webinar updates throughout 2020, including an email invitation to participate in the NSDF Virtual Open House (VOH) from October 12 – 25. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions.

In early December 2020, CNL sent a notification of the submission of the 2020 Final EIS to the CNSC and links to access the EIS online.

In early 2021, Curve Lake First Nation indicated interest in a CNL monthly update meeting. CNL extended the meeting invitation to all WTFN and encouraged participation. These meetings will provide WTFN communities with monthly updates as well as an opportunity to ask questions and share feedback on CNL activities. The monthly meetings will take place the last Wednesday of each month with the first meeting on March 31, 2021.

In February 2021, CNL sent a letter to Georgina Island First Nation providing an update on the status of the NSDF environmental assessment, as well as to provide a summary of commitments that CNL had previously made to Georgina Island First Nation during NSDF Project engagements. CNL indicated that the commitments list is an evergreen list and has asked for a response by March 1, 2021 if there were any concerns regarding the commitments list. Georgina Island First Nation did not provide a response.

In March 2021, CNL shared a link (via email) with Georgina Island First Nation to the draft Environmental Assessment Follow-Up Monitoring Program (EAFMP) for the proposed NSDF Project for review. CNL included a request for input and ideas for NSDF follow-up monitoring as well as an invitation to meet and discuss the draft NSDF EAFMP. CNL also advised of potential focus group workshops, for Georgina Island First Nation participation, on various aspects of the EAFMP in the late spring/early summer 2021 timeframe. As of May 2021, the Georgina Island First Nation has not provided an acknowledgement.

The first monthly update on CNL's environmental remediation projects was held on March 31, 2021 and included an overview on CNL and AECL as well as a discussion on WTFN preferences for the monthly meeting format and future meeting topics and/or topics important to WTFN communities. Georgina Island First Nation did not participate. The second monthly update on CNL's environmental remediation projects was held on April 28, 2021 and included an update on the NSDF Project and NPD Closure Project, as well as Port Hope Area Initiative (PHAI) activities in Port Hope and Port Granby. Georgina Island First Nation did not participate.

6.2.4.8.4.1 Feedback

Georgina Island First Nation has not submitted any written comments on the NSDF Project Description or 2017 and 2019 Draft EIS.

6.2.4.8.4.2 Summary of Interests and Concerns

Georgina Island First Nation has not submitted any written comments nor provided any verbal comments on the NSDF Project. As such, CNL is not aware of any interests and concerns.

6.2.4.8.4.3 Verification

Georgina Island First Nation has not submitted any written comments nor provided any verbal feedback on the NSDF Project. As such, no feedback was received for which CNL can seek to verify with the Georgina Island First Nation to determine if Georgina Island First Nation interests or concerns have been addressed.

CNL has provided opportunities for engagement opportunities to Georgina Island First Nation and kept them informed about the NSDF Project status.

CNL has sought to validate assumptions CNL made in the EIS including those with respect to traditional activities that may be occurring within proximity to the NSDF Project, however the Georgina Island First Nation has not provided a response.

CNL has provided the Georgina Island First Nation with the summary of commitments that CNL has made to the Georgina Island First Nation during NSDF Project engagements and requested a response if there were any concerns regarding the commitment list. Georgina Island First Nation has not provided a response.

6.2.4.8.4.4 Next Steps

CNL will continue to follow-up with Georgina Island First Nation on engagement opportunities and any emerging interests and concerns unless otherwise instructed.

6.2.4.8.5 Chippewas of Rama First Nation Engagement

Table 6.2.4-12 below summarizes Rama First Nation engagement and Appendix T.1 of the IER provides a detailed record of engagement activities that have occurred with Chippewas of Rama First Nation on the NSDF Project.

Table 6.2.4-12: Chippewas of Rama First Nation Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Chippewas of Rama First Nation	7	33	16	—	3	—	—	—	—	—

* The complete table is located in Section 6.2.4.1.

In July 2016, CNL sent Chippewas of Rama First Nation a letter to introduce the proposed NSDF Project which included a request for community input on any potential adverse impacts from project activities followed by a secondary letter in November 2016 which inquired about Chippewas of Rama First Nation asserted rights and traditional activities. As discussed in Section 6.2.4.8.1 (WTFN Process Coordinator), in response to the November 2016 letter sent from CNL, Chippewas of Rama First Nation advised CNL, via letter, that all correspondence was to be sent to the WTFN Process Coordinator.

In early 2017 CNL shared the 2017 Draft EIS and encouraged Chippewas of Rama First Nation to participate in the public and Indigenous environmental assessment comment period. Chippewas of Rama First Nation did not provide comments on the 2017 Draft EIS through the environmental assessment process. In late 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning. CNL did not receive any feedback from Chippewas of Rama First Nation on this report.

Throughout 2018 and 2019, CNL evolved project engagements to meet Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. The Chippewas of Rama First Nation received invitations to all engagement activities and have been in attendance at select events to date. In late 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with the Chippewas of Rama First Nation and encouraged community input for the final revision.

In March 2020, CNL followed up with Chippewas of Rama First Nation on the December 2019 notification of the 2019 revised Draft EIS. This email follow-up included the Chippewas of Rama First Nation consultation representative as indicated by the CNSC. Chippewas of Rama First Nation acknowledged receipt of email and indicated follow-up would be done on the December 2019 content and they would let CNL know if they had any comments. No comments were received.

In April 2020, CNL sent an invitation to WTFN communities to an interactive webinar to provide an overview of the NSDF Project as well as an opportunity for questions. Chippewas of Rama did not participate in the April 29, 2020 webinar – CNL sent a copy of the presentation and an invitation to meet one-on-one. Actions from the webinar resulted in the distribution of the NSDF – Responsible Water Management video and NSDF Stage 4 Archaeological Assessment online links to all WTFN consultation representatives, as well as a request for a future webinar on the NSDF baseliner system and responsible water management. Chippewas of Rama First Nation participated in the June 30, 2020 webinar on the NSDF baseliner system and responsible water management as well as the August 26, 2020 webinar on the NSDF cover system and Waste Water Treatment Plan (WWTP).

In May 2020, CNL sent a follow-up letter to the Chippewas of Rama First Nation regarding the 2019 revised Draft EIS, IER input as well as a request to learn more about Chippewas of Rama First Nation and any asserted rights, interests or activities members might undertake in the local or regional study areas in proximity to the NSDF Project. A follow-up email was sent in May 2020 and to date CNL has not received a response.

In October 2020, CNL sent a letter highlighting the remaining opportunities to provide further input or feedback on the NSDF Project within the formal context of the EA. Chippewas of Rama First Nation can provide formal input through the comment period after the EA report is prepared as well as participation in the CNSC hearing. Additionally, the letter once again encouraged community input for the IER. CNL did not receive a response from

Chippewas of Rama First Nation. CNL continued to provide bi-monthly webinar updates throughout 2020, including an email invitation to participate in the NSDF Virtual Open House (VOH) from October 12 – 25, 2020. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions.

In early December 2020, CNL sent a notification of the submission of the 2020 Final EIS to the CNSC and links to access the EIS online.

In early 2021, Curve Lake First Nation indicated interest in a CNL monthly update meeting. CNL extended the meeting invitation to all WTFN and encouraged participation. These meetings will provide WTFN communities with monthly updates as well as an opportunity to ask questions and share feedback on CNL activities. The monthly meetings will take place the last Wednesday of each month with the first meeting on March 31, 2021.In February 2021, CNL sent a letter to Chippewas of Rama First Nation providing an update on the status of the NSDF environmental assessment, as well as to provide a summary of commitments that CNL had previously made to Chippewas of Rama First Nation during NSDF Project engagements. CNL indicated that the commitments list is an evergreen list and has asked for a response by March 1, 2021 if there were any concerns regarding the commitments list. Chippewas of Rama First Nation did not provide a response.

In March 2021, CNL shared a link (via email) with the Chippewas of Rama First Nation to the draft Environmental Assessment Follow-Up Monitoring Program (EAFMP) for the proposed NSDF Project for review. CNL included a request for input and ideas for NSDF follow-up monitoring as well as an invitation to meet and discuss the draft NSDF EAFMP. CNL also advised of potential focus group workshops, for Chippewas of Rama First Nation participation, on various aspects of the EAFMP in the late spring/early summer 2021 timeframe. As of May 2021, the Chippewas of Rama First Nation has not provided an acknowledgement.

The first monthly update on CNL's environmental remediation projects was held on March 31, 2021 and included an overview on CNL and AECL as well as a discussion on WTFN preferences for the monthly meeting format and future meeting topics and/or topics important to WTFN communities. Chippewas of Rama First Nation did not participate. The second monthly update on CNL's environmental remediation projects was held on April 28, 2021 and included an update on the NSDF Project and NPD Closure Project, as well as Port Hope Area Initiative (PHAI) activities in Port Hope and Port Granby. Chippewas of Rama First Nation attended this meeting.

6.2.4.8.5.1 Feedback

Chippewas of Rama First Nation has not submitted any written comments nor provided any verbal comments on the NSDF Project. Although in response to a letter from CNL in November 2016, Chippewas of Rama First Nation provided feedback with respect to engagement, advising CNL that all correspondence was to be sent to the WTFN Process Coordinator.

6.2.4.8.5.2 Summary of Interests and Concerns

As previously indicated this Summary Discussion of Interests and Concerns is taken from the Tables of Interest that appear in Appendix T.2 of the IER. The discussion of the interests and concerns below is CNL's understanding based on a written submission from the Chippewas of Rama First Nation. CNL has made its best efforts to document the position the Chippewas of Rama First Nation has taken on each interest/concern while acknowledging that the Chippewas of Rama First Nation may articulate the perspective somewhat differently.

Engagement

In response to a letter from CNL in November 2016, Chippewas of Rama First Nation provided feedback with respect to engagement, advising CNL that all correspondence was to be sent to the WTFN Process Coordinator. CNL made multiple inquiries to the WTFN Process Coordinator in 2016, 2017, 2019 and 2020, but no response was received. CNL concerns this concern as resolved since in March 2020, CNL was informed that all engagement activities should be done through each community consultation coordinator/liaison. CNL will also continue to provide notifications of NSDF Project activities to WTFN communities until otherwise instructed.

Along with efforts to consult with WTFNs from 2016 to 2019, CNL renewed engagement with the communities of WTFNs, including the Chippewas of Rama First Nation, in 2020.

6.2.4.8.5.3 Verification

Chippewas of Rama First Nation has not submitted any written comments nor provided any verbal feedback on the NSDF Project. As such, no feedback was received for which CNL can seek to verify with the Chippewas of Rama First Nation to determine if Chippewas of Rama First Nation interests or concerns have been addressed.

CNL has sought to validate assumptions CNL made in the EIS including those with respect to traditional activities that may be occurring within proximity to the NSDF Project, however the Chippewas of Rama First Nation has not provided a response.

CNL has provided the Chippewas of Rama First Nation with the summary of commitments that CNL has made to the Chippewas of Rama First Nation during NSDF Project engagements and requested a response if there were any concerns regarding the commitment list. Chippewas of Rama First Nation has not provided a response.

6.2.4.8.5.4 Next Steps

CNL will continue to follow-up with Chippewas of Rama First Nation on engagement opportunities and any emerging interests and concerns unless otherwise instructed.

6.2.4.8.6 Curve Lake First Nation Engagement

Table 6.2.4-13 below summarizes Curve Lake First Nation engagement and Appendix U.1 of the IER provides a detailed record of engagement activities that have occurred with Curve Lake First Nation on the NSDF Project.

Table 6.2.4-13: Curve Lake First Nation Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 Revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Curve Lake First Nation	7	56	16	Yes	9	—	CA In progress	—	—	—

* The complete table is located in Section 6.2.4.1.

In July 2016, CNL sent Curve Lake First Nation a letter to introduce the proposed NSDF Project which included a request for community input on any potential adverse impacts from project activities. Curve Lake First Nation acknowledged the letter and discussed the opportunity of liaisons from Curve Lake participating in the archeological field work based on their comments submitted on the Project Description for the NSDF through the formal EA process. CNL indicated field work was in Stage 3 and Curve Lake did not provide liaisons. A secondary letter was sent in November 2016, which inquired about Curve Lake First Nation asserted rights and traditional activities. While CNL did not receive a formal response to the November 2016 letter, Curve Lake First Nation requested a copy of the NSDF Project archeological assessment report. The report was provided in December 2016 and Curve Lake First Nation acknowledged receipt of report and indicated that they had no comments.

In early 2017, CNL shared the 2017 Draft EIS and encouraged Curve Lake First Nation to participate in the public and Indigenous environmental assessment comment period. In late 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning. CNL did not receive any feedback from Curve Lake First Nation on this report.

Throughout 2018 and 2019, CNL evolved project engagements to meet Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. Curve Lake First Nation received invitations to all engagement activities and have been in attendance at select events to date. In late 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with Curve Lake First Nation and encouraged community input for the final revision.

In January 2020, CNL followed up with Curve Lake First Nation on the December 2019 notification of the 2019 revised Draft EIS and the opportunity to meet. In March 2020, CNL followed up with Curve Lake First Nation on the December 2019 notification of the 2019 revised Draft EIS and this email follow-up included the Curve Lake First Nation consultation representative as indicated by the CNSC.

In April 2020, CNL sent an invitation to WTFN communities to an interactive webinar to provide an overview of the NSDF Project as well as an opportunity for questions. Curve Lake First Nation participated in the April 29, 2020 webinar. Actions from the webinar resulted in the distribution of the NSDF – Responsible Water Management video and NSDF Stage 4 Archaeological Assessment online links to all WTFN consultation representatives, as well as a request for a future webinar on the NSDF baseliner system and responsible water management. Also due to changes in consultation representatives, the 2016 email correspondence related to the previously sent NSDF Project archeological assessment report to Curve Lake was also included. CNL also followed up in 2020 June on Curve Lake's review of the NSDF Stage 4 Archaeological Assessment, no response has been received to date and CNL will continue to follow-up. Curve Lake First Nation participated in the June 30, 2020 webinar on the NSDF baseliner system and responsible water management as well as the August 26, 2020 webinar on the NSDF cover system and Waste Water Treatment Plan (WWTP).

In May 2020, CNL sent a follow-up letter to Curve Lake First Nation regarding the 2019 revised Draft EIS, IER input, as well as inquiries for Curve Lake First Nation-specific information. A follow-up email was sent in May 2020 and to date CNL has not received a response.

In October 2020, CNL sent a letter highlighting the remaining opportunities to provide further input or feedback on the NSDF Project within the formal context of the EA. Curve Lake can provide formal input through the comment

period after the EA report is prepared as well as participation in the CNSC hearing. Additionally, the letter once again encouraged community input for the IER. Curve Lake First Nation responded to this letter indicating their interest in capacity to support meaningful consultation, engagement, and participation in the NSDF Project. CNL met with Curve Lake First Nation in November and December 2020 to discuss establishing a contribution agreement to support their participation in the EA process for the NSDF Project. CNL continued to provide bi-monthly webinar updates throughout 2020, including an email invitation to participate in the NSDF Virtual Open House (VOH) from October 12 – 25, 2020. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions

In early December 2020, CNL sent a notification of the submission of the 2020 Final EIS to the CNSC and links to access the EIS online.

CNL and Curve Lake First Nation met for a third meeting (January 2021) and fourth meeting (March 2021) to continue discussions on establishing a contribution agreement which will include CNL's environmental remediation projects, such as the NSDF Project and NPD Closure Project, as well as Port Hope Area Initiative (PHAI) activities. CNL is currently drafting a contribution agreement to share with Curve Lake First Nation for review. Meetings will follow to finalize the agreement.

In early 2021, Curve Lake First Nation requested a monthly meeting to receive updates on CNL activities and agreed to include Williams Treaties First Nations (collectively) in the monthly update. An email and meeting notice was sent in February 2021 inviting all WTFN to participate. These meetings will provide WTFN communities with monthly updates as well as an opportunity to ask questions and share feedback on CNL activities. The monthly meetings will take place the last Wednesday of each month with the first meeting on March 31, 2021.

In February 2021, CNL sent a letter to Curve Lake First Nation providing an update on the status of the NSDF environmental assessment, as well as to provide a summary of commitments that CNL had previously made to Curve Lake First Nation during NSDF Project engagements. CNL indicated that the commitments list is an evergreen list and has asked for a response by March 1, 2021 if there were any concerns regarding the commitments list. Curve Lake First Nation did not provide a response.

In March 2021, CNL shared a link (via email) with the Curve Lake First Nation to the draft Environmental Assessment Follow-Up Monitoring Program (EAFMP) for the proposed NSDF Project for review. CNL included a request for input and ideas for NSDF follow-up monitoring as well as an invitation to meet and discuss the draft NSDF EAFMP. CNL also advised of potential focus group workshops, for Curve Lake First Nation participation, on various aspects of the EAFMP in the late spring/early summer 2021 timeframe.

The first monthly update on CNL's environmental remediation projects was held on March 31, 2021 and included an overview on CNL and AECL as well as a discussion on WTFN preferences for the monthly meeting format and future meeting topics and/or topics important to WTFN communities. The second monthly update on CNL's environmental remediation projects was held on April 28, 2021 and included an update on the NSDF Project and NPD Closure Project, as well as Port Hope Area Initiative (PHAI) activities in Port Hope and Port Granby. Curve Lake First Nation attended both monthly updates.

6.2.4.8.6.1 Feedback

Appendix U.2 of the IER provides a Table of Interests for Curve Lake First Nation interests and concerns and CNL responses and also identifies and links the interests and concerns with formally submitted comments made through the environmental assessment process. Although Curve Lake First Nation did not provide formal

comments on the 2017 or 2019 Draft EIS, the First Nation did provide comments on the 2016 NSDF Project Description as well as express concerns verbally at meetings.

The topics in the Table of Interests are briefly summarized below:

- **Engagement.** Based on a comment on the 2016 NSDF Project Description, Curve Lake First Nation identified that the NSDF Project occurred within their traditional territory and that the WTFN Process Co-ordinator should be contacted to provide insight.
- **Archaeological Assessment.** Based on a comment on the 2016 NSDF Project Description, Curve Lake First Nation requested to review the archaeological assessment.
- **Protection of the Environment (specifically the Ottawa River).** In 2020, a Curve Lake First Nation representative verbally inquired as to how the Ottawa River could be environmentally protected being so close to CRL and NSDF.
- **Capacity for Participation in NSDF EA process.** In October 2020, Curve Lake First Nation sent a response to CNL's October 2020 letter indicating their interest in capacity to support meaningful consultation, engagement, and participation in the NSDF Project.

6.2.4.8.6.2 Summary of Interests and Concerns

As previously indicated this Summary Discussion of Interests and Concerns is taken from the Tables of Interest that appear in Appendix U.2 of the IER. The discussion of the interests and concerns below is CNL's understanding based on written submissions and oral discussions with the Curve Lake First Nation. CNL has made its best efforts to document the position the Curve Lake First Nation has taken on each interest/concern while acknowledging that the Curve Lake First Nation may articulate the perspective somewhat differently.

Engagement

Based on a comment on the 2016 NSDF Project Description, Curve Lake First Nation identified that the NSDF Project occurred within their traditional territory and that the WTFN Process Co-ordinator should be contacted to provide insight. CNL made multiple inquiries to the WTFN Process Coordinator in 2016, 2017, 2019 and 2020, but no response was received. CNL considers this resolved since in March 2020, CNL was informed that all engagement activities should be done through each community consultation coordinator/liaison. CNL will also continue to provide notifications of NSDF Project activities to WTFN communities until otherwise instructed.

Along with efforts to consult with WTFNs from 2016 to 2019, CNL renewed engagement with the communities of WTFNs, including the Curve Lake First Nation, in 2020.

Archaeological Assessment

Based on a formal review and comment of the 2016 Project Description. Curve Lake First Nation requested the archaeological assessment. CNL provided the archaeological assessment report. No additional comments were submitted. In May 2020, Curve Lake again requested the archaeological assessment. CNL once again provided the archaeological assessment report. No further comments were received and CNL considers this concern has been addressed.

Protection of the Ottawa River

In 2020, a Curve Lake First Nation representative verbally inquired as to how the Ottawa River could be environmentally protected being so close to CRL and NSDF. CNL provided an overview of the NSDF Project and measures to protect the environment as part of a presentation to the WTFN communities of which Curve Lake First Nation participated. More specifically this interactive webinar discussion and presentation shared information on the following key areas: an overview of the NSDF Project components and timeline, the EA process, the site location, archaeology, interests heard about the NSDF Project from one the WTFN communities, ensuring protection of the Ottawa River, spatial boundaries to the assessment area, monitoring and the effects assessment. The webinar also asked WTFNs to provide any information they have concerning their interests near NSDF on traditional uses, cultural sites, concerns about the NSDF Project. These questions were re-iterated in letters sent to communities of the WTFN in May 2020. A WTFN/CNL action list was created.

Based on questions raised by Curve Lake First Nation in April 2020, CNL hosted follow-up presentations on the NSDF baseliner system and responsible water management for a more focussed discussion on protection of the Ottawa River. These webinars focussed on the NSDF engineered containment mound baseliner and cover system, the wastewater treatment plant, and the surface water assessment for the NSDF. Curve Lake First Nation verbally indicated that the presentations were well done, comprehensive and understandable. CNL provided responses in writing to all the questions raised verbally by Curve Lake First Nation during these webinars. No response or follow up questions to these responses were received.

CNL considers this concern is addressed as CNL has demonstrated how the NSDF will ensure protection of the Ottawa River during various engagements with Curve Lake First Nation. However, CNL acknowledges the protection of the environment is likely to be an ongoing concern from Curve Lake First Nation thus CNL has made the draft EAFMP available to Curve Lake First Nation for technical review and input (March 2021).

Capacity for Participation in NSDF EA process

The Curve Lake First Nation expressed an interest in capacity to support meaningful consultation, engagement, and participation in the NSDF Project. CNL met with Curve Lake First Nation in November and December 2020 and January 2021 to discuss capacity and establishing a contribution agreement to support Curve Lake First Nation's participation in CNL's Environmental Remediation Projects, including the NSDF Project. CNL considers this concern addressed since CNL is committed to continuing discussions with Curve Lake FN on the next steps towards a contribution agreement that supports meaningful participation of Curve Lake FN on the NSDF Project environmental assessment.

6.2.4.8.6.3 Verification

CNL is of the opinion that it is at Process Step 5 of the CNL Verification Process with Curve Lake First Nation given the Curve Lake First Nation comments on the 2016 Project Description have been incorporated and no further comments on those topics were submitted on 2017 and 2019 Draft EIS. CNL has provided opportunities for engagement opportunities to Curve Lake First Nation and kept them informed about the NSDF Project status.

CNL has sought to validate assumptions CNL made in the EIS including those with respect to traditional activities that may be occurring within proximity to the NSDF Project, however the Curve Lake First Nation has not provided a direct response to the questions.

CNL has provided the Curve Lake First Nation with the summary of commitments that CNL has made to the Curve Lake First Nation during NSDF Project engagements and requested a response if there were any concerns regarding the commitment list. Curve Lake First Nation has not provided a response.

6.2.4.8.6.4 Next Steps

CNL will continue to follow-up with Curve Lake First Nation on engagement opportunities and about any outstanding interests and concerns unless otherwise instructed. CNL is committed to continuing discussions with Curve Lake First Nation on the next steps towards a contribution agreement that supports meaningful participation of Curve Lake First Nation on the NSDF Project environmental assessment.

6.2.4.8.7 Hiawatha First Nation Engagement

Table 6.2.4-14 below summarizes Hiawatha First Nation engagement and Appendix V.1 of the IER provides a detailed record of engagement activities that have occurred with Hiawatha First Nation on the NSDF Project.

Table 6.2.4-14: Hiawatha First Nation Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Hiawatha First Nation	6	36	16	Yes	4	—	—	—	—	—

* The complete table is located in Section 6.2.4.1.

In July 2016, CNL sent Hiawatha First Nation a letter to introduce the proposed NSDF Project which included a request for community input on any potential adverse impacts from project activities followed by a secondary letter in November 2016 which inquired about Hiawatha First Nation asserted rights and traditional activities. CNL did not receive a response from Hiawatha First Nation.

In early 2017 CNL shared the 2017 Draft EIS and encouraged Hiawatha First Nation to participate in the public and Indigenous environmental assessment comment period. Hiawatha First Nation provided comments on the 2017 Draft EIS through the environmental assessment process. In late 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning. CNL did not receive any feedback from Hiawatha First Nation on this report.

Throughout 2018 and 2019, CNL evolved project engagements to meet Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. Hiawatha First Nation received invitations to all engagement activities and have been in attendance at select events to date. In late 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with Hiawatha First Nation and encouraged community input for the final revision as well as the opportunity to meet one-on-one to discuss their comments submitted on the 2017 Draft EIS.

In January 2020, CNL followed up with Hiawatha First Nation on the December 2019 notification of the 2019 revised Draft EIS and the opportunity to meet. In March 2020, CNL followed up with Hiawatha First Nation on the December 2019 notification of the 2019 revised Draft EIS and this email follow-up included the Hiawatha First Nation consultation representative as indicated by the CNSC. This email was acknowledged and a recommendation was made by Hiawatha consultation representative to hold WTFN webinar to update the communities collectively. In April 2020, CNL sent an invitation to WTFN communities to an interactive webinar to provide an overview of the NSDF Project as well as an opportunity for questions. Hiawatha First Nation participated in the April 29, 2020 webinar. Actions from the webinar resulted in the distribution of the NSDF – Responsible Water Management video and NSDF Stage 4 Archaeological Assessment online links to all WTFN consultation representatives, as well as a request for a future webinar on the NSDF baseliner system and responsible water management. The webinar on the NSDF baseliner system and responsible water management was held on June 30, 2020 and Hiawatha First Nation was in attendance. The webinar on the NSDF cover system and Waste Water Treatment Plan (WWTP) was held on August 26, 2020 and Hiawatha First Nation declined participation.

In May 2020, CNL sent a letter to Hiawatha First Nation which included draft dispositions to their comments on the 2017 Draft EIS (with another invitation to meet), links to the 2019 revised Draft EIS and IER as well as a request to learn more about Hiawatha First Nation and any asserted rights, interests or activities members might undertake in the local or regional study areas in proximity to the NSDF Project. A follow-up email was sent in May 2020 and while CNL has not received a written response, a verbal acknowledgment of CNL's response to Hiawatha First Nation's comments on the 2017 Draft EIS were addressed during the April 29, 2020 webinar. CNL will continue to engage with Hiawatha First Nation to ensure their comments have been addressed.

In October 2020, CNL sent a letter highlighting the remaining opportunities to provide further input or feedback on the NSDF Project within the formal context of the EA. Hiawatha First Nation can provide formal input through the comment period after the EA report is prepared as well as participation in the CNSC hearing. Additionally, the letter once again encouraged community input for the IER. CNL did not receive a response from Hiawatha First

Nation. CNL continued to provide bi-monthly webinar updates throughout 2020, including an email invitation to participate in the NSDF Virtual Open House (VOH) from October 12 – 25, 2020. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions.

In early December 2020, CNL sent a notification of the submission of the 2020 Final EIS to the CNSC and links to access the EIS online.

In early 2021, Curve Lake First Nation indicated interest in a CNL monthly update meeting. CNL extended the meeting invitation to all WTFN and encouraged participation. These meetings will provide WTFN communities with monthly updates as well as an opportunity to ask questions and share feedback on CNL activities. The monthly meetings will take place the last Wednesday of each month with the first meeting on March 31, 2021.

In February 2021, CNL sent a letter to Hiawatha First Nation providing an update on the status of the NSDF environmental assessment, as well as to provide a summary of commitments that CNL had previously made to Hiawatha First Nation during NSDF Project engagements. CNL indicated that the commitments list is an evergreen list and has asked for a response by March 1, 2021 if there were any concerns regarding the commitments list. Hiawatha First Nation did not provide a response.

In March 2021, CNL shared a link (via email) with Hiawatha First Nation to the draft Environmental Assessment Follow-Up Monitoring Program (EAFMP) for the proposed NSDF Project for review. CNL included a request for input and ideas for NSDF follow-up monitoring as well as an invitation to meet and discuss the draft NSDF EAFMP. CNL also advised of potential focus group workshops, for Hiawatha First Nation participation, on various aspects of the EAFMP in the late spring/early summer 2021 timeframe. As of May 2021, the Hiawatha First Nation has not provided an acknowledgement.

The first monthly update on CNL's environmental remediation projects was held on March 31, 2021 and included an overview on CNL and AECL as well as a discussion on WTFN preferences for the monthly meeting format and future meeting topics and/or topics important to WTFN communities. The second monthly update on CNL's environmental remediation projects was held on April 28, 2021 and included an update on the NSDF Project and NPD Closure Project, as well as Port Hope Area Initiative (PHAI) activities in Port Hope and Port Granby. Hiawatha First Nation attended both of these monthly updates.

6.2.4.8.7.1 Feedback

Appendix V.2 of the IER provides a Table of Interests for Hiawatha First Nation interests and concerns and CNL responses and also identifies and links the interests and concerns with formally submitted comments made through the environmental assessment process.

The topics in the Table of Interests are briefly summarized below:

- **Environmental Protection.** Based on a formal review and comment of the 2017 Draft EIS, the Hiawatha First Nation was concerned and looking for reassurance that wildlife, habitat, and water tributaries will be adequately protected from contamination for seven generations.

6.2.4.8.7.2 Summary of Interests and Concerns

As previously indicated this Summary Discussion of Interests and Concerns is taken from the Tables of Interest that appear in Appendix V.2 of the IER. The discussion of the interests and concerns below is CNL's understanding based on written submissions and oral discussions with the Hiawatha First Nation. CNL has made

its best efforts to document the position the Hiawatha First Nation has taken on each interest/concern while acknowledging that the Hiawatha First Nation may articulate the perspective somewhat differently.

Environmental Protection

Based on a formal review and comment of the 2017 Draft EIS, the Hiawatha First Nation was concerned and looking for reassurance that wildlife, habitat, and water tributaries will be adequately protected from contamination for seven generations. CNL provided an overview of the NSDF Project and measures to protect the environment as part of a presentation to the WTFN communities. More specifically this interactive webinar discussion and presentation shared information on the following key areas: an overview of the NSDF Project components and timeline, the EA process, the site location, archaeology, ensuring protection of the Ottawa River, spatial boundaries to the assessment area, monitoring and the effects assessment. Hiawatha First Nation participated in this webinar and indicated general satisfaction with what was presented but needs to look closer at the NSDF Project and submitted information. CNL hosted a follow-up presentation on protection of water resources, specifically the NSDF baseliner system and responsible water management to provide further information on protection of the environment. Hiawatha First Nation participated in this webinar and requested (and was provided by CNL) a technical supporting document and further information on the waste water treatment plant.

CNL considers this concern is addressed as CNL has demonstrated how the NSDF will ensure protection of the Ottawa River during various engagements with Hiawatha First Nation. However, CNL acknowledges the protection of the environment is likely to be an ongoing concern from Hiawatha First Nation thus CNL has made the draft EAFMP available to Hiawatha First Nation for technical review and input (March 2021).

6.2.4.8.7.3 Verification

In December 2019, CNL sent the Hiawatha First Nation notification of the online posting of the 2019 revised Draft EIS and the updated Indigenous Engagement Report (IER) for review and offered to meet one-on-one to provide updates and discuss how their comments were incorporated. Additionally in May 2020, CNL sent a letter to Hiawatha First Nation which included draft dispositions to their comment on the 2017 Draft EIS. The Hiawatha First Nation did not provide a written response to either of these engagement attempts. However through the series of webinars with the WTFN in 2020, the topic of Hiawatha First Nation was addressed and additional information was provided as a follow-up to the webinars. The Hiawatha First Nation representative at the webinar indicated verbally general satisfaction with what was presented thus CNL is of the opinion that it is at Process Step 5 of the CNL Verification Process with Hiawatha First Nation.

CNL has sought to validate assumptions CNL made in the EIS including those with respect to traditional activities that may be occurring within proximity to the NSDF Project. CNL received verbal feedback from Hiawatha First Nation that members of this community practice harvesting in the Ottawa Valley, but did not provide any details on the proximity to the CRL site.

CNL has provided the Hiawatha First Nation with the summary of commitments that CNL has made to the Hiawatha First Nation during NSDF Project engagements and requested a response if there were any concerns regarding the commitment list. Hiawatha First Nation has not provided a response.

6.2.4.8.7.4 Next Steps

CNL will continue to follow-up with Hiawatha First Nation on engagement opportunities and about any outstanding interests and concerns unless otherwise instructed.

6.2.4.8.8 Mississaugas of Scugog Island First Nation Engagement

Table 6.2.4-15 below summarizes Scugog Island engagement and Appendix W.1 of the IER provides a detailed record of engagement activities that have occurred with Mississaugas of Scugog Island First Nation on the NSDF Project.

Table 6.2.4-15: Mississaugas of Scugog Island First Nation Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Mississaugas of Scugog Island First Nation	6	34	16	—	2	—	—	—	—	—

* The complete table is located in Section 6.2.4.1.

In July 2016, CNL sent Mississaugas of Scugog Island First Nation a letter to introduce the proposed NSDF Project, which included a request for community input on any potential adverse impacts from project activities followed by a secondary letter in November 2016, which inquired about Mississaugas of Scugog Island First Nation asserted rights and traditional activities. CNL did not receive a response from Mississaugas of Scugog Island First Nation.

In early 2017, CNL shared the 2017 Draft EIS and encouraged Mississaugas of Scugog Island First Nation to participate in the public and Indigenous environmental assessment comment period. Mississaugas of Scugog Island First Nation did not provide comments on the 2017 Draft EIS through the environmental assessment process. In late 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning. CNL did not receive any feedback from Mississaugas of Scugog Island First Nation on this report.

Throughout 2018 and 2019, CNL evolved project engagements to meet Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. The Mississaugas of Scugog Island First Nation received invitations to all engagement activities and have been in attendance at select events to date. In late 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with Mississaugas of Scugog Island First Nation and encouraged community input for the final revision.

In March 2020, CNL followed up with Mississaugas of Scugog Island First Nation on the December 2019 notification of the 2019 revised Draft EIS. This email follow-up included the Mississaugas of Scugog Island First Nation consultation representative as indicated by the CNSC. In April 2020, CNL sent an invitation to WTFN communities to an interactive webinar to provide an overview of the NSDF Project as well as an opportunity for questions. Mississaugas of Scugog Island did not participate in the April 29, 2020 webinar – CNL sent a copy of the presentation and an invitation to meet one-on-one. Actions from the webinar resulted in the distribution of the NSDF – Responsible Water Management video and NSDF Stage 4 Archaeological Assessment online links to all WTFN consultation representatives, as well as a request for a future webinar on the NSDF baseliner system and responsible water management. The webinar on the NSDF baseliner system and responsible water management was held on June 30, 2020 and Mississaugas of Scugog Island First Nation did not participate. The webinar on the NSDF cover system and Waste Water Treatment Plan (WWTP) was held on August 26, 2020 and Mississaugas of Scugog Island First Nation was in attendance.

In May 2020, CNL sent a follow-up letter to the Mississaugas of Scugog Island First Nation regarding the 2019 revised Draft EIS, IER input as well as a request to learn more about Mississaugas of Scugog Island First Nation and any asserted rights, interests or activities members might undertake in the local or regional study areas in proximity to the NSDF Project. A follow-up email was sent on May 26, 2020 and to date CNL has not received a response.

Scugog Island First Nation reached out to CNL in August 2020 to introduce the new Community Consultation Specialist. CNL provided background information on engagement with WTFN (collectively) on the NSDF Project followed by a virtual meeting to further discuss the NSDF Project and answer any questions the new Community Consultation Specialist had with regards to CNL and project activities.

In October 2020, CNL sent a letter highlighting the remaining opportunities to provide further input or feedback on the NSDF Project within the formal context of the EA. Mississaugas of Scugog Island First Nation can provide formal input through the comment period after the EA report is prepared as well as participation in the CNSC hearing. Additionally, the letter once again encouraged community input for the IER. CNL did not receive a response from Mississaugas of Scugog Island First Nation. CNL continued to provide bi-monthly webinar updates throughout 2020, including an email invitation to participate in the NSDF Virtual Open House (VOH) from October 12 – 25, 2020. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions.

In early December 2020, CNL sent a notification of the submission of the 2020 Final EIS to the CNSC and links to access the EIS online.

In early 2021, Curve Lake First Nation indicated interest in a CNL monthly update meeting. CNL extended the meeting invitation to all WTFN and encouraged participation. These meetings will provide WTFN communities with monthly updates as well as an opportunity to ask questions and share feedback on CNL activities. The monthly meetings will take place the last Wednesday of each month with the first meeting on March 31, 2021.

In February 2021, CNL sent a letter to Mississaugas of Scugog Island First Nation providing an update on the status of the NSDF environmental assessment, as well as to provide a summary of commitments that CNL had previously made to Mississaugas of Scugog Island First Nation during NSDF Project engagements. CNL indicated that the commitments list is an evergreen list and has asked for a response by March 1, 2021 if there were any concerns regarding the commitments list. Mississaugas of Scugog Island First Nation did not provide a response.

In March 2021, CNL shared a link (via email) with the Mississaugas of Scugog Island First Nation to the draft Environmental Assessment Follow-Up Monitoring Program (EAFMP) for the proposed NSDF Project for review. CNL included a request for input and ideas for NSDF follow-up monitoring as well as an invitation to meet and discuss the draft NSDF EAFMP. CNL also advised of potential focus group workshops, for Mississaugas of Scugog Island First Nation participation, on various aspects of the EAFMP in the late spring/early summer 2021 timeframe. As of May 2021, the Mississaugas of Scugog Island First Nation has not provided an acknowledgement.

The first monthly update on CNL's environmental remediation projects was held on March 31, 2021 and included an overview on CNL and AECL as well as a discussion on WTFN preferences for the monthly meeting format and future meeting topics and/or topics important to WTFN communities. Mississaugas of Scugog Island First Nation did not participate. The second monthly update on CNL's environmental remediation projects was held on April 28, 2021 and included an update on the NSDF Project and NPD Closure Project, as well as Port Hope Area Initiative (PHAI) activities in Port Hope and Port Granby. Mississaugas of Scugog Island First Nation did not participate.

6.2.4.8.8.1 *Feedback*

Mississaugas of Scugog Island First Nation has not submitted any written comments on the NSDF Project Description or 2017 and 2019 Draft EIS.

6.2.4.8.8.2 *Summary of Interests and Concerns*

Mississaugas of Scugog Island First Nation has not submitted any written comments nor provided any verbal comments on the NSDF Project. As such, CNL is not aware of any interests and concerns.

6.2.4.8.8.3 *Verification*

Mississaugas of Scugog Island First Nation has not submitted any written comments nor provided any verbal feedback on the NSDF Project. As such, no feedback was received for which CNL can seek to verify with the Mississaugas of Scugog Island First Nation to determine if Mississaugas of Scugog Island First Nation interests or concerns have been addressed.

CNL has provided opportunities for engagement opportunities to Mississaugas of Scugog Island First Nation and kept them informed about the NSDF Project status.

CNL has sought to validate assumptions CNL made in the EIS including those with respect to traditional activities that may be occurring within proximity to the NSDF Project, however the Mississaugas of Scugog Island First Nation has not provided a response.

CNL has provided the Mississaugas of Scugog Island First Nation with the summary of commitments that CNL has made to the Mississaugas of Scugog Island First Nation during NSDF Project engagements and requested a response if there were any concerns regarding the commitment list. Mississaugas of Scugog Island First Nation has not provided a response.

6.2.4.8.8.4 *Next Steps*

CNL will continue to follow-up with Mississaugas of Scugog Island First Nation on engagement opportunities and any emerging interests and concerns unless otherwise instructed.

6.2.4.9 Anishinabek Nation Engagement

Table 6.2.4-16 below summarizes Anishinabek Nation engagement and Appendix X.1 of the IER provides a detailed record of engagement activities that have occurred with Anishinabek Nation (formerly known as Union of Ontario Indians) on the NSDF Project.

Table 6.2.4-16: Anishinabek Nation Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Anishinabek Nation (Formerly known as Union of Ontario Indians)	6	8	16	Yes	—	—	—	—	—	—

* The complete table is located in Section 6.2.4.1.

In July 2016, CNL sent Anishinabek First Nation a letter to introduce the proposed NSDF Project, which included a request for community input on any potential adverse impacts from project activities followed by a secondary letter in November 2016, which inquired about Anishinabek First Nation asserted rights and traditional activities. CNL did not receive a response from the Anishinabek First Nation.

In March 2017, CNL shared the 2017 Draft EIS and encouraged Anishinabek First Nation to participate in the public and Indigenous environmental assessment comment period. Anishinabek First Nation provided comments on the 2017 Draft EIS through the formal environmental assessment process. In November 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning. CNL did not receive any feedback from Anishinabek First Nation on this report.

Throughout 2018 and 2019, CNL evolved project engagements to meet Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. Anishinabek First Nation received invitations to all engagement activities and have not attended any events to date.

In December 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with Anishinabek First Nation and encouraged community input for the final revision as well as the opportunity to meet one-on-one to discuss their comments submitted on the 2017 Draft EIS. In January 2020, CNL followed up with Anishinabek Nation on the December 2019 notification of the 2019 revised Draft EIS and the opportunity to meet but did not receive a response.

In May 2020, CNL sent a letter to Anishinabek Nation, which included draft dispositions to their comments on the 2017 Draft EIS (with another invitation to meet), links to the 2019 revised Draft EIS as well as inquiries for Anishinabek Nation specific information. A follow-up email was sent on May 26, 2020 and to date CNL has not received a response from Anishinabek Nation.

In August 2020, CNL received new contacts for the Anishinabek Nation from the CNSC and the May 2020 letter with CNL dispositions was resent as an invitation to meet the new contacts.

In October 2020, CNL sent a letter to the Anishinabek Nation highlighting the remaining opportunities to provide further input or feedback on the NSDF Project as well as an invitation to meet one-on-one with the Anishinabek Nation to provide NSDF Project updates. Anishinabek Nation did not provide a response. CNL continued to provide bi-monthly webinar updates throughout 2020, including an email invitation to participate in the NSDF Virtual Open House (VOH) from October 12 – 25, 2020. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions.

In December 2020, CNL sent the Anishinabek Nation notification of the submission of the 2020 Final EIS to the CNSC and the availability of the document online. Anishinabek Nation did not provide a response.

In February 2021, CNL sent a letter to the Anishinabek Nation providing an update on the status of the NSDF environmental assessment, as well as to provide a summary of commitments that CNL had previously made to the Anishinabek Nation during NSDF Project engagements. CNL has asked for a response by March 1, 2021 if there were any concerns regarding the commitments list. Anishinabek Nation did not provide a response.

In March 2021, CNL shared a link (via email) with the Anishinabek Nation to the draft Environmental Assessment Follow-Up Monitoring Program (EAFMP) for the proposed NSDF Project for review. CNL included a request for input and ideas for NSDF follow-up monitoring as well as an invitation to meet and discuss the draft NSDF EAFMP. CNL also advised of potential focus group workshops, for Anishinabek Nation participation, on various aspects of the EAFMP in the late spring/early summer 2021 timeframe. As of May 2021, the Anishinabek Nation has not provided an acknowledgement.

6.2.4.9.1 Feedback

Appendix X.2 of the IER provides a Table of Interests for Anishinabek Nation interests and concerns and CNL responses. The table also identifies and links the interests and concerns with formally submitted comments made through the environmental assessment process.

The topics in the Table of Interests are briefly summarized below:

- **Alternative Means Assessment.** In their review of the 2017 Draft EIS the Anishinabek Nation raised a concern with the location of the facility in proximity to the Ottawa River.
- **Site location.** In their review of the 2017 Draft EIS the Anishinabek Nation expressed their opposition to transport and storage of radioactive waste on First Nations ancestral lands.
- **Assessment of Effects of the Environment on the Project.** In their review of the 2017 Draft EIS, the Anishinabek Nation expressed general concerns about seismic activity, extreme weather events and climate change that occur in the region are not favourable for a nuclear waste storage facility.

6.2.4.9.2 Summary Discussion of Interests and Concerns

As previously indicated this Summary Discussion of Interests and Concerns is taken from the Tables of Interest that appear in Appendix X.2 of the IER. The discussion of the interests and concerns below is CNL's understanding based on written submissions from the Anishinabek Nation. CNL has made its best efforts to document the position the Anishinabek Nation has taken on each interest/concern while acknowledging that the Anishinabek Nation may articulate the perspective somewhat differently.

Alternative Means

In their review of the 2017 Draft EIS the Anishinabek Nation raised a concern with the location of the facility in proximity to the Ottawa River. CNL has provided a response to indicate that the possibility of moving the NSDF Project location further away from the Ottawa River, was considered in the site selection process and is discussed in Section 2.5.5 of the Final EIS. Section 2.5.5 has been expanded to include all fifteen sites considered as part of the site selection process. The NSDF Project also clarified in the written response that the NSDF site is located on a bedrock ridge that naturally forces water away from the Ottawa River. The proposed site is 1.1 km from the main channel of the Ottawa River, but groundwater passing below it, discharges to Perch Creek before draining to the Ottawa River, providing a flow path distance of about 2.6 km. CNL considers this concern to be addressed by the revisions to the EIS. However, CNL remains committed to ongoing engagement with the Anishinabek Nation.

Site Location

In their review of the 2017 Draft EIS the Anishinabek Nation expressed their opposition to transport and storage of radioactive waste on First Nations ancestral lands. CNL acknowledges that First Nations ancestral lands are an on-going area of discussion between the Government of Canada and the First Nations that is not specific to the

NSDF Project. However, 90% of the low level waste proposed to be placed in the NSDF is currently at the CRL site and will not be transported outside of the site boundary. CNL considers the concerns with respect to transportation not specific to the NSDF Project and the storage of radioactive waste at the CRL site is a CRL site level concern.

Assessment of Environmental Events on the Project

In their review of the 2017 Draft EIS, the Anishinabek Nation expressed general concerns about seismic activity, extreme weather events and climate change that occur in the region are not favourable for a nuclear waste storage facility. CNL has provided a detailed response with respect to these topics. CNL has identified that this concern is addressed in Section 10 of the EIS and more specifically provided a detailed response on seismicity, extreme weather and climate change. CNL considers this concern addressed by the revisions to the EIS. However, CNL remains committed to ongoing engagement with the Anishinabek Nation.

6.2.4.9.3 Verification

In December 2019, CNL sent the Anishinabek Nation notification of the online posting of the 2019 revised Draft EIS and the updated Indigenous Engagement Report (IER) for review and offered to meet one-on-one to provide updates and discuss how their comments were incorporated. The Anishinabek Nation did not provide a response.

In May 2020, CNL sent a letter to the Anishinabek Nation which included draft dispositions to their comments on the 2017 Draft EIS. The Anishinabek Nation did not provide a response.

CNL has attempted to engage with the Anishinabek Nation to discuss CNL's responses on multiple occasions through a variety of means (i.e., emails, letters, telephone, webinars, and meetings) however the Anishinabek Nation is unresponsive. Thus CNL cannot complete verification that the Anishinabek Nation's concerns have been addressed and CNL is of the opinion that it is at Process Step 2(b) of the CNL Verification Process with the Anishinabek Nation as CNL awaits either acknowledgement or a response.

CNL has sought to validate assumptions CNL made in the EIS including those with respect to traditional activities that may be occurring within proximity to the NSDF Project, however the Anishinabek Nation has not provided a response.

CNL has provided the Anishinabek Nation with the summary of commitments that CNL has made to the Anishinabek Nation during NSDF Project engagements and requested a response if there were any concerns regarding the commitment list. Anishinabek Nation has not provided a response.

6.2.4.9.4 Next Steps

To date CNL has been unable to arrange a meeting with the Anishinabek Nation to discuss their comments on the 2017 Draft EIS but will continue engagement efforts. CNL will continue to follow-up with the Anishinabek Nation on engagement opportunities and any outstanding interests and concerns unless otherwise instructed.

6.2.4.10 Algonquin Nation Secretariat Engagement

Table 6.2.4-17 below summarizes Algonquin Nation Secretariat engagement and Appendix Y.1 of the IER provides a detailed record of engagement activities that have occurred with Algonquin Nation Secretariat on the NSDF Project.

Table 6.2.4-17: Algonquin Nation Secretariat Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Algonquin Nation Secretariat	6	8	16	—	—	—	—	—	—	—

* The complete table is located in Section 6.2.4.1.

In July 2016, CNL sent the Algonquin Nation Secretariat a letter to introduce the proposed NSDF Project, which included a request for community input on any potential adverse impacts from project activities followed by a secondary letter in November 2016, which inquired about Algonquin Nation Secretariat asserted rights and traditional activities. CNL did not receive a response from the Algonquin Nation Secretariat.

In early 2017, CNL shared the 2017 Draft EIS and encouraged the Algonquin Nation Secretariat to participate in the public and Indigenous environmental assessment comment period. The Algonquin Nation Secretariat did not provide comments on the 2017 Draft EIS through the environmental assessment process. In late 2017, CNL shared the NSDF Aboriginal Engagement Report and requested community input and feedback for incorporation into the EIS and project planning. CNL did not receive any feedback from the Algonquin Nation Secretariat on this report.

Throughout 2018 and 2019, CNL evolved project engagements to meet Indigenous and stakeholder feedback. This included the development of a regular routine of Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. The Algonquin Nation Secretariat received invitations to all engagement activities and have not attended any events to date. In late 2019, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with the Algonquin Nation Secretariat and encouraged community input for the final revision.

In May 2020, CNL sent a letter to the Algonquin Nation Secretariat regarding the 2019 revised Draft EIS, IER input, as well as inquiries for Algonquin Nation Secretariat specific information. A follow-up email was sent on May 26, 2020 and the Algonquin Nation Secretariat notified CNL of a new contact name for the Algonquin Nation Secretariat Director. CNL resent the May 2020 letter to the new contact and to date CNL has not received a response from Algonquin Nation Secretariat.

In October 2020, CNL sent a letter to the Algonquin Nation Secretariat highlighting the remaining opportunities to provide further input or feedback on the NSDF Project as well as an invitation to meet one-on-one with the Algonquin Nation Secretariat to provide NSDF Project updates. Algonquin Nation Secretariat did not provide a response. CNL continued to provide bi-monthly webinar updates throughout 2020, including an email invitation to participate in the NSDF Virtual Open House (VOH) from October 12 to 25, 2020. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions.

In December 2020, CNL sent the Algonquin Nation Secretariat notification of the submission of the 2020 Final EIS to the CNSC and the availability of the document online. Algonquin Nation Secretariat did not provide a response.

In February 2021 CNL sent a letter to the Algonquin Nation Secretariat providing an update on the status of the NSDF environmental assessment, as well as to provide a summary of commitments that CNL had previously made to the Algonquin Nation Secretariat during NSDF Project engagements. CNL has asked for a response by March 1, 2021 if there were any concerns regarding the commitments list. Algonquin Nation Secretariat did not provide a response.

In March 2021, CNL shared a link (via email) with the Algonquin Nation Secretariat to the draft Environmental Assessment Follow-Up Monitoring Program (EAFMP) for the proposed NSDF Project for review. CNL included a request for input and ideas for NSDF follow-up monitoring as well as an invitation to meet and discuss the draft NSDF EAFMP. CNL also advised of potential focus group workshops, for Algonquin Nation Secretariat

participation, on various aspects of the EAFMP in the late spring/early summer 2021 timeframe. As of May 2021, the Algonquin Nation Secretariat has not provided an acknowledgement.

6.2.4.10.1 Feedback

Algonquin Nation Secretariat has not submitted any written comments nor provided any verbal comments on the NSDF Project.

6.2.4.10.2 Summary of Interests and Concerns

Algonquin Nation Secretariat has not submitted any written comments nor provided any verbal comments on the NSDF Project. As such, CNL is not aware of any interests and concerns.

6.2.4.10.3 Verification

Algonquin Nation Secretariat has not submitted any written comments nor provided any verbal feedback on the NSDF Project. As such, no feedback was received for which CNL can seek to verify with the Algonquin Nation Secretariat to determine if Algonquin Nation Secretariat interests or concerns have been addressed.

CNL has attempted to engage with the Algonquin Nation Secretariat to discuss the NSDF Project on multiple occasions through a variety of means (i.e., emails, letters, telephone, webinars, and meetings), however the Algonquin Nation Secretariat is unresponsive.

CNL has sought to validate assumptions CNL made in the EIS including those with respect to traditional activities that may be occurring within proximity to the NSDF Project, however the Algonquin Nation Secretariat has not provided a response.

CNL has provided the Algonquin Nation Secretariat with the summary of commitments that CNL has made to the Algonquin Nation Secretariat during NSDF Project engagements and requested a response if there were any concerns regarding the commitment list. Algonquin Nation Secretariat has not provided a response.

6.2.4.10.4 Next Steps

CNL will continue to follow-up with Algonquin Nation Secretariat on engagement opportunities and any emerging interests and concerns unless otherwise instructed.

6.2.4.11 Mohawks of Bay of Quinte (MBQ)

Table 6.2.4-18 below summarizes MBQ engagement and Appendix Z.1 of the IER provides a detailed record of engagement activities that have occurred with the Mohawks of Bay of Quinte on the NSDF Project.

Table 6.2.4-18: Mohawks of Bay of Quinte (MBQ) Summary of Engagement

NSDF Identified Indigenous Communities and Organizations	Letters from/to CNL via Mail or Registered Mail	Phone & Email Correspondence	General Email (i.e., invites to webinars, etc.)	Comments Submitted via EA Process (Project Description, EIS)	Meetings, Information Sessions & Tours	CNSC Participant Funding Issued	MOUs & Contribution Agreements (CNL funding)	TLKUS or Other Studies	Reviewed the 2019 revised Draft EIS	Long-Term Relationship Agreements (in discussions)
Not on Engagement/Consultation List										
Mohawks of Bay of Quinte (MBQ)	3	8	6	Yes	—	—	—	—	—	—

* The complete table is located in Section 6.2.4.1.

A proposed list of Indigenous communities with a potential interest in the NSDF Project was identified by CNL and the CNSC based on the identified potential or established Indigenous or treaty rights of Indigenous communities in the vicinity of the NSDF Project (inclusion of specific communities considers the nature of the established and/or claimed rights and potential impacts on those rights caused by the proposed project based on a preliminary assessment of existing and available information). While the Mohawks of Bay Quinte are not listed as one of CNL's identified communities to engage, the Mohawks of Bay of Quinte did provide comments on the 2017 Draft EIS through the formal environmental assessment process.

In January 2020, CNL shared the 2019 revised Draft EIS and the latest revision of the IER with the Mohawks of Bay of Quinte and encouraged community input for the final revision as well as the opportunity to meet one-on-one to discuss their comments submitted on the 2017 Draft EIS.

In early May 2020, CNL sent a follow-up letter to the Mohawks of Bay of Quinte regarding the 2019 revised Draft EIS, the IER as well as inquiries for Mohawks of Bay of Quinte specific information. The Mohawks of Bay of Quinte responded to the May 2020 letter and indicated an interest in meeting with CNL and the CNSC for an NSDF Project overview/update. In late May 2020, CNL followed up on the request to meet and were informed by Mohawks of Bay of Quinte that the next steps on the NSDF Project engagement were currently with the Tyendinaga Mohawk Council. Once a decision has been made, Mohawks of Bay of Quinte will reach back to CNL.

The Mohawks of Bay of Quinte have been added to the email distribution for Indigenous and stakeholder engagement events, such as the bi-monthly Breakfast Briefings and quarterly webinar updates. In early 2020, due to the COVID-19 pandemic, CNL combined the bi-monthly Breakfast Briefings and quarterly webinars into a bi-monthly webinar update on the NSDF Project. MBQ received invitations to all engagement activities and have been in attendance at select events to date.

In October 2020, CNL sent a letter to the Mohawks of Bay of Quinte highlighting the remaining opportunities to provide further input or feedback on the NSDF Project as well as an invitation to meet one-on-one with the Mohawks of Bay of Quinte to provide NSDF Project updates. MQB did not provide a response. CNL continued to provide bi-monthly webinar updates throughout 2020, including an email invitation to participate in the NSDF Virtual Open House (VOH) from October 12 to 25, 2020. The VOH provided information about the environmental assessment process, the proposed construction and the proposed operation of a NSDF and live chat sessions.

In December 2020, CNL sent the Mohawks of Bay of Quinte notification of the submission of the 2020 Final EIS to the CNSC and the availability of the document online. Mohawks of Bay of Quinte did not provide a response.

In February 2021 CNL sent a letter to the Mohawks of Bay of Quinte providing an update on the status of the NSDF environmental assessment, as well as to provide a summary of commitments that CNL had previously made to the Mohawks of Bay of Quinte during NSDF Project engagements. CNL has asked for a response by March 1, 2021 if there were any concerns regarding the commitments list. Mohawks of Bay of Quinte did not provide a response.

In March 2021, CNL shared a link (via email) with the Mohawks of Bay of Quinte to the draft Environmental Assessment Follow-Up Monitoring Program (EAFMP) for the proposed NSDF Project for review. CNL included a request for input and ideas for NSDF follow-up monitoring as well as an invitation to meet and discuss the draft NSDF EAFMP. CNL also advised of potential focus group workshops, for Mohawks of Bay of Quinte participation,

on various aspects of the EAFMP in the late spring/early summer 2021 timeframe. As of May 2021, the Mohawks of Bay of Quinte has not provided an acknowledgement.

6.2.4.11.1 Feedback

Appendix Z.2 of the IER provides a Table of Interests for Mohawks of Bay of Quinte interests and concerns and CNL responses. The table also identifies and links the interests and concerns with formally submitted comments made through the environmental assessment process.

The topics in the Table of Interests are briefly summarized below:

- **Alternative Means Assessment.** In their review of the 2017 Draft EIS, the Mohawks of Bay of Quinte raised a concern with the location of the facility in proximity to the Ottawa River.
- **Site location.** In their review of the 2017 Draft EIS, the Mohawks of Bay of Quinte expressed their opposition to transport and storage of radioactive waste on First Nations ancestral lands.
- **General Environmental Protection.** In 2020 the Mohawks of Bay of Quinte raised some general concerns about the NSDF Project and protection of the environment.

6.2.4.11.2 Summary Discussion of Interests and Concerns

As previously indicated this Summary Discussion of Interests and Concerns is taken from the Tables of Interest that appear in Appendix Z.2 of the IER. The discussion of the interests and concerns below is CNL's understanding based on written submissions from the Mohawks of Bay of Quinte. CNL has made its best efforts to document the position the Mohawks of Bay of Quinte has taken on each interest/concern while acknowledging that the Mohawks of Bay of Quinte may articulate the perspective somewhat differently.

Alternative Means

In their review of the 2017 Draft EIS the Mohawks of Bay of Quinte raised a concern with the location of the facility in proximity to the Ottawa River. CNL has provided a response to indicate that the possibility of moving the NSDF Project location further away from the Ottawa River, was considered in the site selection process and is discussed in Section 2.5.5 of the Final EIS. Section 2.5.5 has been expanded to include all fifteen sites considered as part of the site selection process. The NSDF Project also clarified in the written response that the NSDF site is located on a bedrock ridge that naturally forces water away from the Ottawa River. The proposed site is 1.1 km from the main channel of the Ottawa River, but groundwater passing below it, discharges to Perch Creek before draining to the Ottawa River, providing a flow path distance of about 2.6 km. CNL considers this concern to be addressed by the revisions to the EIS. However, CNL remains committed to ongoing engagement with the Mohawks of Bay of Quinte.

Site Location

In their review of the 2017 Draft EIS the Mohawks of Bay of Quinte expressed their opposition to transport and storage of radioactive waste on First Nations ancestral lands. CNL acknowledges that First Nations ancestral lands are an on-going area of discussion between the Government of Canada and the First Nations that is not specific to the NSDF Project. However, 90% of the low level waste proposed to be placed in the NSDF is currently at the CRL site and will not be transported outside of the site boundary. CNL considers the concerns with respect to transportation not specific to the NSDF Project and the storage of radioactive waste at the CRL site is a CRL site level concern.

Environmental Protection

In 2020 the Mohawks of Bay of Quinte raised some general concerns about the NSDF Project and protection of the environment. CNL has followed up with Mohawks of Bay of Quinte with an offer for a direct meeting and discussion of on this topic. In CNL's opinion the EIS sufficiently demonstrates that the NSDF Project can be constructed, operated and closed in a manner that is protective of human health and the environment. The Mohawks of Bay of Quinte have indicated to CNL that they will initiate contact with CNL when they are ready to proceed further with engagement.

6.2.4.11.3 Verification

In January 2020, CNL sent the Mohawks of Bay of Quinte notification of the online posting of the 2019 revised Draft EIS and the updated Indigenous Engagement Report (IER) for review and offered to meet one-on-one to provide updates and discuss how their comments were incorporated. The Mohawks of Bay of Quinte did not provide a response.

In May 2020, CNL sent a letter to Mohawks of Bay of Quinte which included draft dispositions to their comments on the 2017 Draft EIS. The Mohawks of Bay of Quinte acknowledged the receipt of the letter and responses but have indicated to CNL that they will initiate contact with CNL when they are ready to proceed further with engagement. Thus CNL is of the opinion that it is at Process Step 3 of the CNL Verification Process with the Mohawks of Bay of Quinte (i.e., acknowledgement) although CNL cannot complete the verification that the Mohawks of Bay of Quinte have been addressed until they engage.

CNL has provided the Mohawks of Bay of Quinte with the summary of commitments that CNL has made to the Mohawks of Bay of Quinte during NSDF Project engagements and requested a response if there were any concerns regarding the commitment list however the Mohawks of Bay of Quinte has not provided a response.

6.2.4.11.4 Next Steps

In late May 2020, CNL followed up on the request to meet and were informed by Mohawks of Bay of Quinte that the next steps on the NSDF Project engagement was currently with the Tyendinaga Mohawk Council. Once a decision has been made, Mohawks of Bay of Quinte will reach back to CNL.

CNL will continue to follow-up with Mohawks of Bay of Quinte on engagement opportunities and about any outstanding interests and concerns.

6.2.5 Continued Engagement Activities

Engagement activities with Indigenous communities regarding the NSDF Project continue as appropriate, necessary and requested as environmental assessment and NSDF Project planning activities progress. The nature of additional engagement activities will be consistent with CNL's Indigenous engagement objectives identified in Section 6.2.1. CNL will endeavour to evaluate and integrate information provided by these communities in the NSDF Project planning and design.

CNL has identified additional engagement activities that are planned to take place as the NSDF Project progresses. In general, these additional activities may include:

- notifying identified communities and organizations of Final EIS submission;
- sharing updated IERs with identified communities and organizations;

- on-going engagement with identified communities and organizations, including meetings and/or community information sessions to provide NSDF Project updates, solicit feedback on the NSDF Project and traditional land use activities;
- providing opportunity for pre-construction site visits and harvesting should harvestable materials are found;
- input on the NSDF Environmental Assessment Follow-Up Monitoring Program (EAFMP) to consider incorporation of Indigenous valued components and traditional knowledge into the EAFMP;
- involvement in the NSDF environmental monitoring, and discussions on environmental activities and findings;
- technical meetings or workshops, upon request, to provide interested parties with more in-depth information and opportunities to question subject matter experts on the NSDF Project;
- sharing with Indigenous communities and organizations any studies or reports specifically requested, to the extent possible;
- identification of Indigenous community and organizations needs for capacity assistance to effectively participate in the NSDF Project through a collaborative work plan;
- opportunities for NSDF Project site visits, as requested;
- participating in various targeted community initiatives, when appropriate, such as educational events, fairs, science fairs and career days;
- on-going NSDF Project notifications (e.g., letters, email correspondence, newspaper advertisements, updates to NSDF Project website); and
- on-going tracking and recording of comments, questions, concerns and other feedback provided by Indigenous communities and organizations, and providing responses.

Indigenous community specific engagement activities will be determined through discussions and identification of community interests. CNL will continue to engage with Indigenous communities (i.e., Chief and Council, representative bodies, community members) to address community information requirements and input. This activity will address a variety of topics such as VCs, potential environmental effects of the NSDF Project and mitigation identified. On-going engagement will also outline and schedule the documentation that will be shared with Indigenous communities and organizations for their review and comment (e.g., EAFMP, Environmental Protection Plans). Where outstanding concerns or disparities in views are communicated by Indigenous communities and organizations following submission of the EIS, CNL will track, respond to and report this feedback in its updated IER that will submitted to the CNSC prior to the NSDF Project Commission Hearing.

6.2.6 Conclusion

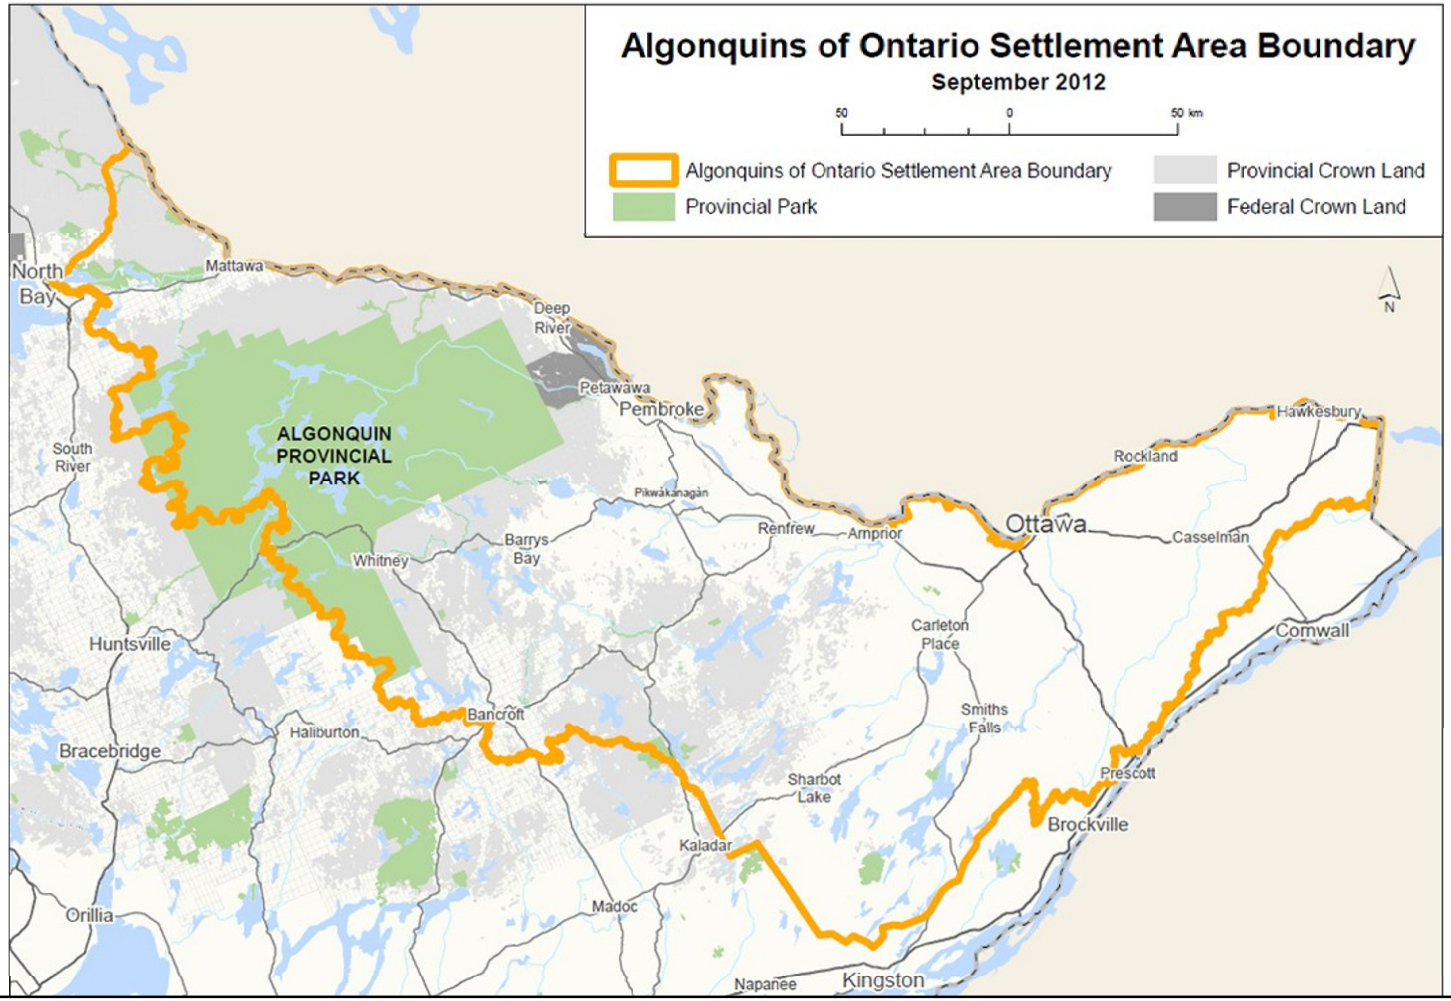
Methods employed to date have helped to establish productive NSDF Project discussions aimed at informing and educating Indigenous communities, thereby enabling valuable feedback into the NSDF Project. The NSDF Project will continue engagement efforts to support growth in awareness and understanding of the NSDF Project.

CNL has proactively addressed key interests and concerns raised by interested Indigenous Peoples, using open and transparent communication to share information in regard to traditional land use, biodiversity and archaeology.

CNL continues to be committed to on-going and meaningful Indigenous engagement and will continue to inform and engage communities to improve understanding of the NSDF Project and environmental protection measures put in place by the NSDF Project.

6.3 Valued Components

VCs refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous communities and organizations, or the public (The Agency 2018). Discussion of VCs in Section 6 focuses on VCs that reflect Indigenous interests, such as those related to Indigenous traditional land and resource use (Section 6.4.2).



Indigenous Peoples have also expressed a great deal of interest in other VCs, particularly those related to the natural environment. VCs were identified based on the potential for the NSDF Project to interact with features or activities of value to Indigenous communities or organizations, as per CNL's IER (CNL 2021).

6.3.1 Methods

6.3.1.1 Indigenous Engagement

The NSDF Project occurs within the general area of the AOO Land Claim (Figure 6.3.1-1), where negotiations with the Crown have occurred since 1991. It also overlaps the Mattawa/Lake Nipissing Traditional Harvesting Territory for the MNO. Discussions with Williams Treaties First Nation communities and AANTC member's communities have also indicated that traditional harvest occurs in the general area surrounding the Chalk River Laboratories site.

Indigenous communities or organizations practice or have likely practiced some traditional activities within the Regional Study Area (RSA – Section 6.4.3.1) of the NSDF Project. Through CNL's engagement process, the MNO have conducted a TKLUS to support the NSDF Project EIS and have identified VCs of particular interest to them. The AOO and the AOPFN have also completed an Algonquin Knowledge and Land Use Study (AKLUS) which identified VCs of concern to Algonquins. Through this engagement process, Indigenous interests have been incorporated into the selection of final VCs for the NSDF Project.

6.3.1.2 Selection of Valued Components by Canadian Nuclear Laboratories

A VC can be a pathway, habitat, a species or a traditional resource (Table 6.3.1-1). The type of VC definitions and associated colour-codes in Table 6.3.1-1 are used to categorize the specific VCs identified for the NSDF Project in Table 6.3.2-1.

Table 6.3.1-1: Colour Coded Table for Valued Components Comparison

Type of VC	Definition
Pathway	VCs selected to capture any potential changes in the natural environment on which other VCs depend.
Habitat	Habitat and ecosystems protection to ensure conservation to a broad range of species that depend on the habitat.
Species at Risk, Surrogate species or Indicator species	▪ A Species at Risk or Regionally Rare Species are either species protected under a regulatory regime or species that have been identified as a priority for conservation. ▪ Surrogate species are species or group of species that represent a large pool of species that have something in common, either feeding habitat, same habitat characteristics or behaviour. ▪ Indicator species are species or group of species selected that are expected to respond to a specific disturbance in a similar fashion as the species it represents. Its response to a specific disturbance is predictable and easily measurable.
Traditional Resources	Traditional activities and resources used by Indigenous Peoples.

VC = Valued Component.

Selection of VCs for this project was accomplished using a coarse and fine filter approach, which considers rarity, sensitivity, uniqueness, habitat and feeding guild (i.e., species that have similar diets) in the development of a list of VCs potentially on site. The coarse filter approach ensures that a diversity of ecosystem functions is maintained over space and time, which enables an assessment of the effects on broad biodiversity, whereas the fine filter approach ensures that the ecological requirements of a particular species or value is considered in the assessment. Combined, the selected coarse and fine filter VCs provide a holistic approach to assessment of the potential effects of the NSDF Project on the environment. Thus, following this process, the selected VCs reflect Indigenous interests raised during the consultation and engagement process.

6.3.2 Results

The VCs selected for the NSDF Project (Table 5.1.2-1) reflect a wide range of environmental effects and Indigenous interests. Table 6.3.2-1 summarizes how the VCs were selected by CNL for the NSDF Project and assessed through Sections 5.2 to 5.10, reflect Indigenous interests. For example, MNO through their TKLUS study, as well as the AOO and the AOPFN through their respective AKLUSs, identified moose, deer and bear as VCs due to traditional harvesting of these specific biota, while CNL has selected hunting as a VC to protect

Indigenous traditional resource use. Turkey, grouse and partridge were also identified as potential VCs and CNL selected the Ruffed grouse (*Bonasa umbellus*) as it is an indicator species that can sufficiently represent the health of populations of other game birds.

A number of species of plants have been noted as important resources for gathering, from which CNL selected all traditionally gathered species as a VC. Cranberries were highlighted as a particularly important resource, so CNL selected reed as it is an indicator species and a measure of habitat quality for cranberries.

Kitigan Zibi First Nation has indicated the importance of the Blanding's Turtle, which was included as a terrestrial VC as it is a SARA-listed species (Section 5.6.2 of the EIS). The AOO have indicated the importance of bald eagle given it is of cultural significance to the AOO and it was included as a VC (Section 5.7 of the EIS). The AANTC expressed concern regarding potential effects to moose, beaver, and waterfowl, which are included or have surrogate species included, as VCs in Section 5.7 of the EIS.

Finally, CNL selected hydrology, surface water quality, fish habitat, fishing and fish species as VCs as these reflect water quality of the Ottawa River as well as lakes and streams on the CRL site, along with the health of many species of interest to all Indigenous communities that provided feedback on the NSDF Project. Surface water quality is an intermediate component that can capture any potential changes in the natural environment on which other VCs depend, however. Air quality and geology are other intermediate components that can assess Indigenous concerns for air and soil quality.

CNL recognizes that Traditional Knowledge is an important way to inform and support the collection of baseline data. CNL is committed to the reconciliation of Algonquin ecological knowledge in cases where it may contradict the western scientific approach to identifying VCs.

Table 6.3.2-1: Comparison of Indigenous Suggested Valued Components and Canadian Nuclear Laboratories Selected Valued Components

Fish, Reptiles and Amphibians	NSDF VCs	Indigenous Communities that Expressed Concern about the VC
▪ All species	▪ Hydrology ▪ Surface water quality	▪ All communities
	▪ Fish habitat	▪ All communities
	▪ Fishing	▪ All communities
	▪ Fish species	▪ All communities

Table 6.3.2-1: Comparison of Indigenous Suggested Valued Components and Canadian Nuclear Laboratories Selected Valued Components

Sport and large bodied species: ▪ Bass ▪ Trout ▪ Walleye ▪ Pickerel ▪ Muskellunge ▪ Whitefish ▪ Burbot ▪ Catfish ▪ Sucker ▪ Yellow perch ▪ Sturgeon ▪ Eel	▪ Northern Pike ▪ Black Bullhead ▪ Brown Bullhead	▪ MNO ▪ AOO ▪ AOPFN
▪ Bait and forage fish	▪ Bluntnose minnow	▪ MNO ▪ AOPFN
▪ Bullfrog ▪ Salamander ▪ Mudpuppy ▪ Five-lined Skink[3]	▪ Green frog	▪ MNO ▪ AOO
▪ Blanding's turtle ▪ Turtle (unknown species)	▪ Blanding's turtle	▪ Kitigan Zibi First Nation ▪ AOPFN
Mammals	**NSDF VCs**	**Indigenous Communities that Expressed Concern about the VC**
▪ All species	▪ Vegetation communities	▪ MNO
▪ Moose and Deer	▪ Moose and White-tailed deer	▪ MNO ▪ AANTC ▪ AOO ▪ AOPFN
▪ Bear	▪ Black bear	▪ MNO ▪ AOO ▪ AOPFN
▪ Moose, Deer, Elk and Bear	▪ Hunting	▪ MNO ▪ AOO ▪ AANTC ▪ AOPFN

[3] CNL has indicated that this species has not been confirmed at or near (within 100 km) the CRL site. However, as a species at risk, if it is incidentally detected at CRL as part of one of our coverboard surveys, it will be added to the list of VC and managed accordingly.

Table 6.3.2-1: Comparison of Indigenous Suggested Valued Components and Canadian Nuclear Laboratories Selected Valued Components

▪ Lynx, Coyote, Fox and Wolf	▪ Eastern wolf	▪ MNO ▪ AOO ▪ AOPFN
▪ Beaver[4] ▪ Marten ▪ Fisher ▪ Mink[4] ▪ Otter[4] ▪ Rabbit/Hare ▪ Muskrat[4] ▪ Badger ▪ Raccoon ▪ Squirrel ▪ Weasel	▪ Small mammals (Meadow Vole, Short-tailed Shrew) and Large Mammals (Moose)	▪ MNO ▪ AOO ▪ AOPFN ▪ AANTC

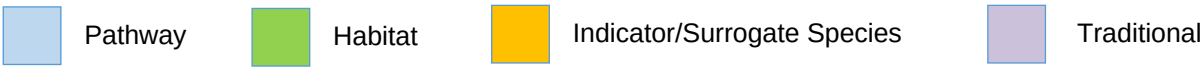
	▪ Reed	▪ MNO ▪ AOO ▪ AOPFN
	▪ Hydrology ▪ Surface water quality	▪ All communities
	▪ Trapping	▪ MNO ▪ AOO ▪ AOPFN
Birds	**NSDF VCs**	**Indigenous Communities that Expressed Concern about the VC**
▪ All species	▪ Hydrology ▪ Surface water quality	▪ MNO
	▪ Vegetation communities	▪ MNO
	▪ Hunting	▪ MNO ▪ AOO ▪ AOPFN
▪ Migratory birds	▪ Migratory birds	▪ MNO ▪ AOO ▪ AOPFN
▪ Partridge ▪ Grouse ▪ Wild Turkey	▪ Ruffed grouse	▪ MNO ▪ AOO ▪ AOPFN
▪ Geese ▪ Ducks	▪ Great Blue Heron ▪ Mallard	▪ MNO ▪ AOO ▪ AANTC ▪ AOPFN



[4] These species are semi-aquatic mammals. Terrestrial exposure pathways are addressed through the meadow vole (herbivore) and short-tailed shrew (omnivore). Exposure pathways to the aquatic environment, including semi-aquatic mammals, are addressed through the hydrology and surface water pathways, reed (aquatic plants for food) and the fish species included in the assessment.

6.4 Traditional Land and Resource Use

This section of the EIS for the NSDF Project seeks to understand and characterize the potential residual effects of the NSDF Project and previous, existing and reasonably foreseeable developments on traditional land and resource use by Indigenous communities.

The assessment of effects on land and resources identifies linkages between the NSDF Project activities and current environment to determine the residual effects of the NSDF Project on traditional land and resource use. Residual effects (i.e., those effects remaining after the implementation of all mitigation) are placed in the context of the cumulative effects of previous, existing and future projects.

6.4.1 Scope of the Assessment

This section focuses on traditional land and resource use. The traditional land and resource use assessment follows the overall environmental assessment approach and methods described in Section 5.1. The assessment was completed following the key steps listed below:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** for the traditional land and resource use assessment (refer to Sections 6.4.2 Valued Components and Section 6.4.3 Assessment Boundaries). The VCs and measurement indicators used to assess Project-related changes to the land and resource use environment are described, along with the spatial and temporal boundaries at which the assessment occurred and the assessment cases considered.
- **Step 2 – Describe the existing conditions** (refer to Section 6.4.4 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the traditional land and resource use environment. The existing conditions provide a reference to which the effects of the NSDF Project can be compared.
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 6.4.5 Project Interactions and Mitigation). Project components and/or activities with the potential to affect traditional land and resource use are identified and mitigation developed to limit or avoid negative effects, or to maximize benefits is presented. A pathways analysis is then used to focus further assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated.
- **Step 4 – Present the methods and results of the residual effects analysis**. This step was not required as no primary pathways were identified in the traditional land and resource use assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty**. This step was not required as no primary pathways were identified in the traditional land and resource use assessment.
- **Step 6 – Classify and determine the significance of the predicted residual effects**. This step was not required as no residual adverse effects were identified in the traditional land and resource use assessment.

- **Step 7 – Identifying monitoring and follow-up** required to confirm effects predictions and address uncertainty (refer to Section 6.4.6 Monitoring and Follow-up).
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** of residual effects on land and resource use (refer to Section 6.4.7 Conclusions).

Information and areas of interest raised by Indigenous Peoples and regulators during engagement that influenced the scope of the traditional land and resource use assessment are summarized in Table 6.4.1-1. A full summary of engagement activities is available in Section 6.2. Other general areas of interests and questions raised during the engagement that pertain to the land and resource use assessment (if any) are documented in CNL's Indigenous Engagement Report (CNL 2021).

Table 6.4.1-1: Summary of Areas of Interest Raised during Engagement Activities that Influenced the Scope of the Traditional Land and Resource Use Assessment

Area of Interest	How the Area of Interest Was Considered or Included in the Land and Resource Use Assessment
Indigenous interest expressed in relation to potential effects on fish and fish harvesting due to concerns of potential contamination or radioactive seepage into Perch Creek, the Ottawa River and other waterbodies from the NSDF Project.	The spatial boundaries of the traditional land and resource use assessment were selected to include consideration of potential effects on water quality and include the aquatics study areas. CNL continues to monitor the aquatic environment extensively, specifically Perch Creek. The NSDF Project has used recent modelling to understand the potential for effects within the Perch Creek basin and the expanded RSA. Existing traditional land use with regard to fishing is described in Section 6.4.4.1.2.3. Potential effects on these VCs are assessed in Section 6.4.5.
Interest in changes in possible land uses caused by accidents and malfunctions, including high levels of precipitation, seismic activity, fault line and system failure, as well as the transportation of radioactive waste through traditional territories.	▪ The EIS identifies a number of planned good practices in the form of mitigation to avoid accidents and malfunctions and proactively address potential effects. The design of the facility addresses plausible operational events and natural disasters. Every precaution will be taken to ensure the protection of workers, the public and the environment. ▪ Potential effects of accidents and malfunctions are addressed in Section 7.0 of the EIS.
Interest in potential effects on Indigenous cultural heritage resources in the RSA. A request to review any future archaeological assessments has formally been made.	▪ An archaeological assessment, including field surveys, was completed for the SSA and surrounding area. Findings of this assessment were used to inform the NSDF Project design team, and the NSDF Project site was subsequently modified so that archaeological sites identified during the field surveys would not be affected. Archeology is addressed in Section 5.9.4.2 and Section 5.9.5.1.2. ▪ CNL is committed to engaging and seeking input from Indigenous Peoples whose traditional territory, Indigenous and treaty rights have the potential to be affected by the NSDF Project. Traditional hunting, trapping, fishing and gathering activities, as well as cultural resources and ceremonies, are addressed in Section 6.4.4.1 and 6.4.5.
Interest in potential effects to continued Indigenous traditional land and resource use.	The NSDF Project occurs within a general area of traditional land and resource use for Indigenous Peoples. Traditional land and resource use are addressed in Section 6.4.4.1 and 6.4.5.
Concerns regarding unidentified Indigenous burial sites and excavation.	If any human remains are identified during construction, CNL will immediately notify Indigenous communities or organizations, as well as the police or coroner and the Registrar of Cemeteries, Ministry of Small Business and Consumer Services. Archeology is addressed in Section 5.9.4.2 and 5.9.5.2.

EIS = Environmental Impact Statement; RSA = Regional Study Area; SSA = Site Study Area; VC = valued component; AOO = Algonquins of Ontario.

The information in Table 6.4.1-1 was used to frame the scope of the assessment and identify VCs (Section 6.4.2). This assessment considers changes in wildlife harvesting and angling and other resource uses identified during the collection of baseline information at the local and regional scales. CNL has and will continue to meet with Indigenous Peoples to receive input on the NSDF Project. The objectives of these meetings are to understand the priorities and interests of recreational and traditional users and to review potential mitigation to reduce or eliminate the effects of the NSDF Project.

6.4.2 Valued Components

VCs refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public (The Agency 2018). Land and resource use VCs were selected based on the potential for the NSDF Project to interact with these features or activities of the land and resource use environment.

In addition, VCs for traditional land and resource use were selected based on consideration of a number of factors, including the following:

- knowledge of traditional land and resource use practices that interact with the environment;
- Indigenous and/or treaty rights;
- community engagement; and
- consideration of other environmental assessments.

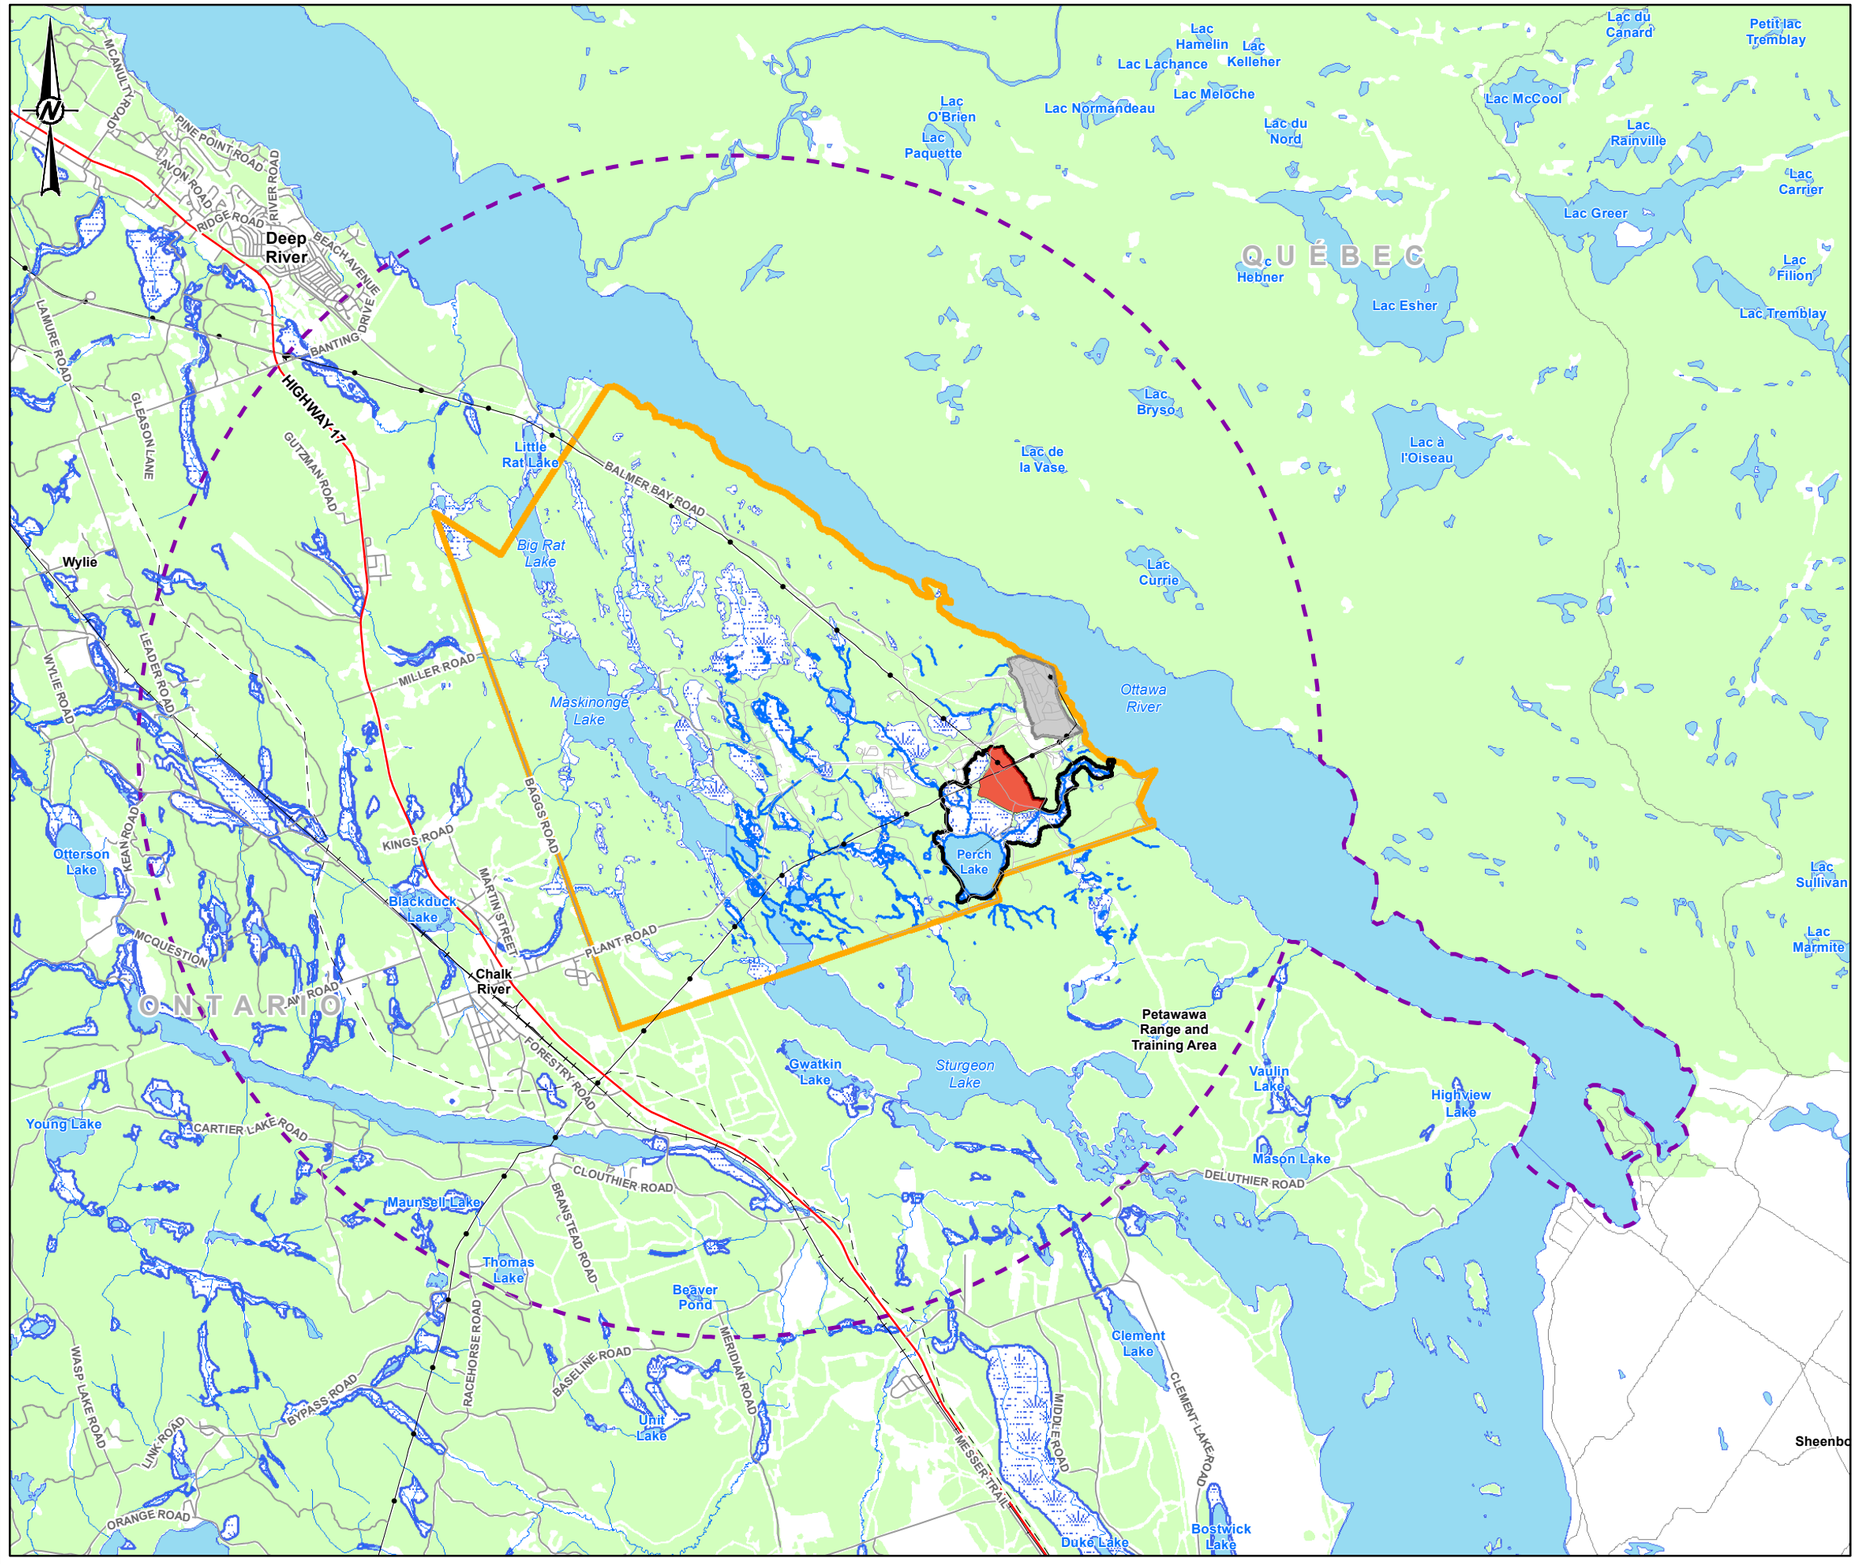
The VCs selected for assessing potential effects on land and resource use conditions are presented in Table 6.4.2-1.

Table 6.4.2-1: Valued Components for the Land and Resource Use Assessment

Valued Component	Rationale for Selection
Traditional land and resource use by Indigenous Peoples	■ Trapping, hunting, fishing and gathering where traditional and are modern day land and resource use activities are practised by Indigenous Peoples in the Ottawa Valley. These activities provide important links to cultural continuity and traditional way of life. These activities are protected under Section 35 of the Constitution Act, which identifies that existing Aboriginal and treaty rights of the Indigenous Peoples of Canada are recognized and affirmed. For Métis people, the rights were affirmed in the courts in 2003 (R. v. Powley) confirming that Métis can assert Aboriginal rights under Section 35 of the Constitution Act. ■ Indigenous Peoples place a high degree of value on specific sites of cultural, historical, spiritual, social or ecological significance. These sites may have broader cultural significance related to the practice of formal or informal ceremonies at or near these sites.

To focus the assessment, the VCs noted in Table 6.4.2-1 are further subdivided into categories, and assessment endpoints and measurement indicators were identified for each category. Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future generations. Measurement indicators represent properties of the environment and VCs that, when changed, could result in or contribute to an effect on a VC. Measurement indicators can be used to monitor the success of mitigation and management programs. The assessment endpoints and measurement indicators identified for the land and resource use VCs are presented in Table 6.4.2-2.

Table 6.4.2-2: Assessment Endpoints and Measurement Indicators for the Land and Resource Use Assessment



Valued Component	Sub-component	Assessment Endpoints	Measurement Indicators
Traditional land and resource use by Indigenous Peoples	Trapping	Continued traditional land and resource use opportunities	▪ Changes in access to lands for trapping opportunities ▪ Changes in quality and quantity of trapping opportunities
	Hunting	Continued traditional land and resource use opportunities	▪ Changes in access to lands for hunting opportunities ▪ Changes in quality and quantity of hunting opportunities
	Fishing	Continued traditional land and resource use opportunities	▪ Changes in access to lands for fishing opportunities ▪ Changes in quality and quantity of fishing opportunities
	Gathering	Continued traditional land and resource use opportunities	▪ Changes in access to lands for gathering opportunities ▪ Changes in quality and quantity of gathering opportunities
	Cultural resources and ceremonies	Continued access to cultural resources for ceremonial purposes	▪ Changes in access to lands for cultural ceremonial purposes ▪ Changes in quality and quantity of ceremonial opportunities

6.4.3 Assessment Boundaries

6.4.3.1 Spatial Boundaries

The spatial boundaries selected for the traditional land and resource use assessment were chosen because they permit a description of existing conditions in sufficient detail to enable potential Project-VC interactions and effects to be identified, understood and assessed, including the contribution of the NSDF Project to cumulative effects. The spatial boundaries selected for the traditional land and resource use assessment are the same as those identified for the land and resource use assessment and are presented on Figure 6.4.3-1 and are described below:

- **Site Study Area (SSA):** The SSA is the NSDF Project footprint (i.e., where project activities would be undertaken, including the NSDF Project's proposed facilities, buildings and infrastructure). The SSA covers an area of approximately 37 ha (Figure 6.4.3-1). The SSA falls within the CRL site boundary.
- **Local Study Area (LSA):** The LSA is selected in consideration of the NSDF Project footprint and the spatial extent of potential direct effects of the NSDF Project on the VCs. The traditional land and resource use LSA corresponds with the combined area of the terrestrial and aquatics LSAs used for the assessment of the groundwater and surface water environment, aquatic biodiversity and terrestrial biodiversity, and covers approximately 226 ha (Figure 6.4.3-1). The aquatics, terrestrial and biophysical LSAs are defined in Sections 5.2 through 5.6. The LSA is defined to capture both direct and indirect effects on the terrestrial and aquatic environments as a result of the NSDF Project (e.g., changes in groundwater and surface water quality, habitat loss and changes in abundance, distribution and disturbances to wildlife and fish) as these effects have the potential to result in subsequent effects on land and resource use. The LSA falls within the CRL site boundary. No traditional land use activities currently occur within the CRL site boundary.
- **Regional Study Area (RSA):** The RSA is defined as the area within which the potential effects of the NSDF Project may interact with the effects of other existing or reasonably foreseeable projects. The traditional land and resource use RSA is the combined area of the air quality, terrestrial and aquatics RSAs, which have been used for the assessment of the air quality, groundwater, and surface water, aquatic and terrestrial environments (Figure 6.4.3-1). The RSA is defined to capture effects on the terrestrial and aquatic environments as a result of the NSDF Project (e.g., habitat loss, sensory disturbance for wildlife and changes to habitat from air quality and surface water quality, changes in groundwater and surface water quality, habitat loss and changes in abundance, distribution and disturbances to wildlife and fish), as these effects have the potential to result in subsequent effects on land and resource use. Therefore, the RSA for traditional land and resource use is a combination of the air quality and aquatic environment RSAs as this is the largest extent of potential cumulative effects on land and resource use. The air quality RSA is defined as an approximately 7.4 km circular radius surrounding the LSA, and the aquatic RSA extends roughly 8 km downstream in the Ottawa River to Harrington Bay. While there are no traditional land use activities occurring within the CRL site boundary, there may be some trapping occurring at Garrison Petawawa and in the RSA. The Ottawa River where it overlaps with the RSA boundaries would also be used for some traditional land and resource uses.

6.4.3.2 Temporal Boundaries

Temporal boundaries (i.e., project phases) establish the timeframe during which NSDF Project effects are assessed. The temporal boundary represents the timeframe during which project activities are actively occurring and considers the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a project activity or stressor (which is related to the project phases) plus the time required for the residual effect to be reversed. In the case of social land use changes, residual effects may be irreversible due to the nature of changes in human activity. The following phases were identified for the NSDF Project.

- **Construction phase**: This phase includes site preparation and all activities associated with the construction of the NSDF, up until the operations phase commences with the delivery of waste. This phase includes activities such as installing the necessary supporting and/or ancillary facilities and infrastructure to facilitate NSDF operation, inactive commissioning and systems testing, and transportation of construction materials. Construction activities are expected take place from 2022 to 2024.
- **Operations phase**: This phase includes all activities associated with waste placement, water management, Wastewater Treatment Plant (WWTP) operations, vehicle movements into and from the SSA and maintenance activities. Operations activities are expected to last approximately 50 years (i.e., 2025 to 2070).
- **Closure phase:** This phase includes activities necessary to complete the installation of the final cover and implementation of long-term monitoring. Closure activities are expected to start in approximately 2070 and continue through to 2100, after which the NSDF Project will transfer into the post-closure phase.
- **Post-closure phase:** This phase has two discrete periods: institutional control and post-institutional control. The institutional control period includes implementation of controls throughout 2100 to 2400 (i.e., 300 years). During institutional control, environmental monitoring will continue to demonstrate compliance with the environmental assessment predictions. Post-institutional control occurs after year 2400 and continues indefinitely.

The temporal boundaries for the land and resource use assessment consider all NSDF Project phases, from construction through post-closure.

6.4.3.3 Assessment Cases

The assessment cases considered in the traditional land and resource use assessment are the Base Case and Application Case (the Reasonably Foreseeable Development Case has not been considered for the reasons outlined below):

- **Base Case:** This scenario represents existing conditions and characterizes effects from previous and existing developments and activities. The Base Case reflects the effects of existing land and resource uses in the area, such as hunting, fishing, trapping, forestry, agriculture, mining and recreational use. Current effects from the existing CRL facilities and operations are considered part of the Base Case.
- **Application Case:** This scenario represents the effects of the Base Case combined with the predicted effects from the NSDF Project. The Application Case considers effects from the NSDF Project during construction through to post-closure.

- **The Reasonably Foreseeable Development (RFD) Case:** This scenario represents the effects of residual adverse effects of the Application case combined with other reasonably foreseeable projects in the traditional land and resource use RSA. Reasonably foreseeable developments within the RSA includes limited planned construction at Garrison Petawawa, and on the CRL site, new and upgraded research and development facilities, construction and operation of a Small Modular Reactor, new support infrastructure, on-going decommissioning and environmental remediation activities. There are currently no traditional land and resource use activities such as hunting, fishing, gathering and cultural ceremonies occurring in either the SSA or LSA as the CRL site is a restricted public access area. The NSDF Project is not predicted to have any terrestrial effects beyond the CRL site, and results of the aquatic environment assessment identify that measurable residual effects on aquatic biodiversity VCs are not predicted as a result of the NSDF Project. Because RFDs will not have any spatial overlap with potential effects of the NSDF Project and/or are not likely to affect traditional land and resource use, an RFD Case is not presented as part of this assessment.

6.4.4 Description of the Environment

This section describes the setting and characterization for traditional land and resource use by Indigenous Peoples, as relevant for the assessment of the NSDF Project. It describes the existing conditions (i.e., Base Case) against which potential changes from the NSDF Project are compared and evaluated.

6.4.4.1 Traditional Land and Resource Use by Indigenous Peoples

6.4.4.1.1 Methods

Indigenous interests expressed to CNL during engagement with Indigenous communities and organizations identified for the NSDF Project (Table 6.2.2-1) have been considered in the following assessment. In 2016 CNL, on two occurrences, sent letters to the identified Indigenous communities and organizations requesting information on traditional land and resource use in the area surrounding the NSDF Project and the CRL site. CNL sent letters again in May 2020 asking relevant questions again to verify assumptions CNL made in lieu of having responses or direct input from the various Indigenous communities and organizations.

Information on traditional land use activities by Indigenous Peoples has been drawn from: existing studies and reports; Indigenous organization websites; the MNO Traditional Knowledge and Land Use Study (KnowHistory 2019); the AOO Algonquin Knowledge and Land Use Study (AKLUS) (SVS, AOO, 2020); the AOPFN Algonquin Knowledge and Land Use Study (AKLUS) (SVS, AOPFN, 2020); formal and informal consultation activities; and general knowledge (i.e., non-Indigenous) of the region. The MNO reviewed the 2020 Final EIS which included incorporation of the findings of the MNO TKLUS. The AOO and the AOPFN have also provided CNL with feedback on how their AKLUS studies were incorporated to this section. Information on traditional land and resource use and how it was gathered for each Indigenous organization and community is also documented below.

In the absence of specific feedback from other Indigenous communities and organizations, traditional land and resource use is assumed wherever there are accessible lands, which is a conservative approach to the assessment and also to reflect the dynamic practice of traditional land and resource use by Indigenous Peoples in time and space. By making this assumption, it is more likely effects will be identified and assessed and potential use will be factored into project planning.

Algonquins of Pikwakanagan First Nation (AOPFN)

Traditional land and resource use knowledge for the AOPFN is primarily derived from the September 2020 AOPFN AKLUS (SVS, AOPFN, 2020). Algonquin Knowledge was defined in the study as:

> *The body of knowledge and information shared by Algonquin peoples and transmitted between Indigenous Peoples, which supports traditional land use for the benefit and well-being of Indigenous Peoples. (SVS, AOPFN 2020, p. 5).*

The same consultant that prepared the AOO AKLUS (SVS, AOO 2020) also prepared the AOPFN AKLUS (SVS, AOPFN 2020).

Some contextual information on Algonquin traditional knowledge and use in this EIS is taken from supporting documents associated with resource management plans for the Ottawa Valley and surrounding region. Specifically, this information has been documented in Supporting Documentation to Forest Management Plans for the Ottawa Valley Forest, Nipissing Forest, Algonquin Park Forest, Mazinaw-Lanark Forest and Bancroft-Minden Forests. These five forests cover a wide area of central-eastern Ontario roughly equivalent to the AOO Settlement Area.

The Supporting Documentation to those Forest Management Plans includes documents such as the Aboriginal Background Information Reports which describes use of natural resources and protection of identified Aboriginal Values. That information is intended to describe traditional uses and protection of natural resources on Ontario crown land over this wide region but does not include private or federal crown land. Those Reports have been referenced in the EIS. Those Reports describe traditional uses undertaken by all AOO communities including the AOPFN. The CRL site is located within the general area of the Ottawa Valley Forest but that Forest Management Plan has no jurisdiction over the CRL site nor describes uses on it. These forest management plans do describe in general terms, traditional use occurring on crown lands near the CRL site; however it should be noted that the findings from these supporting documents were not verified with the AOPFN Knowledge Keepers for the development of this EIS.

Algonquins of Ontario (AOO)

Traditional land and resource use knowledge for the AOO is primarily derived from the December 2020 released AKLUS. The same consultant that prepared the AOO AKLUS (SVS, AOO 2020) also prepared the AOPFN AKLUS which was released in October 2020 (SVS, AOPFN 2020). In the two reports, Algonquin Knowledge was defined in the study as:

> *A body of knowledge and information shared by Algonquin peoples and transmitted between Indigenous Peoples, which supports traditional land use for the benefit and well-being of Indigenous Peoples.*

Some contextual information on Algonquin traditional knowledge and use in this EIS is taken from supporting documents associated with resource management plans for the Ottawa Valley and surrounding region. Specifically, this information has been documented in Supporting Documentation to Forest Management Plans for the Ottawa Valley Forest, Nipissing Forest, Algonquin Park Forest, Mazinaw-Lanark Forest and Bancroft-Minden Forest. These five forests cover a wide area of central-eastern Ontario roughly equivalent to the AOO Settlement Area.

The Supporting Documentation to those Forest Management Plans includes documents such as the Aboriginal Background Information Reports which describes use of natural resources and protection of identified Aboriginal Values. That information is intended to describe traditional uses and protection of natural resources on Ontario crown land over this wide region but does not include private or federal crown land. Those Reports have been referenced in the EIS. Those Reports describe traditional uses undertaken by all AOO communities including the AOPFN. The CRL site is located within the general area of the Ottawa Valley Forest but that Forest Management Plan has no jurisdiction over the CRL site nor describes uses on it. These Forest Management Plans do describe in general terms, Algonquin traditional use occurring on crown lands near the CRL site. It is noted that the forest management planning process does not enable fulsome documentation of Algonquin knowledge, land use and occupancy data and is subject to limitations as a source of this data.

Métis Nation of Ontario (MNO)

The MNO have completed a traditional knowledge and land use study that documents use of lands and waters near the CRL site (KnowHistory 2019). Some other information on traditional land and resource use in this area of Ontario was obtained from the MNO website. Forest management plans for the area around the CRL site describe traditional Algonquin use as consultation occurred with the AOO and the AOPFN but traditional use of the MNO is not described as the Ontario Ministry of Natural Resources and Forests did not extend its duty to consult for those forest management plans to the MNO.

Williams Treaties First Nation (WTFN) Communities

While CNL was unable to find any documents such as forest management plans to describe Williams Treaties First Nation community uses near the CRL site, some WTFN members indicated verbally during an engagement in the spring of 2020 that they may have members living and/or harvesting near the CRL site. CNL has requested any information describing these communities' traditional uses near the CRL site. In the absence of additional feedback from WTFN, CNL has conservatively assumed their harvesting activities by Williams Treaties communities are undertaken in the Ottawa River Valley. Forest management plans for the area around the CRL site describe traditional Algonquin use as consultation occurred with the AOO and the AOPFN but traditional use of the Williams Treaties communities is not described as the Ontario Ministry of Natural Resources and Forests did not extend its duty to consult for those forest management plans to these communities.

Algonquin Anishinabeg Nation Tribal Council (AANTC) Communities

CNL has requested any information describing these communities' traditional uses near the CRL site. While no information describing recent traditional use by AANTC community members has been found or identified CNL is of the opinion that likely there is some use occurring on the Ottawa River or on the Quebec side of the Ottawa River by some individuals from these communities. Thus CNL has conservatively assumed that AANTC community member's access and practice traditional activities along the Ottawa River or on the Quebec side of the Ottawa River. Forest management plans for the area around the CRL site describe traditional Algonquin use as consultation occurred with the AOO and the AOPFN but traditional use of the AANTC communities is not described as the Ontario Ministry of Natural Resources and Forests did not extend its duty to consult for those forest management plans to these communities.

6.4.4.1.2 Results

6.4.4.1.2.1 General

Information gathered on traditional use is described below.

6.4.4.1.2.2 Algonquins Pikwakanagan First Nation

The NSDF Project occurs within the AOPFN's traditional territory and the general area of the AOO Land Claim (of which the AOPFN is a part of), where negotiations with the Crown have occurred since 1991 (see Figure 4 in Appendix 5.9-1).

As part of a submission to the CNSC for a 10-year renewal of the Nuclear Research and Test Establishment Operating Licence for the CRL (Commission Member Document 18-H2.51), the AOO (including the AOPFN) identified that it asserts unextinguished and constitutionally protected Aboriginal rights and title to a traditional territory in Eastern Ontario (referred to as the "Settlement Area") and is currently in negotiations towards a modern day treaty with the governments of Ontario and Canada. The NSDF Project occurs within the Settlement Area. The Settlement Area includes 36,000 km^2 within the watersheds of the Kichi-Sìbì (Ottawa River) and the Mattawa River. This area is the traditional territory of the AOO and the Algonquins of Pikwakanagan First Nation and it is recognized that the AOPFN citizens continue to practise traditional land use activities throughout this region. Algonquin traditional use has occurred for a very long period of time. In the *Aboriginal Background Information Report* to the Forest Management Plan for the Ottawa Valley Forest 2011 to 2021, it was indicated that:

> *Since the 1700s the Algonquins were known to spend the majority of the year occupying the different parts of the Ottawa Valley, hunting, fishing, trapping and gathering among other things. These activities necessitated use of timber and other resources.* (Ottawa Valley Forest 2011a)

The AOO website describes the importance of traditional harvest to all Algonquin communities:

> *The harvesting of flora and fauna for food and trade has been integral to the Algonquin way of life since time immemorial. These practices embody an inherent respect for the environment and a fundamental commitment to the sustainable management of resources, which has been passed from generation to generation.*
>
> *The rights of Indigenous Peoples in Canada to engage in traditional activities, including the harvesting of wildlife, fish, migratory birds and plants, is recognized by the Constitution Act, 1982 and upheld by the Supreme Court of Canada. As stewards of our ancestral lands, the AOO recognize the importance of exercising this right in a responsible manner.* (AOO 2016)

The AOO, including the AOPFN, has further re-iterated the importance of traditional harvest in its Agreement-in-Principle with the Governments of Ontario and Canada. In Chapter 8, it is indicated that:

> *The Final Agreement will provide that Beneficiaries have the right to Harvest Fish, Wildlife, Migratory Birds and Plants for Domestic Purposes throughout the year within the Settlement Area as further described in this Chapter*. (AOO, Government of Ontario, Government of Canada 2016)

As indicated in the quotation above, the intent of such harvest is for subsistence/community use purposes and not for commercial purposes (AOO 2016). It is likely that Indigenous Peoples and possibly the ancestors of the modern day Algonquins living in the Ottawa Valley undertook traditional activities, such as hunting, which would

have likely included lands that are currently under federal government control. Archaeological investigations for the NSDF Project have discovered artifacts from CaGi-40, an Early Archaic Period site (i.e., 6,000 to 10,000 years before present; Swayze and Cameron 2016).

The AOPFN AKLUS identified three major objectives on page 8 (SVS, AOPFN 2020):

- Document evidentiary information that shows where and how Algonquins currently and historically have used the lands and waters around the NSDF and NPD sites, and Algonquin concerns related to these projects.
- Demonstrate how proposed and ongoing nuclear projects may impact Algonquin land use and occupancy.
- Propose appropriate mitigation measures and recommendations to ensure impacts to the AOPFN rights and interests are minimized or accommodated.

The temporal scope of the study included both historic (includes information participants know about through teaching or knowledge transfer from past generations, including oral history) and current (anything that occurred in a participant's lifetime) use. The geographical scope of the study included a 25-kilometer radius study area, which is extended by 5 kilometers more along the downstream side of the Kichi-Sìbì (the Ottawa River). The high importance of the Ottawa River to the Algonquin people is well described in the AOPFN AKLUS (SVS, AOPFN 2020).

Map biography information that was collected included the following: locations of wildlife harvesting, trapping, fishing and gathering of plants or natural materials; locations of culturally and/or historically significant sites; locations of camps or places where people stay overnight on the land; travel routes and trails; areas of ecological importance; and, areas of demographic importance (e.g., locations of current or past residences or birthplaces).

The oral history information that was collected included: harvesting philosophy and techniques; use of harvested species for food, medicine, ceremony, crafts or economic purposes; Algonquin cultural knowledge; perspectives on cultural harvesting areas, cumulative effects on development and changes to the environment and land use activities; perspectives about ways the NSDF Project may alter participants' use of the lands and waters; and, suggestions for how participants would like to see their concerns mitigated. It was also noted by study participants that the knowledge necessary for land-based practices is passed on and learned through generations (SVS, AOPFN 2020, p. 33). This means that continued access to traditional lands is important for this cultural continuance.

The features mapped include the following the AOPFN Algonquin Land Use and Occupancy Categories: travel routes; boat launches or landings; personal fishing areas; commercial trapping or snaring; fish spawning habitat; bird habitat; reptile or amphibian habitat; species at risk habitat; mammal habitat; plant habitat; wildlife harvesting area; plant and natural materials gathering area; overnight locations; and, Algonquin cultural sites or areas of demographic importance.

The AOPFN AKLUS also included sections on Algonquin history and the archaeological assessment that occurred as a part of the NSDF Project (SVS, AOPFN 2020).

The AKLUS involved the participation of 13 members of the AOPFN. CNL recognizes that this survey of members just represented a sample of traditional use in the study area. The AOPFN specifically expressed that this must be viewed as a "snapshot" with the understanding that absence of data does not equate to absence of use and value in a certain location by the AOPFN members (SVS, AOPFN 2020)

Land Use values were reported in the AOPFN AKLUS (Appendix C), but were not specifically shown on maps in the report to protect the confidentiality of the locations. An Algonquin Land Use and Occupancy Map was included in the Report that documented traditional use in the identified study areas near the NSDF site. The map was divided into one square kilometer grid squares. Grid squares were shaded where traditional use was documented within a particular square kilometer (data being present in the square). Unshaded areas do not equate to an absence of use (unless an area is restricted use such as the CRL site or Garrison Petawawa, although traditional use may have occurred prior to occupation of these sites by the Government of Canada) but may be simply an absence of data given the constraints of the study.

Along with mapping and describing land use, the Study team also asked oral history questions that focused on: the participant's Algonquin Knowledge of the area; their perceptions of current harvesting areas; perspectives on cumulative effects of development; and, changes to the environment and land use activities. As indicated on page 30, the AOPFN AKLUS (SVS, AOPFN 2020) notes that the features mapped fall into several different Algonquin land use and occupancy categories. The report notes that:

> *These results demonstrate the extent to which Algonquins exercise their inherent rights and interests on the lands and waters surrounding the NSDF Project site and were used to inform the recommended mitigation and accommodation measures proposed in Section 4.1. (SVS, AOPFN, 2020, p. 30).*

The AOPFN participants in the study expressed their deep connections to the area around CRL:

> *The proposed NSDF Project is located within AOPFN's traditional territory, the lands and waters throughout which hold great cultural, historical and ecological significance to the Algonquins. Interview participants described deep connections to this area extending back through generations, emphasizing the importance of the lands and waters to Algonquin culture and ways of life that have existed throughout history and continue into the present day. Interview participants described exercising their Aboriginal rights and interests throughout the area, mapping sites of both land-use and occupancy, including sites where participants hold Algonquin Knowledge. Given these deep connections Algonquins hold to the NSDF Project study area, interviewees expressed a number of concerns related to the project and how it may impact their connection to and use of these lands and waters*. (SVS, AOPFN, 2020, p. 40)

The AOPFN AKLUS (SVS, AOPFN 2020) goes on to note that there are numerous features mapped in and around the NSDF site. As well there are some values that are mapped on a grid that overlaps the NSDF site. The AOPFN traditional use with respect to trapping, hunting, fishing, gathering and cultural uses and ceremonies is reported further below. Beyond traditional uses and cultural/historic sites, the AOPFN AKLUS also documents areas of important habitat including fish spawning (Oga (Pickerel/Walleye) and Lake Sturgeon), species at risk (bald eagle) and mammal (waboz (rabbit), makwa (bear), wawashkeshi (white-tailed deer), monz (moose) and mahingan (wolf)) habitat.

The AOPFN AKLUS (SVS, AOPFN, 2020) generally describes the concerns harvesters have with respect to environmental impacts from nuclear facilities in the Algonquin Settlement area. These concerns are articulated both in a historical and present-day context (concerns both about the existing facilities and future uses). The concerns are associated with harvesting, health, and overall impact to the environment and specifically the Ottawa River.

Subsequent to the completion and receipt of the AOPFN AKLUS, the AOPFN provided CNL additional perspectives and emphasis on the AOPFN AKLUS (AOPFN 2021). The AOPFN identified what it considered to be limitations of the AKLUS including the number of participants, temporal scope and that the scope and focus of the data collected was considered by them to be narrow. The AOPFN re-iterated and emphasized the importance of key themes identified in the AKLUS including: the importance of nearby and adjacent cultural sites such as Pointe Au Baptême and Oiseau Rock (AOPFN 2021).

As already indicated, the AOPFN AKLUS (SVS, AOPFN 2020) documented the importance of fish spawning, mammal and species at risk habitat areas. The importance of the habitat for these species in close proximity to NSDF was further articulated by the AOPFN in their engagements with CNL. In particular, the AOPFN identified the importance of monz (moose) and wawashkeshi (white-tailed deer) habitat and harvesting areas bordering and/or near the NSDF site. The AOPFN re-articulated their concerns about contamination of these important habitat areas. They further expressed their interest in future monitoring and follow-up in these areas.

CNL considers some of the concerns raised by participants of the AKLUS (SVS, AOPFN 2020), and the AOPFN's additional perspectives of the study (AOPFN 2021), beyond the scope of the NSDF Project, but does recognize that these concerns are more interconnected for the AOPFN and does see the need to respond to all the concerns. CNL has undertaken more extensive engagement with the AOPFN to address the wide variety of concerns. Fuller discussion can be found in Section 6.2 above.

6.4.4.1.2.3 Algonquins of Ontario

The NSDF Project occurs within the unceded AOO Settlement Area, subject to AOO's Land Claim, where negotiations with the Crown have occurred since 1991 (see Figure 4 in Appendix 5.9-1).

As part of a submission to the CNSC for a 10-year renewal of the Nuclear Research and Test Establishment Operating Licence for the CRL (Commission Member Document 18-H2.51), the AOO identified that it asserts unextinguished and constitutionally protected Aboriginal rights and title to a traditional territory in Eastern Ontario (referred to as the "Settlement Area") and is currently in negotiations towards a modern day treaty with the governments of Ontario and Canada. The NSDF Project occurs within the Settlement Area. The Settlement Area includes 36,000 km^2 within the watersheds of the Kichi-Sìbì (Ottawa River) and the Mattawa River. This area is the traditional territory of the AOO, composed of 10 Algonquin communities—the Algonquins of Pikwakanagan First Nation, Antoine, Kijicho Manito Madaouskarini (Bancroft), Bonnechere, Greater Golden Lake, Mattawa/ North Bay, Ottawa, Shabot Obaadjiwan (Sharbot Lake), Snimikobi (Ardoch) and Whitney and Area—and it is recognized that AOO citizens continue to practise traditional land use activities throughout this region. Algonquin traditional use has occurred for a very long period of time. In the *Aboriginal Background Information Report* to the Forest Management Plan for the Ottawa Valley Forest 2011 to 2021, it was indicated that:

> *Since the 1700s the Algonquins were known to spend the majority of the year occupying the different parts of the Ottawa Valley, hunting, fishing, trapping and gathering among other things. These activities necessitated use of timber and other resources.* (Ottawa Valley Forest 2011a)

The AOO website describes the importance of traditional harvest:

> *The harvesting of flora and fauna for food and trade has been integral to the Algonquin way of life since time immemorial. These practices embody an inherent respect for the environment and a fundamental commitment to the sustainable management of resources, which has been passed from generation to generation.*

> *The rights of Indigenous Peoples in Canada to engage in traditional activities, including the harvesting of wildlife, fish, migratory birds and plants, is recognized by the Constitution Act, 1982 and upheld by the Supreme Court of Canada. As stewards of our ancestral lands, the AOO recognize the importance of exercising this right in a responsible manner.* (AOO 2016)

The AOO has further re-iterated the importance of traditional harvest in its Agreement-in-Principle with the Governments of Ontario and Canada. In Chapter 8, it is indicated that:

> *The Final Agreement will provide that Beneficiaries have the right to Harvest Fish, Wildlife, Migratory Birds and Plants for Domestic Purposes throughout the year within the Settlement Area as further described in this Chapter*. (AOO, Government of Ontario, Government of Canada 2016)

As indicated in the quotation above, the intent of such harvest is for subsistence/community use purposes and not for commercial purposes (AOO 2016). It is likely that Indigenous Peoples and possibly the ancestors of the modern day Algonquins living in the Ottawa Valley undertook traditional activities, such as hunting, which would have likely included lands that are currently under federal government control. Archaeological investigations for the NSDF Project have discovered artifacts from CaGi-40, an Early Archaic Period site (i.e., 6,000 to 10,000 years before present; Swayze and Cameron 2016).

Traditional land and resource use knowledge for the AOO is primarily derived from the December 2020 released AKLUS (SVS, AOO, 2020). Twenty (20) individuals participated in the AOO AKLUS, including 16 interviewees from the Algonquin communities of Greater Golden Lake, Kijicho Manito Madousakarini, Mattawa/North Bay, Ottawa and Sinimikobi, and two interviewees from the AOPFN. The AOO AKLUS also included the participation of two non-Algonquin Knowledge Holders, who are not Indigenous rights-holders, but hold a deep understanding of Algonquin knowledge and values and have a strong relationship with the AOO. The Algonquin communities of Bonnechere and Whitney and Area signed on in support of the NSDF Project but were unable to participate in data collection. The total sample size of the AKLUS is small given the number of AOO members.

CNL recognizes that this survey of members just represented a sample of traditional use in the study area and that this must be viewed as a “snapshot” with the understanding that absence of data does not equate to absence of Algonquin land use and values in a certain location (AOO, SVS, 2020).

The AOO AKLUS indicates that the methodology used by the joint AOO and SVS research team is based on the best practices of Terry Tobias in his manual, *Living Proof: The Essential Data Collection Guide for Indigenous Use and Occupancy Map Surveys*.

The goal of the study was documented as:

> *The goal of the Study was to collect specific land use and occupancy data and Algonquin knowledge to determine how and where the NPD and NSDF projects will intersect and impact Algonquin use and occupancy. The research team collected this data through map biography and semi-structured interviews with Algonquin elders, land users, harvesters and Knowledge holders. (AOO, SVS, 2020).*

The temporal scope of the study included both historic (includes information participants know about through teaching or knowledge transfer from past generations, including oral history) and current (anything that occurred in a participant’s lifetime) use. The geographical study area for the AOO AKLUS was a 25 kilometer radius from the NSDF and an additional 5 kilometer radius further downstream on the Kichi-Sìbì (Ottawa River). The temporal

scope of the study was for current and historic use. The high importance of the Kichi-Sìbì to the Algonquin people is well described in the AOO AKLUS report.

Concerns about the proposed NSDF Project were documented in the Report and formalized into a series of comments and recommendations that CNL has formally responded to. Participants expressed general concerns related to the loss of connection to, and use of the lands and water, the proximity of the NSDF Project to the Kichi-Sìbì, contamination of country foods, bioaccumulation of contaminants in important species, threats to species at risk such as lake sturgeon and American eel, as well as the safety of the harvest, access to cultural sites, the archaeological potential of the area and the flow of information to the AOO.

The AKLUS also included sections on Algonquin history and the archaeological assessment that occurred as a part of the NSDF Project.

6.4.4.1.2.4 Métis Nation of Ontario

The NSDF Project also occurs within the Mattawa/Lake Nipissing Traditional Harvesting Territory for the MNO Mattawa Métis Council, North Bay Métis Council and Sudbury Métis Council (MNO 2017, no date), which is part of MNO Region 5. The MNO has indicated that the CRL site occurs on the border of Region 5 and Region 6. Use of the area around the CRL site by other Indigenous Peoples is not certain.

The MNO recently completed a TKLUS (KnowHistory 2019) that was undertaken specifically for the NSDF and NPD projects through funding supplied by the CNSC. The study area used in the TKLUS included a 50 km radius from the NPD and NSDF projects but documented use beyond that radius. While the study only involved 11 participants it did document significant use within its study area. Because the study only involved 11 participants, though, the results should not be taken as the only land uses by MNO citizens in the region.

While best efforts were taken to ensure that the TKLUS was representative of Métis land use, it should be remembered that the study area included a small number of participants and was restricted both due to capacity and by a backlog in the citizenship review process at the MNO registry. Additionally, some Métis Citizens practice avoidance behaviour and do not harvest in the area surrounding the proposed NSDF Project due to concerns about plant and animal contamination.

6.4.4.1.2.5 Williams Treaties First Nations and AANTC

Engagements with the WTFN and AANTC communities have verbally indicated traditional use also occurs near the CRL site. CNL continues to engage these communities on more exact formal indications of traditional use.

6.4.4.1.2.6 Trapping

Trapping in Ontario occurs on licensed traplines administered by the Ministry of Natural Resources and Forestry, as described in Section 5.9.4.1.3.4. There are approximately 50 licensed trapline areas in the Ottawa Valley Forest, which is slightly over 800,000 ha (Ottawa Valley Forest 2011a). The trapping of fur-bearing animals is a traditional and modern day land and resource use activity practised by Indigenous Peoples in the Ottawa Valley.

Trapping is one resource-based activity that has both a traditional and commercial aspect to it. Most Indigenous trappers trap for personal and cultural reasons as well as for the financial benefit of selling the furs.

The right to trap fur-bearing animals is outlined in Section 8.3.24 of the AOO Agreement-in-Principle (AOO, Government of Ontario, Government of Canada 2016). The inclusion of such a section indicates the importance of trapping as a cultural activity to the AOO. Targeted species include (but are not limited to) beaver (*Castor canadensis*), fisher (*Martes pennant*) and marten (*Martes Americana*) (Ottawa Valley Forest 2011b).

CNL has assumed that trapping is likely occurring on provincial land in the Ottawa Valley Forest and/or the nearby Algonquin Park Forest by Algonquins.

The AOO AKLUS did not identify any trapping or snaring by Algonquins immediately adjacent to the CRL site but did identify some non-commercial trapping for rabbits south and west of the CRL site (SVS, AOO 2020).

No trapping or snaring was identified in the quantitative data in the AOPFN AKLUS study area (SVS, AOPFN, 2020). However, qualitative data in the AOPFN AKLUS identified trapping as important historically and today within the RSA at minimum and possibly closer. CNL is also aware that AOPFN members trap in other areas within the traditional territory of the community.

As the AKLUSs are just a survey of a sample of Algonquins, it is possible that there are individuals who are trapping closer to the CRL site. As well, there are most certainly Algonquins that trap beyond the 25 kilometer study limit identified in the AKLUS.

In the MNO TKLUS it was identified that trapping has been a foundational element of Métis way of life and land use since the genesis of the Métis (KnowHistory 2019). Of the 11 participants in the MNO TKLUS, 7 reported participation in trapping although none had trapped within the 50 km study area.

The SSA, LSA and RSA all overlap the PE002 trapline area. Trapline areas PE025 and PE024 also overlap the western section of the RSA. While trapping is prohibited in the LSA and most areas of the RSA due to restricted public access within the CRL site boundary (see Figure 5.9.4-1)[5], results of consultation and engagement have identified that there may be some limited trapping activities at the southern portion of the RSA, beyond the CRL site boundary, on the Garrison Petawawa property. Engagement with all Indigenous communities to the end of May 2021 has not resulted in the identification of any Indigenous trappers operating within the RSA.

6.4.4.1.2.7 Hunting

Hunting is a popular activity in the Ottawa Valley Forest (Ottawa Valley Forest 2011a), and hunting continues to be practiced by Indigenous Peoples in the Ottawa Valley (the Ottawa Valley Forest is the provincial Crown land that surrounds the CRL site). Hunting today includes moose (*Alces alces*), elk (*Cervus canadensis*), white-tailed deer *(Odocoileus virginianus),* small game and waterfowl. Hunting in the both the AOO and the AOPFN AKLUSs is generally described as a “Wildlife Harvesting Area”. The AOO and the AOPFN AKLUSs confirmed that the targeted species were primarily moose and deer (also referred to as monz and wawashkeshi in the AOPFN AKLUS) but also included small game such as grouse, partridge, bears, frogs and rabbits (SVS, AOO, 2020; SVS, AOPFN 2020).

As indicated in the AOO and the AOPFN AKLUSs, harvesting activities such as hunting or fishing hold great significance for the Algonquins beyond the activity or sport:

> *harvesting for many participants is not about the sport of hunting or fishing, it is a way of life that provides an opportunity to apply teachings from Elders, put healthy and culturally important foods on the table, connect with the spirit of ancestors and reap what the Creator has graciously provided to the Algonquin people. (SVS, AOPFN 2020, p. 52; SVS, AOO, 2020, p. 60).*

The AOO (which includes the AOPFN) prepares an annual Algonquin Harvest Management Plan specifically to address the hunting of larger game including moose, elk and deer (AOO 2016). The harvesting of wildlife is

[5] It is noted that CNL contracts a trapper for managing nuisance beavers on the CRL site.

outlined in Section 8.3 of the AOO Agreement-in-Principle (AOO, Government of Ontario, Government of Canada 2016). The inclusion of such a section indicates the importance of hunting as a cultural activity to the AOO. As described in Section 5.9.4.1.3.3, the RSA overlaps wildlife management unit (WMU) 48. Targets for moose have been identified for Algonquin harvest in WMU 48 (AOO 2016). While there is no elk harvest in this WMU, it is expected that there is likely harvest of deer, small game and waterfowl in this management unit.

Seven of the eleven participants in the MNO TKLUS have hunted within the MNO TKLUS 50 km study area, although the mapping demonstrates that most of the use is in the Deux-Rivières area, close to 40 km west of the CRL site (see Figure 3, KnowHistory 2019). The harvest included both large and small game including moose, partridge, grouse, rabbit, deer, duck and goose (KnowHistory 2019). It should be noted that while the TKLUS study did not appear to document any use within 10 km of the CRL site, there could be MNO citizens that hunt closer to the CRL site.

According to the AOO AKLUS, wildlife harvesting was carried out extensively within the AKLUS study area (SVS, AOO, 2020). Wildlife harvesting was reported in and around Algonquin Park. The AOPFN AKLUS demonstrates very extensive hunting northwest, west and southwest of the CRL and further west well into Algonquin Park (which is the western limit of the AKLUS study area) (SVS, AOPFN, 2020). The LSA is restricted to the CRL site, where hunting is prohibited. Therefore, there is no traditional hunting occurring in the SSA or LSA.

While no Indigenous community or organization has indicated that it is harvesting specifically within the RSA, it is likely that there has been traditional hunting in the RSA and hunting has or is occurring very close to the RSA. It is possible that there is waterfowl hunting along the Ottawa River shoreline of the CRL site and Garrison Petawawa property. Hunting for waterfowl in Ontario commonly occurs along waterways, and there are no restrictions preventing an individual from hunting along the Ottawa River. Therefore, it seems reasonable that Indigenous Peoples from any and all of the Indigenous organizations and communities may hunt waterfowl along the Ottawa River. On the Ontario side of the Ottawa River, most of the RSA is occupied by the CRL site, Garrison Petawawa and private land, with only a few isolated parcels of Crown land. Therefore, it is likely that traditional hunting on the Ontario side of the RSA is quite limited, which the MNO TKLUS demonstrates (there was no identified hunting in the RSA). However, it is possible that hunting still occurs on Crown or private land (hunting on private land is subject to landowner permission) but that specific locations are not known or not revealed to their communities or organizations.

Results from the AOO AKLUS would suggest that closer to CRL, hunting for mammals occurred surrounding the CRL site (SVS, AOO, 2020). Again, that hunting cannot occur within the CRL site or Garrison Petawawa and only by permission on private land. Results from the AOPFN AKLUS indicates hunting in the RSA immediately west and northwest of the CRL property for both deer and moose (SVS, AOPFN, 2020).

On the Quebec side of the Ottawa River, the area is fairly remote (i.e., limited road infrastructure and not easy to get access to) but could be used for traditional hunting. Both the MNO and the AOO have agreements on hunting with the Ontario Ministry of Natural Resources and Forests which suggest the majority of their hunting occurs on the Ontario side of the Ottawa River.

6.4.4.1.2.8 Fishing

The importance of the Kichi-Sìbì (Ottawa River) as a major travel and transportation corridor and its overall ecological and cultural importance was mentioned by multiple Indigenous communities. Both the AOO and the AOPFN AKLUSs identify the Kichi-Sìbì (Ottawa River) as a major water travel route for Algonquin peoples. Fishing is a traditional and modern day land and resource activity practiced by Indigenous Peoples in the

Ottawa Valley. The Kichi-Sìbì (Ottawa River) was and is still used for sport and subsistence fishing. Fish species traditionally targeted would have likely included the same type of sport and subsistence fish that occur today such as Walleye (*Sander vitreus)*, Smallmouth Bass (*Micropterus dolomieu)* and Northern Pike (*Esox lucius)* (SENES 2010). Historically, Lake Sturgeon (*Acipenser fulvescens*), Suckers (*Catostomidae* spp.) and American Eel (*Anguilla rostrate*) would have also likely been harvested. Along with these species, the AOO and the AOPFN AKLUSs also identified the following other species that have been harvested including: yellow perch (*Perca flavescens*), catfish (*Ameiurus* spp.) and speckled trout (*Salvelinus fontinalis**)***, lake trout (*Salvelinus namaycush*), burbot (*Lota* sp.) and muskellunge (*Esox masquinongy*). The AOPFN AKLUS specifically mapped fishing areas for Bass, Lake Trout and Walleye (SVS, AOPFN, 2020). But along with those three species the importance of other species was noted: Brook Trout (also known as Speckled Trout), Burbot, Catfish, Chub, Jackfish/Northern Pike, Lake Sturgeon, Lake Whitefish, Mud Pout (or Brown Bullhead), Muskellunge, Sucker, Sunfish and Yellow Perch. Baitfish were also noted to be important, but the species of baitfish weren't identified. The Report also identified the importance of Kichi-Sìbì (Ottawa River) to the AOPFN for cultural and historic reasons but also for traditional use including fishing as well as mentioning the importance of spawning grounds (SVS, AOPFN, 2020).

The AOO AKLUS mapped fishing areas for Bass, Brook Trout, Catfish, Mudpout, Jackfish/Northern Pike, Lake Sturgeon, Muskellunge, Pickerel/Walleye, Speckled Trout and Yellow Perch (SVS, AOO, 2020). Along with those species the AOO AKLUS noted the importance of both American Eel, Burbot and Chub as well.

The harvesting of fish is outlined in Section 8.2 of the AOO Agreement-in-Principle (AOO, Government of Ontario, Government of Canada 2016). The inclusion of such a section indicates the importance of fishing as a cultural activity to the AOO.

Eight of the eleven participants in the MNO TKLUS have fished in the 50 km study area identified in the KnowHistory (2019) study. This included fishing on the Kichi-Sìbì (Ottawa River) north of Rolphton. There was also other MNO fishing in the study in waterbodies to the west of Kichi-Sìbì (Ottawa River) towards Algonquin Park. Fish species harvested in the MNO study included Walleye, Trout, Bass, Northern Pike and Lake Sturgeon. It was also noted that 3 of the 11 participants participated in a commercial sturgeon fishery as children. It is unclear based on the mapping on Figure 5 of the KnowHistory (2019) study where that fishing occurred, but again there is no fishing reported within 10 km of the CRL site. It should be noted that there is no longer a commercial sturgeon fishery on the Kichi-Sìbì (Ottawa River).

The AOO AKLUS reported fishing in various areas throughout the AKLUS study area and specifically fishing in the Kichi-Sìbì (Ottawa River). The AOPFN AKLUS reported fairly limited fishing in the AKLUS study area but did report fishing on the Kichi-Sìbì (Ottawa River) in close proximity to the CRL (SVS, AOO, 2020).

The AOPFN AKLUS also reported fishing in the AKLUS study area and on the Kichi-Sìbì (Ottawa River) in close proximity to the CRL (SVS, AOPFN, 2020).

The LSA and SSA fall within federal lands with restricted access, and fishing within the CRL site is prohibited. Therefore, traditional fishing is not occurring in these areas and has likely not since prior to control of the CRL site by the federal government.

While Indigenous Peoples in the Ottawa Valley likely fish in many lakes and rivers throughout the Ottawa Valley, they also fish in the Kichi-Sìbì (Ottawa River) as there are a diversity of fish species and many access points to the River.

The AOPFN AKLUS reported fishing in the RSA (SVS, AOPFN, 2020). The AOO AKLUS also reported fishing in the RSA (SVS, AOO, 2020).

Indigenous Peoples maintain some commercial fish licenses for inland waters in Ontario. However, there is currently no commercial fishery on the Kichi-Sìbì (Ottawa River). Historically, there likely was a commercial sturgeon fishery on the Kichi-Sìbì (Ottawa River) and members of the MNO in their TKLUS indicated that they had historically participated in a commercial fishery (KnowHistory 2019).

Indigenous individuals may also own and operate resource-based tourism establishments such as sport fishing or other water based tourism industries hunting or eco-tourism. Such commercial tourism activities, to CNL's understanding, would not be rights based but could be operated by Indigenous Peoples. CNL is unaware of any such enterprises operating in the study areas but it is possible.

6.4.4.1.2.9 Gathering

Gathering is a traditional and modern day land and resource use activity practised by Indigenous Peoples in the Ottawa Valley. The gathering of plants, berries and mushrooms is and has been conducted for subsistence, medicines, crafts and other purposes. Gathering activities can also have a commercial component to them. The most common example of this is blueberry picking. Other gathering activities that might have a commercial component to them such as gathering other plant materials for food or craft use. In engagement sessions, documentation, and as demonstrated through the AOO AKLUS has documented the importance of large birch trees for canoe building.

The AOO (including the AOPFN) has indicated the importance of traditional harvest in its Agreement-in-Principle with the Governments of Ontario and Canada. In Chapter 8, it is indicated that: "The Final Agreement will provide that Beneficiaries have the right to Harvest Fish, Wildlife, Migratory Birds and Plants for Domestic Purposes throughout the year within the Settlement Area as further described in this Chapter." (AOO, Government of Ontario, Government of Canada 2016). This would include all Crown lands within the Settlement Area.

The harvesting of plants is outlined in Section 8.5 of the AOO Agreement-in-Principle (AOO, Government of Ontario, Government of Canada 2016).

The AOO AKLUS identified plant and natural material gathering areas and also documented their importance with respect to them not only as food items but also their importance as medicines and for ceremonial reasons. The plants collected included the following: balsam fir, blueberries, cranberries, blackberries, strawberries, thorn apple, sumac, white pine, pearly everlasting, sphagnum moss, wintergreen, etc. (SVS, AOO 2020).

The harvesting of plants by the AOPFN is recognized as a benefit not only in terms of the provision of food but also for medicinal reasons. As well, many of the plants are important for cultural use in terms of ceremonies. The AOPFN AKLUS report demonstrates that there are Algonquin species of importance surrounding the proposed project (SVS, AOPFN 2020).

Both the AOO and the AOPFN AKLUSs documented gathering within the 25 kilometer study area. Gathering in the AOO AKLUS was reported close to the NSDF/CRL site and along the Trans-Canada Highway. The AOPFN documented gathering as close as the Deep River area. Other gathering was reported along the Highway 17 corridor.

The MNO TKLUS documented that the collection of plants, berries, wood and other natural materials is a practice associated with both historical and modern day Métis communities (KnowHistory 2019). Four of the eleven participants in the MNO TKLUS documented collecting and gathering activities within the 50 km study area. The study noted that gathering can be the main reason for a trip or be a secondary reason. The MNO harvesting in this 50 km study area is generally located closer to Deux-Rivières, but there is harvesting closer to the CRL site as it appears harvesting has occurred along and near the Highway 17 corridor. Some of the plant material that was and is gathered includes berries and fruit (raspberries, blueberries, choke cherries); maple syrup; fiddleheads; medicinal plants; tea plants; and materials for crafts and canoe making. Some gathering activities require a wide diversity of plant species for medicinal purposes, tea making and canoe building.

Gathering is an activity that provides important links to cultural continuity and traditional way of life as well as teaching youth about plants and medicinal use. The SSA and the LSA are located within the CRL site and gathering in this area would be prohibited by CNL. Gathering could occur within the RSA. It is possible there may be some gathering along the shoreline of the Kichi-Sìbì (Ottawa River), adjacent to the CRL site. Indigenous Peoples may collect plants and other materials on Crown lands and public waterways without restrictions. There also could be some gathering activities on Crown or private land within the RSA. Both the AOO and the AOPFN documented gathering activities either in or close to the RSA. Both the AKLUSs and the MNOs TKLUS document harvesting in close proximity to the Highway 17 corridor.

6.4.4.1.2.10 Cultural Resources and Ceremonies

Indigenous Peoples place a high degree of value on specific sites of cultural, historical, spiritual, social or ecological significance. These sites may have broader cultural significance related to the practice of formal or informal ceremonies at or near these sites. As previously indicated, the AOPFN, AOO and MNO have all communicated the importance of the Kichi-Sìbì (Ottawa River) to their communities, and without question Algonquin communities on the Quebec side of the river have a similar perspective.

In the MNO TKLUS, interviewees have expressed an important spiritual and cultural connection to the Kichi-Sìbì (Ottawa River) corridor (KnowHistory 2019):

> *Interviewees reported feeling a spiritual and cultural connection to the Ottawa River corridor. They attributed this feeling to their family being present in this area for generations and the historic connection between the Ottawa River and the fur trade. Many participants shared stories about their ancestors which have been passed down from the 19th century. The historic travel routes, burial grounds, religious sites, and gathering places associated with these stories strengthen links to their Métis heritage.* (KnowHistory 2019)

The AOO AKLUS documents locations of culturally and/or historically significant sites and refers to them as Algonquin Cultural Sites (SVS, AOO 2020).

The AOPFN AKLUS also mapped historically significant sites, historic family or village sites and spiritual, ceremonial or sacred sites (SVS, AOPFN, 2020). Both the AOPFN and the AOO AKLUSs document a significant number of culturally important sites to them through the study areas of the AKLUSs. The AOPFN have also documented the high degree of importance of cultural sites immediately adjacent and near to the CRL site (AOPFN 2021).

There is one known site of significance adjacent to the CRL site, the Pointe au Baptême site. According to historical records and information gathered through the AOO AKLUS, this sandy spit was where the Voyageurs baptized new members and where local Algonquin camped frequently in the early 20th century. According to a

local informant, there is a cemetery at the base of the peninsula. Archaeological site CaGi-7 was revisited in 2007 to record historical Wallace Cottage features and to mark the suspected cemetery with an ornamental fence. Pre-contact stone artifacts have been reported over the years from eroded parts of the site as well (Swayze and Cameron 2016).

Both the AOO and the AOPFN AKLUS Reports (SVS, AOO, 2020; SVS, AOPFN, 2020) identified the importance of both Pointe Au Baptême and Oiseau Rock (which is across the River on the Quebec side) as important cultural sites immediately adjacent and near to the CRL site. Given its importance to the Algonquins both historically and culturally, AKLUS participants expressed concerns surrounding their ability to continue to access and protect these sites.

Pointe au Baptême has a high management priority rating due to its historical association and the reported human burials (Kinickinick Heritage Consulting and Cameron Heritage Consulting Inc. 2018). It is of interest to the Algonquin and Métis communities and has a view of Oiseau Rock across the Ottawa River, which is a sacred pictograph site. Pointe au Baptême has been previously disturbed by an access road turn around (Swayze and Cameron 2016).

Given this information on the Pointe au Baptême site, it is of cultural significance to Indigenous Peoples and there are cultural activities associated with it. The Pointe au Baptême site is not within the footprint of the NSDF Project, but is within the RSA.

6.4.5 Project Interactions and Mitigation

6.4.5.1 Methods

This section describes the process by which interactions between NSDF Project components and activities and traditional land and resource use were identified and evaluated. Potential effects pathways are identified and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the NSDF Project and the environment by evaluating the different effects pathways to determine if, after incorporation of mitigation, there is still potential for residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment. As such, the “Project Interactions and Mitigations” section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all phases of the NSDF Project. The next step in the analysis was the development of environmental design features and mitigation that could be incorporated into the NSDF Project to eliminate and/or reduce effects to traditional land and resource use. Environmental design features included NSDF Project design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the Project’s engineering and environmental teams, combined with input from Project-specific or regional engagement with other interested parties. The environmental design features and/or mitigation activities were selected considering their effectiveness for implementation and maintenance and their appropriateness within the context of the identified effects pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific and traditional knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation:

- **No linkage:** The pathway is removed by environmental design features or mitigation such that the NSDF Project would not be expected to result in a measurable environmental change relative to Base Case values and therefore would have no residual effects on traditional land and resource use.
- **Secondary pathway:** The pathway could result in a measurable minor change, but would have a negligible residual effect on traditional land and resource use relative to Base Case values and is not expected to contribute cumulatively to other Project effects or to the effects of other previous, existing or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway:** The pathway is likely to result in an environmental change relative to the Base Case that could contribute to residual effects on traditional land and resource use.

Environmental design features and measures that could be incorporated into the NSDF Project to eliminate and/or reduce adverse effects were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to traditional land and resource use through quantitative and qualitative evaluation of the pathway were also not advanced for further assessment. If identified, primary pathways were carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the NSDF Project.

6.4.5.2 Results

Pathways through which all phases of the NSDF Project may interact with and result in changes to measurement indicators for traditional land and resource use are provided in Table 6.4.4-1. Environmental design features and management policies implemented to reduce potential effects are also described.

CNL has made a significant effort to engage with Indigenous Peoples and to understand their perspectives on possible effects pathways that could affect traditional land and resource use. Three particular concerns are raised here in order to improve the understanding and transparency with respect to traditional land and resource use project interactions and mitigation.

First, as previously indicated, Indigenous communities in proximity to the CRL site have expressed concerns with respect to the perceptions that their harvesters have with regarding contamination associated with the CRL site. These Indigenous communities have indicated that these perceptions can lead harvesters to: avoiding particular areas; feelings of alienation from particular lands and/or consuming less traditional foods than they normally would in particular areas. Engagement with these Indigenous communities and their traditional knowledge and land use studies do not demonstrate that complete avoidance is occurring, but concerns of safety and risk are prevalent. CNL does recognize its obligation to continue to work with Indigenous communities in addressing such concerns through commitments made to Indigenous communities, including awareness of actual risk through engagement activities and involvement in environmental monitoring. This is discussed more in Section 6.4.6 (Monitoring and Follow-Up).

Second, Indigenous communities have raised concerns about the potential loss of habitat and how the potential loss of habitat could affect traditional use. The loss of habitat is not considered directly within the traditional land and resource use VC but is evaluated as part of the assessment with respect to the aquatic and terrestrial

environment components (Sections 5.5 and 5.6 respectively). Mitigations to offset habitat loss have been proposed by CNL, which results in no significant impact for the aquatic and terrestrial environment, thus resulting no linkage to traditional land and resource use.

Third, an area of concern raised by Indigenous communities in proximity to the CRL site related to sensory perception including noise, air, and aesthetic effects. The concern expressed is that these sensory or nuisance effects generated from the NSDF Project could result in off-site effects that disturb traditional use. Project activities that lead to changes in air quality, ambient noise and visual disturbance are considered in Section 5.10 (Socio-economic Environment), as the valued component quality of life. CNL has proposed mitigations measures to eliminate and/or reduce such effects resulting in no linkage to traditional land and resource use.

Table 6.4.5-1: Pathways Analysis for the Traditional Land and Resource Use Valued Components

Project Activity	Valued Component	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Construction, operations, closure, post-closure (institutional control)	Traditional land and resource use by Indigenous Peoples – trapping	There could be changes in access to trapping activities or quality and quantity of trapping activities.	▪ Access to the LSA and CRL site is restricted; therefore, there are no trapping activities undertaken within the LSA or within the CRL site outside of the LSA. ▪ There is potential trapping identified in the southern portion of the RSA in the Garrison Petawawa property and two trapline areas in the western portion of the RSA. To date, these have not been identified as traplines belonging to Indigenous Peoples. ▪ While terrestrial effects are limited to the CRL site, which is restricted access, CNL will work to consult with the trappers to understand any concerns should they be raised. ▪ The RSA has been expanded to include a reach of the Ottawa River extending 8 km downstream of CRL where trapping of aquatic species may take place. Results of the aquatic environment assessment (Section 5.5) identify that measurable residual effects on aquatic biodiversity VCs are not predicted as a result of the NSDF Project. Therefore, trapping of aquatic species will not be affected by the NSDF Project.	Secondary

Construction, operations, closure, post-closure	Traditional land and resource use by Indigenous Peoples – cultural resources and ceremonies	There could be changes in access to cultural resources for ceremonial purposes. There could be changes to the quality of activities associated with these sites.	▪ CNL does not restrict access to Pointe au Baptême which is adjacent to but not on CRL property. ▪ Access to Pointe au Baptême is publicly accessible via the Ottawa River. ▪ Visual/aesthetic concerns are addressed through the sensitive location of the NSDF facility so that it is not visible to traditional use outside of CRL. ▪ Ecological health and sensory off-site effects on traditional use (e.g., noise and odour) will be protected through implementation of mitigation including: ▪ CNL's procedure for Management and Monitoring of Emissions, which includes operational control monitoring and verification monitoring. ▪ Basing the strategy for wastewater treatment on optimizing public and environmental protection by defining an approach to wastewater treatment that uses the best available technology that is economically achievable and capable of meeting regulatory requirements.	No Linkage

LSA = Local Study Area; RSA = Regional Study Area; VC = valued component.

6.4.5.2.1 No Linkage Pathways

The following pathway was assessed as having no measurable environmental change and hence, no linkage to residual effects on traditional land and resource use VCs during construction, operations and post-closure phase.

- **Changes in access to or the quality and quantity of traditional land and resource use activities – hunting, fishing (including commercial and tourism based), gathering and cultural ceremonies (except trapping)**

There are no traditional land and resource use activities occurring in either the SSA or LSA as this is a restricted public access area. Traditional land and resource use activities likely did occur prior to federal control of the CRL site. Effects to wildlife and vegetation by the NSDF Project are limited to the CRL site where access is restricted; therefore, no hunting or gathering activities will be affected by the NSDF Project. Any potential sensory effects on traditional use outside of the CRL boundary are expected to be negligible as CNL will have in place a series of management actions and mitigations to control for effects such as noise and odour. As well, the proposed NSDF Project will not be visible from outside the CRL boundary.

The RSA extends 8 km downstream of the CRL site where fishing may take place. There are no known commercial fishing licences in the Ottawa River. The results of the aquatic environment assessment (Section 5.5) identify that measurable residual effects on aquatic biodiversity VCs are not predicted as a result of the NSDF Project. Therefore, fishing will not be affected by the NSDF Project. The aquatic and terrestrial environment assessments also consider conclusions of the ecological health assessment (Section 5.7).

The ecological health assessment found no significant residual effects to terrestrial or aquatic species through potential radiological dose and exposure to non-radiological indicator compounds through operations, closure and post-closure of the NSDF. Results of the radiological dose assessment for the operations and closure phase and post-closure phase indicates that doses to ecological health VCs are below their respective benchmark values. The predicted non-radiological concentrations in surface water during operations were less than the selected guidelines for most non-radiological parameters, although some predicted concentrations were greater than their guidelines for some scenarios. However, with the exception of selenium, predicted concentrations did not exceed local ambient concentrations in surface waterbodies. Selenium concentrations were less than the US EPA guidelines for protection of aquatic life and therefore are predicted to not result in adverse effects on aquatic life.

Traditional access to the Pointe au Baptême site along the Ottawa River will continue to occur and will not be restricted due to the NSDF Project. As described in Section 5.9.5.2.1, there are no effects anticipated to archaeological resources as mitigation for archaeological resources is applied and completed in advance of ground disturbance activities. Further, based on the archaeological assessments completed to date, potential archaeological sites within the SSA have been fully excavated and documented to the extent required under the Standards and Guidelines (OMTC 2011). No cultural heritage value or interest remains and the locations have been fully documented and the information is preserved for future study; therefore, no further archaeological work was recommended for the NSDF Project. Should previously undocumented archaeological resources be discovered, CNL will suspend construction immediately and will engage a licensed consultant to carry out archaeological fieldwork, in compliance with Sec. 48 (1) of the *Ontario Heritage Act*. If any human remains are identified during construction, CNL will immediately notify the police or coroner and the Registrar of Cemeteries, Ministry of Small Business and Consumer Services, and Indigenous communities or organizations. CNL will work with each Indigenous community that is interested on a chance find procedure should any artifacts be identified during construction.

The Comprehensive Preliminary Decommissioning Plan (CPDP) for the CRL site recognizes that the CRL site will be maintained under institutional control for at least 300 years. Where the continued land use designation of the LSA during post-closure is as a monitored site with restricted access, the presence of the NSDF will continue to be aligned, with no pathway to affect other land uses within the SSA.

Overall, there are no anticipated residual effects on continued traditional land and resource opportunities related to hunting, fishing, gathering and cultural ceremonies. No further assessment or characterization of residual effects is undertaken for this VC. However, to address Indigenous Peoples concerns with regard: to perceived risks on the safety and quality of lands and waters currently utilized for traditional land and resource use activities; or with the effectiveness of environmental and cultural mitigation and monitoring measures considerations for monitoring and follow-up programs are provided in Section 6.4.6.

6.4.5.2.2 Secondary Pathways

Two secondary pathways were identified as having a linkage to the traditional land and resource use by Indigenous Peoples – trapping VC during construction, operations and post-closure phase. These secondary pathways have been identified for changes in access to or quality and quantity of trapping opportunities for land and resource users, including Indigenous Peoples.

- **Changes in access to traditional land and resource use – trapping**
- **Changes in the quality and quantity of traditional land and resource use – trapping**

The results of research identified that there may be a very limited amount of trapping occurring on Garrison Petawawa property; however, there is no evidence to date that these traplines are held by individuals from Indigenous communities. It is possible that a portion of the RSA extends into the Garrison Petawawa property, and trapline PE002 is located on the Garrison Petawawa property (see Figure 5.9.4-1). Also, two trapline areas (PE025 and PE024) are located in the western portion of the RSA. However, the NSDF Project is not predicted to have terrestrial effects beyond the CRL site, and results of the aquatic environment assessment (Section 5.5) identify that measurable residual effects on aquatic biodiversity VCs are not predicted as a result of the NSDF Project. Further, there is a substantial amount of Crown and private land available for trapping outside the CRL site but in the vicinity of the NSDF Project.

CNL will work with Garrison Petawawa to consult with trappers about their use of the Garrison Petawawa property for trapping activities. CNL will also consult with trappers in the western portion of the RSA to understand any concerns; however, given the distance from the NSDF Project and that terrestrial effects are limited to the CRL site, no effects to trapping in these areas are anticipated.

No further assessment or characterization of residual effects is undertaken for this VC.

- **Changes in access to in the quality and quantity of traditional land and resource use – hunting, trapping, fishing, or gathering**

As previously noted, there are no traditional land and resource use activities occurring presently in either the SSA or LSA as this is a restricted access area. Traditional land and resource use activities likely did occur within the LSA prior to federal control of the CRL site. Restricted access at the NSDF Project site will be maintained until the end of institutional control, after which access within this area may be re-established. This represents a potential beneficial change to access for any hunting, trapping, fishing or gathering resources that may occur at that time and become accessible. However, given the limited areas of the LSA (226 ha) or SSA (37 ha) that may become

accessible, this is anticipated to represent a negligible change to the total area within which traditional use is practiced. Access to fishing areas on the Ottawa River or traditional access to the Pointe au Baptême site along the Ottawa River will not be restricted due to the NSDF Project during any project phase.

Quality and quantity of hunting, trapping and fishing consider the health and well-being of people undertaking the activity, as well as ecological health. The effect of radiological and non-radiological releases on terrestrial and aquatic biota during the post-closure phase is assessed in the *Post-Closure Safety Assessment* (Arcadis and Quintessa 2020b) and the Ecological Risk Assessment (Arcadis 2020a), summarized in the assessment of effects of ambient radioactivity and ecological health in Section 5.7. No potential residual effects were identified for ambient radioactivity and ecological health during the post-closure phase. As well, the *Post-Closure Safety Assessment* (Arcadis and Quintessa 2020b) models potential effects of radiological and non-radiological releases on human health, using varying scenarios. Section 5.8 reports these findings as part of the assessment of effects to human health. One of the scenarios, detailed further in Section 6.6, included a Self Sufficient Indigenous Group receptor, selected to assess potential future effects of the NSDF Project assuming this group obtains all of their food through hunting, and gathering in the area, has increased consumption of fish and wild game and gathers local mushrooms and berries. Modelling (Arcadis and Quintessa 2020b) has demonstrated the results for Self Sufficient Indigenous Group receptor are below the acceptance criteria, and the modelled radiological dose is 13 times lower than the regulatory dose limit of 1 mSv/y. The highest exposure concentrations for chemical contaminants to human receptors, including the self sufficient Indigenous receptor group is below the relevant guidelines (Arcadis and Quintessa 2020b).

Any potential sensory effects on traditional use outside of the CRL boundary are expected to be negligible as CNL will have in place a series of management actions and mitigations to control for effects such as noise and odour. As well, the proposed NSDF Project is not visible from outside the CRL boundary.

As no residual effects were identified to the health of terrestrial or aquatic biota, or to the self sufficient Indigenous receptor group, no change to the quality of hunting, trapping or fishing activities during the post-closure phase is anticipated.

6.4.5.2.3 Primary Pathways

No pathways were identified as having a primary linkage to land and resource use VCs. Therefore, the assessment has concluded that no residual effects on traditional land and resource use are anticipated as a result of the NSDF Project. As such, a residual effects analysis and assessment of significance is not required for traditional land and resource use VCs.

6.4.6 Monitoring and Follow-up

Monitoring and follow-up programs are not specifically identified for traditional land and resource use; rather, monitoring for environmental pathways noted above (e.g., for air quality, surface water quality, groundwater quality and terrestrial biota) will be implemented to verify effects predictions for land and resource use, and to promote land user comfort around the safety of the LSA, RSA and surrounding areas for traditional land and resource use (i.e., to reduce perceptions of adverse NSDF Project effects on traditional land and resource use that are not anticipated to occur).

The AOPFN and MNO, have indicated that their citizens have negative perceptions associated with performing traditional activities (such as harvesting) near the CRL site. Some participants in the AOO AKLUS indicated concerns about contamination and the risks associated with harvesting and consuming foods from the area. For the different Indigenous communities and organizations, this may result in: individuals not using an area

(KnowHistory 2019) such as suggested in the MNO study or individuals harvesting less food in the immediate area or just promoting a feeling of discomfort or concern associated with contamination and risks (SVS, AOO, 2020; SVS, AOPFN, 2020). CNL's Public Information Program (CNL 2021b) and enhanced engagement with Indigenous Peoples is meant to address these negative perceptions by providing educational opportunities and sufficient factual information. CNL will continue to work with Indigenous communities and organizations to address any of these negative perceptions. This may also mean working with each of the communities to ensure that proposed management actions and mitigations are well understood and effective. There are varying levels of confidence in the effectiveness of the proposed mitigation measures and CNL is committed to working with each community uniquely to address outstanding concerns.

Monitoring to verify effects predictions will be on-going during operations, closure and post-closure (institutional control) phases, and the need for and duration of monitoring will be reviewed based on an annual review of monitoring data. This monitoring will be integrated into the CNL Environmental Monitoring Program.

As part of CNL's Public Information Program CNL will continue to engage with Indigenous communities, and share the results of the monitoring and follow-up programs recommended for air quality, surface water quality and groundwater quality data through an accessible format (e.g., NSDF Project website), a recognized best practice used by projects with high levels of perceived risk that may have the potential to alter or reduce land and resource use activity without primary or secondary pathways.

CNL has been carrying out discussions with some Indigenous communities on greater involvement by them in the environmental follow-up monitoring programs. CNL has carried out discussions with the AOO, the AOPFN and MNO on any future monitoring and their potential involvement. More detailed discussions of participation in monitoring for all CNL activities at the CRL site have occurred with the AOO and the AOPFN, but the specifics of such programs have not yet been decided upon. CNL is open to having ongoing discussions on this topic with Indigenous Peoples. Follow-up programs for archaeological resources are anticipated to be minimal as most mitigation for archaeological resources is applied and completed in advance of ground disturbance activities. Monitoring will be used to identify unanticipated archaeological resources and apply adaptive management through the implementation of the CNL Archaeological Master Plan (CNL 2008) and Cultural Resource Management Program. Should previously undocumented archaeological resources be discovered, CNL will suspend construction immediately and will engage a licensed consultant to carry out archaeological fieldwork, in compliance with Section 48(1) of the *Ontario Heritage Act*.

6.4.7 Conclusions

VCs refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous Peoples, or the public (The Agency 2018). Traditional land and resource use VCs were selected based on the potential for the NSDF Project to interact with the features of the land and resource use environment. In addition, VCs for traditional land and resource use were selected based on a consideration of knowledge of traditional land and resource use practices that interact with the environment, Indigenous and/or treaty rights and community engagement.

The NSDF Project SSA and LSA are located entirely within the CRL site boundary, on federal lands. Therefore, aside from the operations and activities undertaken by CNL, other land uses of the CRL site are prohibited due to restricted public access. The lands of the RSA also extend into Garrison Petawawa, other federal lands with restricted public access. As such, there are limited land and resource use tenures, other registered interests, or outdoor tourism and recreational areas occurring within the RSA that have the potential to be disturbed by the

NSDF Project. Land users have been identified as potentially trapping in the southern and western portions of the RSA, which overlaps the land and resource use RSA. However, the NSDF Project is not predicted to have any terrestrial effects beyond the CRL site, and results of the aquatic environment assessment identify that measurable residual effects on aquatic biodiversity VCs are not predicted as a result of the NSDF Project. Therefore, no effects on terrestrial or aquatic species defined as traditional land and resource use VCs are expected. Traditional access to the Pointe au Baptême site along the Ottawa River will continue to occur and not be restricted because of the NSDF Project. There are no effects anticipated to archaeological resources as most mitigation for archaeological resources is applied and completed in advance of ground disturbance activities. The Cultural Resource Management portion of the Environmental Protection Program will be used to identify unanticipated archaeological resources and implement adaptive management. Consequently, the NSDF Project is not expected to affect the traditional land and resource VCs.

6.5 Indigenous Health and Indigenous Receptor

Indigenous Peoples have expressed a general concern about the potential effect of the NSDF Project on their health. This has partially arisen from the view that they have a greater degree of reliance on foods obtained from traditional land and resource use than the general public.

There is no harvesting at the CRL site because it is restricted access and limited harvesting near or adjacent to the CRL site as there is little to no accessible land in the immediate area (see Section 6.4). No pathways were identified as having a primary linkage to traditional land and resource use VCs.

The hunter/recreational receptor within the Post-closure Safety Assessment (Arcadis and Quintessa 2020b) generally represents CNL's understanding of how Indigenous Peoples may interact with the site based on their current practices. This group is represented by a small number of adults and children making hunting and/or recreational use of the area surrounding the ECM, including Perch Creek and the Ottawa River. This group occasionally drinks water from the creek, and eats deer hunted from the site.

To address potential future safety concerns of Indigenous Peoples, as part the NSDF Post-closure Safety Assessment (Arcadis and Quintessa 2020b) a Self Sufficient Indigenous Group receptor was selected to assess potential future effects of the NSDF Project on such a group. This assessment addresses uncertainty in future lifestyle of Indigenous Peoples.

The Self Sufficient Indigenous Group receptor is defined as:

> *"a group of indigenous Peoples, including adults and children, using area surrounding the ECM, including Perch Creek and the Ottawa River, for hunting and gathering. Individuals in this group are assumed to obtain all of their food through hunting, and gathering in the area. It is assumed that this group would have increased consumption of fish and wild game. Furthermore, this group is assumed to gather local mushrooms and berries." (Arcadis and Quintessa 2020b)*

The exposure pathways for the Self Sufficient Indigenous Group are:

- drinking water from Perch Creek;
- ingestion of fish caught from the Ottawa River;

- groundshine (i.e., radiation from radioactive material on the ground), inhalation of dust and inadvertent consumption of soil from occasional use of the area between the ECM and Perch Creek, and while fishing from the river shore;
- hunting of game, such as deer, moose, duck and grouse, that uses the river and creek for drinking water and grazes the area between the ECM and Perch Creek; and
- foraging of wild honey, berries and mushrooms.

Therefore, the Self Sufficient Indigenous Group receptor is one in which the group is physically located at the NSDF site and relies completely on local food and water consumption in the future. As such, it represents an extreme or cautious future scenario.

Final modelling (Arcadis and Quintessa 2020b) has demonstrated the results for Self Sufficient Indigenous Group receptor are below the acceptance criteria. Radiological dose to the Self Sufficient Indigenous Group Receptor is 0.077 mSv/yr and occurs 520 years after closure. This dose is 13 times lower than the public dose limit of 1 mSv/yr.

6.6 Canadian Nuclear Laboratories' Long-term Relationship with Indigenous Peoples

In engagements with Indigenous communities, it is clear that Indigenous Peoples do not want to look at the NSDF Project solely in isolation from all other concerns and matters pertaining to the AECL properties in the Ottawa Valley and the CRL site specifically. Concerns raised by Indigenous communities and organizations engaged on the NSDF Project have included concerns associated with the historical take-up of the lands, long-term operations and future operations and scenarios. CNL respects and understands these opinions and has approached its Indigenous engagement in such a way as to answer and address some of these broader questions as well as engaging directly on the NSDF Project.

CNL has received input from different Indigenous communities and organizations that:

- Is NSDF project specific;
- Is or may be relevant to the NSDF Project but is also a concern or interest applicable to CRL site wide operations; or
- Is beyond the scope of the NSDF Project, as termed elsewhere in Section 6 to NSDF project and the proposed NSDF Project would have no impact on.

In responding to formal and informal comments CNL has provided a response to all interests and concerns but specifically notes whether an interest or concern is relevant to the NSDF Project or not.

Some of the CRL site wide concerns that have been raised by some Indigenous communities and organizations include general environmental concerns associated with CRL site wide operations and perceptions of fears or anxiety associated with traditional uses occurring adjacent to and near the CRL site.

There are also some specific concerns raised such as access to and impacts the NSDF Project may have on cultural sites such as Pointe au Baptême or Oiseau Rock. However, these cultural sites are not within the NSDF Project footprint thus the NSDF Project has no effect on either of these cultural sites. Furthermore, as these sites are not within the CRL site boundary, CNL does not restrict access to them either.

As part of this EIS and its engagement with Indigenous communities and organizations, CNL has been explicit as possible in indicating and demonstrating whether interests or concerns are related to the NSDF Project, what interests and concerns are CRL site wide, or what interests and concerns are beyond the scope of CNL. However, CNL recognizes that there is a complex history associated with the CRL site and there has been more limited engagement particularly with certain communities and organizations. As such, historical concerns have been raised by Indigenous communities as part of the NSDF Project and recorded by CNL even though they may not be pertinent. CNL and AECL are committed to engagement with interested Indigenous communities in examining some of the CRL site-wide and broader historical concerns. Moreover, in engaging in these broader conversations some of the solutions and mitigation measures that are being discussed will be more appropriately addressed and organized as corporate solutions. For example, a few of the Indigenous communities have recommended that an increased comfort with the NSDF Project and CRL site wide operations would be more achievable if they participated directly in environmental and cultural monitoring and stewardship activities. As such, while CNL can commit to involvement of Indigenous Peoples in the monitoring program associated with the NSDF Project, both CNL and the Indigenous communities see the benefit and efficiency in a consistent approach to monitoring for both NSDF and the CRL site in general. In fact, it is realized that an understanding of the broader CRL site wide monitoring program will facilitate the comprehension on the approach to environmental monitoring for the NSDF Project.

To this end, CNL is working towards developing long-term relationships with Indigenous Peoples that occupy and have traditional territories and modern day interests near its CRL site operations. CNL recognizes that such relationships may take a long time to form but believes this is consistent with the Government of Canada's approach to reconciliation with Indigenous Peoples.

CNL has been working closely with AECL on the approach to and activities with respect to Indigenous Peoples. AECL's roles and responsibilities on Indigenous engagement and consultation arise from it being a federal Crown corporation and agent of the Government of Canada. As well, AECL is the appropriate entity that can respond to Indigenous Peoples on questions surrounding the original take-up of the lands by the Crown, ownership of the lands and future uses of the land. AECL is committed to engaging with Indigenous Peoples in an open and cooperative way to work towards mutual understanding and opportunities for mutual benefit.

CNL and AECL has been in discussions with interested Indigenous communities and organizations and has signed MOUs with the MNO and AOO on developing longer-term relationships. CNL and AECL are currently working with the AOPFN on establishing an MOU. CNL is able to work with Indigenous Peoples on subject matters within the scope of its operations. This includes topics such as employment, contracting, engagement, cultural heritage and environmental monitoring as well as other interests and concerns. AECL's involvement is required on topics that relate to the property holdings and also out of the Crown's wider responsibilities with respect to Indigenous Peoples.

CNL is working closely with AECL and Indigenous communities on matters that reside more within AECL's responsibility. Engagement with Indigenous Peoples has demonstrated that these communities are also interested in fostering such long-term relationships. As such, CNL, AECL and the Indigenous communities see their relationships as evolving and beyond the scope of a single regulatory project such as the NSDF Project. Mechanisms will be built into any such formal or informal relationship agreement that show how specific NSDF Project concerns or commitments are to be addressed. For example, longer-term relationship agreements may discuss the topic of Indigenous participation in environmental monitoring, which may be both CRL site wide and/or NSDF Project specific. As well, CNL has moved forward on employment and contracting opportunities for the CRL

site in general which would also include the NSDF Project. CNL and AECL are of the opinion that such a broader approach is more consistent with the Government of Canada's approach to reconciliation and its principles respecting the Government of Canada's relationship with Indigenous Peoples.

The discussions on long-term relationships and on specific aspects of projects such as the NSDF Project will be on-going up until and after the Commission Hearing for the NSDF Project. Due to the on-going nature of these discussions and relationships, CNL intends to provide an updated IER as part of the Commission Member Document package for the CNSC Commission Hearing on the NSDF Project. That revised IER would document the on-going engagement, discussions and negotiations with Indigenous Peoples that would be relevant both corporately and NSDF Project-specific, as well as describing where outstanding concerns or disparities in views are communicated by Indigenous communities and organizations following submission of the EIS.

7.0 ACCIDENTS AND MALFUNCTIONS

This section of the Environmental Impact Statement (EIS) for the Canadian Nuclear Laboratories (CNL) Near Surface Disposal Facility (NSDF) for the disposal of solid, low-level radioactive waste at Chalk River Laboratories (CRL) (the 'NSDF Project'), identifies accidents and malfunctions, and their potential health and environmental effects that may occur during pre-closure (i.e., construction, operations and closure phases) of the NSDF Project.

Accidents and malfunctions refer to events or upset conditions that are not part of the normal activity/operation of the NSDF Project as planned. An accident is any unintended event, including operating errors, equipment failures or other mishaps, the consequences or potential consequences of which are significant from the point of view of protection of safety (*REGDOC-3.6 Glossary* [CNSC 2018]). The risk of accidents and malfunctions can be reduced and mitigated through design, administrative controls, adoption of safety measures and emergency response planning.

Accidents and malfunctions that may occur during pre-closure of the NSDF Project were identified, characterized and evaluated in the *NSDF Safety Analysis Report* (CNL 2020). The assessment of potential accidents and malfunctions considered both radiological and non-radiological conventional events. Radiological accidents and malfunctions are events that involve radioactive substances and could result in the release of radioactivity as well as non-radiological substances. Non-radiological conventional accidents and malfunctions are events that involve only non-radiological substances and therefore have no potential for the release of radioactivity. Following pre-closure is the post-closure phase of the NSDF Project, where monitoring and long-term care and maintenance will take place during the institutional control period. The *Post-Closure Safety Assessment* (Arcadis and Quintessa 2020) considered disruptive event scenarios and "what-if" cases, which examine the potential effects of unlikely disruptive events that lead to possible penetration of barriers and abnormal degradation and loss of containment. These post-closure disruptive scenarios are designed to test the robustness of the NSDF Project and are not considered accidents and malfunctions. In the post-institutional control period, there will be no workers or activities on-site, and as such there is no possibility for accidents or malfunctions to occur.

The post-closure phase disruptive event scenarios are summarized in Section 5.7 Ambient Radioactivity and Ecological Health and Section 5.8 Human Health.

7.1 Regulatory Context

The EIS Guidelines (CNSC 2016a) dictate that the information in Appendix A.3.4 of *REGDOC-2.9.1 Environmental Protection: Environmental Principles, Assessments and Protection Measures* (CNSC 2017) be used to assess the potential health and environmental effects from postulated accident and malfunction scenarios.

As per *REGDOC-2.9.1* (CNSC 2017), the applicant should provide an assessment of the potential health and environmental effects that occur from radiological and conventional accidents and malfunctions. The EIS should also include mitigation such as monitoring, contingency, clean-up or remediation work in the surrounding environment that would be required during or immediately following the postulated accident and malfunction scenarios.

The safety analysis in the *NSDF Safety Analysis Report* (CNL 2020) follows the safety objectives as defined in CNSC's *REGDOC-2.4.1 Deterministic Safety Analysis* (CNSC 2014).

7.2 General Approach

A systematic and comprehensive approach was used to identify the major hazards and postulated initiating events associated with the design and operations of the NSDF Project. The accident and malfunction assessment includes:

1) Hazard identification and hazard analysis.

2) Screening of hazards.

3) Assessment of bounding or key accidents and malfunctions.

Further details on the hazard identification, hazard analysis and screening process are provided in the *NSDF Safety Analysis Report* (CNL 2020).

7.2.1 Hazard Identification and Hazard Analysis

Hazard identification and hazard analysis was conducted at several stages during the design of the NSDF Project. A series of workshops were conducted with subject matter experts including engineers, safety analysts, waste operations specialists to systematically identify and categorize major hazards and the postulated initiating events associated with the design, construction and operation of the NSDF Project.

In general, the hazard identification and analysis process consisted of:

- Systematically evaluate hazards and initiating events, and develop accident sequences/scenarios and potential consequences.
- Identify the category of the scenario consequence being radiological, industrial (conventional) or environmental.
- Qualitatively estimate the frequency and the severity for the consequence of the mitigated hazard or initiating event scenario.
- The frequency and severity are combined to determine the risk ranking of the mitigated hazard or initiating event scenario.
- Identify mitigation including administrative and engineered controls for the mitigated hazard or initiating event scenario.

Table 7.2.1-1 is the consolidated list of major hazards and initiating events, and potential scenarios applicable to the NSDF, and this list of hazards was used during the hazard analyses.

Table 7.2.1-1: List of Major Hazards/Postulated Initiating Events and Potential Scenarios Applicable to the Near Surface Disposal Facility

Initiating Event / Hazard	Potential Scenarios and Applicable NSDF System
Containment Failure	1. Liner failure (applicable to ECM). 2. Rupture of waste packages (applicable to ECM, WWTP). 3. Failure of piping or tank (applicable to ECM, WWTP and VDF). 4. Final cover degradation on closed disposal cell (applicable to ECM). 5. Leaks from vehicles (applicable to all NSDF systems).
Contamination	1. Contamination on waste packages and bulk waste (applicable to ECM). 2. Contamination (airborne) released during waste placement and compaction (applicable to ECM). 3. Contamination transfer by wildlife (applicable to ECM). 4. Worker contaminated or exposed during facility operations (applicable to ECM, WWTP and VDF). 5. Contamination on transport vehicle (applicable to VDF).
Corrosion	1. Corrosion of waste containers (applicable to ECM). 2. Corrosion of chemical containers (applicable to WWTP).
Crane Failure	1. Crane failure during transfer waste placement (applicable to ECM and WWTP).
Dropped Load	1. Dropped waste package or chemical container due to mechanical failure, malfunction of lifting/hoisting equipment or human error (applicable to ECM and WWTP). 2. Waste package(s) or chemical container(s) fall off of transport vehicle during transport (applicable to ECM).
Explosion (deflagrations and detonations)	1. Burning combustible material in facility (applicable to all NSDF systems). 2. Facility/equipment (applicable to all NSDF systems). 3. Adjacent buildings (applicable to all NSDF systems). 4. Passing vehicle (applicable to all NSDF systems).
External Hazard (Natural)[1]	1. Earthquake (seismic activity) (Applicable to all NSDF systems). 2. Extreme meteorological conditions – temperature, snow, freezing rain, wind, drought, and rain (Applicable to all NSDF systems). 3. Ground subsidence, soil erosion or frost heave (Applicable to all NSDF systems). 4. Flooding – precipitation, dam failure, snow melt, and rise in water table (Applicable to all NSDF systems). 5. Wildland fire (Applicable to all NSDF systems). 6. Tornados and microbursts (with or without projectiles) (Applicable to all NSDF systems). 7. Lightning (Applicable to all NSDF systems). 8. Biological phenomena (e.g., algae, fauna and flora invasion and biological contamination) (Applicable to ECM and WWTP). 9. Intrusion of non-human biota (e.g. animals such as fox, bear, deer, geese, etc.) (Applicable to all NSDF systems).
Damaged Structure	1. Structural collapse (Applicable to all NSDF systems). 2. Collapse or damage of structures during waste placement and compaction (applicable to ECM).
Fire	1. Internally caused fire within ECM 2. Internally caused fire within WWTP. 3. Vehicle fire (applicable to all NSDF systems).
Hazardous Reaction	1. Chemical reaction hazards—applicable to the ECM and WWTP.

Table 7.2.1-1: List of Major Hazards/Postulated Initiating Events and Potential Scenarios Applicable to the Near Surface Disposal Facility

Initiating Event / Hazard	Potential Scenarios and Applicable NSDF System
Loss of Services	1. Loss of facility power due to natural phenomena events and certain external events, (applicable to all NSDF systems). 2. Interruption of electrical power/loss (applicable to all NSDF systems). 3. Loss of facility support systems. 4. Loss of natural gas (applicable to WWTP and associated facilities). 5. Loss of active drain (applicable to WWTP). 6. Loss or malfunction of emergency equipment (applicable to all NSDF systems).
Loss of Shielding	1. Damage to shielded package, leading to worker exposure (applicable to ECM). 2. Loss of shielding, leading to worker exposure (applicable to WWTP).
Loss of Ventilation	1. Failures in ventilation system, including failure or malfunction of high-efficiency particulate air filter, fan and duct (applicable to WWTP and VDF).
Radiation	1. Temporary waste storage area (applicable to ECM). 2. Excessive dose rate encountered (applicable to ECM and WWTP). 3. High doses due to high fields and airborne contamination emanating from waste (applicable to ECM, WWTP and VDF).
Unintended Contents	1. Chemical hazards in waste not adequately treated (applicable to ECM and WWTP). 2. Waste placed in disposal cell is retrieved due to not meeting the WAC (applicable to ECM). 3. Bulk waste is stuck in International Organization for Standardization container being disposed into disposal cell (applicable to ECM). 4. Release of liquid effluent that does not meet effluent discharge targets (applicable to WWTP).
Vehicle Collision	1. Collision of transport vehicles (applicable to all NSDF systems). 2. Transport vehicle falls into disposal cell (applicable to ECM). 3. Vehicle impact with structure (applicable to all NSDF systems). 4. Snow removal equipment impacting structure (applicable to all NSDF systems).
Equipment Failure	1. Loss or malfunction of instrumentation or equipment (Applicable to all NSDF systems). 2. Maintenance or inspection deficiency (applicable to all NSDF systems). 3. Aging of equipment (applicable to all NSDF systems).

ECM = engineered containment mound; WWTP = Wastewater Treatment Plant; VDF = vehicle decontamination facility; WAC = Waste Acceptance Criteria.

1) External hazards (natural) that could result in accidents and malfunctions are not discussed in Section 7 Accidents and Malfunctions and are discussed in Section 10 Effects of the Environment.

7.2.2 Screening of Hazards and Events

The hazards and the events screening involves:

1) Grouping the hazards and events based on the event frequency.

2) Assessing the risk ranking of the mitigated hazards and events. The risk rankings are mitigated risks, taking into account mitigation and administrative controls that potentially lower the frequency and/or the severity of the event. The risk rankings are based on a risk matrix combining qualitative assessments of event frequency and severity, reproduced in Table 7.2.2-1. The risks are described qualitatively in Table 7.2.2-2 and are based on frequency ratings as shown in Table 7.2.2-3 and severity ratings as shown in Table 7.2.2-4.

3) Assessing and selecting the bounding or key accidents and malfunctions based on the mitigated hazards and events with the higher risk ranking and consequence severity.

The hazards and events are grouped based on the frequency of the event (see Table 7.2.2-3):

- Anticipated Operational Occurrences.
- Design Basis Accidents.
- Beyond Design Basis Accidents, including Design Extension Conditions (DECs).

An Anticipated Operational Occurrence is an operational process deviating from normal operations, which is expected to occur once or several times during the operating lifetime of the NSDF Project but which, in view of the appropriate design provisions, does not cause any significant damage to items important to safety nor lead to accident conditions. These include events with frequencies of occurrence greater than or equal to 10^{-2} events per year (i.e., 1 event in 100 years).

Design Basis Accidents are accident conditions against which the NSDF Project is designed according to established design criteria, and for which the release of radioactive materials are kept within authorized limits. These include all events with frequencies of occurrence equal to or greater than 10^{-5} per year (1 event in 10 000 years), but less than 10^{-2} per year (1 event in 100 years). This class of events also includes any events that are used as a design basis for a safety system, regardless of whether the estimated frequencies are less than 10^{-5} per year.

Beyond Design Basis Accidents are accidents falling outside the design envelope of a Nuclear Facility's safety systems (accident conditions more severe than those of a Design Basis Accidents). These include events with frequencies of occurrence less than 10^{-5} per year (less than 1 event in 10,000 years).

Design Extension Conditions are a subset of beyond-design-basis accidents that are considered in the design process of the facility in accordance with best-estimate methodology to keep releases of radioactive material within acceptable limits. Design Extension Conditions could include severe accident conditions. Design Extension Conditions are assessed as a subset of Beyond Design Basis Accidents.

The credible malfunctions and accidents events are Anticipated Operational Occurrences, Design Basis Accidents, and Design Extension Conditions.

Table 7.2.2-1: Risk Matrix

Frequency	S0	S1	S2	S3
Anticipated Operational Occurrences ($\geq 10^{-2}$/a)	R0	R1	R2	R3
Design Basis Accidents ($\geq 10^{-5}$/a to $<10^{-2}$/a)	R0	R0	R1	R2
Beyond Design Basis Accidents (10^{-6}/a to $<10^{-5}$/a)	R0	R0	R0	R1

Table 7.2.2-2: Guidelines for Interpreting Risk Rankings

Risk Ranking	Definition
R0	The risk is negligible; no further action necessary.
R1	The risk is tolerable; further protective measures are not essential but should be considered1.
R2	The risk is unreasonable; engineered solutions must be put in place to protect against the hazard.
R3	The risk is unreasonable; the proposed process or equipment is inherently unsafe, major modifications to the proposed design are required.

Table 7.2.2-3: Frequency Ratings

Frequency Class	Frequency Range (events/year)	Definition
F0	10^{-6} to $<10^{-5}$	Selected Beyond Design Basis Accident that is very unlikely to occur over the lifetime of the Facility. An accident less frequent and potentially more severe than a design-basis accident.
F1	$\geq 10^{-5}$ to $<10^{-2}$	Design Basis Accident that is unlikely to occur over the lifetime of the facility, but is considered plausible.
F2	$\geq 10^{-2}$	An occasional event, Anticipated Operational Occurrence, upset condition, this event is expected to occur over the lifetime of the facility but is not considered a normal operation.

[1] Further measures are typically additional administrative controls and/or simple design changes.

Table 7.2.2-4: Severity Ratings

Severity Rating	Definition
S0	**Industrial Consequences**: Consequences are negligible, minor injury requiring First Aid treatment which does not result in lost time from work [(a)]. **Operational Consequences**: No operational impacts and facility does not require a shutdown (e.g., for clean-up, etc.). **Radiological Consequences**: Effective doses up to 1 mSv (on-site) and/or 0.1 mSv (off-site). **Environmental Consequences**: Negligible release to the environment, effect may be measurable. Impacts to the environment are very small/negligible and localised (on-site)/short duration.
S1	**Industrial Consequences**: Consequences are minor, injury or an occupational disease requiring medical treatment by a medical practitioner[(b)] (other than CNL health centre nurse), a disabling injury resulting in a medical practitioner prescribing work restrictions (and modified work is offered by CNL)[(c)] or time off from work (lost time) of up to 5 days [(d)]. **Operational Consequences**: Minor operational impact and facility may require shut down for up to 1 day. **Radiological Consequences**: Effective doses in the range of 1 to 5 mSv (on-site) and/or 0.1 to 0.5 mSv (off-site). **Environmental Consequences**: Minor release to the environment, effect is measurable. Impacts to the environment are moderately extensive (on-site, may be off-site) and moderate duration.
S2	**Industrial Consequences**: Consequences are moderate, electric shock, toxic atmosphere, or oxygen deficient atmosphere that causes loss of consciousness. The implementation of rescue, revival or other similar emergency procedures. A disabling (non-permanent) injury/disease (to one or more workers) [(e)] resulting in a total lost time >5 days and up to 60 days [(f)]. **Operational Consequences**: Moderate operational impact and facility may require shut down for >1 to 5 days. **Radiological Consequences**: Effective doses in the range of 5 to 50 mSv (on-site) and/or 0.5 to 20 mSv (off-site). **Environmental Consequences**: Moderate release to the environment. Impacts to the environment are extensive (on-site and off-site) and long duration.
S3	**Industrial Consequences**: Consequences are severe, fatality, a disabling injury resulting in loss of a body member or a part thereof, or the complete loss of the usefulness of a body member or a part thereof, permanent impairment of a body function, a disabling (non-permanent) injury (to one or more workers)[(e)] resulting in a total lost time >60 days. **Operational Consequences**: Major operational impact and facility shut down for greater than 5 days. **Radiological Consequences**: Effective doses >50 mSv (on-site) and/or >20 mSv (off-site). **Environmental Consequences**: Major release to the environment. Impacts to the environment are catastrophic.

Note:

(a) Minor cut treated at the CNL health centre (not requiring stitches).

(b) Cut requiring stitches.

(c) Doctor prescribes ‘no manual lifting’ for employee whose employment requires lifting.

(d) Injury requiring medication to be prescribed which makes it unsafe to attend work.

(e) One person injured or summation of lost time for multiple injured individuals.

(f) Broken bones preventing return to work.

mSv = millisievert.

7.2.3 Assessment of Key Accidents and Malfunctions

The assessment of key accidents and malfunctions includes:

- Identify the hazard.
- Description of the accident or malfunction scenario.
- Identify the potential health and environmental effects.
- Identify mitigation in the NSDF Project design and CNL processes that mitigate the hazard and minimize the potential health and environmental effects.

7.2.3.1 *Identification of Valued Components*

The bounding or key accidents and malfunctions were evaluated to assess the effects to humans and non-human biota. Human receptors included workers and members of the public (see Section 5.8 Human Health). The list of proposed Valued Components was developed for non-human biota that are found in the vicinity of the NSDF Project site, have potential for exposure, play a key role in the food web, and represent a variety of habits and trophic levels (see Section 5.7). To determine the potential effect of radiological and non-radiological emissions on the environment, a smaller group of indicator species was chosen to represent Valued Components selected for assessment. Tables in Section 7.3 and Section 7.4 identify if there is any pathway linkage to non-human biota, which requires an effects assessment in Section 5.7.

7.3 Radiological Accidents and Malfunctions

This section describes the accidents and malfunctions with radiological consequences during construction, operations and closure. Detailed information on the radiological accidents and malfunctions is available in the *NSDF Safety Analysis Report* (CNL 2020).

7.3.1 Radiological Dose Acceptance Criteria for Accidents

The CNSC has set the regulatory limits for exposure to workers and members of the public (*Radiation Protection Regulations*) to ensure that the probability of occurrence of effects is acceptably low. For normal operations, the radiological doses from radionuclide releases and direct radiation exposure must not exceed 50 millisieverts (mSv) annually for Nuclear Energy Workers and 1 mSv annually for members of the public (at the NSDF Project site boundary) to meet the CNSC regulatory dose limits (SOR/2000-203). In addition, the CRL licensing handbook (CNSC 2019) sets an annual dose constraint of 0.3 mSv for members of the public.

CNL's *Safety Analysis for Decommissioning and Waste Management* (CNL 2019a) and the NSDF Safety Analysis Report (CNL 2020) defines the dose acceptance criteria for accidents, dependent on the frequency of the event, and is provided in Table 7.3.1-1.

For the protection of non-human biota from radiation exposure, the primary concern is the total radiation dose to the organisms resulting in deterministic effects (i.e., threshold below which the effect does not occur). If the estimated dose is less than the no-effects concentration, then the radiological risk is considered acceptable.

Table 7.3.1-1: Dose Acceptance Criteria for Accidents

Frequency	Qualitative Event Description	Off-Site Doses[(a)] (mSv)	On-Site Doses[(b)] (mSv)
≥10^{-2}	Anticipated Operational Occurrences	0.5	5
≥10^{-5} to <10^{-2}	Design Basis Accidents	20	50
10^{-6} to <10^{-5}	Selected Beyond Design Basis Accidents, including Design Extension Conditions	Assessed[(c)]	Assessed[(c)]

(a) Off-site doses represent the dose to the public.

(b) On-site personnel, not directly involved in the accident.

(c) When identified, dose assessments should be performed, and if the dose exceed the 20 mSv Design Basis Accidents limit, emergency procedures should be reviewed to determine if new mitigating measures can be identified.

mSv = millisievert.

7.3.2 Construction

Radiological hazards during the site preparation and construction periods are very limited because the NSDF Project site is an area that has never been used by operations at CRL that have involved radioactive (or otherwise contaminated) materials.

7.3.2.1 Assessment of Construction Radiological Accidents and Malfunctions

Table 7.3.2-1 is the assessment of the key potential radiological accident and malfunction that could occur during the construction of the Facility.

Table 7.3.2-1: Assessment of the Key Potential Radiological Accident and Malfunction During Construction

ID	Radiological Hazard	Scenario	Mitigation	Potential Health and Environmental Effects After Mitigation
A1	Radioactive source associated with industrial radiography.	Radiography equipment containing a radioactive source is used for non-destructive testing and human error results in the source being unshielded and potential worker dose.	▪ Proper training of Certified Exposure Device Operators. ▪ Shot Plan for radiography. ▪ Administrative controls, such as restricting access and maintaining a safe distance. ▪ Shielding. ▪ Barriers. ▪ Personal Alarming Dosimeter.	▪ The potential radiological consequence to worker health is minor. There is no linkage pathway to the public or non-human biota as the effect is localized.

7.3.3 Operations and Closure

The radiological accidents and malfunctions during the operations period bound those during the closure period, since the radiological source term in the NSDF Project is greater during the operations period.

7.3.3.1 *Assessment of Key Potential Hazards and Accidents during the Operations*

Table 7.3.3-1 is the assessment of the key potential radiological accident and malfunction that could occur during the operations of the NSDF Project.

Table 7.3.3-1: Assessment of the Key Potential Radiological Accident and Malfunction During Operations

ID	Radiological Hazard	Scenario	Mitigation	Potential Health and Environmental Effects After Mitigation
B1	Dropped Load – ECM	Dropped load at the ECM during waste package placement or handling could result in potential damage to the waste package and the spread of contamination.	▪ PPE&C. Personal alarming dosimeter. Preventative maintenance of equipment and vehicles. Barriers. Line of fire awareness.	▪ A dropped load results in a localized effect that is readily remediated. The potential health effects to workers is negligible. The dose to the worker is 0.04 mSv (CNL 2020). The primary radionuclides contributing to the worker dose are americium-241, cobalt-60 and plutonium-239 (CNL 2020). ▪ There is no linkage pathway to the public or non-human biota as effects are localized (on-site) with a very short duration.
B2	Internal Fire – ECM	An internal fire resulting in the in the ignition of combustible waste materials, occurs at the Temporary Storage and Waste Receiving and Processing Area (TSWRPA) within the ECM. An internal fire within ECM could be initiated by the wildland fire, lightning, vehicle fire or equipment electrical failure.	▪ CRL Fire Department. ▪ NSDF Fire Water Pump Station. ▪ Vehicle/equipment maintenance. ▪ Portable fire extinguishers on the vehicles.	▪ The waste fire in the TSWRPA results in a localized effect that is readily remediated. The potential health effects are negligible to the on-site receptors and the public, and minor to the NSDF workers. The dose to the NSDF worker is 2.4 mSv (CNL 2020). The dose to the on-site receptor located 1,000 m away is 0.052 mSv (CNL 2020). The doses to the off-site adult and 1-year old child receptors located 3 km away are 0.021 mSv and 0.014 mSv, respectively (CNL 2020). The primary radionuclide contributing to the dose is Cobalt-60 (CNL 2020). ▪ There is a secondary pathway for changes in air quality which can then affect non-human biota. Potential effects are expected to be negligible because they will be short in duration and localized to the NSDF Project site.
B3	Dropped Load - WWTP	Dropped load at the WWTP involving the filter press dewatered residuals bin resulting in the dewater residuals being spilled.	▪ PPE&C. ▪ Personal alarming dosimeter. ▪ Preventative maintenance of equipment and vehicles. Barriers. ▪ Line of fire awareness.	▪ A dropped load results in a localized effect that is readily remediated. The potential health effects to the workers and the public are negligible. The dose to the worker is 0.0074 mSv for a 10-minute exposure, and 0.044 mSv for a 60-minute exposure (CNL 2020). The primary radionuclide contributing to the dose is cobalt-60 (CNL 2020). ▪ There is no linkage pathway to the public or non-human biota as effects are localised (on-site) and for a short duration.

Table 7.3.3-1: Assessment of the Key Potential Radiological Accident and Malfunction During Operations

ID	Radiological Hazard	Scenario	Mitigation	Potential Health and Environmental Effects After Mitigation
B4	Internal Fire - WWTP	An internal fire in the WWTP Residuals Management Area could be initiated due flammable gas release, spontaneous combustion from chemical reaction, vehicle fire or electrical fire resulting in potential dose to the on-site and off-site receptors.	▪ WWTP fire detection system. ▪ CRL Fire Department. ▪ NSDF Fire Water Pump Station. ▪ Vehicle/equipment maintenance. ▪ Portable fire extinguishers on the vehicles.	▪ The fire in the WWTP Residuals Management Area results in a localized effect that is readily remediated. The potential health effects are negligible to the workers and the public. The dose to the on-site receptor located 1,000 m away is 0.00000056 mSv (CNL 2020). The doses to the off-site public adult and 1-year old child receptors located 3 km away are 0.00000024 mSv and 0.00000015 mSv, respectively (CNL 2020). The primary radionuclide contributing to the dose is cobalt-60 (CNL 2020). ▪ There is a secondary pathway for changes in air quality which can then affect non-human biota. Potential effects are expected to be negligible as they will be short in duration and localized to the NSDF Project site.
B5	Contamination - WWTP	WWTP worker could be splashed during the sampling of the process tanks resulting in potential dose to the worker.	▪ PPE&C. ▪ Chemical shower / eye wash stations. ▪ Spill kits.	▪ A worker being splashed in the WWTP results in a localized effect that is readily remediated. The potential health effects to the worker is negligible. The dose to the worker is 0.0003 mSv (CNL 2020). The primary radionuclide contributing to the dose is cobalt-60 (CNL 2020). ▪ There is no linkage pathway to the public or non-human biota as effects are localised (on-site) and would be contained.
B6	Spill/leak of wastewater at WWTP	Mechanical failure of the WWTP tanks, piping and/or valves could result in a spill of wastewater. The event is assumed to affect the membrane filter feed tanks, membrane filter process tanks and associated piping resulting in a spill of 96,000 L with a small amount of water becoming suspended in air following the free-fall spill.	▪ Secondary containment. ▪ Leak detection. ▪ Active drain system. ▪ PPE&C. ▪ Spill kits.	▪ A spill of wastewater in the WWTP results in a localized effect that is readily remediated. The potential health effects to the worker is negligible. The dose to the WWTP worker is 0.000076 mSv (CNL 2020). The primary radionuclides contributing to the dose are cobalt-60 and tritium (CNL 2020). ▪ There is no linkage pathway to the public or non-human biota as effects are localised (on-site) and would be contained.

Table 7.3.3-1: Assessment of the Key Potential Radiological Accident and Malfunction During Operations

ID	Radiological Hazard	Scenario	Mitigation	Potential Health and Environmental Effects After Mitigation
B7	Spill/leak of contaminated IX resin at WWTP	A contaminated IX resin spill may occur during the replacement or transfer of spent resins.	▪ Secondary containment. ▪ Leak detection. ▪ Active drain system. ▪ PPE&C. ▪ Spill kits.	▪ A spill of contaminated IX resin in the WWTP results in a localized effect that is readily remediated. The potential health effects to the worker are negligible. The dose to the worker is 0.0052 mSv for a 10-minute exposure and 0.0031 mSv for a 60-minute exposure (CNL 2020). The primary radionuclide contributing to the dose is cobalt-60 (CNL 2020). ▪ There is no linkage pathway to the public or non-human biota as effects are localised (on-site) and would be contained.

ECM = Engineered Containment Mound; mSv = millisievert; PPE&C = personal protective equipment and clothing; TSWRPA = Temporary Storage and Waste Receiving and Processing Area; WWTP = Wastewater Treatment Plant.

7.3.4 Risk Matrix of Radiological Accidents and Malfunctions

Table 7.3.4-1 presents the risk matrix overlaid with the eight key radiological accidents and malfunctions, according to their severity, frequency and risk ratings. For the radiological accidents and malfunctions, the dose to the workers and the public meet the dose acceptance criteria for accidents, and the risks are acceptable and low with mitigation in place.

Table 7.3.4-1: Risk Matrix of Radiological Accidents and Malfunctions

Frequency	S0	S1	S2	S3
Anticipated Operational Occurrences ($\geq 10^{-2}$/a)	R0 (B1, B3, B5)	R1 (A1, B6)	R2	R3
Design Basis Accidents ($\geq 10^{-5}$/a to $<10^{-2}$/a)	R0 (B3, B7)	R0 (B2, B4)	R1 (B1[1])	R2
Beyond Design Basis Accidents (10^{-6}/a to $<10^{-5}$/a)	R0	R0	R0	R1

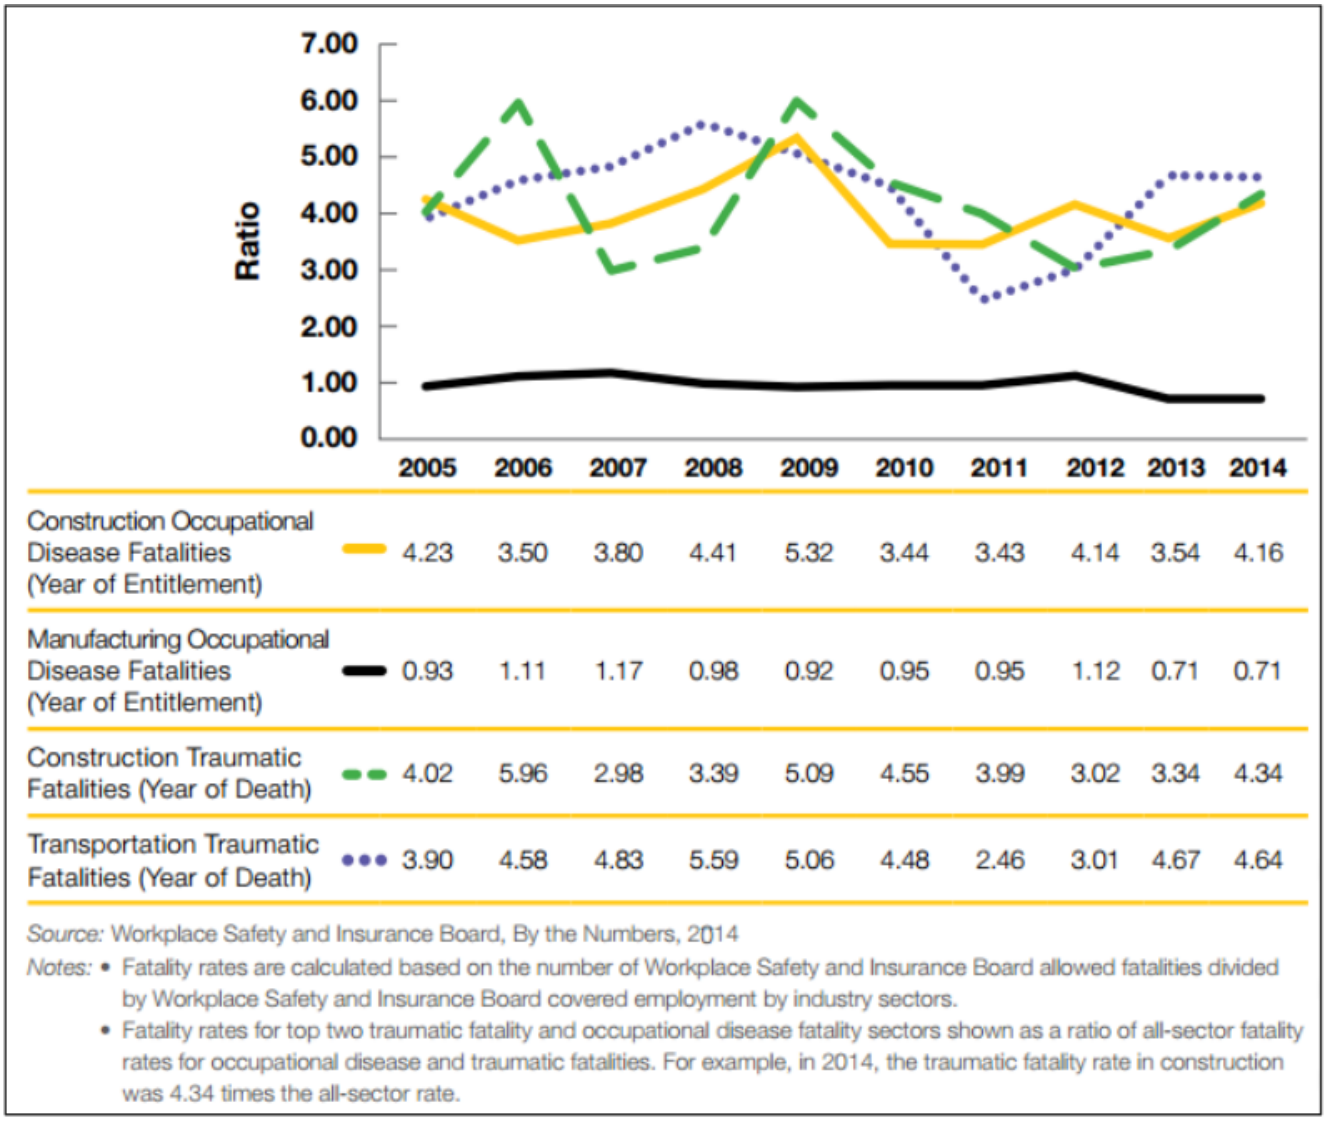
[1] High dose rate waste package (>2 mSv/hour near contact or >0.1 mSv/hr at 1 m).

7.4 Conventional (Non-radiological) Accidents and Malfunctions

This section describes the accidents and malfunctions with conventional non-radiological consequences during construction, operations and closure. Detailed information on the conventional accidents and malfunctions is available in the *NSDF Safety Analysis Report* (CNL 2020) and the *Conventional Safety Analysis* (AECOM 2018).

7.4.1 Construction

Major construction projects (which includes decommissioning activities) involve the interaction of personnel with hazards such as moving and stationary heavy equipment/machinery, electricity and temporary power lines, working at heights, working in confined spaces, working with potentially unstable structures, etc. In contrast to specific industrial facilities where each activity/position is routine, with little variability, well characterized, and the occupational settings are well defined, construction projects can involve several ad hoc tasks performed by workers as part of the execution of a larger overall activity. Such projects may also use equipment that are generally rotated from one site to another (e.g., cranes). In these situations, conventional non-radiological accidents and malfunctions are governed by the limits of human performance as well as the reliability of the equipment (related to its maintenance).



According to the Ontario Ministry of Labour (MOL) report titled *Occupational Health & Safety in Ontario 2014-2015* (MOL 2016), from 2005 to 2014, 28.3% of traumatic fatalities and 28.0% of occupational disease fatalities occurred in the construction sector, while this sector accounted for 7.0% of total employment under provincial jurisdiction (2014). These statistics indicate that higher fatality rates occur in the construction industry compared with other industrial sectors. The MOL (2015) report also noted that for the last 10 years, construction and transportation sectors have been the top two sectors in terms of the fatality rates (depicted in Figure 7.4-1).

The fatality rate in the construction sector has not appeared to change over this time period. This consistency over time suggests that the rates of these accidents and malfunctions in these sectors are being controlled by human performance in typical industry practices, and as such, rates have reached an as-low-as-reasonably-possible state under the existing health and safety regulatory framework. Given the awareness of the roles of human factors in these accidents and malfunctions, provisions including training, procedures, and mitigation have been put in place by CNL to achieve as-low-as-reasonably-possible accidents and malfunctions rates.

It should also be noted that the work-place accident statistics mentioned above are aggregated data collected from a large number of industrial sectors, some of which may not have robust occupational health and safety programs. In contrast, the work carried out for the NSDF Project will be subject to additional oversight, as a result of the safety culture developed in the nuclear industry.

The NSDF construction activities will follow the construction process as defined in CNL's *Construction Program Description Document* (CNL 2017a) and CNL's *Construction Program Requirements Document* (CNL 2019b). The Construction Process establishes the requirements to ensure the successful execution of construction and installation activities (CNL 2019b). An effective Construction Process ensures that activities comply with the design intent, the applicable codes, standards, regulatory requirements, quality standards and applicable environmental and health and safety requirements (CNL 2019b).

A *Construction Safety Hazards Evaluation* is required to be developed during the pre-construction period, to identify and mitigate any known or potential hazards (CNL 2017b). Construction conventional hazards are controlled and managed by the CNL's *Occupational Safety and Health Program* (CNL 2018a).

	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014
Construction Occupational Disease Fatalities (Year of Entitlement)	4.23	3.50	3.80	4.41	5.32	3.44	3.43	4.14	3.54	4.16
Manufacturing Occupational Disease Fatalities (Year of Entitlement)	0.93	1.11	1.17	0.98	0.92	0.95	0.95	1.12	0.71	0.71
Construction Traumatic Fatalities (Year of Death)	4.02	5.96	2.98	3.39	5.09	4.55	3.99	3.02	3.34	4.34
Transportation Traumatic Fatalities (Year of Death)	3.90	4.58	4.83	5.59	5.06	4.48	2.46	3.01	4.67	4.64

Source: Workplace Safety and Insurance Board, By the Numbers, 2014

Notes:
- Fatality rates are calculated based on the number of Workplace Safety and Insurance Board allowed fatalities divided by Workplace Safety and Insurance Board covered employment by industry sectors.
- Fatality rates for top two traumatic fatality and occupational disease fatality sectors shown as a ratio of all-sector fatality rates for occupational disease and traumatic fatalities. For example, in 2014, the traumatic fatality rate in construction was 4.34 times the all-sector rate.

Figure 7.4.1-1: Comparison of Conventional Accident Statistics by Sector (MOL 2016)

7.4.1.1 *Assessment of Potential Conventional Accidents and Malfunctions during Construction*

The potential conventional non-radiological hazards that exist during site preparation and construction include but not limited to:

- Material movement – lifting and hoisting;
- Drilling and excavation;
- Trenching, sloping and shoring;
- Tree clearing and removal;
- Electrical;
- Traffic (Vehicle and/or pedestrian);
- Welding, cutting and grinding;
- Work at heights;
- Operation of heavy equipment;
- Exhaust from vehicles including heavy equipment;
- Tripping hazards due to un-level surfaces;
- Fuel for equipment;
- Hazardous materials and chemicals;
- Pinch points;
- Environmental including weather, and heat and cold stress;
- Noise;
- Use of power tools;
- Wildlife incursions (e.g., bears);
- Particulate matter and dust generation;
- Leak/spill;
- Vehicle collision;
- Rock blasting, including the hazards:
  - detonator malfunction; and
  - overblasting.
- Fire (internal).

Table 7.4.1-1 is the assessment of the key potential conventional accidents and malfunctions that could occur during the construction of the NSDF Project.

Table 7.4.1-1: Assessment of the Key Potential Conventional Accidents and Malfunctions During Construction

Conventional Hazard	Scenario	Mitigation	Potential Health and Environmental Effects After Mitigation
Leak/spill	Spill of fuel during fueling heavy equipment. Failure of hydraulic oil hose on the heavy equipment.	▪ Heavy equipment fueling utilizes secondary containment ▪ Spill kits ▪ Vehicle maintenance and inspections ▪ Refueling will kept away from surface water features	▪ A leak/spill results in a localized effect that is readily remediated. The potential health effect to the worker are negligible. ▪ There is no linkage pathway to the public as effects are localised (on-site), short in duration and would be contained. ▪ Potential effects to non-human biota related to leaks/spills during the construction of the transfer line to Perch Lake are assessed in Section 5.4.2.5.2.2 (Surface Water Quality) and Section 5.6.5.2.2 (Terrestrial Environment).
Vehicle collision	Construction vehicle collision resulting in potential worker injury and the leak of oil and or fuel from the damaged vehicle.	▪ Speed restriction in the construction area ▪ Seat belts ▪ Vehicle design ▪ Blanding's Turtle Road Mortality Mitigation Plan	▪ The potential health effects are minor, injury or an occupational disease requiring medical treatment by a medical practitioner (other than CNL health centre nurse), a disabling injury resulting in a medical practitioner prescribing work restrictions (and modified work is offered) or time off from work (lost time) of up to 5 days. ▪ Negligible release to the environment due leak of oil or fuel, effect may be measurable. ▪ There is no linkage pathway to the public as effects are localised (on-site), short in duration and would be contained. ▪ Potential effects to Blanding's Turtle and Eastern Milksnake from road mortality are assessed in Section 5.6.7.8 (Blanding's Turtle) and Section 5.6.7.9 (Eastern Milksnake).

Table 7.4.1-1: Assessment of the Key Potential Conventional Accidents and Malfunctions During Construction

Conventional Hazard	Scenario	Mitigation	Potential Health and Environmental Effects After Mitigation
Overblasting	Uncontrolled or unmanaged blasting would result in excess noise and vibration or damage resulting from fly rock extending beyond defined boundaries.	▪ Blasting plan ▪ Barriers ▪ Defined safety limit around the blast area to isolate biota/VCs from the potential effects of flying rock ▪ A 30 m buffer area has been established along all identified wetlands near the ECM and no new construction is permitted within this 30 m buffer zone to protect the wetlands	▪ Noise and vibration effects from an uncontrolled explosion would be short in duration. ▪ The potential environmental effects are negligible. The potential health effects are moderate for workers and negligible for the public.
Fire (internal)	A fire may occur as the result of an accident associated with the activities of the NSDF Project including vehicle and equipment malfunction, and human error resulting in airborne release to the environment.	▪ Fire Department ▪ Fire extinguishers on vehicle ▪ Engine compartment fire suppression system on heavy equipment	▪ The potential health to the on-site worker is negligible. ▪ Negligible release to the environment, effect may be measurable. ▪ There is no linkage pathway to the public or non-human biota as effects are localized (on-site) and are very small/negligible.
Malfunction of detonators used for rock blasting	Malfunction of non-electronic detonator during rock blasting. The detonator malfunction could be the result of: ▪ Manufacture defect. ▪ Pinch or tear in the shock tube during the placement of blasting mats. ▪ Improper tie-in hookup or missed detonator during tie-in hookup. ▪ Damaging the shock tube during the loading operation.	▪ Blasting Plan ▪ Blasting Safety Plan ▪ Blasting system notification and detonator redundancies ▪ Visual inspection of blasting tie-in sequence and shock tube condition prior to placing blasting mats ▪ In the event of a primary detonator malfunction, immediate blasting using the redundant secondary detonator will occur ▪ Barriers for access restrictions ▪ Blasting mats	▪ The potential health effect to the worker is negligible. ▪ The potential environmental effects are negligible and there is no release to the environment. ▪ There is no linkage pathway to the public and non-human biota as effects are localized and are negligible.

Table 7.4.1-1: Assessment of the Key Potential Conventional Accidents and Malfunctions During Construction

Conventional Hazard	Scenario	Mitigation	Potential Health and Environmental Effects After Mitigation
Malfunction of detonators used for rock blasting (cont'd)	Malfunction of electronic detonator during rock blasting. The detonator malfunction could be the result of: ▪ Manufacture defect. ▪ Pinch or tear in the leg wire or the trunk line during the placement of blasting mats. ▪ Improper tie-in hookup or missed detonator during tie-in hookup. ▪ Damaging the leg wire during the loading operation.	▪ Blasting Plan ▪ Blasting Safety Plan ▪ Blasting system notification and detonator redundancies ▪ Testing of the electronic detonators and circuit prior to blast initiation ▪ Testing of the electronic detonators and circuit prior to, during and after placing blasting mats ▪ In the event of a primary detonator malfunction, immediate blasting using the redundant secondary detonator will occur ▪ Barriers for access restrictions ▪ Blasting mats	▪ The potential health effect to the worker is negligible. ▪ The potential environmental effects are negligible and there is no release to the environment. ▪ There is no linkage pathway to the public and non-human biota as effects are localized and are negligible.
Particulate Matter and dust generation	Particulate matter and dust is expected to be generated during the following site preparation and construction activities: ▪ Clearing, grading and excavation to support construction. ▪ Rock blasting. ▪ Hauling and loading of excavated materials for construction and transport to spoil or stockpiles areas. Stockpiles are created for imported soil materials including clay, granular materials, and material excavated from the ECM area.	▪ Dust management plan ▪ Water spraying or misting techniques using water trucks	▪ The potential health effect to the worker is negligible. ▪ The potential environmental effects are negligible. ▪ There is no linkage pathway to the public or non-human biota as effects are localized (on-site) and are very small/negligible.

VC = valued component.

7.4.2 Operations and Closure

Conventional non-radiological hazards were evaluated only to the extent of determining their ability to initiate or contribute to accidents with radiological consequences; otherwise such hazards are adequately covered by CNL's *Occupational Safety and Health Program* (CNL 2018a). The conventional non-radiological hazards that exist in the NSDF Project for routine work activities include:

- operation of the filter press in the WWTP;
- handling of large, heavy containers;
- exhaust from vehicles including heavy equipment;
- tripping hazards due to unlevel surfaces;
- pinch points;
- heat and cold stress;
- excavation;
- noise;
- material movement—lifting and hoisting;
- use of power tools;
- operation of heavy equipment;
- fuel for equipment;
- wildlife incursions (e.g., bears);
- confined space;
- working at heights;
- impact/collision;
- chemical exposure;
- hazardous reaction;
- spill or leak; and
- dropped load.

7.4.3 Assessment of Potential Conventional Accidents and Malfunctions during Operations and Closure

Table 7.4.3-1 is the assessment of the key potential conventional accidents and malfunctions that could occur during the operations and closure of the Facility.

Table 7.4.3-1: Assessment of the Key Potential Conventional Accidents and Malfunctions During Operations and Closure

ID	Conventional Hazard	Scenario	Mitigation	Potential Health and Environmental Effects After Mitigation
D1	Impact/collision	Vehicle collision due to human error, resulting in potential worker injury.	▪ Speed restriction in the construction area ▪ Seat belts ▪ Vehicle design ▪ Blanding's Turtle Road Mortality Mitigation Plan	▪ The potential health effects are minor to on-site worker. ▪ Negligible release to the environment, effect may be measurable. ▪ There is no linkage pathway to the public as effects are localised (on-site). ▪ Potential effects to Blanding's Turtle and Eastern Milksnake from road mortality are assessed in Section 5.6.7.8 (Blanding's Turtle) and Section 5.6.7.9 (Eastern Milksnake).
D2	Fall	Worker falls into the contact water or non-contact water pond at the ECM resulting in potential worker injury.	▪ Raised berm ▪ Spotter ▪ Barriers ▪ PPE&C	▪ The potential health effects are minor to on-site worker. ▪ There is no linkage pathway to the public or non-human biota as effects are localised (on-site).
D3	Chemical Spill/Leak	Chemical drum/tote is dropped due to human area in the WWTP chemical storage area resulting in loss of containment, spill and the worker being splashed. Chemical feed tank is overfilled from the chemical totes and or drums.	▪ PPE&C ▪ Secondary containment (chemical room sumps) ▪ Spill kit and chemical neutralizer ▪ Chemical shower / eye wash stations ▪ Spotter ▪ Chemical Feed Tanks have high-level alarms and overflow lines to chemical room sumps	▪ The potential health effects are minor to on-site worker. ▪ There is no linkage pathway to the public or non-human biota as effects are localised (on-site) and would be contained.
D4	Hazardous reaction	Incorrect chemical mixing, wrong chemical addition sequence, or wrong chemical addition resulting in an adverse chemical reaction and potential worker injury and worker exposure to off gassing.	▪ Chemical addition system interlocks ▪ PPE&C ▪ Two separate Chemical Rooms for acidic and caustic chemicals ▪ Secondary containment (chemical room sumps) ▪ Chemical shower / eye wash stations. Hydrogen sulphide monitors with alarms	▪ Hydrogen sulphide gas could be generated by the mixing of incompatible chemicals. The potential health effects are negligible to workers. ▪ There is no linkage pathway to the public or non-human biota as effects are localised (on-site) and would be contained.

Table 7.4.3-1: Assessment of the Key Potential Conventional Accidents and Malfunctions During Operations and Closure

ID	Conventional Hazard	Scenario	Mitigation	Potential Health and Environmental Effects After Mitigation
D5	Dropped load	Dropped load due to human error and or mechanical resulting in potential worker injury.	▪ Spotter ▪ Equipment maintenance and inspection ▪ Barriers ▪ Line of fire (awareness)	▪ The potential health effects are moderate to the workers. ▪ There is no linkage pathway to the public or non-human biota as effects localised (on-site) with a very short duration.

PPE&C = personal protective equipment and clothing; WWTP = Wastewater Treatment Plant.

7.4.4 Risk Matrix of Conventional Accidents and Malfunctions

Table 7.4.4-1 presents the risk matrix overlaid with the five key conventional accidents and malfunctions during the operations, according to their severity, frequency and risk ratings. The risk of the key conventional accidents and malfunctions are acceptable and low with mitigation in place.

Table 7.4.4-1: Risk Matrix of Conventional Accidents and Malfunctions

Frequency	S0	S1	S2	S3
Anticipated Operational Occurrences ($\geq 10^{-2}$/a)	R0 (D4)	R1 (D1, D2, D3)	R2	R3
Design Basis Accidents ($\geq 10^{-5}$/a to $<10^{-2}$/a)	R0	R0	R1 (D5)	R2
Beyond Design Basis Accidents (10^{-6}/a to $<10^{-5}$/a)	R0	R0	R0	R1

7.4.5 Mitigation for Conventional Non-radiological Hazards

The risks of the potential conventional non-radiological hazards are mitigated by the following administrative mitigation and controls:

- use of spotters at a safe distance during material movement, hoisting and heavy equipment operation;
- work/rest cycles based on environmental working conditions;
- work areas controlled with barriers and signage;
- fire protection screening;
- personal protective equipment and clothing, including hard hats, safety footwear, hearing protection, respirators, gloves and safety glasses/face shields/goggles;
- worker training;
- procedural adherence;
- equipment maintenance and inspection—maintenance schedule and monitoring equipment performance; and
- use of spotters and noise makers during wildlife incursions.

The risks of the potential conventional non-radiological hazards are mitigated by the following design mitigation/safeguards and controls:

- interlocks associated with the chemical addition system, chemical precipitation system, polishing system and final pH adjustment;
- separate chemical storage areas for acids and caustics; and
- hydrogen sulphide monitors with alarms.

7.5 Emergency Preparedness

If an accident or malfunction situation occurs, CNL has procedures in place that address requirements for immediate response and post-event clean-up or remediation. Of note, CNL's *Emergency Preparedness Program* (CNL 2018b) (described in Section 3.5.2.5) has been designed for immediate response to emergency situations. The program ensures emergency readiness and emergency management to support programs such as reactor safety/accident management, decommissioning, radiation and environmental protection, fire and occupational health and safety. In terms of post-event clean-up or remediation CNL's *Environmental Protection Program* (CNL 2018c) (see Section 3.5.2.2) includes procedures that address the identification, management and remediation of lands that are contaminated.

Canadian Nuclear Laboratories will establish a project-specific Emergency Preparedness Plan for the NSDF Project, including emergency response procedures. The NSDF Project Emergency Preparedness Plan will establish practices for safe and environmentally sound management of the facility during the construction, operations, closure and post-closure periods.

Emergency response procedures for the NSDF Project will be prepared to address any potential emergencies from accidents including internal fires, minor spill, major spill, natural gas/carbon monoxide leak, loss of power, high radiation, radiological contamination, bomb threat/suspicious package, hold and secure and stay-in. Checklists are also created for evacuation and floor plans and assembly area locations are also defined.

8.0 SUMMARY OF CUMULATIVE EFFECTS

8.1 Introduction and Approach

The *Canadian Environmental Assessment Act, 2012* requires that each environmental assessment of a designated project take into account any cumulative environmental effects that are likely to result from the designated project in combination with the environmental effects of other physical activities that have been or will be carried out (The Agency 2015). The method for assessment of cumulative effects is outlined in Section 5.1 and is consistent with the Canadian Nuclear Safety Commission (CNSC) Generic EIS Guidelines (CNSC 2016) and the Canadian Environmental Assessment Agency's *Technical Guidance for Assessing Cumulative Effects under the Canadian Environmental Assessment Act, 2012* (The Agency 2018). Cumulative effects are assessed using the same approach used for the project-specific effects analysis. The approach follows the same five general steps outlined in the cumulative effects technical guidance document (The Agency 2018):

- **Step 1 – Scoping:**
  - identifying Valued Components (VCs; see Section 5.1.2 Valued Components);
  - determining spatial boundaries (see Section 5.1.3.1 Spatial Boundaries);
  - determining temporal boundaries (see Section 5.1.3.2 Temporal Boundaries); and
  - examining physical activities that have been and will be carried out (see Section 5.1.3.3 Assessment Cases).
- **Step 2 – Analysis** (see Section 5.1.5 Project Interactions and Mitigation and 5.1.6 Residual Effects Analysis).
- **Step 3 – Mitigation** (see Section 5.1.5 Project Interactions and Mitigation and 5.1.6 Residual Effects Analysis).
- **Step 4 – Significance** (see Section 5.1.8 Residual Effects Classification and Determination of Significance).
- **Step 5 – Follow-up** (see Section 5.1.9 Monitoring and Follow-up).

The purpose of the cumulative effects assessment is to evaluate the contribution of effects from the Near Surface Disposal Facility (NSDF) Project (i.e., Application Case) in combination with previous, existing, or reasonably foreseeable developments or activities in the region (i.e., Reasonably Foreseeable Developments [RFD] Case) that may overlap spatially (i.e., the same geographic area) and temporally (i.e., over time). RFDs or activities in the region that have not yet been approved or developments and activities that are currently under application review, or that have officially entered a regulatory application process, are considered reasonably foreseeable. The cumulative effects assessment considers all primary pathways that are likely to result in detectable changes in measurement indicators and subsequent residual effects on VCs after implementation of environmental design features and mitigation.

The VCs requiring an analysis under the RFD Case are determined by understanding whether the residual effects from the NSDF Project and one or more additional developments (or activities) overlap or interact with the temporal or spatial distribution of the VC. For some VCs, there is no potential for cumulative effects to environmental components because there is no overlap of Project effects with the potential effects of other developments. Where potential cumulative effects from the RFD Case are identified for these VCs, these effects were assessed using the same approach used for the Project-specific effects analysis.

For the malfunctions and accidents scenarios described in Section 7.0, all radiological doses meet the acceptance criteria for design basis accidents, for both on-site and off-site workers. The maximum estimated dose during the operations period for an on-site worker is 5 times lower than the regulatory limit of 50 millisieverts per year (mSv/yr) and for the public is almost 50 times lower than the regulatory dose limit of 1 mSv/yr. During post-closure, the maximum estimated dose associated with the most likely future state of the facility is more than 60 times lower than the regulatory dose limit of 1 mSv/yr.

Non-radiological malfunction and accident scenarios were assessed to represent risks classified to be negligible or tolerable, where further protective measures are identified in Section 7.0. As no residual adverse effects are advanced for consideration of significance, no assessment of cumulative effects is identified to be required.

8.2 Reasonably Foreseeable Developments

As described in Section 8.1, the NSDF Project has the potential to interact with previous, existing and reasonably foreseeable developments or activities in the region. Table 8.2-1 provides a summary of the other projects considered in the RFD Case. The potential effects of these projects and activities were then further considered as to whether they were likely to overlap with VCs affected by the NSDF Project.

Table 8.2-1: Reasonably Foreseeable Developments Considered in the Assessment

Type of Project	Location	Examples	Timeframe
Activities related to Canadian Nuclear Laboratories (CNL) Long-Term Strategy (10-Year Integrated Plan)			
New/upgraded research and development facilities	Chalk River Laboratories (CRL)	Advanced Nuclear Material Research Centre Small Modular Reactor	2022 and onward
New support infrastructure	CRL	Office buildings, maintenance facility, logistics facility	2016 to 2026
Infrastructure decommissioning	CRL	Over 100 buildings on CRL site including nuclear laboratories and conventional buildings	2016 to 2026
Environmental remediation	CRL	Remediation of affected lands and non-operating waste management areas (WMAs).	On-going
In situ disposal of Nuclear Power Demonstration (NPD) reactor	Rolphton	The NPD Closure Project (in situ disposal of the NPD waste facility in Rolphton, Ontario)	2022 to 2024
Garrison Petawawa			
Construction of new infrastructure at Garrison Petawawa	Petawawa	Construction of new facility for the Royal Canadian Dragoons (e.g., renovation of three existing buildings, and the replacement of eight obsolete buildings with a single, centralized 9,900 m facility)	2020 to 2021

8.2.1 Ten-year Integrated Plan for Chalk River Laboratories

Over the next decade, Canadian Nuclear Laboratories (CNL) will be transforming its Chalk River Laboratories (CRL) through the revitalization of essential site infrastructure, the decommissioning of aging infrastructure and a significant investment in new, world-class science facilities (CNL 2017a). The *2016–2026 10-Year Integrated Plan* (CNL 2017a) outlines CNL's 10-year science and technology strategic objectives to support the evolving science and technology needs of the Canadian and global nuclear industry by:

- *providing global sustainable energy solutions, including the extension of reactor operating lifetimes, hydrogen energy technologies, and fuel development for the reactor designs of tomorrow;*
- *demonstrating the commercial viability of advanced reactors, including the small and very small modular reactor (SMR);*
- *continuing support of radiochemical therapies, including collaboratively pioneering new alpha therapies; and*
- *protecting Canada's environment by removing and responsibly managing nuclear liabilities.*

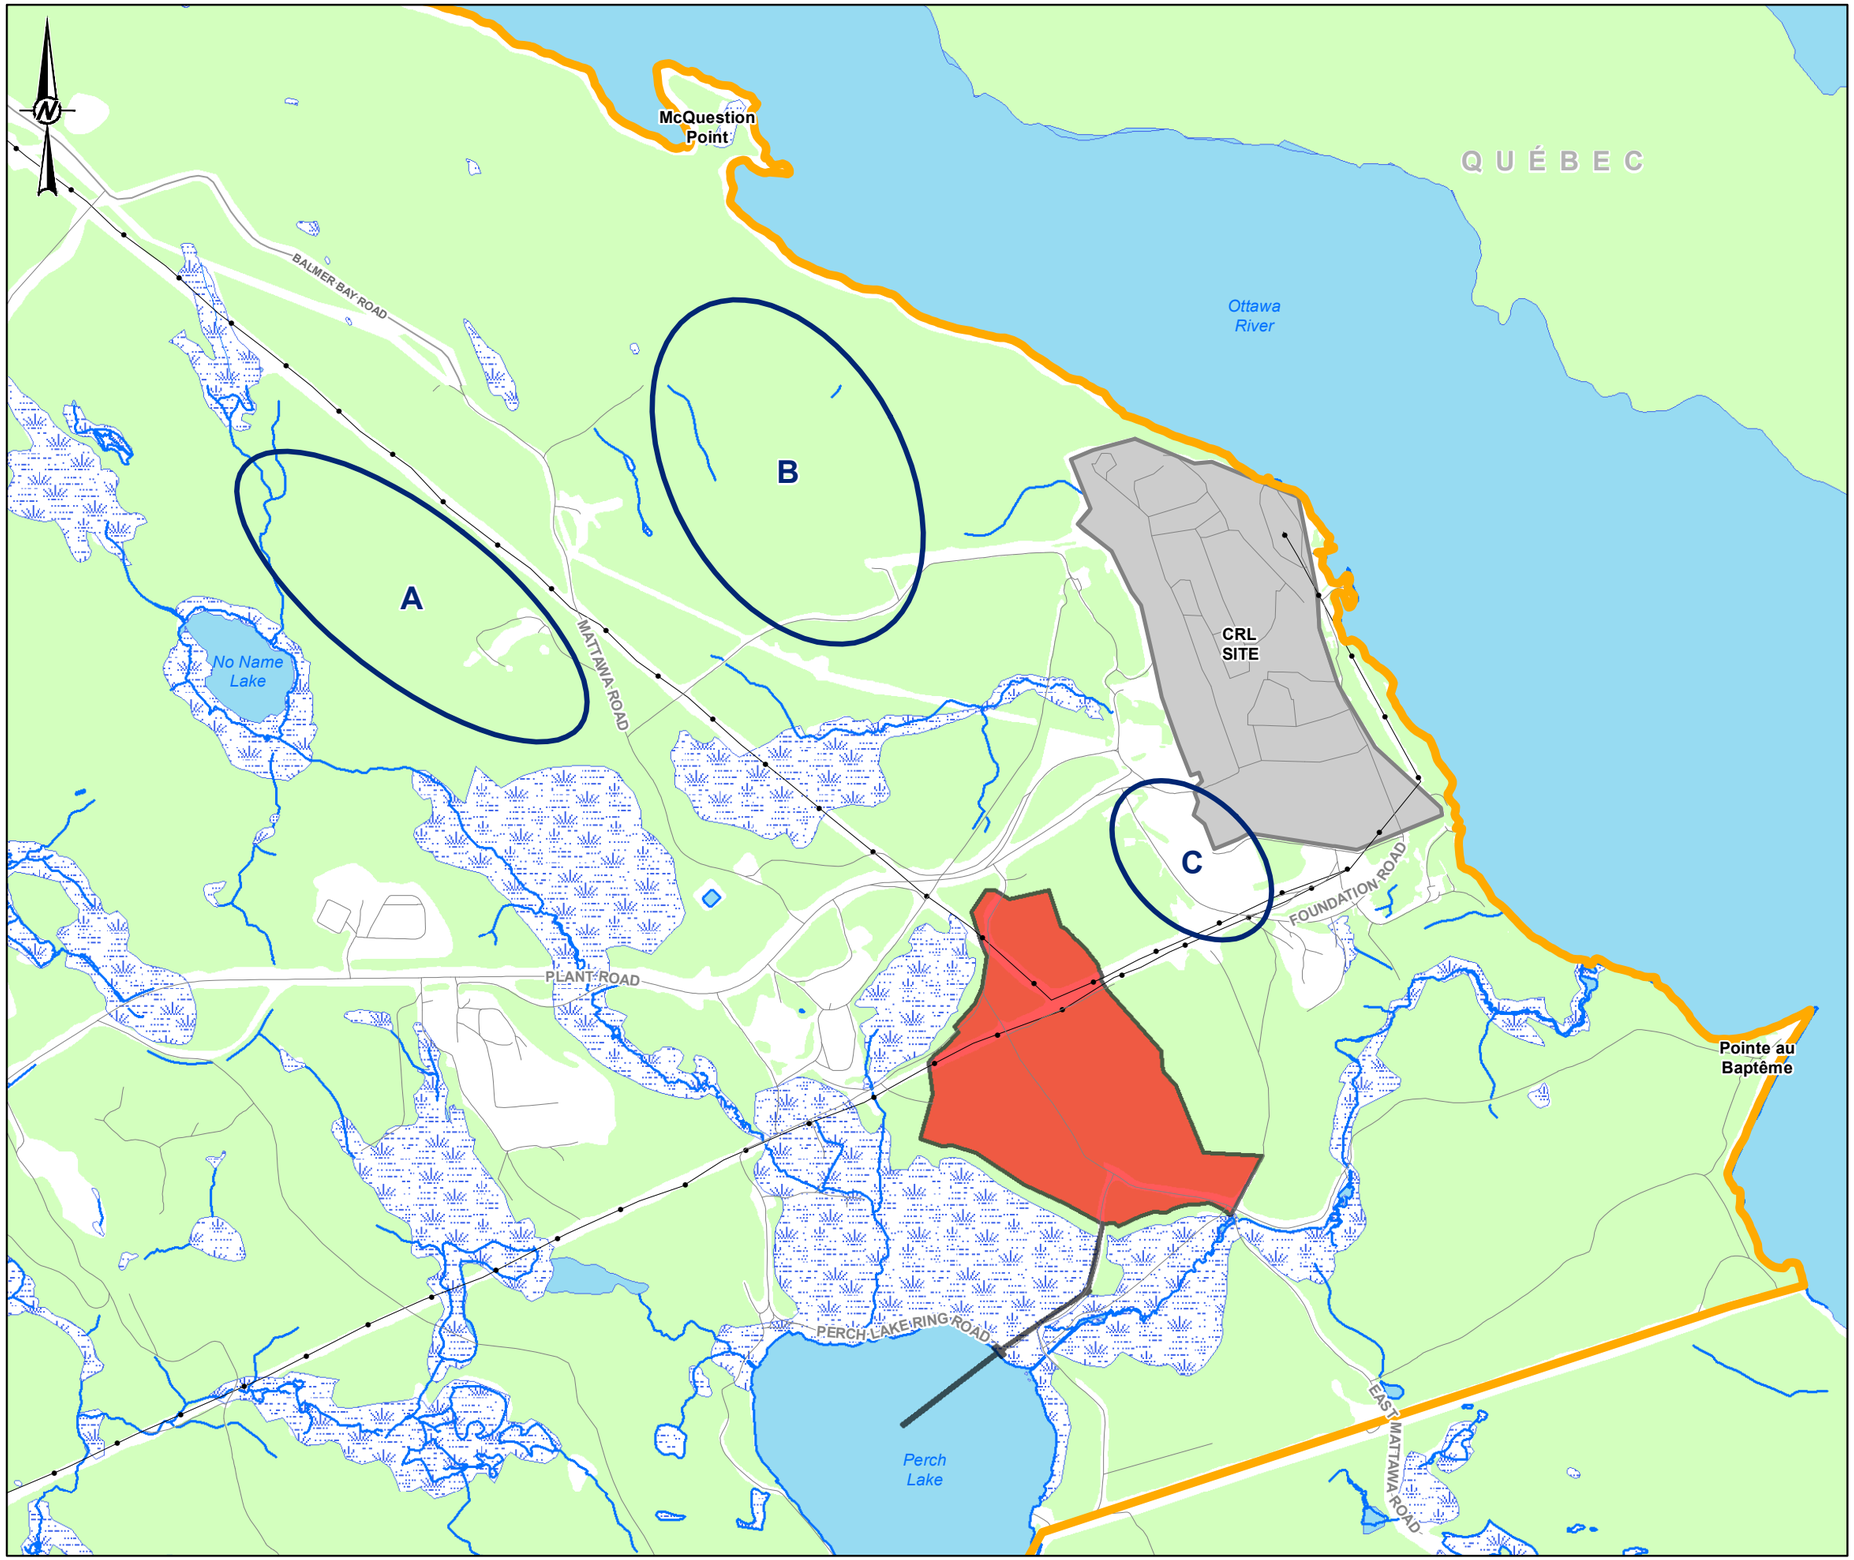
CNL's mission also includes a commitment to "enhance national and global nuclear safety and security by developing new technologies to prohibit contraband nuclear material, respond to nuclear incidents, prevent nuclear accidents and strengthen cyber security for nuclear reactors" (CNL 2017a).

Over the next 10 years, CNL will be decommissioning more than 100 buildings and structures to make room for new, renovated and repurposed facilities. The first step in the site revitalization was the creation of the Site Master Plan that meets the goals of the site development and objectives of the Science and Technology Mission outlined in the 10-Year Integrated Plan (CNL 2017a). Through completion of the Site Master Plan, CNL will reduce the site footprint and transform the CRL site to a national nuclear laboratory campus where similar activities are consolidated and co-located to improve efficiency and foster internal and external collaboration, and with sustainable facilities that are reconfigurable to meet changing needs of developing science and technology. Decommissioning redundant facilities and assets also helps to reduce the cost of on-going management.

As presented in Table 8.2-1, these goals will be met through a combination of revitalization activities (i.e., developing new or upgrading existing research and development facilities at CRL, constructing new support infrastructure), decommissioning old infrastructure and conducting environmental remediation.

8.2.1.1 Small Modular Reactor

To meet CNL's long-term strategy goal of demonstrating commercial viability of advanced reactors, including SMRs, an invitation was issued in April 2018 seeking proponents of SMR demonstration projects for construction and operation at a CNL-managed site. In February 2019, CNL announced that the proposal presented by Global First Power had advanced to the third stage of its review process. In July 2019, Global First Power released its Project Description for the Micro Modular Reactor™ (MMR) Project at Chalk River (Global First Power 2019), to provide the CNSC with the required information to make an Environmental Assessment Determination under the *Canadian Environmental Assessment Act, 2012* and establish the requirements for the MMR Project.



The Project Description explains that:

> *The proposed [MMR] Project will involve the site preparation, construction, operation, and decommissioning of one MMR nuclear reactor and supporting infrastructure on a Project site within the CRL property. The main physical works related to the Project are a Nuclear Plant, which includes an MMR High Temperature Gas-cooled Reactor that will provide approximately 15 MW [thermal] of process heat to a (non-nuclear) Adjacent Plant via molten salt. The process heat will be used in the Adjacent Plant to generate electrical power and/or heat that could be used by CRL, or electrical power to the area grid, over an anticipated life span of 20 years. The Adjacent Plant consists of the equipment and systems that convert the process heat to electrical power or other forms of energy (Global First Power 2019).*

The project has the potential to replace the current heat and power sources at the CRL site. The fenceline of the nuclear plant of the SMR is planned to be approximately 130 m by 100 m and the adjacent plant 180 m by 100 m, with total site dimensions of approximately 180 m by 200 m (Global First Power 2019).

Three candidate sites were identified as feasible by CNL within the CRL site, under consideration for locating the SMR (Figure 8.2.1-1). The closest of these (Site C) is located more than 1 km to the northeast of the NSDF Site Study Area (SSA) near the built-up area of the site, within the Ottawa River direct watershed. The other two candidate sites include some undisturbed vegetated areas (Global First Power 2019) and are located more than 2 km to the north of the SSA, one within the Ottawa River direct watershed (Site B) and the other within the Perch Creek and Perch Lake Watershed (Site A).

Bounding estimated dates indicate SMR site preparation and construction is planned to occur over approximately 2 years between 2023 and 2025 with operation of approximately 20 years between 2025 and 2055. The construction of the SMR may overlap with the construction of the NSDF Project. Following the end of its operational life, decommissioning would occur over approximately two to three years between 2055 and 2059, with abandonment activities occurring over two to three years between 2058 and 2060. For non-radiological components, SMR decommissioning activities are considered to be bounded by the activities of its construction for the purposes of the RFD Case assessment; both SMR construction and decommissioning are scheduled to occur during the operations phase of the NSDF Project. SMR development activities, which will include site characterization and impact assessment activities, are currently underway and anticipated to be completed by 2021, during which a formal project schedule will be finalized.

8.2.2 Nuclear Power Demonstration Closure Project

The purpose of the Nuclear Power Demonstration (NPD) Closure Project is to safely complete the decommissioning of the NPD Waste Facility, located near the CRL site at Rolphton, Ontario. In situ disposal is the preferred approach proposed by the project to carry out these activities. The Class I nuclear facility is presently in the storage with surveillance phase of decommissioning and has a Decommissioning Waste Facility Licence issued in 2014. The NPD Nuclear Generating Station, consisting of a 20 MW electrical Canada Deuterium Uranium ("CANDU") reactor, was placed in service in 1962 and was operated by Ontario Hydro until 1987. The reactor was heavy water moderated, cooled by pressurized heavy water and fuelled with natural uranium. The main components of NPD Nuclear Generating Station were the reactor, heat transport system, turbine and electrical power generator equipment. Following permanent shutdown of the station, the operating and compliance responsibilities were transferred from Ontario Hydro to Atomic Energy of Canada Limited.

The proposed in situ disposal activities include removing the above-grade structure and placing contaminated materials into the below-grade structure (CNL 2017b). The below-grade structure, reactor vessel and systems and components will be sealed by grouting. The structure will then be capped with concrete and covered with an engineered barrier. In situ disposal will isolate the contaminated systems and components inside the below-grade structure.

The conclusion of the Draft Environmental Impact Statement for the NPD Closure Project (CNL 2017b) identifies that no residual adverse effects are identified as a result of the Project.

8.2.3 Garrison Petawawa

In support of Canada's defense policy, "Strong, Secure, Engaged," a pilot project was announced in January 2019 to deliver new and enhanced facilities for the Royal Canadian Dragoons at 4th Canadian Division Support Base, Garrison Petawawa, located adjacent to the CRL site (Government of Canada 2019). The project includes renovation of three existing buildings and replacement of eight buildings no longer in use with a single, centralized approximately 10,000 m^2 facility with construction planned for 2020 to 2021.

8.3 Summary of Cumulative Effects

8.3.1 Atmospheric Environment

The atmospheric environment assessment (Section 5.2) considered potential cumulative effects as part of the Base Case, Application Case and RFD Case.

Reasonably foreseeable developments in the RSA with potential to overlap with the residual effects of the NSDF Project include revitalization activities (i.e., new/upgrades to research and development facilities, new support infrastructure), on-going decommissioning and environmental remediation activities on the CRL site.
These revitalization and decommissioning activities involve renovation of some current buildings, construction of new buildings, and removal of more than 100 existing buildings on the CRL site over the ten-year period 2016 to 2026. A specific new research and development project announced in 2019 is the planned construction and 20-year operation of a SMR at the CRL site. As well, there may be overlap of the construction period with limited construction at neighbouring Garrison Petawawa.

8.3.1.1 Air Quality

Site revitalization, SMR construction, construction at Garrison Petawawa and on-going decommissioning activities on the CRL site will generate air and dust emissions such as CO, oxides of sulphur (SO_x includes SO_2), oxides of nitrogen (NO_x includes NO_2), particulate matter ($PM_{2.5}$, PM_{10}), and suspended particulate matter (SPM). Air emissions, such as SO_x and NO_x, can result from the use of fossil fuels in generators, vehicles, and machinery. Vehicle exhaust and fugitive dust from unpaved and paved roads is expected to be the largest contributor to particulate matter (SPM, PM_{10}, and $PM_{2.5}$). The waste from the decommissioning of the CRL structures will be placed in the NSDF and the Application Case assessed for the operations phase considers the transport of this waste for disposal in the ECM.

Decommissioning of eight buildings, renovation of three and construction of a new 9,900 m^2 facility for the Royal Dragoons planned within the built-up area at Garrison Petawawa (approximately 10 km south of the SSA) in 2020-2021 are also expected to follow best practice construction techniques. As a result, emissions to air are expected to be short term and limited. Given the distance of these activities from the SSA and limited potential overlap in time of the construction periods, no potential for cumulative effects is identified.

The airborne emissions from new facility construction and decommissioning projects on the CRL site will be assessed as part of the approval process for these projects. Examples of mitigation expected to be implemented by site revitalization, SMR construction and on-going decommissioning activities on the CRL site to limit potential effects to air quality include:

- limiting the construction activities required on-site through the use of modular structures for construction of the SMR (Global First Power 2019);
- staging site revitalization and decommissioning activities over a ten-year period to reduce periods of simultaneous construction at the CRL site;
- implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and verification monitoring;
- implementation of best practice dust management techniques such as water spraying or misting techniques (e.g., water trucks);
- using on-site vehicles and equipment engines that meet Tier 2 emission standards and maintaining them in good working order; and
- limiting idling of vehicles on site.

Site revitalization and decommissioning activities include several small projects staged over a ten-year period where best practices, mitigation and monitoring for management of emissions will to be followed. Accordingly, the incremental additional equipment use and emissions at any one time are expected to be small, distributed across the CRL site and removed from the more intensive activities within the SSA. The conclusions of the NSDF Project assessment in Section 5.2.1.6.2 for the Assessment Case indicate that the predicted concentrations of indicator compounds for air quality are below the relevant guideline/standard during the construction and operations phases, except for 1-hour NO_2. These predictions are based on conservative assumptions around number of heavy-duty vehicles and intensity of use, as well as meteorological conditions. When compared with current CRL site operations and NSDF Project activities, it is anticipated that the small incremental effect to indicator compounds from site revitalization and decommissioning activities in progress at any one time would be

negligible to air quality outside of the CRL site. Similarly, the scale and modular construction technique for the SMR limits the length of its construction period, as well as associated equipment use. The locations for placement of the SMR under consideration are removed from the SSA within the CRL site. During operation of the SMR, dry cooling towers may be used to dissipate excess heat from steam condensation in operation of the steam turbine generator. No additional activities or new sources for release of indicator compounds are planned (Global First Power 2019). With effective implementation of mitigation measures and monitoring programs, no cumulative residual effect is identified to air quality.

8.3.1.2 Greenhouse Gas

Consistent with the consideration of the RFD Case for air quality, revitalization activities (i.e., new/upgrades to research and development facilities, new support infrastructure), on-going decommissioning and environmental remediation activities on the CRL site, as well as construction and operations of a SMR at the CRL site will generate GHG emissions that may overlap with residual effects of the Project. As Project contributions within the LSA represent a negligible change to GHG emissions to provincial and national totals, contribution by the limited construction at neighbouring Garrison Petawawa would be anticipated to be similarly negligible and the areas of effect would not be anticipated to overlap.

The airborne emissions from new facility construction and decommissioning projects on the CRL site will be assessed as part of the approval process for these projects. Examples of mitigation to limit effects from GHG emissions applicable to all projects on the CRL site include:

- implementation of CNL's procedure for *Management and Monitoring of Emissions* (CNL 2018), which includes operational control monitoring and verification monitoring;
- on-site vehicles and equipment engines will meet Tier 2 emission standards and be maintained in good working order; and
- limiting idling of vehicles on-site.

Revitalization and decommissioning activities at the CRL site are planned to be staggered over the ten- year period (2016 to 2026), and the required activities to be completed at any one time are anticipated to be less than that required for the larger scale construction of the NSDF Project. Similarly, the equipment requirements for construction and operations of the SMR are expected to be less than that assessed for the NSDF Project. Consistent with the conclusions in Section 5.2.2.6.2 for the Application Case, GHG emissions as a result of RFD Case projects are anticipated to result in a negligible change relative to provincial and national totals. With effective implementation of mitigation measures and monitoring programs, no cumulative residual effect is identified to GHGs.

8.3.2 Geology and Hydrogeology

Measurements of radionuclide concentrations have been performed at specific areas of concern within the CRL site. This included studies of groundwater contamination in areas affected by groundwater plumes from waste management areas at CRL. Radiological contamination in the East Swamp wetland is relevant to the NSDF Project, as this area is immediately west of the SSA. Because this wetland is potentially downgradient of parts of the SSA, characterization of the contamination present is important in defining Base Case conditions. The East Swamp wetland has existing contamination associated with a shallow subsurface plume from the Chemical Pit and a second plume from Reactor Pit 2. Cumulative effects of previous and existing projects

on hydrogeology have been considered through assessment of the Base Case and Application Case (see Section 5.3.2.6).

New and upgrades to research and development facilities, construction and operation of the SMR and new support infrastructure are planned within areas of the CRL site removed from the NSDF Project site and generally within existing disturbed areas. Best practices, such as surface water management systems and waste management programs, are expected to be implemented to minimize any potential effects to measurement indicators for geology and hydrogeology, including soil quality, groundwater flow or quality during construction and operation of these facilities. No process intakes of water from or discharges to surface or groundwater are identified in the description of the planned SMR (Global First Power 2019). As such, potential effects from the construction and operation of the SMR or revitalization activities are not expected to spatially overlap with potential effects to geology or hydrogeology from the NSDF Project during normal operations. The end-state plan for the CRL site will be to return lands disturbed by site activities to a condition that is physically stable and safe in keeping with the land use and landscape of the day. Therefore, decommissioning and environmental remediation activities are anticipated to positively affect measurement indicators for geology or hydrogeology such as soil and groundwater quality. As well, no potable water wells are anticipated to be installed within the RSA during the time up to the end of the institutional control period during post-closure.

Because RFDs will either have no spatial overlap, or are likely to positively affect the geology and hydrogeology VCs, an RFD Case is not presented as part of these assessments.

8.3.3 Surface Water Environment

Surface water sampling locations are currently monitored routinely throughout the Perch Creek and Perch Lake watershed. The East Swamp wetland, located in the Perch Creek and Perch Lake watershed, has existing contamination associated with a shallow subsurface plume from the Chemical Pit and a second plume from Reactor Pit 2. Treated effluent from the Wastewater Treatment Plant (WWTP) will be released to an exfiltration gallery to promote the exfiltration of treated water into the local groundwater regime, where small quantities of residual contaminants will migrate towards the East Swamp Stream. Treated effluent will also be discharged directly to Perch Lake via a transfer line. The transfer line to Perch Lake has been designed to manage the full annual volume of treated effluent, if required, which will prevent the potential for overland flow at the exfiltration gallery.

The East Swamp Stream feeds Perch Lake, which is connected to the Ottawa River through Perch Creek. Residual contaminants from the WWTP effluent will be most concentrated with the East Swamp Stream due to further dilution in downstream waterbodies (e.g., Perch Lake, Perch Creek). Because this wetland is potentially downgradient of parts of the SSA, characterization of the contamination present is important in defining Base Case conditions. Cumulative effects of previous and existing projects on surface water have been considered through assessment of the Base Case and Application Case. It is noted that no measurable changes in surface water quality are predicted downstream of the NSDF Project in the Ottawa River.

RFDs within the CRL site (i.e., the RSA) include only the new or upgrades to research and development facilities, construction and operation of the SMR, new support infrastructure, and on-going decommissioning and environmental remediation activities. New support infrastructure and research and development facilities will generally be located within existing disturbed areas on the CRL site (i.e., minimal disturbance to largely undeveloped areas). Disturbance of an approximately 3.5 ha may be required for development of the SMR based on the candidate site selected (Global First Power 2019); therefore, the footprint of the SMR will be approximately 10% of the footprint of the NSDF site.

Applicable erosion and sediment control practices and surface water management systems already in place at the CRL site will be implemented for all new or upgrades to research and development facilities (including the SMR), new support infrastructure, and on-going decommissioning and environmental remediation activities. No process intakes of water from or discharges to surface or groundwater are identified in the description of the planned SMR (Global First Power 2019). It is noted that a small amount of radioactive liquid waste from decontamination activities during the operation of the SMR will be monitored and stored in a holding tank for further processing (Global First Power 2019). A septic field may be used to manage sewage from the SMR site, depending on the candidate site chosen, that would follow required standards and would be located approximately 2 km from the NSDF Project site. Consequently, potential effects from revitalization activities and through development of the SMR are not expected to spatially overlap with potential effects to surface water quality from the NSDF Project. The NSDF Project will enable the remediation of contaminated lands and legacy waste management areas, as well as decommissioning of outdated infrastructure at the CRL site and CNL's other business locations to support future CNL work. The end-state plan for the CRL site will be to return lands disturbed by site activities to a condition that is physically stable and safe in keeping with the land use and landscape of the day. Therefore, decommissioning and environmental remediation activities are anticipated to positively affect hydrology and surface water quality. Because RFDs will either have no spatial overlap (i.e., localized change to surface water quality through surface water or sewage management), no interaction (i.e., change to infiltration on hydrology through site revitalization) or are likely to positively affect the surface water environment VCs (i.e., environmental remediation of hydrology and surface water quality), an RFD Case is not presented as part of the assessment.

Although no measurable residual adverse effects were identified to surface water quality as a result of the NSDF Project, or through consideration of cumulative effects, additional context is provided here with respect to the Ottawa River as a key stakeholder concern.

Construction water will be sourced from the Ottawa River using an existing intake structure to fill temporary storage containers. The intake of water from the Ottawa River for construction purposes (i.e., up to a maximum of 276,000 m^3/yr based on the peak daily usage) is anticipated to have a negligible effect on the overall Ottawa River annual flow rate of 25 billion m^3/yr (as recorded at the Des-Joachims monitoring point) and on the downstream hydrology.

During operations, treated effluent will be sampled and confirmed that it meets effluent discharge targets before release to the environment. A portion of the treated effluent from the WWTP will be released to an exfiltration gallery to promote the exfiltration of treated water into the local groundwater regime; from here, small quantities of residual contaminants will migrate from the East Swamp Wetland to East Swamp Stream. The remaining treated effluent will be released into Perch Lake using a submerged diffuser. It is anticipated that the diffuser placement will result in a ten-fold dilution of any treated effluent discharge to Perch Lake within 100 m of the discharge (Golder 2019a). The East Swamp Stream flows into Main Stream and then Perch Lake, which is connected to the Ottawa River through Perch Creek.

Both aquatic and terrestrial species will be exposed to contaminated surface water and sediment in the East Swamp Stream, Perch Lake, Perch Creek, and possibly the Ottawa River. Doses to non-human biota were calculated based on water concentrations from East Swamp Stream. Although dilution will occur in Perch Lake, Perch Creek and the Ottawa River, the exposure limits within the aquatic environment was conservatively assessed to match that of East Swamp Stream during the period of leachate management system and WWTP operations. Doses to non-human biota were calculated based on the waterborne and airborne emissions from the engineering containment mound and assessed against the most conservative criteria available such as

Environmental Quality Guidelines (CCME 2019) for non-radiological contaminants and No-Effect Concentrations for non-human biota derived for the boreal Canadian Shield forest ecosystem (Arcadis 2019) for radiological contaminants. For most contaminant of potential concern (COPCs), the incremental changes in concentration as a result of the NSDF Project are expected not to be measurable in the Ottawa River. COPCs that increase above background in the Ottawa River included only tritium and gross beta. However, these increases are expected to be within the uncertainty bounds of the surface water quality modelling. Further, results of the radiological dose assessment for the operations phase and post-closure phase also indicates that doses to ecological health VCs are below their respective No Effect Concentrations.

The NSDF Project is confident that there will be no adverse effects to biota during operations phase by ensuring that releases and subsequent environmental concentrations are below the relevant guidelines or are below levels that would result in potential adverse effects on aquatic life. The Ottawa River is expected to adequately rapidly assimilate any discharge from the Perch Creek and Perch Lake Watershed to existing conditions in the river, such that surface water quality and aquatic biodiversity VCs are unlikely to be affected. Given that the effluent discharge meets applicable effluent discharge targets, exposure to humans and biota through this pathway are considered negligible during the operations and closure phase.

Many of the site's existing WMAs, including WMAs A and B and the Liquid Dispersal Area (which includes Reactor Pit 1, Reactor Pit 2 and the Chemical Pit) may also affect the Perch Creek and Perch Lake Watershed. Contaminants are transported by groundwater to nearby wetlands, including East Swamp and via the transfer discharge line directly into Perch Lake, which will be the recipient waterbodies for the NSDF Project wastewater. Contaminants released into the Perch Lake then migrate to Perch Creek from where they reach the Ottawa River, which is the ultimate receptor for all CRL discharges. Estimated doses resulting from historic contamination, due to releases from WMAs and Liquid Dispersal Areas, fall below benchmark values for Perch Lake and Perch Creek.

Residual effects on Ottawa River water quality are determined to be negligible during operations and post-closure phases and may result in a net benefit due to remediation of legacy waste storage areas.

8.3.4 Aquatic Environment

Consistent with Section 8.3.3, RFDs expected within the CRL site (i.e., the RSA) that may interact with the aquatic environment include new or upgrades to research and development facilities, construction and operation of the SMR, new support infrastructure, and on-going decommissioning and environmental remediation activities. Considering the design features and the mitigation for RFD projects described in the preceding sections, potential effects of RFD projects are not identified to spatially overlap with Project effects to surface and groundwater. New support infrastructure and research and development facilities will be located within existing disturbed areas on the CRL site (i.e., no disturbance to largely undeveloped areas). Disturbance of approximately 3.5 ha may be required for development of the SMR depending on the candidate site selected, but no watercourses are identified within any of the three candidate sites (Global First Power 2019). The Project Description document for the SMR notes that the nearest waterbody to Site A is "No Name" lake within the Perch Lake Watershed, and the nearest waterbody to Sites B and C is the Ottawa River within the Ottawa River direct watershed. No process intakes of water from or discharges to surface or groundwater are identified in the description of the planned SMR (Global First Power 2019).

Potential effects from these RFD activities are not expected to spatially overlap with potential effects to the aquatic environment biodiversity from the NSDF Project. No primary pathways, and therefore, no measurable residual adverse effects were identified as a result of the NSDF Project to the aquatic environment. The end-state

plan for the CRL site will be to return lands disturbed by site activities to a condition that is physically stable and safe in keeping with the land use and landscape of the day. Therefore, decommissioning and environmental remediation activities are anticipated to positively affect fish and fish habitat. Because RFDs will have no spatial overlap in effect or are likely to positively affect the fish and fish habitat, an RFD Case is not presented as part of the assessment.

Although no residual adverse effects were identified to surface water quality or to the aquatic environment as a result of the NSDF Project, or through consideration of cumulative effects, additional context in provided above in Section 8.3.3 with respect to the Ottawa River as a key stakeholder concern:

8.3.5 Terrestrial Environment

For the terrestrial environment, the RSA was used as the scale at which cumulative effects to terrestrial biodiversity VCs were assessed (see Section 5.6). Regional disturbance factors (e.g., forestry and climate change) were considered if they were likely to affect vegetation communities or populations of wildlife VCs that overlap with the RSA. The assessment considered the Base Case, which represents existing conditions and characterizes effects from previous and existing developments and activities, as well as the Application Case, which represents the effects of the Base Case combined with the predicted incremental effects from the NSDF Project through all project phases for each VC. The Base Case reflects the effects of existing disturbances in the area, such as forestry, transportation, agricultural, mining, and residential and recreational development.

The VCs selected for the terrestrial environment assessment were vegetation communities, migratory birds, Canada warbler (*Cardellina canadensis*), eastern whip-poor-will (*Antrostomus vociferous*), eastern wood-peewee (*Contopus virens*), golden-winged warbler (*Vermivora chrysoptera*), wood thrush (*Hylocichla mustelina*), bats, Blanding's turtle (*Emydoidea blandingii*), eastern milksnake (*Lampropeltis Triangulum*) and monarch butterfly (*Danaus plexippus*). The assessment endpoint for the terrestrial environment is the maintenance of self-sustaining and ecologically effective vegetation communities or wildlife populations.

Residual effects on terrestrial VCs are primarily associated with vegetation clearing and grubbing and the associated loss or alteration of existing vegetation and topographical features, sensory disturbance from NSDF Project activities during construction and operations, and increased risk of injury or mortality on roads due to equipment and vehicle traffic. The cumulative effects from the NSDF Project and previous and existing activities and developments in the RSA on the population of terrestrial biodiversity VCs that overlap with the RSA are predicted to be not significant for all VCs, with the exception of bats and Blanding's turtle, which are discussed in Sections 8.3.5.1 and 8.3.5.2, respectively.

RFDs expected within the CRL site (i.e., the RSA) that may interact with the terrestrial environment include new or upgrades to research and development facilities, construction and operation of the SMR, new support infrastructure, and on-going decommissioning and environmental remediation activities. New support infrastructure and research and development facilities will generally be located within existing disturbed areas on the CRL site (i.e., no disturbance to largely undeveloped areas) where erosion and sediment control practices and surface water management systems already in place will be implemented. Disturbance of approximately 3.5 ha including potentially undisturbed areas of the CRL site, may be required for development of the SMR based on the candidate site selected (Global First Power 2019). The three candidate sites for locating SMR on the CRL site are located away from the SSA (Figure 8.2.1-1). It is expected that removal of and other potential effects on terrestrial habitat including to species at risk through development of SMR will be reduced through consideration of siting and through mitigation similar to that implemented for the NSDF Project. Potential effects from these

revitalization activities, as well as construction and operation of the SMR, are not expected to spatially overlap with potential effects on terrestrial biodiversity from the NSDF Project.

The revitalization of the CRL site is planned to occur over the 10-year period 2016-2026. The workforce numbers and types of work required for site revitalization activities over that period are expected to maintain a similar condition to the site revitalization activities occurring at present on-site, therefore reflected in Base Case characterization such as traffic monitoring. This workforce is anticipated to be approximately equal to that required for the construction of the NSDF Project and the existing roads within the CRL site will continue to be used to access the site. Traffic generated for construction and operations of the SMR will be small compared to that required for NSDF and negligible compared to on-going CRL site operations. Mitigation has been or will be implemented on the CRL Site to limit and offset traffic-related wildlife mortality from previous and existing anthropogenic activities in the RSA.

The end-state plan for the CRL site will be to return lands disturbed by site activities to a condition that is physically stable and safe in keeping with the land use and landscape of the day. Therefore, decommissioning and environmental remediation activities are anticipated to positively affect terrestrial biodiversity. Once existing infrastructure is removed and the CRL site is reclaimed and ceases to be frequented by large numbers of employees, the level of anthropogenic disturbance within the site will be greatly reduced, benefiting the terrestrial environment in the RSA.

RFDs, as currently understood, will either have no spatial overlap or are likely to positively affect terrestrial biodiversity, so no residual adverse cumulative effects are identified. Future, beyond regional disturbance factors (e.g., climate change) were considered qualitatively as part of the Application Case.

8.3.5.1 Bats

Populations of little brown myotis (*Myotis lucifugus*), northern myotis (*Myotis septentrionalis*) and tri-colored bats (*Perimyotis subflavus*) that overlap the terrestrial environment RSA are highly sensitive to changes in survival and reproduction because white nose syndrome has resulted in dramatic declines of these species across the eastern portions of their Canadian range, which includes the RSA. Therefore, the existing level of pressure on these bat species in the Base Case has likely already exceeded their resilience and adaptability limits and they are unlikely to be self-sustaining or ecologically effective. Consequently, the cumulative effects of existing disturbance and especially the introduced white nose syndrome are considered significant in the Base Case (i.e., even before the NSDF Project is included).

The NSDF Project will contribute a small increment to this existing significant adverse cumulative effect. Importantly, because vegetation clearing will be undertaken outside of the maternity roosting season, no mortality of roosting bats is expected as a result of the NSDF Project and effects or the NSDF Project to survival and reproduction are considered neutral. In addition, the remaining availability of potential maternity roosting habitat is not likely a limiting factor in the terrestrial environment RSA. The contribution of the NSDF Project to the existing significant adverse cumulative effect to bats is predicted to be negligible (i.e., no detectable changes to bat populations), and the NSDF Project does not contribute to the spread of white nose syndrome, which is the primary driver of the existing significant adverse cumulative effect.

Maternity roost habitat is currently not considered critical habitat under the *Species At Risk Act* and as such, offsetting the removal of potential bat maternity roost trees is not required. However, the use of appropriately designed bat boxes can increase the availability of maternity roosting locations and may aid in the recovery of bats (ECCC 2018). Bat boxes have been installed in suitable locations in the terrestrial environment RSA is

recommended to mitigate the incremental contribution of the NSDF Project. Monitoring is being conducted to determine if boxes are being used. As well, a comprehensive Sustainable Forest Management Plan is being developed for the CRL site, with an objective to ensure the long-term retention of trees serving as maternity roosts for bat species.

8.3.5.2 Blanding's Turtle

The SSA would permanently remove 26 ha of critical habitat for Blanding's turtle critical habitat during construction which represents 14.5% of the currently available critical habitat in the LSA. The upland habitat and riparian habitat affected by the NSDF Project has the potential to be used by Blanding's turtle for nesting, thermoregulation and summer inactivity. Females who use the area for nesting may experience a reduction in reproductive success until they find new areas within which to nest. Additionally, females may need to travel greater distances if the availability of new nesting sites is limited and/or use lower quality habitats. The use of lower quality habitats could affect hatchling success rates. In searching for new habitats, individual Blanding's turtles may become exposed to other risks (e.g., roads).

With the implementation of the comprehensive mitigation outlined in the *Blanding's Turtle Road Mortality Mitigation Plan* (Golder 2019b), along with monitoring and adaptive management, CNL's activities in the RSA are predicted to have a net neutral or positive effect on the local Blanding's turtle population during the Base Case. That is, the mitigation that is or will be implemented on the CRL site is considered sufficient to limit and offset mortality from previous and existing anthropogenic activities in the RSA. There is uncertainty regarding the effectiveness of mitigation, but CNL is committed to monitoring and adaptive management, including implementing additional conservation actions should these be necessary, such that CRL operations result in a net neutral or positive effect on the Blanding's turtle population in the RSA.

Potential effects associated with critical habitat loss have been identified according to a precautionary approach. The importance of effects may be overestimated because the occupancy of critical habitat identified in the SSA remains unconfirmed despite considerable survey effort. To mitigate these potential effects, CNL will create new nesting mounds on both sides of Priority 2 culverts after they are replaced. Nest mounds will be monitored weekly during the nesting season and after periods of rain and maintenance of these mounds (e.g., vegetation removal) will also be completed at this time, if females are not present.

The weight of evidence suggests that, with mitigation committed to by CNL, effects from the NSDF Project will not jeopardize the survival of the regional Blanding's turtle population. With sufficient mitigation implemented at CRL, reductions in Blanding's turtle road mortality are possible, even with increased traffic volumes associated with the NSDF Project. Moreover, critical habitat will be assessed annually to ensure no significant loss at CRL and to determine compensation measures initiated at CRL or elsewhere.

8.3.6 Ambient Radioactivity and Ecological Health

Cumulative effects of previous and existing projects on ecological health have been considered through assessment of the Base Case and Application Case (see Section 5.7.6) and no significant adverse effects were identified.

CNL reports the results of the Environmental Monitoring Program for the CRL site each year to the CNSC. The Environmental Monitoring Program data are collected to verify that radiation exposure to ecological receptors as a result of the operations of the CRL site remain as low as reasonably achievable. It is noted that additional future site activities may affect the baseline radioactivity prior to NSDF operations. For example, the National Research Universal reactor was shut down in March 2018, which has reduced airborne emissions at CRL and

has lowered environmental concentrations of some radiological contaminants (e.g., tritium). In addition, emissions from the B206 stack and cemented molybdenum waste storage have ceased as the facility has been shut down (production ended in 2016).

Measurements of radionuclide concentrations have been performed at specific areas of concern within the CRL site, and included studies of ambient radiation as well as soil, groundwater and vegetation contamination in areas affected by groundwater plumes from waste management areas at CRL. Radiological contamination in the East Swamp wetland is relevant to the NSDF Project, as this area is immediately west of the SSA. Because this wetland is potentially downgradient of parts of the SSA, characterization of the contamination present is important in defining Base Case conditions. The East Swamp wetland has existing contamination associated with a shallow subsurface plume from the Chemical Pit and a second plume from Reactor Pit 2. The surface contamination distribution in the East Swamp has been characterized on a five-year frequency, with radiation field surveys, surface surveys and vegetation contamination surveys performed in 2002, 2007, and 2012. Additional relevant surveying has been performed to characterize the Chemical Pit plume.

RFDs within the CRL site (i.e., the RSA) include only the new or upgrades to research and development facilities, construction and operation of the SMR, new support infrastructure, and on-going decommissioning and environmental remediation activities. Revitalization projects at the site (i.e., new or upgrades to research and development facilities, new support infrastructure) and decommissioning include several small projects staged over a 10-year period where best practices, mitigation and monitoring for management of emissions will to be followed. No process intakes of water from or discharges to surface or groundwater, or releases to air beyond potential for a limited amount of steam from dry cooling towers, are identified in the description of the planned SMR (Global First Power 2019). During normal operations, the SMR will introduce a very small radiological exposure to the environment near the plant, within the CRL site (Global First Power 2019). The incremental radiological (in proximity to the SMR) and non-radiological emissions from RFD Projects at any one time are expected to be small, distributed across the CRL site and removed from the more intensive activities within the SSA (i.e., the NSDF Project footprint). Potential effects from RFD Projects are not expected to spatially overlap with potential effects to ecological health from the NSDF Project.

The NSDF Project will enable the remediation of contaminated lands and legacy waste management areas, and decommissioning of outdated infrastructure at the CRL site and CNL's other business locations to support future CNL work. The end-state plan for the CRL site will be to return lands disturbed by site activities to a condition that is physically stable and safe in keeping with the land use and landscape of the day. Therefore, decommissioning and environmental remediation activities are anticipated to positively affect ecological health. Because RFDs will have no spatial overlap or are likely to positively affect ecological health, an RFD Case is not presented as part of the assessment.

8.3.7 Human Health

Cumulative effects of previous and existing projects on human health have been considered through assessment of the Base Case and Application Case (see Section 5.8.6) and no residual adverse effects were identified.

CNL reports the results of the Environmental Monitoring Program for the CRL site each year to the Canadian Nuclear Safety Commission. The Environmental Monitoring Program data are collected to verify that radiation doses to members of the public as a result of the operations of the CRL site remain as low as reasonably achievable. The calculated radiation dose to members of the public from CRL operations in 2018 represents the most current baseline radiation dose from CRL prior to the NSDF Project (i.e., Base Case). The 2018 dose

assessment of 0.032 millisieverts per year (mSv/yr), showed that radiation dose to the public from CRL operations was below the effective dose limit of 1 mSv/yr for members of the public (CNL 2019).

RFDs within the CRL site (i.e., the RSA) include only the new or upgrades to research and development facilities, construction and operation of the SMR, new support infrastructure, and on-going decommissioning and environmental remediation activities. Revitalization projects at the site (i.e., new or upgrades to research and development facilities, new support infrastructure) and decommissioning include several small projects staged over a 10-year period where best practices, mitigation and monitoring for management of emissions will be followed. No process intakes of water from or discharges to surface or groundwater, or releases to air beyond potential for a limited amount of steam from dry cooling towers, are identified in the description of the planned SMR (Global First Power 2019). During normal operations, the SMR will introduce a very small radiological exposure to workers or members of the public near the plant, within the CRL site (Global First Power 2019). The incremental radiological (in proximity to SMR) and non-radiological emissions from RFD Projects at any one time are expected to be small, distributed across the CRL site and removed from the more intensive activities within the SSA (i.e., the NSDF Project footprint). Potential effects from RFD Projects are not expected to spatially overlap with potential effects to human health from the NSDF Project.

The NSDF Project will enable the remediation of contaminated lands and legacy waste management areas and decommissioning of outdated infrastructure at the CRL site and CNL's other business locations to support future CNL work. The end-state plan for the CRL site will be to return lands disturbed by site activities to a condition that is physically stable and safe in keeping with the land use and landscape of the day. Therefore, decommissioning and environmental remediation activities are anticipated to positively affect human health. Because RFDs will have no spatial overlap or are likely to positively affect human health, an RFD Case is not presented as part of the assessment.

8.3.8 Land and Resource Use

The land and resource use RSA is defined as the area within which the potential effects of the NSDF Project may interact with the effects of other existing or reasonably foreseeable projects. The land use and resource use RSA corresponds with the combined area of the terrestrial and aquatics RSAs and is defined to capture direct and indirect effects on the terrestrial and aquatic environment resulting from the NSDF Project (e.g., habitat loss, sensory disturbance for wildlife and changes to habitat from dust deposition) as these effects have the potential to result in subsequent effects on land and resource use. No cumulative effects with RFDs were identified in Sections 8.3.4 and 8.3.5 (aquatic environment, terrestrial environment) that could potentially introduce indirect effects to land and resource use. Similarly, of the RFDs identified (see Section 8.2), none will result in change in broad land use category, use or access to land outside of the CRL site. As such, potential effects from RFDs are not expected to spatially overlap with potential effects to land and resource use from the NSDF Project. Because RFDs will have no spatial overlap, an RFD Case is not presented as part of the assessment.

8.3.9 Socio-economics

The socio-economics assessment (Section 5.10) considered potential cumulative effects as part of the Base Case, Application Case and RFD Case. RFDs in the RSA that are anticipated to overlap with the NSDF Project include new or upgrades to research and development facilities, construction and operation of the SMR, new support infrastructure, and on-going decommissioning and environmental remediation activities on the CRL site and the NPD Closure Project. As well, there may be overlap of the construction phase with limited construction at neighbouring Garrison Petawawa. The effects of the RFD projects were considered for their potential to affect

socio-economic VCs (i.e., labour market and economic development, services and infrastructure, and housing and accommodation).

8.3.9.1 Labour Market and Economic Development

CNL is planning new nuclear research facilities and support buildings to revitalize the CRL site. The revitalization of the CRL site is planned to occur over the 10-year period 2016-2026. The workforce required for site revitalization activities at any point is expected to be maintain a similar rate to the workforce on-site supporting those activities at present, captured as part of existing conditions. This workforce is anticipated to be approximately equal to that required for the construction of the NSDF Project. CNL will continue to provide updated information to interested contractors and suppliers on work packages as they develop. Nonetheless, the business prospective of the NSDF Project has motivated prospective contractors to engage local and Indigenous companies. A specific new research and development project announced in 2019 is the proposal by Global First Power to build and operate a small modular reactor at the CRL site. Based on the small scale of the development, labour resources for construction will be small compared to that required for the NSDF Project and negligible compared to on-going CRL site operations.

CNL's proposed NPD Closure Project is expected to be executed over a two-year period from 2022 to 2024. It will employ an average of 40 people (approximately 30 existing CNL employees and 10 external contractors). External contractors that may be sourced from the LSA and RSA communities, with possibly some specialized contractors coming from Ottawa and beyond. The peak workforce is expected to be approximately 340 workers in RFD Case (300 peak workforce for the NSDF Project and approximately 40 person workforce for the NPD Closure Project).

Decommissioning of eight buildings, renovation of three and construction of a new 9,900 m facility for the Royal Dragoons planned within the built-up area at Garrison Petawawa (approximately 10 km south of the SSA) in 2020 to 2021 may require labour resources for construction from within the RSA.

Given the size of the labour force in the LSA and RSA in 2016 of approximately 3,370 and 791,985 respectively, with an unemployment rate of 6.6% for both the LSA and RSA (Statistics Canada 2017a,b,c,d), it is not expected that local labour will be constrained in consideration of the demand for labour from the RFD Case. A positive cumulative effect is identified on employment opportunities and income generation (see Section 5.10.8.2.1 Labour Market and Economic Development).

8.3.9.2 Service and Infrastructure

8.3.9.2.1 Transportation and Traffic

It is anticipated that there will be additional traffic associated with an estimated average of 225 full time equivalent workers commuting to and from the CRL site each day for the NSDF Project. CNL is planning new nuclear research facilities and support buildings to revitalize the CRL site. The revitalization of the CRL site is planned to occur over the 10-year period 2016-2026. The workforce required for site revitalization activities at any point is expected to be maintain a similar rate to the workforce on-site supporting those activities at present, captured as part of traffic monitoring to characterize existing conditions. This workforce is anticipated to be approximately equal to that required for the construction of the NSDF Project. On-going decommissioning and environmental remediation activities on the CRL site will primarily be completed by CNL employees.

Traffic generated for construction and operations of the SMR, as well as for limited construction at Garrison Petawawa will be small compared to that required for NSDF and negligible compared to on-going CRL site operations.

The NPD Closure Project is not expected to require regular transportation to and from the CRL site. The NPD Closure Project is projected to increase traffic on local roads including Highway 17 by approximately 70 trips per day delivering materials, personnel and services to the CNL NPD site (approximately 30 trips a day for raw materials and 40 trips per day for personnel travel).

Overall, if there is temporal overlap of the NSDF Project, NPD Closure Project and the CNL site revitalization projects, this could result in an average additional 265 workers (225 for the NSDF Project and 40 for the NPD Closure Project) commuting in the region, with approximately 225 of these additional workers commuting to the CRL site. As well, based on estimates of truck deliveries to the NSDF Project site during the 24-month construction period, approximately 200 shipments per day are anticipated during the nine-month construction season.

In consideration of the increased traffic from the NSDF Project and applicable RFD Projects, and the annual average daily traffic levels in the LSA and RSA, which range from 6,700 to 12,300 vehicles per day, the cumulative effects of traffic from the RFD Case may slightly increase traffic levels during the morning and evening commutes.

The increase in traffic from the transportation of workers, supplies and equipment for the NSDF Project and applicable RFD projects is expected to result in degradation of public transportation infrastructure. The incremental increase in traffic expected from applicable RFD Projects is small, when considered with the NSDF Project during construction. Overall, the cumulative residual effect on transportation and traffic is predicted to be not significant for the RFD Case (see Section 5.10.8.2.3 Services and Infrastructure).

8.3.9.2.2 Emergency and Protective Services

Emergency and protective services at CRL generally rely on CNL's own internal capacity. For medical emergencies, trained CNL personnel will conduct initial evaluation and assistance, and will request external EMS, as required. Chalk River Laboratories' existing emergency and protective services at the CRL site are expected to be sufficient for the NSDF Project, construction and operation of the SMR, and on-going decommissioning and revitalization projects. Existing emergency and protective services around the NPD site are also expected to be sufficient for the NPD Closure Project activities. There may be an increase in demand for emergency and protective services in the LSA and RSA communities, as well as the County of Renfrew, due to the need to support more serious project-related incidents (e.g., incidents requiring hospitalization). However, the predicted residual effect is expected to be limited due to the size of the workforces at any one time for the RFD projects. The cumulative residual effects on emergency and protective services for the RFD Case are determined to be not significant (see Section 5.10.8.2.3 Services and Infrastructure).

8.3.9.3 Housing and Accommodations

Similar to the NSDF Project, it is expected that a portion of the RFD project workforce would come from the LSA and RSA and, therefore, already be residents of the area and not require temporary accommodation. In addition, not all of the RFD projects would occur at the same time. For example, the NPD Closure Project is anticipated to occur over a 2-year period from 2022 to 2024, whereas revitalization and decommissioning activities at the CRL site will occur progressively over the 10-year period 2016 to 2026. The construction of the SMR may overlap with the construction of the NSDF Project; however, based on the small scale of the development, labour resources for construction will be small compared to that required for the NSDF Project. Based on the small scale of the development and short timeline for construction, labour requiring temporary accommodation will be small compared to that required for the NSDF Project. Limited construction at neighboring Garrison Petawawa is planned between 2020 and 2021. When considered with the NSDF Project temporary accommodation

requirements, and the availability of hotels, motels and other accommodation in the LSA and RSA, it is not expected that the combined effects of the RFD projects will place considerable constraints on temporary accommodation in LSA and/or RSA communities. Overall, the cumulative residual effect on commercial accommodation availability is predicted to be not significant for the RFD Case (see Section 5.10.8.2.2 Housing and Accommodations).

8.3.10 Indigenous Interests

8.3.10.1 Traditional Land and Resource Use

RFDs in the Regional Study Area (RSA) may overlap with potential effects from the NSDF Project include new or upgrades to research and development facilities, construction and operation of the SMR, new support infrastructure, and on-going decommissioning and environmental remediation activities on the CRL site, as well as, briefly, the construction at Garrison Petawawa.

The traditional land and resource use RSA is defined to capture effects on the terrestrial and aquatic environments as a result of the NSDF Project (e.g., habitat loss, sensory disturbance for wildlife and changes to habitat from air quality and surface water quality, changes in groundwater and surface water quality, habitat loss and changes in abundance, distribution and disturbances to wildlife and fish), as these effects have the potential to result in subsequent effects on land and resource use. The RSA for traditional land and resource use is a combination of the air quality and aquatic environment RSAs as this is the largest extent of potential cumulative effects on land and resource use. There are no traditional land and resource use activities such as hunting, fishing, gathering and cultural ceremonies occurring in either the SSA or LSA as this is a restricted public access area. Traditional land and resource use activities likely did occur prior to federal control of the CRL site. It is possible that traditional land uses continue with parts of the RSA outside of the restricted public access areas such as fishing or waterfowl hunting along the Ottawa River shoreline of the CRL site and Garrison Petawawa property. There is potential trapping identified in the southern portion of the RSA in the Garrison Petawawa property and two trapline areas in the western portion of the RSA. To date, these have not been identified as traplines belonging to Indigenous Peoples.

The NSDF Project is not predicted to have any terrestrial effects beyond the CRL site, and results of the aquatic environment assessment identify that measurable residual effects on aquatic biodiversity VCs are not predicted as a result of the NSDF Project. Therefore, no effects on traditional land users are expected. Because no residual effects are identified and therefore RFDs will have no spatial overlap, an RFD Case is not presented as part of the assessment.

8.3.10.2 Socio-economics

RFDs in the Regional Study Area (RSA) may overlap with potential effects from the NSDF Project include new or upgrades to research and development facilities, construction and operation of the SMR, new support infrastructure, and on-going decommissioning and environmental remediation activities on the CRL site, as well as, briefly, the construction at Garrison Petawawa.

No pathways were identified as having a primary linkage to Indigenous socio-economic VCs. Secondary pathways were identified related to employment, contracting and supplier opportunities and potential noise and air quality effects related to construction activities. The NSDF Project may result in small positive effects to local Indigenous Peoples through potential contracting or employment opportunities, which may act cumulative with similar small positive effects resulting from the identified RFDs.

8.3.11 Uncertainty in the Assessment

Consideration of cumulative effects is based on understanding at the time of assessment of what developments are reasonably foreseeable and how those developments will be implemented.

It is noted that transport of waste from decommissioning activities for facilities on the main CRL campus are considered through this assessment. The decommissioning activities and haulage of waste from remediation of WMAs on the CRL site located outside of the main campus are anticipated to use existing roadways to NSDF; however, remedial action plans for the large-scale cleanup of the WMAs are not yet developed thus there is uncertainty on the extent of waste that will be received in NSDF and their transport routes. Once Remedial Action Plans are developed for WMAs (or other areas of large land contamination), the waste transport plans would be developed and trigger the appropriate Environmental Reviews at that time.

If NSDF Project follow-up monitoring identifies a residual effect not predicted or anticipated by the EIS, the cumulative effects of the NSDF Project would be re-evaluated.

This page intentionally left blank

9.0 SUMMARY OF SIGNIFICANCE OF RESIDUAL EFFECTS

The following assessments were completed to evaluate the biophysical and human environment effects of the Near Surface Disposal Facility (NSDF) Project and to satisfy the requirements of the review being undertaken under the *Canadian Environmental Assessment Act, 2012* (CEAA 2012):

- Section 5.2 Atmospheric Environment;
- Section 5.3 Geological and Hydrogeological Environment;
- Section 5.4 Surface Water Environment;
- Section 5.5 Aquatic Environment;
- Section 5.6 Terrestrial Environment;
- Section 5.7 Ambient Radioactivity and Ecological Health;
- Section 5.8 Human Health;
- Section 5.9 Land and Resource Use;
- Section 5.10 Socio-economic Environment; and
- Section 6.0 Indigenous Interests.

The residual effects classification of primary pathways and the associated predicted changes in measurement indicators provide the foundation for determining the significance of incremental and cumulative effects from the NSDF Project and other existing, approved and reasonably foreseeable developments on valued component (VC) assessment endpoints. The overall environmental assessment approach described in Section 5.1 was used for the assessment of residual effects that cannot be avoided or mitigated through the re-design or relocation of the proposed NSDF Project or through proponent commitments. Modifications in the approach (where applicable) are described in detail in the discipline assessments (Sections 5.2 through 6.0).

Table 9-1 summarizes the proposed environmental design features and mitigation, residual effects and significance of effects (where applicable) for the Application Case and the Reasonably Foreseeable Development (RFD) Case (where applicable) for each of the VCs. The classification of residual adverse effects and the determination of significance are completed only for those VCs that have assessment endpoints. The intent of the environmental assessment is to predict if the NSDF Project is likely to cause a significant adverse (i.e., negative) effect on the environment. Although the neutral and positive residual effects associated with the NSDF Project are reported in the relevant discipline assessments, they are not assessed for significance.

No pathways were identified as having a primary linkage to land and resource use VCs, Indigenous traditional land and resource VCs or Indigenous socio-economic VCs, so no assessment of significance was undertaken. The NSDF Project may result in small positive effects to local Indigenous Peoples through potential contracting or employment opportunities.

Table 9-1: Summary of Predicted Residual Effects on Valued Components and Significance – Application Case and Reasonably Foreseeable Developments Case

Discipline	Valued Component	Assessment Endpoint	Residual Effect	Project Phase the Effect Occurs in	Contributing Project Activity	Mitigation	Significance	
							Application Case	RFD Case
Atmospheric Environment	Air Quality	Performance against criteria and thresholds for protection of human health and the environment	■ Construction activities use vehicles and equipment that combust fuel and emit indicator compounds. These activities involve material handling, vehicles travelling on paved and unpaved roads, and wind erosion of stockpiles that will result in fugitive dust emissions.	Construction	■ Site preparation ■ Construction of the engineered containment mound (ECM) ■ Development of surface water management structures ■ Construction of the Wastewater Treatment Plant (WWTP) and other support facilities ■ On-site road and access development ■ Vehicle traffic on-site including soil spoils haulage to a soil storage area	■ Implementation of CNL's procedure for Management and Monitoring of Emissions (CNL 2018), which includes operational control monitoring and air verification monitoring. ■ The *Dust Management Plan* (AECOM 2018) to be implemented for the NSDF Project will provide information on dust mitigation, including: ▪ Use of water spraying or misting techniques (e.g., water trucks) as the primary dust control method. ▪ Use of fixatives (e.g., chemical suppressant) for dust control. ▪ Covering stockpiles and exposed areas prior to high wind or dry conditions where standard dust suppressants may be inadequate in preventing dust generation caused by wind erosion. ▪ Minimizing the size of the exposed working areas containing contaminated materials to the extent practicable using a phased excavation approach. ▪ Revegetating affected areas or adding mulch to completed cells and excavated areas as soon as practicable. ▪ Dampening soil in dry areas prior to commencing truck/machinery activities in the area. ▪ Reducing activities to avoid unnecessary dust generation; ▪ Using wind fencing around work areas. ▪ Postponing work activities likely to cause dust if sustained wind speeds are predicted to exceed 40 km/hr, unless it can be shown that the work site is sufficiently protected that wind will not generate unacceptable amounts of dust. ■ On-site vehicles and equipment engines will meet Tier 2 emission standards and be maintained in good working order. ■ Limit idling of vehicles on-site. ■ Processed wastewater will not be heated within the WWTP (raising the temperature increases potential release rates). ■ There is active ventilation within the WWTP building and all active ventilation exhaust will be filtered through HEPA prior to release.	Not Significant	Not applicable
			■ Most activity and material handling occur during the operations phase and pathways include: ▪ vehicles and equipment combust fuel and emit indicator compounds. ▪ material handling, vehicles travelling on paved and unpaved roads and wind erosion of stockpiles emit fugitive dust. ▪ release of emissions from the disposal cell cover and passive vents. ▪ emissions from the decomposition of waste. ▪ the disposal cell cover and the WWTP emit odour.	Operations	■ Phased development of ECM disposal cells ■ On-site transportation of waste and placement of waste in the ECM ■ Progressive closure of disposal cells and installation of final cover ■ Operation of the WWTP		Not Significant	Not applicable
			■ Air emissions from the decomposition of waste.	Operations and Post-closure	■ Placement of waste in the ECM	■ Installation of the interim and final covers will reduce release of emissions from the ECM.	Not Significant	Not applicable

Table 9-1: Summary of Predicted Residual Effects on Valued Components and Significance – Application Case and Reasonably Foreseeable Developments Case

Discipline	Valued Component	Assessment Endpoint	Residual Effect	Project Phase the Effect Occurs in	Contributing Project Activity	Mitigation	Significance	
							Application Case	RFD Case
Atmospheric Environment (continued)	Greenhouse Gases (GHG)	Comparison to provincial and national totals	▪ GHG emissions from the decomposition of waste.	Operations and Post-closure	▪ Placement of waste in the ECM	▪ Installation of the interim and final covers will reduce release of emissions from the ECM.	Not Significant	Not applicable
			▪ Construction activities use vehicles that combust fuel and emit GHGs. These vehicles travel on roads on CRL site and are used for material handling. ▪ Additionally, there are GHG emissions associated with land clearing for the NSDF Project. One-time emissions will be presented over the life-time of the NSDF Project. ▪ Most activity and material handling occur during Operations. Vehicles and equipment combust fuel and emit GHGs. These activities involve material handling with vehicles travelling on roads. The disposal cell emits GHG emissions from the decomposition of waste. The WWTP will be fuelled by Natural Gas. Additionally, there is a loss of carbon sink as a result of the cleared land for the NSDF Project.	Construction and Operations	**Construction** ▪ Site preparation ▪ Construction of the ECM ▪ Development of surface water management structures ▪ Construction of the WWTP and other support facilities ▪ On-site road and access development ▪ Vehicle traffic on-site including soil spoils haulage to a soil storage area **Operations** ▪ Phased development of disposal cells ▪ On-site transportation of waste and placement of waste in the ECM ▪ Progressive closure of disposal cells and installation of final cover ▪ Operation of the WWTP	▪ Implementation of CNL's procedure for Management and Monitoring of Emissions (CNL 2018a), which includes operational control monitoring and verification monitoring. ▪ On-site vehicles and equipment engines will be maintained in good working order. ▪ Limit idling of vehicles on-site.	Not Significant	Not applicable

Table 9-1: Summary of Predicted Residual Effects on Valued Components and Significance – Application Case and Reasonably Foreseeable Developments Case

Discipline	Valued Component	Assessment Endpoint	Residual Effect	Project Phase the Effect Occurs in	Contributing Project Activity	Mitigation	Significance	
							Application Case	RFD Case

Hydrogeology	Groundwater Quantity	Intermediate component (i.e., it does not have an assessment endpoint)	▪ The construction of the NSDF Project will physically alter groundwater levels and flows.	▪ All phases	▪ Project activities during the construction phase:
					  ▪ Site preparation
					  ▪ Construction of the ECM
					  ▪ Development of surface water management structures
					  ▪ Construction of the WWTP and other support facilities
					  ▪ On-site road and access development
						▪ The NSDF Project Footprint has been designed to limit disturbance to the natural environment.
						▪ Discharge of treated effluent primarily to the exfiltration gallery area will help to reduce water loss from the hydrogeological system.
						▪ Discharge of treated effluent to Perch Lake via transfer line will help reduce high water table conditions in the area of the exfiltration gallery.
							Significance is not determined as Valued Component (VC) does not have an assessment endpoint.	Not applicable

		Intermediate component (i.e., it does not have an assessment endpoint)	▪ Adverse changes to groundwater quality from the discharge of treated effluent from the WWTP to the exfiltration gallery.	Operations	▪ Discharge of treated effluent to the exfiltration gallery	▪ The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses the best available technology that is economically achievable, and capable of meeting regulatory requirements. ▪ Effluent discharge targets for wastewater discharges are protective of the environment and human health. ▪ Discharge targets for non-radiological contaminants are sourced from federal and provincial guidelines for protection of aquatic biota. ▪ Discharge targets for radionuclides are the Canadian Drinking Water Guidelines with the exception of tritium for which a site-specific target is developed (Section 3.4.2.5.1). ▪ Treated effluent will be sampled and confirmed that it meets the effluent discharge targets before release to the environment. ▪ When applied, the proposed exfiltration gallery will promote the exfiltration of treated water into the local groundwater regime where further retention of radioactivity by the geosphere is anticipated. ▪ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water and groundwater quality. ▪ Appropriate procedures will be in place to effectively identify spill occurrences in the event treated effluent is released to areas other than directly to the exfiltration gallery and initiate appropriate emergency responses.	Significance is not determined as Valued Component (VC) does not have an assessment endpoint.	Not applicable

Table 9-1: Summary of Predicted Residual Effects on Valued Components and Significance – Application Case and Reasonably Foreseeable Developments Case

Discipline	Valued Component	Assessment Endpoint	Residual Effect	Project Phase the Effect Occurs in	Contributing Project Activity	Mitigation	Significance	
							Application Case	RFD Case
Hydrogeology (continued)	Groundwater Quality	Intermediate component (i.e., it does not have an assessment endpoint)	▪ Leakage of leachate from the ECM during the post-closure phase (i.e., after Year 2400) from liner and final cover degradation as a result of normal evolution can cause changes to groundwater quality.	Closure and Post-closure	▪ Installation of final cover, restoration and grading of Site Study Area (SSA). ▪ On-going long-term performance monitoring, transfer of NSDF Project into Institutional Control. ▪ Liner and final cover degradation as a result of normal evolution.	▪ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound and minimize leachate generation. ▪ The final cover system design incorporates a series of shallow, trapezoidal, riprap-lined drainage channels that are designed to convey water at low velocity. ▪ The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the final cover and underlying waste materials, destabilization of the ECM structure and damage to access roads. ▪ The ECM final grading and drainage plan also includes collection ditches along the top of the ECM berm road to collect side slope drainage. ▪ The design life for the ECM is 550 years to meet the required time period to allow for radioactive decay of the waste placed in the facility (i.e., until it has decayed to levels that do not present a risk to the public and environment). ▪ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to groundwater quality.	Significance is not determined as VC does not have an assessment endpoint.	Not applicable
Surface Water Environment	Hydrology	Intermediate component (i.e., it does not have an assessment endpoint)	▪ The construction of the NSDF Project will physically alter drainage patterns in the Perch Creek and Perch Lake Watershed and may change downstream discharge, water levels, channel and bank stability, and water levels in adjacent wetlands.	Construction	▪ Site Preparation ▪ Construction of the ECM ▪ Development of surface water management structures ▪ Construction of the WWTP and other support facilities ▪ On-site road and access development ▪ Construction of transfer line and Perch Lake diffuse	▪ The NSDF Project footprint has been designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. ▪ A 30 m buffer will be established along identified wetlands near the SSA; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion. ▪ Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the CRL site will be used during construction around disturbed areas, where appropriate. ▪ During the construction phase, erosion and sediment control measures in place to mitigate the effects of sediment transport include the use of erosion control blankets, as needed, to control erosion on steep slopes, check dams in ditches and swale. ▪ Surface water from all external areas will be conveyed by ditches, swales and culverts to SWMPs to address water quality and water quantity criteria established for the wetland receiving waters and, ultimately, Perch Creek. ▪ Where drainage crosses roadways, culverts are sized to convey the 25-year design event without road overtopping. ▪ The SWMPs are designed to address erosion and sediment control concerns during construction by providing interim sediment control and by providing water quality/quantity controls during operations, closure and post-closure. ▪ Annual maintenance activities will identify any erosion problems. ▪ Inspections will be undertaken and maintenance activities completed, as required, after major storm events and after the annual spring melt to confirm there are no major erosion issues.		

Table 9-1: Summary of Predicted Residual Effects on Valued Components and Significance – Application Case and Reasonably Foreseeable Developments Case

Discipline	Valued Component	Assessment Endpoint	Residual Effect	Project Phase the Effect Occurs in	Contributing Project Activity	Mitigation	Significance	
							Application Case	RFD Case
Surface Water Environment (continued)	Hydrology	Intermediate component (i.e., it does not have an assessment endpoint)	▪ The installation of the ECM will physically alter drainage patterns and may change downstream discharge, water levels in adjacent wetlands, and channel and bank stability.	Closure and Post-closure	▪ Construction of the ECM ▪ Development and operation of surface water management structures ▪ Construction the WWTP and other support facilities ▪ On-site road and access development	▪ The final cover and site grading are designed to promote positive drainage from the NSDF SSA and reduce erosion or abrasion of the final cover. ▪ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound and minimize leachate generation. ▪ The final cover system design incorporates a series of shallow, trapezoidal, riprap-lined drainage channels that are designed to convey water at low velocity. ▪ The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the final cover and underlying waste materials, destabilization of the ECM structure and damage to access roads. ▪ The ECM final grading and drainage plan includes collection ditches along the top of the ECM berm road to collect side slope drainage. ▪ The SWMPs are designed to address erosion and sediment control concerns by providing water quality/quantity controls during operations, closure and post-closure. ▪ Environmental monitoring will be completed as required during the institutional control period for the NSDF Project to confirm that the final cover is functioning as intended.	Significance is not determined as VC does not have an assessment endpoint.	Not applicable

	Surface Water Quality	Intermediate component (i.e., it does not have an assessment endpoint)	▪ Adverse changes to downstream surface water quality from the discharge of treated effluent from the WWTP to the exfiltration gallery and/or Perch Lake.	Operations and Closure	▪ Discharge of treated effluent
					▪ Surface water management
					▪ Operation of the WWTP
						▪ The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses best demonstrated available technology that is economically achievable and capable of meeting regulatory requirements.
						▪ Effluent discharge targets for wastewater discharges are protective of the environment and human health:
						  ▪ Discharge targets for non-radiological contaminants are sourced from federal and provincial guidelines for protection of aquatic biota.
						  ▪ Discharge targets for radionuclides are the Canadian Drinking Water Guidelines with the exception of tritium for which a site-specific target is developed (Section 3.4.2.5.1).
						▪ Treated effluent will be sampled to confirm it meets treatment targets before release to the environment.
						▪ When applied, the proposed exfiltration gallery will promote the exfiltration of treated water into the local groundwater regime where further retention of radioactivity by the geosphere is anticipated.
						▪ The Perch Lake diffuser design provides additional dilution of treated effluent at the point of release
						▪ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water quality.
						▪ Appropriate procedures will be in place to effectively identify spill occurrences in the event treated effluent is released to areas other than directly to the exfiltration gallery or to Perch Lake and initiate appropriate emergency responses.
							Significance is not determined as VC does not have an assessment endpoint.	Not applicable

Surface Water Environment (continued)	Surface Water Quality (continued)	Intermediate component (i.e., it does not have an assessment endpoint) (continued)	▪ Leakage of leachate from the ECM during the post-closure phase (i.e., after Year 2400) from liner and final cover degradation as a result of normal evolution can cause changes to downstream surface water quality.	Closure and Post-closure	▪ Installation of final cover, restoration and grading of SSA ▪ On-going long-term performance monitoring, transfer of NSDF Project into institutional control ▪ Liner and final cover degradation as a result of normal evolution	▪ The final cover system will be constructed to promote the shedding of surface water to mitigate infiltration into the mound and minimize leachate generation. ▪ The final cover system design incorporates a series of shallow, trapezoidal, riprap-lined drainage channels that are designed to convey water at low velocity. ▪ The perimeter road ditch will route the runoff around the ECM perimeter to minimize ponding of water into the closed ECM, erosion of the final cover and underlying waste materials, destabilization of the ECM structure and damage to access roads. ▪ The ECM final grading and drainage plan includes collection ditches along the top of the ECM berm road to collect side slope drainage. ▪ The design life for the ECM is 550 years to meet the required time period to allow for radioactive decay of the waste placed in the facility (i.e., until it has decayed to levels that do not present a risk to the public and environment). ▪ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water and groundwater quality.	Significance is not determined as VC does not have an assessment endpoint.	Not applicable
Terrestrial Environment	Vegetation Communities (including wetlands)	Maintenance of self-sustaining and ecologically effective vegetation communities	▪ Permanent loss of 33 ha of forested communities. ▪ Permanent changes to the distribution of forested habitats; no changes to the distribution of wetlands. ▪ Permanent edge effects may alter adjacent vegetation community richness.	All phases	▪ Vegetation clearing and grubbing	▪ The SSA has been designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. ▪ A 30 m buffer will be established along identified wetlands near the SSA; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion. ▪ A 5 m tree-line buffer is established from all property lines on the NSDF site to limit disturbance to vegetation and large tree roots at the treeline.	Not Significant	Not applicable

Terrestrial Environment (continued)	Canada Warbler	Maintenance of self-sustaining and ecologically effective populations	▪ Permanent loss of 28 ha of suitable habitat. ▪ Possible long-term avoidance in the Local Study Area (LSA) from sensory disturbance. ▪ Permanent small change in movement in the LSA. ▪ Permanent small reduction in carrying capacity.	All phases	▪ Vegetation clearing and grubbing ▪ Mobilization of equipment ▪ Hauling of materials ▪ Blasting	▪ The SSA has been designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. ▪ A 30 m buffer will be established along identified wetlands near the SSA; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion. ▪ A 5 m tree-line buffer is established from all property lines on the NSDF site to limit disturbance to vegetation and large tree roots at the treeline. ▪ Avoid conducting the activities with highest levels of noise and habitat disturbance during most sensitive life history phase (i.e., breeding and nesting for birds) by conducting vegetation clearing and grubbing before April 8, or after August 31 to avoid effects on nesting birds.	Not Significant	Not applicable
	Eastern Whip-poor-will	Maintenance of self-sustaining and ecologically effective populations	▪ Permanent loss of 2 ha of suitable habitat. ▪ Possible long-term avoidance in the LSA from sensory disturbance. ▪ Permanent small change in movement in the LSA. ▪ Permanent small reduction in carrying capacity.	All phases	▪ Vegetation clearing and grubbing ▪ Mobilization of equipment ▪ Hauling of materials ▪ Blasting		Not Significant	Not applicable
	Eastern Wood-pewee	Maintenance of self-sustaining and ecologically effective populations	▪ Permanent loss of 18 ha of suitable habitat. ▪ Possible long-term avoidance in the LSA from sensory disturbance. ▪ Permanent small change in movement in the LSA. ▪ Permanent small reduction in carrying capacity.	All phases	▪ Vegetation clearing and grubbing ▪ Mobilization of equipment ▪ Hauling of materials ▪ Blasting		Not Significant	Not applicable
	Golden-winged Warbler	Maintenance of self-sustaining and ecologically effective populations	▪ Permanent loss of 27 ha of suitable habitat. ▪ Possible long-term avoidance in the LSA from sensory disturbance. ▪ Permanent small change in movement in the LSA. ▪ Permanent small reduction in carrying capacity.	All phases	▪ Vegetation clearing and grubbing ▪ Mobilization of equipment ▪ Hauling of materials ▪ Blasting		Not Significant	Not applicable
	Wood Thrush	Maintenance of self-sustaining and ecologically effective populations	▪ Permanent loss of 28 ha of suitable habitat. ▪ Possible long-term avoidance in the LSA from sensory disturbance. ▪ Permanent small change in movement in the LSA. ▪ Permanent small reduction in carrying capacity.	All phases	▪ Vegetation clearing and grubbing ▪ Mobilization of equipment ▪ Hauling of materials ▪ Blasting		Not Significant	Not applicable

							Application Case	RFD Case
Terrestrial Environment (continued)	Bats	Maintenance of self-sustaining and ecologically effective populations	▪ Permanent loss of 28 ha of potential maternity roost habitat. ▪ Potential long-term avoidance of adjacent maternity roosting habitat in the LSA from sensory disturbance. ▪ Permanent negligible change in movement corridors between maternity roosting habitat patches.	All phases	▪ Vegetation clearing and grubbing ▪ Mobilization of equipment ▪ Hauling of materials ▪ Blasting	▪ The SSA has been designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. ▪ A 30 m buffer will be established along identified wetlands near the SSA; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion. ▪ A 5 m tree-line buffer is established from all property lines on the NSDF site to limit disturbance to vegetation and large tree roots at the treeline. ▪ Avoid conducting the activities with highest levels of noise and habitat disturbance during most sensitive life history phase (i.e., maternity roosting for bats) by conducting vegetation clearing and grubbing before April 8, or after August 31 to avoid effects on bat maternity roosts. ▪ Bat boxes are relatively inexpensive and can be highly effective at providing habitat for roosting little brown myotis and possibly northern myotis. Tri colored bats are less likely to use bat boxes, but may use other forms of artificial roosting habitat; these options may be considered. Installation of bat boxes in suitable locations in the RSA is recommended to offset the incremental contribution of the NSDF Project to cumulative effects on SARA listed bats. ▪ In consultation with CNL biologists and in consideration of future losses of anthropogenic structures that may provide roosting habitat, offsetting in the form of 16 bat boxes was recommended. Bat boxes were installed in May 2017. Each two chambered box (Bat Conservation International approved design) was installed back to back on wooden poles in eight different locations around the proposed NSDF location. Occupancy was confirmed in July 2018 and has been increasing since then. This box design is suggested to have capacity for 350–400 individual bats per box, providing roosting habitat for a potential maximum of 6,400 individual bats (with 16 boxes). ▪ Criteria for appropriate siting included accessibility of box locations for installation and future monitoring of utilization/effectiveness, avoidance of areas with radiological contamination in surface water features and appropriate distance to anthropogenic disturbances to avoid sensory effects (i.e., noise). Immature forested areas adjacent to larger uncontaminated waterbodies and wetlands are high priority locations because these forest types do not currently provide high quality roosting habitat and would be most benefited by installation of bat roost boxes to expand the spatial coverage of potential roosting habitat within the RSA. Final site selection will be at the discretion of CNL biologists. ▪ Monitoring is being conducted at least weekly to determine if boxes are being used. Boxes not being used may be moved to an alternate location. ▪ A project in collaboration with Trent University is currently underway, where bats are being trapped and tracked back to the roost site (natural tree or bat box). Guano collection is being performed as well. This work has a duration of two years and will provide CNL with a better understanding of habitat occupancy by the bat species at risk, including bat boxes, and habitat preference. This work will support the objective of addressing knowledge gaps on the three bat species at risk ▪ A comprehensive Sustainable Forest Management Plan will be implemented to ensure the long-term retention of trees serving as maternity roosts for the bat species.	Not Significant	Not applicable

Terrestrial Environment (continued)	Blanding's Turtle	Maintenance of self-sustaining and ecologically effective populations	▪ Long-term loss of 26 ha of critical habitat with implementation of mitigation to ensure no significant loss of critical habitat. ▪ Permanent change in potential movement corridors between habitat patches. ▪ Long-term increased risk of injury or mortality on roads from increased traffic (but mitigation may be sufficient to prevent this effect). ▪ Permanent increased risk of mortality from changes to movement patterns.	All phases	▪ Vegetation clearing and grubbing ▪ Mobilization of equipment ▪ Hauling of materials ▪ Installation and maintenance of perimeter fencing	▪ The SSA has been designed to avoid wetlands and limit disturbance to the natural environment to the extent feasible. For example, as the ECM is developed sequentially, undeveloped cells may be prepared and used as stockpile areas to store overburden soils to be used during construction or for daily ECM cover stockpiles. This approach reduces the required area for the laydown and stockpile of materials. ▪ A 30 m buffer will be established along identified wetlands near the SSA; where the buffer can not be maintained, appropriate mitigation will be established to address any risk of erosion. ▪ A 5 m tree-line buffer is established from all property lines on the NSDF site to limit disturbance to vegetation. ▪ Critical Blanding's turtle habitat will be assessed annually to ensure no significant loss at CRL and to determine compensation measures initiated at CRL or elsewhere. ▪ Artificial nest mounds will be constructed on both sides of new and replaced culverts. ▪ New and replaced culverts will be enhanced by planting native vegetation around the culvert entrances, while maintaining a clear line of site through the culvert. ▪ Reptile exclusion fencing will be installed around the perimeter of the SSA prior to initiating activities during the construction phase and prior to the active Blanding's turtle season (i.e., prior to April). ▪ Damaged or ineffective fencing and signage will be repaired. ▪ Road grading and levelling activities will not be completed during the turtle nesting season (May 15 to June 30). ▪ Temporary exclusion fencing will be installed around the NSDF EMR footprint during construction of the NSDF Project. This temporary exclusion fencing will be replaced by permanent fencing by the end of construction of the NSDF Project. ▪ A road mortality survey will be completed for turtles in the species' active seasons of April 15 to September 30. ▪ After replacement, culverts will have appropriate permanent fencing installed for 200 m on either side of the culvert to guide turtles through the tunnel. ▪ Following approval of the NSDF Project, additional permanent exclusion fencing will be installed in reptile hotspots along Plant Road. ▪ Drivers have standard safety training and are provided with environmental awareness training. ▪ Enforce existing CRL site speed limits on access roads. ▪ Post signs warning drivers of high use wildlife areas and reduce speed limits in these areas. ▪ Employees in vehicles encountering wildlife of concern (e.g., Blanding's turtle) on roads are required to communicate the presence of wildlife on the roads to other employees working in the area and to CNL's Environmental Staff. ▪ The existing CNL Employee Education Program will be adapted to the NSDF Project prior to construction. All employees and contractors will be trained on the identification and safe handling of Blanding's turtle to help the turtle across the road. ▪ As per CNL's Management of Land, Habitat and Wildlife procedure (CNL 2018b), dead or wounded animals on roads must be reported to the environmental department. ▪ Blanding's turtle collisions with vehicles will be monitored, which provides feedback for adaptive management.	Not Significant	Not applicable

							Application Case	RFD Case

Ambient Radioactivity and Ecological Health	All Ecological Health VCs	Protection of ecological health	▪ Dust may be created during the handling of bulk materials, and emissions of gases may be released during storage and disposal of radioactive materials, which can affect ecological health.
			▪ Emissions may be released from the WWTP to air during operations, which can affect ecological health.
				Operation and Closure	▪ Phased development of disposal cells in the ECM
					▪ On-site transportation of waste and placement in the ECM
					▪ Progressive closure of disposal cells and installation of final cover
					▪ Operation of the WWTP
						▪ CNL's procedure for Management and Monitoring of Emissions (CNL 2018a), which includes operational control monitoring and verification monitoring will be implemented.
						▪ The buildup of gaseous emission from waste in closed cells is mitigated by gas venting in the final cover.
						▪ The *Dust Management Plan* (AECOM 2018) for the NSDF Project will include:
						  ▪ restricting or suspending activities if unacceptable amounts of dust are generated due to winds or other site conditions;
						  ▪ use of water spraying or misting techniques (e.g., water trucks) as the primary dust control method;
						  ▪ use of fixatives (e.g., chemical suppressant) for dust control, and for use as daily/interim cover;
						  ▪ suspension of excavating, loading, hauling and disposal operations when wind speeds exceed the specified criterion; and
						  ▪ vehicles that have come into contact with contamination will be required to pass through the vehicle decontamination facility
						▪ Processed wastewater will not be heated within the WWTP (raising the temperature increases potential release rates).
						▪ There is active ventilation within the WWTP building, and active ventilation exhaust will be filtered through HEPA prior to release.
						▪ A perimeter fence around the NSDF will be implemented to prevent terrestrial land-based wildlife from gaining access to the ECM. Given the transient nature of exposure to birds and the low expected ambient concentrations, low exposures are expected for birds and as such no specific mitigations have been proposed.
							Not Significant	Not applicable

	All Ecological Health VCs	Protection of ecological health	▪ Discharge of treated effluent from the WWTP to the East Swamp Wetland via the exfiltration gallery and/or directly to Perch Lake can cause changes to groundwater quality in the wetland and downstream surface water quality, which can affect ecological health.	Operation and Closure	▪ Surface water management
					▪ Operation of the WWTP
					▪ Discharge of treated effluent from the WWTP
						▪ The strategy for wastewater treatment is based on optimizing public and environmental protection by defining an approach to wastewater treatment that uses the best available technology that is economically achievable and capable of meeting regulatory requirements.
						▪ Effluent discharge targets for wastewater discharges are protective of the environment and human health:
						  ▪ Discharge targets for non-radiological contaminants are sourced from federal and provincial guidelines for protection of aquatic biota.
						  ▪ Discharge targets for radionuclides are the Canadian Drinking Water Guidelines with the exception of tritium for which a site-specific target is developed (Section 3.4.2.5.1).
						▪ Treated effluent will be sampled to confirm that it meets effluent discharge targets before release to the environment.
						▪ When applied, the proposed exfiltration gallery will promote the exfiltration of treated water into the local groundwater regime where further retention of radioactivity by the geosphere is anticipated.
						▪ The Perch Lake diffuser design provides additional dilution of treated effluent at the point of release
						▪ The Waste Acceptance Criteria developed for the NSDF Project will limit the level of contamination (i.e., only LLW) and types of waste to be disposed in the ECM. This will limit the magnitude of potential changes to surface water quality.
						▪ Appropriate procedures will be in place to effectively identify spill occurrences in the event treated effluent is released to areas other than directly to the exfiltration gallery and initiate appropriate emergency responses.
							Not Significant	Not applicable

10.0 EFFECTS OF THE ENVIRONMENT ON THE PROJECT

This section of the Environmental Impact Statement (EIS) discusses the effects of the environment on the Near Surface Disposal Facility (NSDF) Project, in a manner consistent with Section 19(1)(h) of the *Canadian Environmental Assessment Act, 2012*, which indicates that, among other considerations, the environmental assessment of a designated project must take into account "any change to the designated project that may be caused by the environment". Accordingly, this section focuses on the effects of natural hazards (i.e., extreme weather events, forest fires, seismic events, glaciation and climate change on the NSDF Project. It summarizes the risks associated with each kind of environmental change, along with environmental design features, management practices and other mitigation to reduce the risks. Malfunctions and accident scenarios, which are not caused by natural hazards, are identified in Section 7.0 Malfunctions and Accidents, including the estimated likelihoods and consequences to the environment and public and worker safety.

As discussed in Section 3.0, the NSDF Project incorporates design features to minimize its effect on the environment during facility operation and after facility closure. To ensure the effects on the environment are minimized, the design basis of the NSDF accounts for the expected environmental conditions of the site.

The systematic and comprehensive approach, documented in Section 7.2, was used to identify and categorize the major external hazards (natural) and postulated initiating events associated with the design and operations of the NSDF Project. Table 7.3.2-1 provides the consolidated list of external hazards and initiating events, and potential scenarios applicable to the NSDF Project. Further details on the hazard identification, hazard analysis and screening process are provided in the NSDF *Safety Analysis Report* (CNL 2020).

In the post-closure phase of the NSDF Project, many scenarios and models, including those involving major external events, are developed by examining the features, events and processes (FEPs) that could affect the long-term performance and safety of the NSDF Project. This includes physical FEPs directly or indirectly influencing the release and transport of contaminants (radiological and non-radiological) from the NSDF Project or subsequent radiation exposures to humans, as well as factors such as regulatory requirements or modelling issues that constrain or focus the analysis (IAEA 2004). The FEPs list was developed in a systematic manner following the latest readily available Nuclear Energy Agency (NEA) International FEP list (NEA 2014). Further details on the FEP screening and analysis are provided in the NSDF *Post-Closure Safety Assessment* (PostSA; Arcadis and Quintessa 2020).

10.1 Extreme Weather Events

Weather events can produce extreme conditions affecting the performance of facilities and management systems. These events include extreme temperature fluctuations, thunderstorms, flooding and tornadoes, among others. In this section, potential effects from extreme weather events and the associated mitigation to be implemented are described. Potential effects from shifts in the frequency and/or intensity of extreme weather events due to climate change are discussed in Section 10.4.

10.1.1 Temperature Fluctuations

Temperature fluctuations and the effects of freeze-thaw cycles are considered in the design of the engineered containment mound (ECM) base and final cover system. There are multiple natural and synthetic components of the base and cover lining systems, including a high density polyethylene (HDPE) geomembrane liner, geosynthetic clay liner, compacted clay liner and final granular/soil cover; these lining systems are expected to perform effectively through the ECM's 550-year design life (i.e., 50-year of operations and 500 years of post-closure).

Natural freeze-thaw cycles could damage the linings of the ECM final cover system, leading to water infiltration into the waste. To mitigate this, the NSDF Project has been designed to include a layer of clean fill on the floor of the ECM of sufficient thickness to prevent freezing of the base liner systems prior to waste placement. Placement of similar frost protection fill on the perimeter sideslopes of the ECM is not practical and would be susceptible to erosion given that parts of the slopes will remain exposed for several years prior to buttressing with waste fill. Hence, the sideslope lining system will be subjected to freeze-thaw action. A freeze-thaw assessment (AECOM 2017a) concluded that the sideslope HDPE geomembrane liner component of the sideslope lining system will not be adversely affected by freeze-thaw cycles, whereas the geosynthetic and compacted clay liner components of the sideslope lining system could undergo an increase in hydraulic conductivity prior to placement of the wastes on the sideslopes. However, after placement of the waste, the clay liners will consolidate under the weight of the waste, healing the voids caused by freezing such that the potential increase in hydraulic conductivity would be negligible for the geosynthetic clay liner and up to a factor of 2 for the compacted clay liner. The final cover system will be installed to its full thickness progressively as areas of the ECM reach the final waste contours. The final cover system design has 1.75 m of granular/soil materials above the lining system, which is sufficient to prevent freezing of the final cover system liner components.

Extreme temperature fluctuations could also affect the successful establishment of vegetation used in remediation of the site. For example, the vegetated top of the final cover system has been designed to withstand erosion and gully initiations. The vegetation for the final cover system will be limited to grass species that are drought resistant. Bare or eroded areas will be rolled, regraded, replanted and remulched in the same way as in the original installation to produce a uniformly smooth grassed surface. Treatments will be applied as required to keep grass and soil free of pests and pathogens or disease (AECOM 2017b).

10.1.2 Extreme Rainfall Events, Snowmelts and Flooding

Extreme rainfall and snowmelt events and the potential for flooding are considered in the design of the surface water management systems, berms and the final cover system for the ECM. The NSDF Project design will comply with all relevant federal and provincial regulations, guidelines, acts, standards and codes, including standard industry practice.

The NSDF Project uses different design criteria to size contact and non-contact surface water management systems. The different criteria reflect the different potential for significant environmental effects. For example, the contact water management and the non-contact water management systems are sized for the back-to-back, 24-hour, 100-year storm (the most rigorous criterion), because this is a large volume of potentially contaminated water and would cause the most adverse effects if it were released to the environment. The NSDF water collection and conveyance systems are typically designed to resist erosion, safely convey flows and maintain structural integrity during peak flows generated from various design storms up to a probable maximum precipitation (PMP) storm event. Major non-contact surface water systems (e.g., surface water management ponds and major conveyance systems) are designed for a single 100-year storm plus 25%, reflecting the lower level of environmental risk from high volumes of uncontaminated water. The design of the non-contact water ponds is consistent with the typical standard for surface water management pond design in Ontario and typically applies to all land development projects in the Province. Minor non-contact water systems (e.g., minor ditches and culverts) are designed for a 25-year storm, supplemented by overland flow routes for larger storm events, reflecting the lowest level of environmental risk from low volumes of uncontaminated water.

During the Operations phase, the strategy for wastewater treatment of contact water (Section 3.4.2 Wastewater Treatment) is based on optimizing public and environment protection by defining an approach to wastewater treatment that uses best available technology that is economically achievable, and is capable of

meeting or exceeding regulatory requirements. Another important design consideration is the maximum wastewater flow rate that must be received and processed by the Wastewater Treatment Plant (WWTP). The maximum flow rate was determined by evaluating the expected contact water volume that would be produced during two back-to-back 100-year, 24-hour storm events. Under these conditions, it is expected that a maximum of approximately 4,700 m^3 of contact water would be produced, and that this contact water would be removed from the ECM at a maximum rate of approximately 100 m^3/hr. This was selected as a worst-case design condition for determining the required volume of wastewater collection tanks. The contact water ponds are expected to overflow during events larger than a 100-year storm (such as a PMP storm), however all of the water which falls will be contained within the ECM berm during the event so that no contact storm water, that is storm water that has come into contact with waste, will escape into the surrounding environment. In the event that the contact water ponds do overflow, there is possibility that contact water will mix with non-contact water in the ECM. In order to avoid release of any potentially contaminated water outside of the ECM boundary during this scenario, when water levels suggest there is a possibility of overtopping in the contact water pond, the non-contact water pumps would be shut off or flows diverted back into the ECM until all of the contained water can be treated by the WWTP.

The surface water management ponds for non-contact water are designed to address erosion and sediment control concerns during construction. Severe precipitation generates surface water that may result in the release of silt/sediment to the adjacent wetlands. The mitigation in place included silt fencing (heavy and light duty) for sediment control, and the three stormwater management ponds are used as interim sediment control. The surface water management ponds also provide water quality and quantity controls during operations, closure and post-closure. The current surface water management pond footprints reflect the overall storage required to control post-closure flows to predevelopment levels for the 2-year through to 100-year rainfall events at the site (Section 3.4.4.5.1 Surface Water Management Ponds). This volume also contains the storage required for sediment control during construction and water quality control during operations. The current footprints typically assume a maximum 100-year operating water level at a 3 m depth with 1 m of freeboard that includes allowance for climate change effects and rain on snowmelt. Major system (i.e., 100-year) flow routes follow the road system and ditches to the relevant surface water management ponds. The PMP flow generally follows the major system route using the road, related ditches and adjacent lands. The PMP flow will exceed the surface water management ponds' attenuation capacity but is adequately conveyed by inlet and emergency outlet structures adjacent to the surface water management ponds (Section 3.4.4.5.1 Surface Water Management Ponds).

Severe rainstorms or snowmelts could also affect roads and cause damage to natural or engineered slopes (e.g., berms). All roads, including the perimeter road, have ditches that convey not only road drainage but drainage from adjacent lands to the surface water management ponds. These have been designed to convey the 25-year post-development peak design flow (Section 3.4.4.5.2 Drainage Ditches and Swales). Annual inspection and maintenance activities will identify any erosion problems. In addition, an inspection and maintenance review will be completed after major storm events and after the annual spring melt to confirm there are no major erosion issues. Where drainage crosses roads, culverts are sized to convey the 25-year design event without road overtopping. A box storm sewer has been sized to convey the 100-year flow to Surface Water Management Pond 1, and is adjacent to the access road due to constraints imposed by property and road limits that preclude the use of a ditch (Section 3.4.4.5.3 Culverts and Sewers). Annual maintenance activities will identify any erosion or blockage problems. In addition, a maintenance review will be completed after major storm events and after the annual spring melt to confirm there are no major erosion or blockage issues at the culvert and sewer inlet or outlet.

The perimeter berm from the NSDF Project consists of three main geotechnical elements, or layers, each contributing to the soundness and integrity of the berm itself and the whole ECM (Section 3.4.1.5 Berms). The inside face of the berm will be covered with the various liner system layers, while the outer face will be covered with the intrusion barrier rockfill over geomembrane, geotextile cushion and geogrid. The top of the berm is covered with various layers of granular “A” material, HDPE geomembrane and geotextile cushion, with the top layer of granular A material becoming the top-of-berm road. During the post-closure period, disruptive scenarios where the berm becomes damaged are assessed (e.g., Damage to the Berm), and the resulting consequences are within the regulatory dose limit. The full assessment can be found in the PostSA (Arcadis and Quintessa 2020).

Extreme rainfall and snowmelt events could also lead to soil erosion on the ECM final cover system. As part of the closure phase, a final cover system will be installed on the ECM. The final cover system is designed to limit water infiltration, to direct infiltration and surface water runoff away from the ECM waste placement area, and to resist degradation by surface geologic processes and biotic activity (e.g., prevent burrowing of animals) and inadvertent intruder attempts to access or excavate into the waste cell (Section 3.4.1.9.3 Final Cover). A series of drainage control features will be installed in conjunction with placement of the final cover system over the ECM. The finished surface of the ECM is elevated from the surrounding terrain, which limits the quantity of surface water entering the ECM from areas outside the extent of the ECM. The topographical slopes within the ECM footprint are sufficient to promote drainage, and by lining the ECM surface water collection ditches and stilling basins with rip rap and other erosion control measures, sediment transport and erosion will be minimized (Section 3.4.1.9.3 Final Cover). Construction, operation and closure activities of the ECM are designed to provide a stabilized waste array with the purpose of minimizing settlement and water infiltration. The PostSA studies the effect of enhanced erosion on the engineered containment mound in the “Enhanced Erosion Case” scenario. Results of the assessment are within the dose acceptance criteria for Disruptive Events. The full assessment is found in the PostSA (Arcadis and Quintessa 2020). In addition, the low point of the ECM has an elevation of approximately 156 metres above sea level (masl), while the 100-year flood elevation for the portion of the Ottawa River adjacent to the Chalk River Laboratories (CRL) site is 115 masl. When the potential failure of the two upstream dams is considered combined with a 1 in 10,000-year precipitation event and snow melt from 1 in 100-year snow accumulation, the flood elevation is 122 masl for the portion of the Ottawa River adjacent to the CRL site. Therefore, the ECM is above the Ottawa River flood level.

Heavy downpours and runoff could increase the probability of a vehicle accident, as a result of reduced visibility and poor road conditions. These concerns are already addressed by procedures in place at site, including reduced traffic speeds, increased following distance, addressing road conditions (e.g., adding aggregate) as quickly as possible and, if necessary, issuing stop-work orders.

10.1.3 Heavy Snowfall

Severe snowstorms are primarily a concern during the construction and operations phases related to worker safety, performance of facilities and loss of production. The NSDF Project is designed for year-round operation; however, waste placement operation may be constrained during the winter months.

Severe snowstorms could affect vehicle operation at the site because of reduced traction and visibility and could increase the probability of vehicle accidents. Safety procedures are in place to address worker safety, including reduced traffic speeds, increased following-distances, addressing road conditions (e.g., snow removal, sanding) as quickly as possible, and if necessary, issuing work-stop orders.

Weather uncertainties have been accounted for, and risks associated with severe snowstorms and snow loadings to facilities are managed through design criteria for the NSDF Project. For example, requirements for surface water management systems include considerations for climate change, as well as accounting for at least 1 m of snowfall accumulation on the ground in advance of all design storm events. In addition, building structures at the CRL main campus are designed according to the relevant requirements regarding withstanding large accumulations of snow, such as Part 4 of the National Building Code of Canada (NBCC) 2015 (NRCC 2015). Infrastructure and facilities required to support the NSDF Project will be built to meet or exceed this code. Furthermore, the infrastructure and facilities design will comply with all relevant federal and provincial regulations, guidelines, acts, standards and codes, including standard industry practice. Consequences of potential heavy snowfalls, such as a power outage, are also encompassed by CNL's Emergency Preparedness Program.

10.1.4 High Winds

High winds can occur either on a large scale, from extra-tropical storms or low-pressure systems and fronts, or on a small scale, from thunderstorms or the local geography. High winds generally fall into three categories:

- tornadoes;
- extra-tropical storms (hurricanes); and
- thunderstorm winds.

Only tornadoes and thunderstorms are relevant to the NSDF Project site; hurricanes do not affect locations that are more than a few hundred kilometres from the ocean. Tornadoes are recognized as a hazard to the facilities on the CRL site, including the NSDF Project. Tornadoes are intense rotary storms of small diameter and are associated with thunderstorms. The vortex is usually visible as a funnel cloud. The frequency for a tornado strike on the CRL site is estimated to be 0.000054 per year and a return period of 200,000 years (Cheng et al. 2013). The *CRL Site Characteristics* report (CNL 2018a) analyzes the location of the CRL site and concludes that the CRL site is in a geographical area that could reasonably expect a tornado strike once in 100,000 years. The maximum wind speed for a tornado event of this caliber is 220 km/hr. There is concern that climate change will increase the frequency and severity of summer storms, including tornadoes, hailstorms and lightning events (Peterson et al. 2008). These summer storms are encompassed by CNL's Emergency Preparedness Program, including extreme storms such as an EF2 tornado (i.e., wind speeds up to 220 km/hr). The design basis tornado event for the CRL site was reviewed in 2018 after a series of tornados occurred in the Ottawa Valley. The current choice of an upper EF2 tornado for the CRL site remains appropriate (CNL 2018b).

High winds, atmospheric pressure changes and wind-induced projectiles have the potential to cause structural damage and/or failure of infrastructure. The NBCC was updated in 2005 to include provisions so that basic structural resilience under low-end tornadic loads in areas of Canada defined as "tornado prone," and Environment and Climate Change Canada has recently compiled an updated 30-year national tornado database (Cheng et al. 2013). Extreme winds including tornado or microburst events may cause potential minor damage to the building structures which are designed to NBCC. The collection tanks are designed to API-650 (API 2013) and designed to withstand a design basis tornado.

Severe winds or tornadoes are primarily a concern during the Construction and Operations phases related to worker safety, performance of facilities and loss of production, and are already encompassed by CNL's Emergency Preparedness Program. The risks associated with severe winds or tornadoes are managed through design criteria and management practices described above. Facilities are designed according to the appropriate

codes, such as the NBCC 2015 (NRCC 2015). Consequences of potential tornadoes, such as a power outage, are encompassed by CNL's Emergency Preparedness Program.

High winds during construction and operations have the potential to cause increased dust generation and airborne emissions. Dust control will be conducted to support waste placement operations in accordance with the Dust Management Plan during loading, transportation, placement and compaction operations (Section 3.4.1.7.1 Waste Placement Procedures). Work areas that have the potential for generating dust will require dust suppression techniques and monitoring. The primary dust control method will include water spraying or misting techniques (e.g., water trucks).

High winds could also cause soil erosion on the ECM final cover system, leading to water infiltration into the waste. In addition to the mitigation described in Section 10.1.2, the final cover system will be vegetated to enhance evapotranspiration and reduce the potential for soil erosion from wind and water. The vegetation will be limited to grass species that are drought resistant. Trees will not be allowed to establish on the final cover system as they may cause considerable damage to the topsoil and soil cover layers, as well as exposing the intrusion barrier if uprooted due to heavy winds (3.4.1.9.3 Final Cover). Bare or eroded areas will be rolled, regraded, replanted and remulched, and treatments will be applied as required to keep grass and soil free of pests and pathogens or disease (AECOM 2017b).

A soil loss/erosion calculation was completed for the proposed ECM final cover system (AECOM 2017b). The Revised Universal Soil Loss Equation for Application in Canada method was used in the calculation (AECOM 2017b). The results show that the average soil loss for the final ECM cover system is estimated at 0.21 tonnes per hectare per year and 1.12 tonnes per hectare per year, for the vegetated top slope and vegetated upper side slope portions of the final cover system (AECOM 2017b). Both of these calculated soil loss amounts are lower than the maximum annual allowable soil loss of 12.36 tonnes per hectare per year.

In addition to the calculations for the operational period, the PostSA assesses the consequences of erosion in both the Normal Evolution Scenario and the disruptive event of "Enhanced Erosion". The dose consequences from these scenarios are within the dose acceptance criteria (Arcadis and Quintessa 2020).

10.2 Forest Fires

At the NSDF Project site boundary, there is a neighbouring forested area, which represents a potential fire hazard. The potential for a forest fire to affect the NSDF Project is limited through meeting minimum distances between the NSDF Project and the forest edge. At its closet point the top of the ECM perimeter berm is approximately 45 m from the NSDF fence line and the forest edge is 4 m beyond the NSDF fence line. This is in compliance with the National Fire Protection Association 1144, "Standard for Reducing Structure Ignition Hazards from Wildland Fires" (NFPA 2013).

Having an effective response to fires is facilitated through CNL's Emergency Preparedness Program (Section 3.5.2.5 Emergency Preparedness Program) and the Fire Protection Program (Section 3.5.2.9 Fire Protection Program). The risks associated with wildfires will continue to be managed through existing procedures and design criteria. The probability of such an event has been assessed as very low; however, a fire buffer zone (5 m minimum) between forest stands and equipment will be established to further reduce the probability of a neighbouring forest fire affecting operations (Algonquin Forestry Services 2001). In the event of a forest fire, the CRL Fire Department provides firefighting capacity 24 hours a day, 7 days a week, and firefighting procedures are in place and are backed up by CNL's Emergency Preparedness Program.

Design of infrastructure incorporates fire protection as appropriate in accordance with the NBCC 2015 (NRCC 2015). The Fire Protection Program is dedicated to the delivery of a compliant Fire Protection Program that will provide the highest level of fire and life safety to all CNL employees and facilities. The objectives of the Fire Protection Program include preventing fire losses, providing responsible fire protection management, demonstrating compliance with applicable fire protection codes and standards, and providing reliable facilities from a fire protection perspective. The Fire Protection Program provides services including developing fire prevention processes and conducting fire safety inspections. Fire hazard analyses, code compliance reviews and fire protection screenings are also conducted as part of the program. Consequences of a fire, such as a power outage, are encompassed by CNL's Emergency Preparedness Program.

In addition, as part of the *Safety Analysis Report* (CNL 2020), an assessment of the consequences of a fire during the Operations phase at the NSDF Project site, caused by a forest fire, lightning strike or other means, was completed. A scenario was developed to evaluate the effects of 800 m^3 of bulk waste and packaged waste burning in a temporary staging area for 1 hour. The evaluation concludes radiological doses to workers and member of the public are below regulatory limits and meet safety objectives for the NSDF Project.

10.3 Seismic Events

Major seismic events (i.e., earthquakes) are related to movements at tectonic plate boundaries. The CRL site is located in the Ottawa-Bonnechere Graben geologic feature and adjacent to the Western Quebec Seismic Zone. This region of the country has continued to experience minor to moderate seismic activity, and within this zone, several earthquakes were documented. These include the following:

- Timiskaming, Quebec, earthquake of 1935 (6.2 on the Richter Scale and epicentre over 100 km away);
- Cornwall, Ontario, earthquake of 1944 (5.6 on the Richter Scale and epicentre over 200 km away); and
- Val-des-Bois, Quebec, earthquake of 2010 (5.0 on the Richter Scale and epicentre over 137 km away).

Most recently, an earthquake with a magnitude of 3.7 on the Richter Scale occurred on October 15, 2015, approximately 40 km from the NSDF Project site, and an earthquake with a magnitude of 3.5 occurred on May 14, 2016, approximately 10 km from the NSDF Project site, 6 km north of Petawawa, Ontario.

Should a seismic event occur at or near the NSDF Project site, this could lead to a rupture of soil material beneath the ECM and potentially result in a failure of the engineered berms and final cover system, resulting in damage to ECM liners and the leachate collection system. This could result in the exposure of radioactive waste at surface and leachate to flow into the groundwater without treatment.

To support the design of the NSDF Project, a probabilistic seismic hazard assessment was prepared, which outlines the site-specific seismic conditions and discusses applicable seismic design criteria (AECOM 2019). To characterize the seismic hazard, the peak horizontal ground acceleration at the site is determined using seismic information from the seismic hazard maps developed for the NBCC in 2015 (NRCC 2015). The peak ground acceleration at the NSDF Project site is comparable to typical high seismic zones in North America.

The NSDF Project facilities, including the final cover system design and infrastructure, are designed to meet safety factors and earthquake loading requirements, as outlined in the following design guides:

- National Building Code of Canada Seismic Design Parameters (NRCC 2015); and
- AECL's Design for Earthquakes (Seismic Qualifications at CRL) (CNL 2017).

The design of buildings and other conventional structures for the NSDF Project was based on a NBCC (NRCC 2015) design basis earthquake with a 2,475-year frequency of occurrence. However, the seismic design of the ECM was based on a design basis earthquake with a 10,000-year frequency of occurrence as defined by Canadian Standards Association Standard N289.1-18 (CSA Group 2018).

An analysis of liquefaction potential was completed and indicated that the 10,000-year design seismic event scenario may cause liquefaction in the saturated native sand to silty sand soils underlying the ECM resulting in unacceptable vertical and horizontal displacements. Based on this, CNL has added additional mitigation to limit the potential for liquefaction. Overburden soils beneath the ECM containment berm will be excavated down to the top of the bedrock, extending horizontally from beneath the containment berm to a distance at which the slopes of the containment berm intersect the bedrock surface. The removed overburden soils then can be replaced with backfill material in multiple lifts. Each lift can be compacted to the desired density using vibratory roller compactors. The edges of excavation can be sloped back temporarily to provide stability. Dynamic compaction could also be used in select areas of the construction site where the existing grade is relatively flat and in the limited areas where proximity of the existing wetlands would require the use of sheet piling or other temporary excavation support. This excavation and replace method can produce a high-quality ground mass with high density and desired permeability. Since the sand layer components of the ECM will be installed in a controlled manner with a high level of compaction, the sand layer components will be similar to dense sand deposits, which are generally not susceptible to liquefaction.

Based on the conclusions of a seismic analysis completed on the NSDF Project design and with the incorporation of the liquefaction mitigation described above, the ECM is expected to remain functional under the 10,000-year design seismic event scenario (AECOM 2019). During operations through the institutional control phases of the NSDF Project, the consequences of any damage to the engineered berms or the ECM final cover system from a beyond-design earthquake would be mitigated as required. Consequences to the facility, such as a power outage, are encompassed by CNL's existing Emergency Preparedness Program.

In the post-closure phase the consequence of a significant seismic event is evaluated through a number of disruptive events (e.g., failure of the berm, cap and liner). The dose consequences of these scenarios are within dose acceptance criteria (Arcadis and Quintessa 2020).

10.4 Climate Change

Changes in the global and regional climate could affect the NSDF Project during the approximately 50-year operations phase and into the long-term post-closure phase (i.e., 500 years) and beyond. The Canadian Nuclear Safety Commission requires that effects assessments take into account any potential effects of climate change on a project, including an assessment of whether the project might be sensitive to changes in climate condition during its life span (CNSC 2016). As such, an effects assessment of climate change was completed that follows the guidance provided by the Federal-Provincial-Territorial Committee on Climate Change and Environmental Assessment. This general guidance document is for practitioners incorporating climate change issues into an environmental assessment (FPTCCCEA 2003).

10.4.1 Global Climate Change Trends

The world's climate is changing as a result of a combination of natural and anthropogenic factors, and the changes over the twentieth century can largely be attributed to human activities (AMAP 2011; IPCC 2007; NRCan 2011). Human activities affect climate by changing the land surface and altering the composition of the atmosphere. A 100-year warming trend in surface air temperature of 0.85°C was observed over the period from 1880 to 2012 (IPCC 2013). Over the Canadian landmass, the annual average surface air temperature warmed by

1.5°C from 1950 to 2010 (Vincent et al. 2012), and for 2011 and 2012 surface air temperatures were 1.5°C and 1.9°C, respectively, warmer than the reference period from 1961 to 1990 (Bush et al. 2014). Also, Canada has generally become wetter in recent decades, with an increase in annual precipitation of about 16% over the period from 1950 to 2010 (Mekis and Vincent 2011). Even if considerable measures to reduce greenhouse gas emissions are introduced today, it is predicted that climate change will continue to have an environmental effect for centuries. It is recognized that these effects will not occur uniformly across the country, but will vary regionally (NRCan 2004).

Climate change projections are provided by mathematical models based on the physical laws governing the behaviour of the climate. Climate change scenarios, as summarized by the Intergovernmental Panel on Climate Change (IPCC), predict that mean global temperatures are likely to increase by 1.1°C to 5.4°C for the period of 2090 to 2099 as compared to the reference period from 1980 to 1999. The IPCC is generally considered to be the definitive source of information related to past and future climate change, as well as climate science.

It is predicted that the North and the southern and central Prairies of Canada will experience more of a warming than other regions (NRCan 2004). This warming is expected to vary on a seasonal basis, being greater in the winter than the other seasons, and with nights warming more than days. As warm air can hold more moisture, changes in precipitation patterns and shifts in the frequency and intensity of extreme climate events are expected to accompany this warming (NRCan 2004). Mean results for Canada show that even under lowered emission scenarios, summer and winter temperatures by the middle of the century are anticipated to warm by about 1.5°C to 2.5°C and 3°C to 7°C, respectively (NRCan 2014).

10.4.2 Current and Future Climate Change Trends

10.4.2.1 Current Climate Trends

The current climate is based on available long-term daily meteorological observations from a climate station in the vicinity of the NSDF Project. In general, the current climate normals and trends indicate a climate that has likely become warmer and wetter over time. The analysis of climate station data shows that temperatures are increasing, with the exception of spring, and the total seasonal precipitation shows increasing trends except for winter and spring, which show a decreasing trend as shown in the NSDF Project Climate Change Assessment Technical Supporting Document (TSD) (Golder 2019).

An analysis of the Petawawa Hoffman climate station data was completed illustrating:

- Total annual precipitation is increasing; however, the trend was not statistically significant.
- Summer total precipitation is increasing.
- The number of days with more than 20 mm of rainfall is increasing.
- Average annual temperature is increasing.
- Average annual summer temperature is increasing.
- Average annual fall temperature is increasing.
- The number of periods (more than three days) with minimal temperatures below 15°C are decreasing.

10.4.2.2 Future Climate Conditions

Future climate projections were derived using general circulation models for two time periods, the Mid Term representing the second half of the operations phase (2041 through 2070) and the Far Term representing the closure phase and beginning of the post-closure phase (2070 through 2100) (Golder 2019). Climate projections were also considered for the Long Term (2100 through 3000) using publicly available literature (Golder 2019).

The model projected means for the Mid Term and Far Term are greater than the observed climate normals for both temperature and precipitation as shown in Tables 10.4.2-1 and 10.4.2-2 and in the NSDF Project Climate Change Assessment TSD (Golder 2019). On a month-to-month basis, the projections indicate a future that is likely warmer and wetter than currently observed. The change in temperature normal between the currently observed and projected monthly periods is more pronounced than the monthly projected changes in precipitation. The projected changes in monthly temperature appear reasonably uniform over the year, while the fall and early winter show the largest change in the mean precipitation.

Table 10.4.2-1: Model Projected Mean and Climate Normal for NSDF Project for the Mid Term – 2041 to 2070

Period	Temperature (°C)			Precipitation (mm)		
	Climate Normal	Projected Mean	Difference	Climate Normal	Projected Mean	Difference
Spring	5.0	6.1	1.1	201.1	208.7	7.5
Summer	19.0	21.0	1.9	251.1	263.7	12.7
Fall	7.5	10.8	3.3	243.9	294.7	50.9
Winter	-9.3	-6.8	2.5	155.9	192.6	36.6
Annual	5.7	7.8	2.2	852.0	924.1	72.0

Table 10.4.2-2: Model Projected Mean and Climate Normal for NSDF Project for the Far Term – 2070 to 2100

Period	Temperature (°C)			Precipitation (mm)		
	Climate Normal	Projected Mean	Difference	Climate Normal	Projected Mean	Difference
Spring	5.0	6.9	1.8	201.1	214.2	13.1
Summer	19.0	21.8	2.8	251.1	265.2	14.1
Fall	7.5	11.6	4.1	243.9	302.6	58.8
Winter	-9.3	-6.0	3.3	155.9	207.0	51.0
Annual	5.7	8.6	3.0	852.0	940.6	88.6

For the Long Term, based on representative concentration pathways described in IPCC's fifth assessment report, global temperatures are predicted to rise between 0.6°C and 7.8°C by the year 3000, as shown in Table 10.4.2-3 and in the NSDF Project Climate Change Assessment TSD (Golder 2019). The majority of the warming will occur before 2300. Changes in precipitation distribution and variability are anticipated to increase after 2100, with an estimated increase in global precipitation of 1% to 3% per degree Celsius of increase in temperature over the period from 2100 to 3000 (IPCC 2013).

Table 10.4.2-3: Projected Climate for the Mid Term, Far Term and Long Term

Period	Temperature (°C)	Precipitation (mm)
	Climate Normal	Climate Normal
Current Climate (1994 to 2015)	5.7	852.0
Mid Term Change (2041 to 2070)	2.2	72.0
Far Term Change (2071 to 2100)	3	88.6
Long Term (2100 to 3000)[a]	0.6 to 7.8[b]	1%/°C to 3%/°C[b]

a) Long Term projections are provided as global values, while Current Climate, Mid Term and Far Term projections represent the NSDF Project site.

b) Projections represent change above those of the reference period of 1986 to 2005.

%/°C= percentage increase in precipitation per degree Celsius.

10.4.3 Climate Change Effects on the NSDF Project

Climate change may result in shifts in the frequency and/or intensity of the extreme weather events and forest fires. As such, the NSDF Project design features and mitigation described in Section 10.1 and 10.2, respectively, also take into consideration the potential effects of climate change. Further, the PostSA (Arcadis and Quintessa 2020) considered potential climate change as part of the Normal Evolution Scenario to inform the evolution of the environment over time. The effects of climate change are typically measured over longer periods, with the potential for climate change effects increasing as the period over which they are measured increases.

Shifts in the frequency and/or intensity of extreme weather events are expected to accompany the general warming of surface air temperatures. Increased evaporation will result in more moisture in the air, and warmer air can hold more moisture; therefore, more intense precipitation events (i.e., rainstorms and snowmelts) are expected. As discussed in Section 10.1, the WWTP is designed to accommodate a maximum flow rate that would be produced during two back-to-back 100-year, 24-hour storm events. This was selected as a worst-case design condition for determining the required volume of wastewater storage. In addition, surface water management design will consider climate changes over 500 years (post-closure design life) and will incorporate the 2-year, 5-year, 10-year, 25-year, 50-year and 100-year (or prevailing regional) precipitation storm events and seasonal precipitation averages. For example, historical peak precipitation has been considered in design of surface water management structures (i.e., surface water management ponds, drainage ditches, culverts). The annual snowfall for Canada has increased by about 4% over the time period of 1950 to 2009 (Mekis and Vincent 2011) and the current climate general circulation models for the NSDF Project indicate that snowfall is increasing. In addition, the conservative freeboard estimate includes the effects of climate change (a 25% increase in rainfall intensity over the next 100 years) and rain on snowmelt. All building design specifications will meet NBCC 2015 code requirements (NRCC 2015).

As described in Section 10.1, the ECM base liner and final cover system have been designed as multilayer systems to withstand effects from extreme weather events, such as freeze-thaw cycles, extreme rainfall and snowmelt, and high winds. These design features also take into account potential effects from climate change.

Climate change has the potential to greatly influence Canada's forests, since even small changes in temperature and precipitation can affect forest growth and survival. A small increase in temperature can result in a longer growing season, increased plant growth and a shift in tree species occurrence and abundance (NRCan 2004). None of these biological changes could directly affect the NSDF Project; however, the probability of forest fires increases with dry conditions, as well as lightning strike probability, and a forest fire could affect the NSDF Project infrastructure and workers' safety.

A Closure Plan has been developed as part of the NSDF Project, which describes the program for completing final closure of the ECM and associated facilities. The intention is for this plan to be an evolutionary document that continues to be refined throughout the life of the NSDF Project. The plan will be reviewed prior to implementation such that changes in environmental conditions (i.e., weather events, forest fires and seismic events); improved technologies; confirmation of predicted effects; and adaptive management can be integrated. An updated and revised Final Closure Plan will be prepared based on actual, verified conditions, either two years prior to the end of the operations phase or when 90% of the total waste volume has been placed in the ECM, whichever comes first (AECOM 2017b).

As an adaptation measure for climate change, the potential effects of a changing climate will be considered as part of the re-evaluation of the plan. During the post-closure phase, monitoring will be incorporated into the Final Closure Plan to help identify any potential future climate change effects beyond what has been considered in the assessment. This would include evaluating long-term monitoring results, documented changes in the local climate and up-to-date climate change predictions. Examples of adaptive management to be integrated into closure and post-closure planning could include mitigation to address:

- changes to temperature and precipitation have affected the vegetation used in the rehabilitation of the site; or
- climate changes (e.g., increased erosion rates) have affected the final cover system design.

10.5 Glaciation

The earth is currently in an interglaciation period, meaning that it is between ice ages. It is estimated that the current period, called the Holocene, began approximately 11,700 years ago (Clark et al. 2016). Records suggest that previous interglaciation periods have lasted anywhere from 10,000 to 20,000 years (Berger et al. 2003). The global warming projected until the year 3000 (0.6°C to 7.8°C over 1,000 years) represents a much higher warming rate than the rate seen at the end of the last glacial period (4°C over an estimated 8,000 years). Coupling of climate change models and glaciation models predicts a relatively long interglacial period; the next significant glacial event is not projected to occur before 60,000 (Berger et al. 2003) to 100,000 years (Peltier 2011) after present.

Typically, glacial cycles are assumed to be approximately 100,000 years, with the glaciation phase lasting approximately 90,000 years and the deglaciation phase lasting approximately 10,000 years (Peltier 2011). Peltier (2011) also notes that if the concentrations of greenhouse gases remain similar to the present, another glacial event is unlikely due to the increased surface warmth. However, projections for atmospheric concentrations 60,000 years after present are not available; therefore, the potential for a glacial event should not be discounted.

Hallet (2011) studied the potential erosion from glacial activity in Kincardine, Ontario. Results of several studies provided a broad range of glacial scouring (erosion resulting from glacial action). The depths ranged from several metres to approximately 300 m at the most over a 1,000,000-year time scale, assuming a 100,000-year glacial cycle. These studies did not include topographic features or other factors that would tend to localize erosion. In addition, studying the past record of erosion near Kincardine showed a more site-specific estimate of 100 m for a 1,000,000-year time scale. No site-specific information was available for the NSDF Project site.

Global warming is projected until the year 3000, up to about 8°C over 1,000 years (Golder 2019). This represents a much higher warming rate than that seen at the end of the last glacial period and corresponds to a higher rate of increase in atmospheric carbon dioxide concentrations than in previous periods. It is therefore expected that there will be a relatively long interglacial period, so the next glaciation cycle is not likely to occur before 100,000 years after present (Peltier 2011). It is predicted that glacier will cover the territory of Ontario, which includes the CRL site, for tens of thousands of years.

The assessment timeframe for the Post-SA (Arcadis and Quintessa 2020) is 10,000 years. The timeframe was determined using the criteria within *REGDOC-2.11.1 Waste Management: Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* (CNSC 2018). The 10,000-year assessment timeframe captures the period of peak radioactivity[1] and dose consequence[2], the design life of the engineered and natural barriers, and takes the 1-in-10,000-year seismic design basis into account. By 10,000 years post-closure, the radioactivity concentration in the ECM is very close to natural background concentrations. Glaciation may occur 100,000 years into the future, far beyond the timeframe that the facility is hazardous.

10.6 Summary of NSDF Project Design Features and Mitigation

Table 10.6-1 summarizes the design features and mitigation implemented to reduce or eliminate potential effects of the environment on the NSDF Project components and activities.

Table 10.6-1: Environmental Factors That Can Affect the NSDF Project and Associated Mitigation

Project Component or Activity	Factors	Mitigation
Infrastructure and Support Facilities	Extreme Events	Extreme events (e.g., storms) may result in a potential interaction with infrastructure and support facilities, but this is accounted for in the design specifications and will be addressed through on-going maintenance. For example, all building layouts will meet NBCC 2015 requirements. The effects of the PMP were considered by identifying flowpaths and possible risk to infrastructure.
Wastewater Treatment Plant	Rain, Extreme Events	Extreme rainfall and snowmelt events and the potential for flooding are considered in the design of the WWTP. The maximum flow rate was determined by evaluating the expected contact water volume that would be produced during two back-to-back 100-year, 24-hour storm events. This was selected as a worst-case design condition for determining the required volume of wastewater collection tanks.

[1] Peak radioactivity: the maximum concentration of a radionuclide in the receiving environment as a result of releases from the Engineered Containment Mound over the assessment timeframe.

[2] Dose consequence: the maximum radiological dose to humans from internal and external exposure to radioactivity over the assessment time frame.

Table 10.6-1: Environmental Factors That Can Affect the NSDF Project and Associated Mitigation

Project Component or Activity	Factors	Mitigation
Drainage Ditches and Culverts	Rain, Extreme Events	Extreme rainfall and snowmelt events and the potential for flooding are considered in the design of the surface water management systems. All roadways, including the perimeter road, have ditches that convey not only roadway drainage but drainage from adjacent lands to the surface water management ponds. These have been designed to convey the 25-year post-development peak design flow, which includes consideration of climate change. For example, historical peak precipitation has been considered in design of drainage ditches and culverts. Where drainage crosses roads, culverts are sized to convey the 25-year design event without road overtopping. Annual maintenance activities will identify any erosion or blockage problems for ditches and culverts. In addition, a maintenance review will be completed after major storm events and after the annual spring melt to confirm there are no major erosion or blockage issues at the culvert and sewer inlet or outlet.
Surface Water Management Ponds	Rain, Extreme Events	Extreme rainfall and snowmelt events and the potential for flooding are considered in the design of the surface water management ponds. The current surface water management pond design considers climate change over 500 years and reflects the overall storage required to control flows for the 2-year through to 100-year rainfall events at the site. This volume also contains the storage required for sediment control during construction and water quality control during operations. The current footprints typically assume a maximum 100-year operating water level at a 3 m depth with 1 m of freeboard that includes allowance for climate change effects and rain on snowmelt. Major system (i.e., 100-year) flow routes follow the road system and ditches to the relevant surface water management ponds. The PMP flow generally follows the major system route using the road, related ditches and adjacent lands. The PMP flow will exceed the surface water management ponds attenuation capacity, but is adequately conveyed by inlet and emergency outlet structures adjacent to the surface water management ponds.
Engineered Containment Mound Berm	Rain, Extreme Events	Severe rainstorms or snowmelts could affect roads and cause failure of natural or engineered slopes (e.g., berms). Designed berms consist of three main geotechnical elements, or layers, each contributing to the soundness and integrity of the berm itself and the whole ECM.

Table 10.6-1: Environmental Factors That Can Affect the NSDF Project and Associated Mitigation

Project Component or Activity	Factors	Mitigation
Engineered Containment Mound and Berm	Seismic	The design of the ECM has considered significant seismic events such to mitigate against damage to the safety features. The NSDF Project facilities, including the final cover system design, are designed to meet safety factors and earthquake loading requirements. To support the design of the NSDF Project, a PSHA was prepared and an analysis of liquefaction potential was conducted; mitigation has been implemented into the design of the ECM to limit the potential for liquefaction. Based on the conclusions of the seismic analysis and with the implementation of the proposed mitigation for liquefaction, the ECM is expected to remain functional under the 10,000-year design seismic event scenario. During operations through the institutional control phases of the NSDF Project, the consequences of any damage to the engineered berms or the ECM final cover system from a beyond design earthquake would be mitigated as required.
Engineered Containment Mound Final Cover System	Extreme Rain and Wind	The final cover system is designed to limit water infiltration, to direct infiltration and surface water runoff away from the ECM waste placement area, and to resist degradation by surface geologic processes and biotic activity (e.g., prevent burrowing of animals) and inadvertent intruder attempts to access or excavate into the waste cells. A series of drainage control features will be installed in conjunction with placement of final cover system over the ECM. The finished surface of the ECM is elevated from the surrounding terrain, which limits the quantity of surface water entering the ECM from areas outside the extent of the ECM. The topographical slopes within the ECM footprint are sufficient to promote drainage, and by lining the ECM surface water collection ditches and stilling basins with rip rap and other erosion control measures, sediment transport and erosion will be minimized. Meteorological records will be reviewed annually to confirm that the final cover system performance is not overloaded in any post-closure year.
Engineered Containment Mound Final Cover System and Liner	Temperature	The NSDF Project has been designed to include a layer of clean fill on the floor of the ECM of sufficient thickness to prevent freezing of the base liner systems prior to waste placement. The HDPE geomembrane liner components of the sideslope lining system will not be adversely affected by freeze-thaw cycles, whereas the geosynthetic and compacted clay liner components of the sideslope lining system could undergo an increase in hydraulic conductivity prior to placement of the wastes on the sideslopes. However, after placement of the waste, the clay liners will consolidate under the weight of the waste, healing the voids caused by freezing. The final cover system will be installed to its full thickness progressively as areas of the ECM reach the final waste contours. The final cover system design has 1.75 m of granular/soil materials above the lining system, which is sufficient to prevent freezing of the final cover system liner components.

Table 10.6-1: Environmental Factors That Can Affect the NSDF Project and Associated Mitigation

Project Component or Activity	Factors	Mitigation
Remediation	Temperature, Precipitation	Grading of the site will be designed taking into consideration the potential for future extreme weather events. Changes to temperature and precipitation may affect the vegetation used in remediation of the site and will be considered in the closure and post-closure planning. For example, the vegetated top of the final cover system will be designed for withstanding erosion and gully initiations. The vegetation for the final cover system will be limited to grass species that are drought-resistant. Treatments will be applied as required to keep grass and soil free of pests and pathogens or disease (AECOM 2017b). Changes to climate can be addressed through adaptive management plans that consider projected changes in climate relevant to the local vegetation.

Note: The factors include consideration of the shifts in frequency and/or intensity of these events due to climate change.

NBCC = National Building Code of Canada; WWTP = Wastewater Treatment Plant; PMP = probable maximum precipitation; ECM = engineered containment mound; HDPE = high density polyethylene; PSHA = Probabilistic Seismic Hazard Assessment.

11.0 SUMMARY OF MONITORING AND FOLLOW-UP PROGRAMS

Each of the discipline-specific assessments presented in Sections 5.2 through 5.10 and Section 6.0 of the Environmental Impact Statement (EIS) propose conceptual monitoring and follow-up programs to be undertaken by Canadian Nuclear Laboratories (CNL) during the construction, operations, closure and post-closure (institutional control) phases of the Near Surface Disposal Facility (NSDF) Project. These monitoring and follow-up programs will serve to address the uncertainties associated with the effects predictions and the performance of mitigation, verify the effects predictions, identify any unanticipated effects and provide for the implementation of adaptive management to limit these effects.

Table 11.0-1 summarizes the proposed environmental assessment follow-up monitoring programs discussed in Sections 5.2 through 5.10 and Section 6.0. The programs will be carefully integrated with CNL's on-going monitoring and management plans, where appropriate, and will reference CNL Standard Practices and Procedures. Wherever possible, existing programs will be adapted to meet the objectives of monitoring the predictions made by the environmental assessment for the NSDF Project. CNL's existing compliance programs are summarized in Section 3.5.2.

The monitoring and follow-up plan presented in this section is conceptual and provides a preliminary description of the activities and framework for monitoring proposed for the NSDF Project. This plan will be developed into detailed monitoring and follow-up programs as detailed NSDF Project design is finalized, which may influence the nature, frequency and locations of monitoring. In addition, input from regulatory agencies, the public and Indigenous Peoples will be considered. These monitoring and follow-up programs will include sufficient information on the type, quantity and quality of information required to reliably verify predicted effects (or absence of them) and confirm the effectiveness of mitigation. These programs will also be prepared consistent with the Canadian Standards Association's Standards N288.4-10 (*Environmental Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [CSA Group 2010]), N288.5-11 (*Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [CSA Group 2011]) and N288.7-15 (*Groundwater Protection Programs At Class I Nuclear Facilities and Uranium Mines and Mills* [CSA Group 2015), as applicable.

One key component of the monitoring and follow-up plan will be the implementation of the Waste Acceptance Criteria (WAC) verification for the NSDF Project. The WAC verification ensures that all waste received for disposal is in compliance with the design and safety basis of the facility. The tracking of the waste inventory into the facility allows for the verification of the assumptions used in this EIS (e.g., pathways analysis modelling is based on the licensed inventory proposed to be disposed in the ECM).

CNL's Functional Support Manager for Environmental Protection will be responsible for the delegation of resources to develop, implement and integrate the environmental assessment monitoring and follow-up programs identified in Table 11.0-1. Monitoring and follow-up programs will be carried out throughout all phases of the NSDF Project. The following phases were identified for the NSDF Project:

- **Construction Phase**: includes site preparation and all activities associated with the construction of the NSDF Project. This phase includes activities such as installing the necessary supporting and/or ancillary facilities and infrastructure to facilitate NSDF Project operations, inactive commissioning and systems testing, and transportation of construction materials. Construction activities are expected take place from 2022 to 2024

- **Operations Phase**: includes all activities associated with waste placement, water management, Wastewater Treatment Plant (WWTP) operations, vehicle movements into and from the NSDF Project site and maintenance activities. Operations activities are expected to last approximately 50 years (i.e., 2025 to 2070). Follow-up monitoring during operations will be incorporated into CNL's routine environmental monitoring programs.
- **Closure Phase:** includes activities necessary to complete the installation of the final cover and implementation of long-term monitoring. Closure activities are expected to start in 2070 and continue through to 2100, after which the NSDF Project will transfer into the post-closure phase.
- **Post-closure Phase:** has two discrete periods: institutional control and post-institutional control. The institutional control period includes implementation of controls throughout 2100 to 2400 (i.e., 300 years). During institutional control, groundwater monitoring and groundwater quality management will continue to demonstrate compliance with the Post-Closure Safety Assessment assumptions (Arcadis and Quintessa 2020). Post-institutional control occurs after year 2400 and continues indefinitely.

11.1 Data Management

The development and implementation of mitigation identified for the NSDF Project and housed in the monitoring and follow-up programs are tracked in relevant management plans, where data management, including collection, storage, standards and responsible roles, are defined. Data collected will meet the required guidelines for collection and quality assurance and control. CNL will store information generated from the environmental assessment monitoring and follow-up program in a robust database for future analysis and reporting. Analysis of results from the monitoring and follow-up program will be reported and submitted to the relevant regulatory agencies as required.

11.2 Adaptive Management

CNL is committed to achieving continual improvement in environmental performance through its management systems. CNL manages environmental related matters through an existing Environmental Protection Program that is registered to ISO 14001. CNL's Chalk River Laboratories have been ISO 14001 certified since 2004 (CNL 2019a). CNL's Environmental Protection Program includes compliance and adaptive management systems to evaluate areas for improvement or trending. The program will continue to be implemented for the NSDF Project during construction and operations and will be updated, as needed, as part of an annual management review process.

The development and implementation of mitigation identified in the NSDF Project environmental assessment monitoring and follow-up programs will be tracked in existing CNL management plans. Adaptive management is a means by which uncertainties in outcomes can be reduced through monitoring. CNL's approach to adaptive management is defined in each plan. As site conditions and monitoring dictate, CNL will adaptively manage site practices and monitoring programs to meet the defined objectives. For some programs, this involves regular evaluation of predictive models; which are clearly defined in each applicable management plan.

If an environmental monitoring and follow-up program identifies that adverse environmental effects are greater than predicted, then CNL will evaluate whether they result in changes to the conclusions in this EIS. If changes are confirmed, then CNL will evaluate the need for revised mitigation actions and management practices to manage effects. CNL's evaluation process for monitoring data include environmental performance criteria that are based on statistical measures and ecological health benchmarks. An exceedance of

environmental performance criteria triggers CNL's non-conformance and corrective action process and includes notifying management and further investigation. Where the need for revised mitigations is identified they will be developed and implemented. This evaluation process is documented in Chalk River Laboratories' environmental protection procedures.

Some aspects of the adaptive management which may require revised mitigations can come from public input and feedback related to NSDF activities. As an example, the residual effects of changes in ambient noise due to construction and road traffic may affect the quality of life of local residents (Indigenous and non-Indigenous) near the NSDF site. Through the Public Information Program (PIP, CNL 2021), which provides a platform for two-way dialogue between CNL and its stakeholders, CNL is able to record feedback and concerns from the general public about the NSDF as it progresses through the construction, operations, closure, and post-closure period. While the PIP can provide a short-term complaints response plan, marked changes can be recorded in follow-up monitoring as trends throughout the NSDF phases. Adaptive measures can then be developed and implemented as part of follow-up monitoring to permanently mitigate concerns.

Monitoring during the institutional control period will confirm the performance of the containment system, and if necessary, remedial actions will be taken. Examples of mitigation that would be implemented include:

- If erosion were present, the final cover would be repaired.
- If a localized breach of the final cover were present, the cover would be repaired and the leachate system would be periodically assessed and inspected.
- If there were multiple or and indeterminant number of breach locations in the final cover, another cover / cap system could be installed over the existing cover.
- If the monitoring wells detected abnormal performance results, additional wells could be installed and the monitoring frequency increased.
- Erosion of the berm would be mitigated by maintaining a healthy vegetation cover.

11.3 Engagement and Communication

Recognizing people's interest in understanding and participating in decisions that affect them, CNL will proactively seek, engage and support meaningful discussion with the public and Indigenous Peoples on issues and opportunities related to the NSDF Project, including the environmental assessment monitoring and follow-up programs, through CNL's PIP (CNL 2021), which can be found on the CNL website (www.CNL.ca). The PIP includes specific communications to stakeholders and public access to information related to routine activities as well as new projects such as the NSDF Project. These measures are meant to mitigate questions and complaints regarding CNL activities, as well as ensure community input is sought, received and action is taken to respond to these inputs.

The PIP also provides a platform for the public to voice their concerns related to NSDF Project activities and for CNL to address and develop resolutions to these concerns; the process includes:

- Corporate Communications receives issues and concerns through the formal feedback submission on the CNL website (https://www.cnl.ca/contact us), emails (communications@cnl.ca), phone calls (1-800-364-6989), and social media platforms (e.g., Facebook and Twitter).

- All NSDF Project-related issues and concerns (including complaints about noise disturbances) received are forwarded to the NSDF Project for resolution.
- The NSDF Project address and resolve concerns about the Project on a case-by-case basis and resolution may include further mitigation of NSDF site activities.
- Throughout this process, CNL will maintain two-way dialogue between the stakeholder and the NSDF team until the issue is resolved.
- All inquiries are tracked and resolution or responses are recorded once completed.

CNL will continually evaluate both the process and the outcome of the on-going engagement and communication activities to address and manage issues as they arise.

Table 11.0-1: Environmental Assessment Monitoring and Follow-up Programs Proposed for the NSDF Project

EIS Section	Valued Component	Project Phase and Potential Effect	Monitoring Program Objective	Conceptual Monitoring Program	Suggested Duration	Implementing Program
Section 5.2 Atmospheric Environment	Air Quality	Construction activities will result in fugitive dust emissions.	▪ Verify that mitigation is being implemented effectively. ▪ Verify predictions in the assessment are reasonable and conservative. ▪ Verify predictions are within air quality criteria (SPM monitoring).	▪ Application of aggregate to unpaved roads – a record will be kept of the date of each application of aggregate to unpaved roads. ▪ Road misting and fixative application – a record will be maintained of dust suppression applications. ▪ Site inspection – during periods of high dust susceptibility, regular inspections will be carried out to monitor the efficacy of dust mitigation and any potential concerns with regards to fugitive dust, and, if required, implementation of mitigation will be recommended. Environmental conditions will be recorded. ▪ Particulate monitoring –SPM using a high volume sampler.	Through the construction phase.	Dust Management Plan (AECOM 2018a) to be implemented for the NSDF Project.
		Operations activities will result in fugitive dust emissions.	▪ Verify that the mitigation is being incorporated as planned, and are effective. ▪ Verify predictions in the assessment are reasonable and conservative. ▪ Verify predictions are within air quality criteria.	▪ Application of aggregate to unpaved roads – a record will be kept of the date of each application of aggregate to unpaved roads. ▪ Road misting and fixative application – a record will be maintained of dust suppression application. ▪ Site inspection – during periods of high dust susceptibility, regular inspections will be carried out to monitor the efficacy of dust mitigation and any potential concerns with regards to fugitive dust, and if required implementation of mitigation will be recommended. Environmental conditions will be recorded. ▪ Particulate monitoring – SPM using a high volume sampler.	Based on observations and monitoring data during first year of operation, the frequency of monitoring will be determined.	Captured through the implementation of the Dust Management Plan (AECOM 2018a) and CNL's procedure for Management and Monitoring of Emissions (CNL 2018a), which includes operational control monitoring and air verification monitoring.
	Greenhouse gases	GHG emissions from the decomposition of waste during operations and closure.	▪ Verify that the measures for controlling landfill gas generated from waste deposited in the ECM during operations and following final closure are adequate. ▪ Verify that methane emission rates used in the assessment are reasonable and conservative. ▪ Verify that there is no combustion hazard from methane gas generation.	▪ Monitoring for methane will be performed using handheld portable combustible gas meter detectors. ▪ A passive landfill gas venting system will be constructed contemporaneously with installation of the ECM cover system which will provide measured concentrations and emission rates. ▪ The landfill gas monitoring probes will also be installed around the perimeter of the ECM to detect evidence of potential landfill gas migration away from the ECM.	Periodic monitoring during operations and for a specific period of time during closure phase (during which the frequency may be progressively reduced and possibly ultimately eliminated if no evidence of landfill gas migration from the ECM is detected).	Landfill Gas Management Plan (AECOM 2018b) to be implemented for the NSDF Project.
		Construction and operations activities will result in increased GHG emissions.	Verify that GHG emission rates used in the assessment are reasonable, but conservative. Monitoring results will be used for GHG reporting requirements.	Fuel Usage – a record will be kept of the fuel usage related to the NSDF Project.	Annual estimations and GHG reporting as required.	Captured through the implementation of CNL's procedure for Management and Monitoring of Emissions (CNL 2018a), which includes operational control monitoring and verification monitoring.
Section 5.3 Geological and Hydrogeological Environment	Hydrogeology	The NSDF may affect groundwater quality during operations, closure and post-closure (institutional control).	▪ Verify environmental assessment predictions on groundwater from the ECM and WWTP operation. ▪ Verify the effectiveness of mitigation.	▪ Groundwater elevation measurements to determine groundwater flow direction and gradients. ▪ Sampling to confirm groundwater quality to detect potential releases of constituents from the ECM containment area. ▪ Initial sampling frequency will likely be twice per year (Spring and Fall).	Groundwater monitoring will continue through operations, closure and post-closure (institutional control). The number of parameters, locations and frequency may change based on review of monitoring data.	NSDF Project groundwater monitoring will be integrated into the overall CNL Groundwater Monitoring Program, and will be compliant with CSA N288.7-15.

Table 11.0-1: Environmental Assessment Monitoring and Follow-up Programs Proposed for the NSDF Project

EIS Section	Valued Component	Project Phase and Potential Effect	Monitoring Program Objective	Conceptual Monitoring Program	Suggested Duration	Implementing Program
Section 5.4 Surface Water Environment	Hydrology	The installation of the ECM will physically alter drainage patterns, and may change downstream discharge, water levels in adjacent wetlands and channel and bank stability.	Operational monitoring – Verify the SWMPs are performing as designed.	Monitoring of water levels and sediment build up in the SWMPs.	The water level at the SWMP will be monitored during construction and operations. The need for and duration of monitoring will be revaluated based on an annual review of monitoring data.	Integrated into the NSDF Project Environmental Protection Plan (AECOM 2018c) to be implemented for the NSDF Project.
			Environmental monitoring – Confirm that the ecological function and structure of the wetland system is maintained.	Monitoring of wetland water elevations and surface water flows to verify changes from the presence of the ECM.	Water level and surface water flows monitoring of the wetland system will be initiated pre-construction (baseline) and continue through construction and operations. The need for and duration of monitoring will be evaluated based on an annual review of monitoring data.	Water level and surface water flows monitoring of the wetland system will be integrated into the CNL Environmental Monitoring Program.
	Surface Water Quality	▪ Discharge of treated effluent from the WWTP to the East Swamp Wetland and/or Perch Lake can cause changes to downstream surface water quality. ▪ Leakage of leachate from the ECM during the post-closure phase (i.e., after Year 2400) from liner and final cover degradation as a result of normal evolution can cause changes to downstream surface water quality.	Environmental monitoring – Verify environmental assessment predictions related to surface water quality.	Monitor the quality of surface water surrounding the ECM footprint area to evaluate whether the quality of the water is affected by the ECM or by operation of surface water management pond(s).	Water quality monitoring will continue through operations, closure and post-closure (institutional control). The number of parameters and locations may change based annual review of monitoring data.	Surface water monitoring in the receiving environment is integrated into the CNL Environmental Monitoring Program.
			▪ Operational monitoring – Verify the surface water management ponds are performing as designed. ▪ Demonstrate compliance with effluent discharge targets developed for the NSDF Project.	▪ Each pond weir outlet water quality will be sampled to identify if any contact surface water or leachate contamination of the non contact surface water is entering the surface water management ponds and to confirm total suspended solid concentrations. ▪ WWTP effluent verification monitoring consistent with CSA Standard N288.5-11.	▪ Routine visual inspections and surface water sampling during operations, closure and post-closure (institutional control) as required. ▪ Effluent monitoring will continue throughout operation of the WWTP.	Effluent water quality monitoring will be integrated into the CRL Radioactive Effluent Verification Monitoring Program.

Table 11.0-1: Environmental Assessment Monitoring and Follow-up Programs Proposed for the NSDF Project

EIS Section	Valued Component	Project Phase and Potential Effect	Monitoring Program Objective	Conceptual Monitoring Program	Suggested Duration	Implementing Program
Section 5.5 Aquatic Environment	▪ Perch Creek and Perch Lake Watershed Fish Habitat (i.e., Fish Habitat) ▪ Perch Creek and Perch Lake Watershed Fish Community (i.e., Fish Community) ▪ Perch Creek and Perch Lake Watershed Brown Bullhead ▪ Fish Species of Conservation Concern	▪ Measurable residual effects on aquatic biodiversity VCs are not predicted as a result of the NSDF Project. Potential effects are related to: ▪ Physical change to fish habitat and temporary riparian area disturbances from the installation of diffuser and transfer line construction and footprint that may affect fish and fish habitat. ▪ Non-radiological air emissions and dust emissions (including sulphur dioxide, nitrogen oxides and particulate matter) and subsequent deposition may cause a change in surface water quality and fish habitat quality. ▪ Discharge of treated effluent from the WWTP to the exfiltration gallery and Perch Lake may cause changes to groundwater quality and to downstream surface water quality, which can affect fish habitat quality, survival and reproduction. ▪ Leakage of leachate from the ECM during the post-closure phase (i.e., after Year 2100 to 2400) from liner and final cover degradation as a result of normal evolution may cause changes to groundwater quality and downstream surface water quality in wetlands, affecting fish habitat quality, survival and reproduction.	▪ Operational monitoring – Verify the surface water management ponds are performing as designed. ▪ Demonstrate compliance with effluent treatment targets developed for the NSDF Project.	See Surface Water Quality. If the environmental monitoring program for surface water quality identifies that adverse environmental effects are greater than predicted, then CNL will evaluate the need for revised mitigation actions and management practices to manage effects. CNL's evaluation process for monitoring data include environmental performance criteria that are based on statistical measures and ecological health benchmarks. An exceedance of environmental performance criteria triggers CNL's non-conformance and corrective action process and includes notifying management and further investigation. Where the need for revised mitigations is identified they will be developed and implemented. The evaluation process is documented in CNL's Environmental Monitoring Program (CNL 2018b).	See Surface Water Quality.	See Surface Water Quality.

Table 11.0-1: Environmental Assessment Monitoring and Follow-up Programs Proposed for the NSDF Project

EIS Section	Valued Component	Project Phase and Potential Effect	Monitoring Program Objective	Conceptual Monitoring Program	Suggested Duration	Implementing Program
Section 5.6 Terrestrial Environment	Canada warbler	▪ **Habitat Availability**: Permanent, direct loss of 28 ha of suitable habitat. Long-term reduction in quality of nesting habitat and possible avoidance in the LSA from sensory disturbance. ▪ **Habitat Distribution**: Small, permanent change in local movement. ▪ **Survival and Reproduction**: Small reduction in reproductivity from habitat loss and sensory disturbance.	Verify environmental assessment predictions through collection of data on relative abundance and other key demographic parameters for breeding bird populations that overlap with the RSA.	Data on relative abundance and other key demographic parameters for breeding birds in the RSA will be collected during pre- and post-construction surveys using automated recording units. Collected data will be used to evaluate trends in populations of breeding birds that overlap with the RSA, including Canada warbler, eastern whip-poor-will, eastern wood-pewee, golden-winged warbler and wood thrush. If declining trends are observed for these species in the RSA, then the need for additional mitigation will be evaluated.	Every 5 years	Monitoring will be integrated into CNL's existing Species at Risk Program.
	Eastern whip-poor-will	▪ **Habitat Availability**: Permanent, direct loss of 2 ha of suitable habitat. ▪ **Habitat Distribution**: Small, permanent change in local movement. ▪ **Survival and Reproduction**: Small reduction in reproductivity from habitat loss and sensory disturbance.				
	Eastern wood-pewee	▪ **Habitat Availability**: Permanent, direct loss of 18 ha of suitable habitat. ▪ **Habitat Distribution**: Small, permanent change in local movement. ▪ **Survival and Reproduction**: Small reduction in reproductivity from habitat loss and sensory disturbance.				
	Golden-winged warbler	▪ **Habitat Availability**: Permanent, direct loss of 27 ha of suitable habitat. ▪ **Habitat Distribution**: Small, permanent change in local movement. ▪ **Survival and Reproduction**: Small reduction in reproductivity from habitat loss and sensory disturbance.				
	Wood thrush	▪ **Habitat Availability**: Permanent, direct loss of 28 ha of suitable habitat. ▪ **Habitat Distribution**: Small, permanent change in local movement. ▪ **Survival and Reproduction**: Small reduction in reproductivity from habitat loss and sensory disturbance.				

Table 11.0-1: Environmental Assessment Monitoring and Follow-up Programs Proposed for the NSDF Project

EIS Section	Valued Component	Project Phase and Potential Effect	Monitoring Program Objective	Conceptual Monitoring Program	Suggested Duration	Implementing Program
Section 5.6 Terrestrial Environment (cont'd)	Bats	▪ **Habitat Availability**: Permanent, direct loss of 28 ha of potential maternity roosting habitat. ▪ **Habitat Distribution**: Gap in potential maternity roosting habitat, but negligible change in local movement patterns. ▪ **Survival and Reproduction**: No residual effects due to the NSDF Project.	Verify effectiveness of bat boxes as maternity roosting habitat offsetting measure, by determining number of individuals and species of bats using boxes for roosting habitat.	▪ Installation of bat boxes in suitable locations in the RSA is recommended to offset the incremental contribution of the NSDF Project to cumulative effects on SARA-listed bats. Monitoring is being conducted at least weekly to determine if bat boxes are being used. Boxes not being used may be moved to an alternate location. ▪ A project in collaboration with Trent University is currently underway, where bats are being trapped and tracked back to the roost site (natural tree or bat box). ▪ Guano collection is being performed as well. This work has a duration of two years and will provide CNL with a better understanding of habitat occupancy by the bat species at risk, including bat boxes, and habitat preference. This work will support the objective of addressing knowledge gaps on the three bat species at risk.	Bat boxes will remain in place throughout the construction and operations phases. Visual monitoring of bat boxes will be conducted weekly every year during the pre-construction phase and will continue through construction and for three years after start of operations.	Monitoring will be integrated into CNL's existing Species at Risk Program.
	Blanding's Turtle	▪ **Habitat Availability**: Direct, permanent loss of 26 ha of critical habitat. ▪ **Habitat Distribution**: Permanent change in local movement. ▪ **Survival and Reproduction**: Reduced reproductive success and mortality of individuals over the lifespan of the NSDF Project.	Confirm effectiveness of mitigation through tracking wildlife mortality and use information for adaptive management.	Wildlife-vehicle collision monitoring will be conducted in the SSA. — Vehicle-caused Blanding's turtle mortality will be reported and data will be compiled in be used to inform adaptive management for the site.	On-going during the construction and operations phases and closure.	Monitoring will be integrated into CNL's existing Species at Risk Program.
			Identify and map critical habitat in the SSA.	As part of the SARA permitting process for the removal of critical habitat, critical habitat will be assessed annually to ensure no significant loss at CRL and to determine compensation measures initiated at CRL or elsewhere. Monitoring will be integrated into CNL's existing Species at Risk Program.	Critical habitat will be assessed annually to ensure no significant loss at CRL and to determine compensation measures initiated at CRL or elsewhere.	Habitat compensation will be implemented as part of the SARA permitting process and consist of the creation of nest mounds for the species.
			Confirm integrity temporary and permanent of exclusion fencing.	Exclusion fencing will be inspected for integrity.	Annually during the construction and operations phases and closure.	Monitoring will be integrated into CNL's existing Species at Risk Program.
			Confirm integrity of culverts in the RSA.	Culverts will be inspected for barriers to turtle movements.	Weekly during the active season for Blanding's turtle (April 15 to October 15).	Monitoring will be integrated into CNL's existing Species at Risk Program.
			Confirm integrity of artificial nest mounds.	Nesting mounds will be inspected for suitability and mounds will be maintained by removing vegetation as needed.	Weekly during the nesting season for Blanding's turtle (May 15 to June 30).	Monitoring will be integrated into CNL's existing Species at Risk Program.

Table 11.0-1: Environmental Assessment Monitoring and Follow-up Programs Proposed for the NSDF Project

EIS Section	Valued Component	Project Phase and Potential Effect	Monitoring Program Objective	Conceptual Monitoring Program	Suggested Duration	Implementing Program
Section 5.6 Terrestrial Environment (cont'd	Blanding's Turtle (cont'd)		Confirm integrity of nest cages.	Nest cages will be inspected for integrity.	Weekly during the nesting and hatchling emergence season for Blanding's turtle (May 15 to October 15).	Monitoring will be integrated into CNL's existing Species at Risk Program.
			Confirm use of culverts by Blanding's turtles.	Cameras will be installed at culverts and will record photographs on a time-lapse basis. Photographs will be reviewed and data compiled.	Continuously during the active season for Blanding's turtle (April 15 to October 15) every year for the next 5 years.	Monitoring will be integrated into CNL's existing Species at Risk Program.
	Eastern Milksnake	▪ Habitat Availability: Direct, permanent loss of habitat. ▪ Habitat Distribution: Permanent change in local movement. ▪ Survival and Reproduction: increased risk of injury/mortality on roads.	Confirm effectiveness of road mitigation to minimize or eliminate the potential for road mortality in the LSA.	Exclusion fencing will be inspected for integrity.	Annually during the construction and operations phases and closure.	Monitoring will be integrated into CNL's existing Species at Risk Program.
			Confirm effectiveness of road mitigation to minimize or eliminate the potential for road mortality in the LSA	Road mortality surveys to be conducted weekly during pre-construction and operations within the NSDF Project site. During construction, mortality survey to be conducted daily during the species active period (April 15 to September 30).	On-going during construction and operation phases.	Monitoring will be integrated into CNL's existing Species at Risk Program.
	Monarch butterfly	▪ Habitat Availability: Permanent, direct loss of 5 ha of suitable habitat. ▪ Habitat Distribution: Small, permanent change in local movement. ▪ Survival and Reproduction: Small reduction in reproductivity from habitat loss.	N/A(a)	N/A[(a)]	N/A[(a)]	N/A[(a)]
▪ Section 5.7 Ambient Radioactivity and Ecological Health ▪ Section 5.8 Human Health	All VCs	During the operations and closure phases: ▪ Airborne emissions may be released from the ECM from contaminated dust created during handling of bulk materials and emissions of gases may be released during storage and disposal of radioactive materials. ▪ Emissions may be released from the WWTP to air during operations and closure. ▪ Discharge of treated effluent from the WWTP to the East Swamp Wetland and Perch Lake can cause changes to groundwater quality in the wetland and downstream surface water quality, which can affect ecological health. During the post-closure phase (institutional control): ▪ Volatiles (e.g., radon, tritium) may be released to air. ▪ Leachate may be released to soil via overtopping the berm. ▪ Leachate may be released through the base liner to groundwater.	Verify effectiveness of mitigation.	▪ Air quality (i.e., dust) will be monitored at the SSA and air effluent verification monitoring may be required at the WWTP. ▪ Dust samples collected in the high volume air sampler during construction and operations will be screened for radioactivity. ▪ Treated effluent from the WWTP, storm water pond effluent and surrounding surface water quality will be monitored. ▪ Ambient radioactivity will be measured at the SSA. ▪ Groundwater monitoring will be performed surrounding the ECM, to confirm groundwater quality and detect potential releases of constituents from the ECM containment area.	On-going during operations, closure and post-closure (institutional control). The need for and duration of monitoring will be reviewed based on annual review of monitoring data.	▪ Integrated into the existing Effluent Verification Monitoring Program, Groundwater Monitoring Program and Environmental Monitoring Program.

Table 11.0-1: Environmental Assessment Monitoring and Follow-up Programs Proposed for the NSDF Project

EIS Section	Valued Component	Project Phase and Potential Effect	Monitoring Program Objective	Conceptual Monitoring Program	Suggested Duration	Implementing Program
Section 5.9 Land and Resource Use	▪ Land and Resource Tenures and Other Registered Interests ▪ Outdoor Tourism and Recreation ▪ Archaeological Sites	▪ No residual adverse effects identified. Potential effects are related to: ▪ Change in access to or availability of tenured land use opportunities and other registered interests. ▪ Changes in access to or quality and quantity of outdoor tourism and recreation activities (except trapping). ▪ Ground disturbance from the NSDF Project during construction may cause disturbance or destruction to archaeological sites.	Verify mitigation is effective	Monitoring and follow-up programs are not specifically identified for land and resource use; rather, monitoring for environmental pathways (i.e., for air quality, surface water quality and groundwater quality) will be implemented to verify effects predictions for land and resource use, and to promote land user comfort around the safety of the Land and Resource Use LSA, RSA and surrounding areas for land and resource use, outdoor tourism and recreation, and commercial (i.e., tenured) land use activities (i.e., to reduce perceptions of adverse NSDF Project effects on land and resource use that are not anticipated to occur). Monitoring will be used to identify unanticipated archaeological resources and apply adaptive management through the implementation of the CNL Archaeological Master Plan and Cultural Resource Management Program.	▪ On-going during operations, closure and post-closure (institutional control) phases. ▪ The need for and duration of monitoring will be reviewed based on an annual review of monitoring data.	▪ Integrated into CNL's Environmental Monitoring Program. ▪ Executed as part of CNL's Public Information Program. ▪ CNL's Archaeological Master Plan and Cultural Resource Management Program.
Section 5.10 Socio-economic Environment	▪ Labour Market ▪ Economic Development ▪ Government Finances ▪ Housing and Accommodations ▪ Services and Infrastructure ▪ Quality of Life ▪ Noise Levels ▪ Public Safety	Employment of personnel, procurement of goods and services, and expenditures from the NSDF Project: ▪ Increased pressure on commercial accommodations. ▪ Increased road degradation due to increased traffic volume from the transportation of workers, supplies and equipment. ▪ Increased demand for emergency services. ▪ Increased demand for protective services. Construction and Operations Phase ▪ Increased traffic along local roadways (i.e., Highway 17 and Plant Road).	Verify mitigation is effective	▪ Monitoring and follow-up programs are not specifically identified for socio-economics; rather, monitoring for environmental pathways (i.e., for air quality, surface water quality and groundwater quality) will be implemented to verify effects predictions. ▪ CNL will proactively seek, engage and support meaningful discussion on issues and opportunities related to the NSDF Project as part of the Public Information Program (PIP, CNL 2021), which can be found on the CNL website (www.CNL.ca). CNL, as part of the PIP, will notify residents of NSDF Project construction commencement via door-to-door delivery of letters, where stakeholders will have the opportunity to voice their questions or concerns about activities related to the NSDF Project construction commencement. As part of the notification, the letter will include all CNL contact details (e.g., website, telephone, email) to provide clear direction on how to contact CNL if they have questions, concerns or complaints related to the NSDF Project. A web link to a Feedback Form that is currently on the NSDF webpage on www.CNL.ca will also be included in the notification and will outline the above process of when an issue or concern is submitted. CNL will continually evaluate both the process and the outcome of the on-going engagement and communication activities to address and manage issues as they arise. ▪ As part of the Environmental Assessment Monitoring and Follow-up Program, with respect to the noise assessment, a traffic count study will be completed along Highway 17 and Plant Road as a pre-construction activity. Traffic counts will be obtained along both; Highway 17 and Plant Road to establish an Annual Average Daily Traffic (AADT) count in accordance with accepted practices and will consider traffic by type. The study will consider Highway 17 north and south of Plant Road and will include precise study location maps. Average hourly distribution will be established for Highway 17 and Plant Road that will allow for the establishment of daytime and nighttime traffic levels. The gathered traffic count data will be used to verify the noise modelling result, and if required, additional mitigation will be implemented for the NSDF Project.	On-going during the construction, operations and closure phases and the need for and duration of monitoring will be reviewed based annual review of monitoring data. The level and nature of engagement with the communities will depend on feedback received.	▪ Integrated into CNL's Environmental Monitoring Program. ▪ Executed as part of CNL's Public Information Program.

Table 11.0-1: Environmental Assessment Monitoring and Follow-up Programs Proposed for the NSDF Project

EIS Section	Valued Component	Project Phase and Potential Effect	Monitoring Program Objective	Conceptual Monitoring Program	Suggested Duration	Implementing Program
Section 6 Indigenous Interests - Traditional Land and Resource Use	Traditional Land and Resource Use by Indigenous Peoples	No residual adverse effects identified. Potential effects are related to: ▪ Changes in access to or quality and quantity of trapping opportunities. ▪ Changes in access to the quality and quantity of traditional land and resource use – trapping.	Verify mitigation is effective	▪ Monitoring and follow-up programs are not specifically identified for traditional land and resource use; rather, monitoring for environmental pathways (i.e., for air quality, surface water quality, groundwater quality and terrestrial biota) will be implemented to verify effects predictions for traditional land and resource use, and to promote land user comfort around the safety of the Traditional Land and Resource Use LSA, RSA and surrounding areas for traditional land and resource use (i.e., to reduce perceptions of adverse NSDF Project effects on traditional land and resource use that are not anticipated to occur). ▪ As part of CNL's Public Information Program, CNL will continue to engage with Indigenous Peoples, and share the results of the air quality, surface water quality, groundwater quality and terrestrial biota monitoring through an accessible format (e.g., NSDF Project website), a recognized best practice used by projects with high levels of perceived risk that may have the potential to alter or reduce land and resource use activity without primary or secondary pathways. ▪ Monitoring will be used to identify unanticipated archaeological resources and apply adaptive management through the implementation of the CNL Archaeological Master Plan and Cultural Resource Management Program.	▪ On-going during operations, closure and post-closure (institutional control) phases. ▪ The need for and duration of monitoring will be reviewed based on an annual review of monitoring data.	▪ Integrated into CNL's Environmental Monitoring Program. ▪ Executed as part of CNL's Public Information Program. ▪ CNL's Archaeological Master Plan and Cultural Resource Management Program.
Section 6 Indigenous Interests - Indigenous Socio-economic Environment	▪ Decision-making ▪ Population and demographics ▪ Economy and employment ▪ Housing and infrastructure ▪ Indigenous resident – use and enjoyment of private property	No residual adverse effects identified. Potential effects are related to: ▪ The NSDF Project could affect air quality through the generation of emissions and fugitive dust. ▪ The NSDF Project could affect ambient noise levels due to construction traffic. ▪ The NSDF Project could affect ambient noise levels due to blasting activities. ▪ The NSDF Project could have a negative effect on visual aesthetics. ▪ Direct and indirect employment requirements may affect employment and income within the local and regional study areas. ▪ The NSDF Project may provide contracting and supplier opportunities to Indigenous local and regional businesses. ▪ Involvement with the NSDF Project may require more time on the part of Indigenous governance bodies.	Verify mitigation is effective	▪ Monitoring and follow-up programs are not specifically identified for Indigenous socio-economics; rather, monitoring for environmental pathways (i.e., for air quality, surface water quality and groundwater quality) will be implemented to verify effects predictions. ▪ CNL will proactively seek, engage and support meaningful discussion on issues and opportunities related to the NSDF Project as part of the PIP (CNL 2019b), which can be found on the CNL website (www.CNL.ca). CNL, as part of the PIP, will notify residents of NSDF Project construction commencement via door-to-door delivery of letters, where stakeholders will have the opportunity to voice their questions or concerns about activities related to the NSDF Project construction commencement. As part of the notification, the letter will include all CNL contact details (e.g., website, telephone, email) to provide clear direction on how to contact CNL if they have questions, concerns or complaints related to the NSDF Project. A web link to a Feedback Form that is currently on the NSDF webpage on www.CNL.ca will also be included in the notification and will outline the above process of when an issue or concern is submitted. CNL will continually evaluate both the process and the outcome of the on-going engagement and communication activities to address and manage issues as they arise.	▪ On-going during the construction, operations and closure (institutional control) phases and the need for and duration of monitoring will be reviewed based annual review of monitoring data. ▪ The level and nature of engagement with the Indigenous Peoples will depend on feedback received.	▪ Integrated into CNL's Environmental Monitoring Program. ▪ Executed as part of CNL's Public Information Program.

GHG = greenhouse gas; ECM = engineered containment mound; N/A = not applicable.

[(a)]Monitoring programs are not proposed for monarch butterfly.

12.0 CONCLUSIONS

This Environmental Impact Statement (EIS) describes the NSDF Project and the existing environmental conditions on the Chalk River Laboratories (CRL) site, and assesses the likely effects of the NSDF Project on the environment. The EIS also includes an assessment of likely cumulative effects of the NSDF Project in combination with other previous, existing or reasonably foreseeable developments, as required. It describes the effects for normal conditions and as a result of accidents and malfunctions. The EIS also describes and assesses the likely effects of the environment on the NSDF Project. Throughout the environmental assessment process, Canadian Nuclear Laboratories (CNL) has solicited input from the public and Indigenous Peoples and incorporated this feedback into the EIS where appropriate. Examples of this includes changes to the waste inventory (i.e., only low-level waste) and expansion of the EIS study areas to include a larger downstream portion of the Ottawa River. Further, CNL has entered into long-term relationship agreements with Indigenous Peoples to work collaboratively to meet the needs of the individual communities as well as CNL's Project requirements.

The development of a near surface disposal facility for solid, low-level radioactive waste at the CRL site will reduce potential risks associated with Atomic Energy of Canada Limited's legacy wastes liabilities. The NSDF Project will enable the remediation of historically contaminated lands and legacy waste management areas, as well as decommissioning of outdated infrastructure to facilitate the CRL site revitalization. The current CRL waste management practice is to safely store radioactive waste on-site in individual facilities in accordance with current licence conditions. However, appropriate nuclear waste management includes full life cycle management from generation to disposal. The NSDF Project will accommodate the permanent disposal of current and future low-level radioactive waste at the site. The EIS demonstrates that the NSDF Project can be constructed, operated and closed in a manner that is protective of human health and the environment.

The significance of the likely environmental effects of the NSDF Project has been assessed in Section 5.0 and Section 6.0. A summary of the residual adverse effects, mitigation and significance of residual adverse effects is provided in Section 9.0. The proposed monitoring and follow-up programs to be undertaken during all phases of the NSDF Project (i.e., construction, operations, closure and post-closure) are summarized in Section 11.0.

Residual adverse effects were identified for air quality (including greenhouse gases), hydrogeology, hydrology, surface water quality, terrestrial biodiversity, ecological health, human health and socio-economics (housing and accommodations, and services and infrastructure). Beneficial effects were identified for socio-economics (labour market, economic development, Indigenous). CNL has proactively addressed key issues raised by interested Indigenous Peoples, using open and transparent communication to share information in regard to traditional land use, biodiversity and archaeology. Overall, it is CNL's conclusion that with the identified mitigation, the implementation of the NSDF Project is not likely to result in significant residual adverse effects.

All predicted effects for human health are well below regulatory criteria during the life of the NSDF Project, including post-closure. The maximum estimated dose during the operations period for an on-site worker is 5 times lower than the regulatory limit of 50 millisieverts per year (mSv/yr) and for the public is almost 50 times lower than the regulatory dose limit of 1 mSv/yr. During post-closure, the maximum estimated dose associated with the most likely future state of the facility is more than 60 times lower than the regulatory dose limit of 1 mSv/yr. Residual effects on Ottawa River water quality are determined to be negligible during operations and post-closure phases and may result in a net benefit due to remediation of legacy waste storage areas.

Potential effects of the NSDF Project on the environment are limited because the NSDF Project has been designed in consideration of site-specific characteristics and to be suitable for the proposed inventory, the vast majority of which are comprised of impacted soils and demolition debris. The engineered containment mound is designed to contain and isolate the wastes from the environment for 550 years. Since the NSDF only accepts LLW and most of the radioactivity; thus, the hazard, decays in the first 100 years after closure, the design of the NSDF is commensurate with the hazard. The safety of the NSDF during post-closure is provided by means of passive features (e.g., berm, base liner and cover systems) that will end the need for active management, in alignment with Canadian Nuclear Safety Commission requirements and International Atomic Energy Agency guidance.

A conceptual follow-up and monitoring program was developed to verify that mitigation is being implemented effectively and to confirm environmental assessment predictions. The details of this program will be further developed into detailed monitoring and follow-up programs as detailed NSDF Project design is finalized, with input from the public, Indigenous Peoples and regulatory agencies. The facility will be a licenced nuclear facility under the *Nuclear Safety and Control Act* with regulatory oversight as long as required.

None.

14.0 GLOSSARY, ACRONYMS AND UNITS

14.1 Glossary

Table 14.1-1: Glossary of Terms

Term	Definition
Abiotic	Relating to the non-living parts of the environment such as air, rock, soil and water. Some abiotic components are topography, hydrology, drainage, climate, meteorology, and land-use patterns by members of the public.
Acceptance Criteria	Specified bounds on the value of a functional or condition indicator used to assess the ability of a structure, system or component to meet its design and safety requirements.
Accident	Any unintended event, including operating errors, equipment failures or other mishaps, the consequences or potential consequences of which are significant from the point of view of protection or safety. With respect to nuclear criticality safety, the term **accidents or accident sequences** means events or event sequences, including external events, that lead to violation of the subcriticality margin (that is, to exceeding the upper subcritical limit).
Acute	With reference to toxicity, having a sudden onset, lasting a short time (usually within hours or days). With reference to a stimulus, severe enough to rapidly induce a response.
Acute Toxicity	Adverse effects occurring following oral or dermal administration of a single dose of a substance, or multiple doses given within 24 hours, or an inhalation exposure of 4 hours.
Adaptive Management	A planned and systematic process for continuously improving management practices (primarily environmental) by learning from their outcomes. For an environmental assessment, it involves, among other things, the implementation of new or modified mitigation measures over the life of a project to address unanticipated environmental effects.
Adiabatic	Relating to or denoting a process or condition in which heat does not enter or leave the system concerned.
Advection	The transfer of matter by the flow of a fluid.
Aeolian	Relates to or arising from the action of the wind.
Alpha particle	A positively charged particle ejected spontaneously from the nuclei of some radioactive elements. **Note**: An alpha particle is identical to a helium nucleus, which has a mass number of 4 and an electrostatic charge of+2. An alpha particle has low penetrating power and a short range (a few centimetres in air). Alpha particles will generally fail to penetrate the dead layers of cells covering the skin and can be easily stopped by a sheet of paper. However, alpha-emitting isotopes are harmful if ingested.
Alpha radiation	The emission of an alpha particle from the nucleus of an atom.
Ammonia	A colorless, pungent gas used to manufacture a wide variety of nitrogen-containing organic and inorganic chemicals.
Anaerobic Conditions	Anaerobic conditions refer to a lack of free oxygen within a watercourse or waterbody. During anaerobic conditions, there is little to no biologically available oxygen.
Ancillary Infrastructure	Infrastructure necessary to support the transmission of electric power from seller to purchaser given the obligations of control areas and transmitting utilities within those control areas to maintain reliable operations of the interconnected transmission system.
Anion	A negatively charged ion.

Table 14.1-1: Glossary of Terms

Term	Definition
Anisotropic	An object or substance having a physical property that has a different value when measured in different directions.
Anoxic	Deficient in oxygen or having no oxygen.
Anthropogenic	Coming from or having been caused by humans.
Anticipated Operational Occurrences	An operational process deviating from normal operation which is expected to occur at least once during the operating lifetime of a facility but which, in view of appropriate design provisions, does not cause any significant damage to items important to safety nor lead to accident conditions.
Archaeological Resources	Any material remains of past human life or activities which are of archaeological interest.
Areas of Natural and Scientific Interest (ANSI)	An official designation by the provincial Government of Ontario in Canada applied to contiguous geographical regions within the province that have geological or ecological features which are significantly representative provincially, regionally, or locally.
As Low As Reasonably Achievable (ALARA)	An optimization tool in radiation protection used to keep individual, workplace and public dose limits as low as reasonably achievable, social and economic factors being taken into account. ALARA is not a dose limit; it is a practice that aims to keep dose levels as far as possible below regulatory limits.
Assessment Endpoints	Assessment endpoints are qualitative expressions used to assess the significance of residual effects on Valued Components (VCs) and represent the key properties of the VC that should be protected for future generations.
Background Radiation	The dose or dose rate (or an observed measure related to the dose or dose rate) attributable to all sources other than the one specified.
Baseline	A set of measurements (or metrics) representing the starting level of performance for a structure, system or component.
Bathtubbing	A process in which the waste material degrades, producing voids within a disposal trench, followed by subsidence of the overlying soil and the entry of surface water into the trench. In cases where the soil surrounding the trenches is sufficiently impermeable, the trenches fill with water. Overflow of water from this "bathtub" would have the potential to distribute radionuclides across the surrounding ground.
Bear Management Area (BMA)	An area of Crown land licenced annually to a tourist operator for providing bear hunting services to non-resident clients. Some BMAs can completely surround private or patent land. Bear hunting services can occur on these lands provided the licenced tourist operator allocated the BMA has obtained permission of the land owner to provide bear hunting services on the property.
Best Available Technology and Techniques Economically Achievable (BATEA)	Minimum pollution prevention performance standards for which effluent and/or emission concentrations have been demonstrated to be achievable within an industrial sector and are therefore economically achievable across that industrial sector. BATEA takes into account both treatment technologies and techniques used to achieve the desired effluent and/or emission concentrations. The way in which the installation is designed, built, maintained, operated and decommissioned is also considered as part of these technologies and techniques.
Best Estimate	An unbiased estimate obtained by using a mathematical model, calculation method or data to realistically predict behaviour and important parameters.
Becquerels	The International System unit of radioactivity, corresponding to one disintegration per second.

Table 14.1-1: Glossary of Terms

Term	Definition
Beta Particle	A charged particle that is emitted from the nucleus of a radioactive element during radioactive decay of an unstable atom. Large amounts of beta radiation may cause skin burns, and beta emitters are harmful if they enter the body. Beta particles may be stopped by thin sheets of metal or plastic.
Beta Radiation	The emission of a beta particle from the nucleus of an atom.
Beyond-design-basis accident (BDB)	An accident less frequent and potentially more severe than a design-basis accident.
Bioassay	The study of all living organisms to measure the effect of a substance, factor or condition by comparing before-and-after exposure or other data. **Note**: Specific to radiation exposure in humans, bioassay is any procedure used to determine the nature, activity, location or retention of radionuclides in a body by direct (*in vivo*) measurement or by indirect *(in vitro*) analysis of material excreted or otherwise removed from a body. *In vivo* bioassay may be referred to as direct bioassay; *in vitro* bioassay may be referred to as indirect bioassay.
Biophysical	Of or pertaining to a combination of biology and physics.
Bounding Scenario	An accident or disruptive event with consequences larger (i.e., greater releases to the environment) than others considered.
Brownfield	Abandoned, idled or under-used industrial and commercial facilities where expansion or redevelopment is complicated by real or perceived environmental contamination.
CANDU reactor	A Canadian-invented pressurized heavy-water reactor that uses heavy water (deuterium oxide) for moderator and coolant and natural uranium for fuel. "CANDU" is short for CANada Deuterium Uranium. Also called CANDU.
Catchment area	An extent or an area of land where all surface water from rain, melting snow, or ice converges to a single point at a lower elevation, usually the exit of the basin, where the waters join another body of water, such as a river, lake, reservoir, estuary, wetland, sea, or ocean.
Chelating Agents	A substance whose molecules can form several bonds to a single metal ion.
Chronic	Involving stimulus that is lingering or continues for a long time; often signifies periods from several weeks to years, depending on the reproductive life cycle of the species. Can be used to define either the exposure or the response to an exposure (effect). Chronic exposure typically induces a biological response of relatively slow progress and long continuance.
Cloudshine	External exposure to penetrating radiation (i.e., gamma radiation) in a plume.
Contact Water	Water that has come in contact with waste and is considered contaminated.
Contaminated Areas	An area where the condition or state of soil, water, or air caused by a substance release or escape results in an impairment of, or damage to, the environment, human health, safety, or property.
Corporate Social Responsibility	A business approach that contributes to sustainable development by delivering economic, social and environmental benefits for all stakeholders.
Criticality	The creation of a series of nuclear reactions that is self-sustaining. This is the normal operating condition of a nuclear reactor.
Crown Corporation	Any corporation that is established and regulated by a country's state or government.

Table 14.1-1: Glossary of Terms

Term	Definition
CSA Group	A standard-setting body that works with the regulator, industry and stakeholders to produce consensus-based Canadian industry standards that may be used by the regulator or industry. Formerly called Canadian Standards Association.
Daily Cover	Daily cover is applied at the end of each work day over the active disposal area or the placed waste working face, to control the release of fugitive dust from the surface of the waste. The daily cover consists of 0.150 m layer of clean soil or an alternative daily cover material that is pre-approved for use including tarpaulin, fixative (crusting agent), or similar temporary cover system material.
Dangerous goods	Dangerous goods include explosives, gases, flammable liquids, flammable solids, oxidizing substances and organic peroxides, toxic and infectious, radioactive material, corrosives and miscellaneous.
Datum	A fixed starting point of a scale or operation.
Decommissioning	Administrative and technical actions taken to allow the removal of some or all of the regulatory controls from a facility. This does not apply to a repository or to certain nuclear facilities used for mining and milling of radioactive materials, for which closure is used.
Deep Geological Repository	A facility for disposal of radioactive waste located underground (usually several hundred metres or more below the surface) in a geological formation to provide long-term isolation of radionuclides from the biosphere.
Deglaciation	Transitions from full glacial conditions to warm interglaciations (within an ice age), characterized by global warming and sea level rise due to change in continental ice volume.
Delineation	The action of describing or portraying something precisely.
Derived Release Limit	As defined in the CSA Group publication CSA N288.1, *Guidelines for calculating derived release limits for radioactive material in airborne and liquid effluents for normal operation of nuclear facilities*: The release rate that would cause an individual of the most highly exposed group to receive and be committed to a dose equal to the regulatory annual dose limit due to release of a given radionuclide to air or surface water during normal operation of a nuclear facility over the period of a calendar year.
Design Basis	The range of conditions and events taken explicitly into account in the design of a nuclear facility, according to established criteria, such that the facility can withstand this range without exceeding authorized limits. **Note**: Design extension conditions are not part of the design basis.
Design-Basis-Accident (DBA)	Accident conditions for which a nuclear facility is designed according to established design criteria and for which damage to the fuel and the release of radioactive material are kept within authorized limits. DBA is a plant state.
Detritus	Waste or debris of any kind.
Dioxin	A colourless toxic liquid used as an organic solvent.
Discharge Criteria	Legislative criteria detailing the amount of radioactive material acceptable within gas or liquid for a planned and controlled release to the environment.
Disposal	The placement of radioactive waste without the intention of retrieval.
Disposal Cell	Individual engineered cell as part of the engineered containment mound. The cells hold disposed radioactive waste.
Drainage Basins	Area draining to a lake, stream, reservoir or other body of water.

Table 14.1-1: Glossary of Terms

Term	Definition
Duty to Consult	In Canada, the duty to consult and accommodate with Indigenous Peoples arises when the Crown contemplates actions or decisions that may affect an Indigenous person's Aboriginal or Treaty rights.
Dystrophic	Brown acidic water that is low in oxygen and supports little life, owing to high levels of dissolved humus.
Effective Porosity	Effective porosity is the total porosity less the fraction of the pore space occupied by shale or clay. In very clean sands, total porosity is equal to effective porosity.
Effluent	Liquid waste or sewage discharged into a river, lake or the sea.
Engineered Containment Mound	A physical structure designed to prevent the dispersion of radioactive substances consisting of a primary and secondary composite base liner system and composite final cover system, made up of both natural materials (e.g., compacted clay, granular materials) and synthetic materials (e.g., geosynthetic clay liner, geomembrane, geotextiles).
Environmental Assessment	An assessment of the environmental effects of a project.
Environmental Impact Statement	A detailed technical document prepared by the proponent of a designated project to be assessed pursuant to the *Canadian Environmental Assessment Act, 2012*. The environmental impact statement identifies the potential adverse environmental effects of a designated project including cumulative effects, measures to mitigate those effects, and an evaluation of whether the designated project is likely to cause any significant adverse environmental effects.
Environmental Management System (EMS)	The part of an organization's management system used to develop and implement its environmental policy and manage its environmental aspects. An EMS consists of policies and procedures forming an integrated set of documented activities to provide a framework for effective environmental protection measures.
Environmental Media	Soil, water, air, biota (plants and animals), or any other parts of the environment that can contain contaminants.
Environmental Risk Assessment (ERA)	A process that identifies, quantifies and characterizes the risk posed by contaminants (nuclear or hazardous substances) and physical stressors in the environment. An ERA is a practice or methodology primarily developed by regulatory agencies to provide scientific input to decision makers. In this way, ERAs commonly serve as a supportive tool providing technical information in a manageable form to a larger environmental assessment.
Eutrophic	A lake or other body of water that is rich in nutrients and supporting a dense plant population, the decomposition of which kills animal life by depriving it of oxygen.
Exfiltration Gallery	A series of underground trenches of clear stones that encourage dispersal of treated effluent into the groundwater, similar to a septic system.
Evapotranspiration	The process by which water is transferred from the land to the atmosphere by evaporation from the soil and other surfaces and by transpiration from plants.
Fissile	Capable of undergoing fission by interaction with slow neutrons.
Fission	The division of a heavy nucleus into two (or, rarely, more) parts with masses of equal order of magnitude; usually accompanied by the emission of neutrons and gamma radiation.
Frac-out	The condition where drilling mud is released through fractured bedrock into the surrounding geology and travels toward the surface.

Table 14.1-1: Glossary of Terms

Term	Definition
Fugitive Dust	Small airborne particulate matter which generally comes from soil. Fugitive dust is suspended in the air by wind action and human activities.
Fulvic Acid	A highly soluble organic phenol found in humus that chelates elemental mineral nutrients.
Furan	A cyclic flammable liquid (chemical compound C4H4O) that is obtained from wood oils of pines or made synthetically and is used especially in organic synthesis.
Gamma Radiation	Penetrating electromagnetic radiation emitted from an atom's nucleus. Also called gamma rays.
Gamma Spectroscopy	The quantitative study of the energy spectra of gamma-ray sources, in the nuclear industry, geochemical investigation, and astrophysics. Most radioactive sources produce gamma rays, which are of various energies and intensities.
Gamma-emitters	Radionuclides that emit gamma ray photons during radioactive decay.
Geiger Tube	It is a gaseous ionization detector and uses the Townsend avalanche phenomenon to produce an easily detectable electronic pulse from as little as a single ionising event due to a radiation particle.
Geomembrane	Is a very low permeability synthetic membrane liner or barrier used with geotechnical engineering related material to control fluid (or gas) migration in a human-made project, structure, or system.
Geomorphology	The science dealing with relief features of the Earth and interpretation of them based on their origins and development.
Glacial Till	Unsorted sediment of glacial origin derived by erosion and entrainment of material by the moving ice of a glacier.
Gneissic Rocks	A highly foliated, coarse-grained metamorphic rock consisting of light-colored layers, usually of quartz and feldspar, alternating with dark-colored layers of other minerals, usually hornblende and biotite.
Gray (Gy)	The International System of Units (SI) unit of measurement used to express absorbed dose. One gray is defined as the absorption of 1 joule of ionizing radiation by 1 kilogram of matter. For gamma and beta radiations, the gray is numerically equal to the Sievert.
Green Algae	Photosynthetic algae that contain chlorophyll and store starch in discrete chloroplasts. They are eukaryotic and most live in fresh water, ranging from unicellular flagellates to more complex multicellular forms.
Greenfield	Parkland, undeveloped open space and agricultural land, usually located near the outskirts of cities and large metropolitan areas.
Greenhouse Gases	A gas in the atmosphere that absorbs and emits radiation within the thermal infrared range. The primary greenhouse gases in the Earth's atmosphere are water vapor, carbon dioxide, methane, nitrous oxide, and ozone.
Groundshine	Exposure to penetrating radiation from radioactive material that is deposited on the ground.
Ground-truthing	Information provided by direct observation (i.e., empirical evidence) as opposed to information determined by inference.
Groundwater Discharge	The movement of groundwater from the subsurface to the surface. There is natural discharge which occurs into lakes, streams and springs as well as human discharge, which is generally referred to as pumping.

Table 14.1-1: Glossary of Terms

Term	Definition
Groundwater Recharge	A hydrologic process, where water moves downward from surface water to groundwater. Recharge is the primary method through which water enters an aquifer.
Grouted	Radioactive waste materials that have been treated and conditioned into forms that are suitable for their subsequent management, including transportation, storage and disposal. Grout is typically a cementitious mortar or paste that can fill gaps and crevices.
Guild	A group of species that that use the same resources, or that use different resources in similar ways.
Halocarbon Refrigerants	Chemicals in which one or more carbon atoms are linked by covalent bonds with one or more halogen atoms (fluorine, chlorine, bromine or iodine) resulting in the formation of organofluorine, organochlorine, organobromine, and organoiodine compounds.
Hazardous Materials	Materials that are potentially hazardous to human health and/or the environment due to their nature and quantity and that require special handling and storage techniques.
Hibernacula	Plural of hibernaculum. Places of refuge occupied by animals, such as bats, during the winter when the species becomes dormant to avoid times when resources are limited and temperatures are below freezing.
High Level Waste	Used nuclear fuel and other wastes (e.g., reprocessing wastes) that have been declared as radioactive waste that generates significant heat via radioactive decay. Used nuclear fuel is associated with penetrating radiation and contains significant quantities of long-lived radionuclides.
Holocene Period	Denoting the present period (epoch) of geologic time, which began after the Pleistocene approximately 11,700 years before present.
Humic Acid	Humic acids are a principal component of humic substances, which are the major organic constituents of soil (humus), peat and coal.
Hydraulic Conductivity	Symbolically represented as K, is a property of vascular plants, soils and rocks that describes the ease with which a fluid (usually water) can move through pore spaces or fractures.
Hydrofluorocarbons	Organic compounds that contain fluorine and hydrogen atoms, are the most common type of organofluorine compounds. They are commonly used in air conditioning and as refrigerants.
Hypolimnion	The hypolimnion, or under lake, is the dense, bottom layer of water in a thermally-stratified lake. It is the layer that lies below the thermocline. Typically, the hypolimnion is the coldest layer of a lake in summer, and the warmest layer during winter. Being at depth, it is isolated from surface wind-mixing during summer, and usually receives insufficient irradiance (light) for photosynthesis to occur.
Indicator Species	An organism whose presence, absence or abundance reflects a specific environmental condition. Indicator species can signal a change in the biological condition of a particular ecosystem, and thus may be used as a proxy to diagnose the health of an ecosystem.
Indigenous Peoples	Includes the First Nations, Inuit and Métis people of Canada.
Induced Employment	Employment opportunities arising from Project employees (direct employment) and employees of business supporting the Project (indirect employment) spending their Project-generated income in the broader economy (e.g., food, clothing, entertainment).
Infrared Radiation	A type of electromagnetic radiation, as are radio waves, ultraviolet radiation, X-rays and microwaves. Infrared light is the part of the electromagnetic spectrum that people encounter most in everyday life, although much of it goes unnoticed. It is invisible to human eyes, but people can feel it as heat.

Table 14.1-1: Glossary of Terms

Term	Definition
In-situ Treatment	A method of managing or treating contaminated soils, sludges and waters “in place” in a manner that does not require the contaminated material to be physically removed or excavated from where it originates.
Interim Cover	The interim cover consists of 0.3 m layer of clean soil or clean sand that is overlain by a sacrificial liner to promote non-contact surface water run-off, and minimize precipitation infiltration into the waste material. The interim cover is applied to: 1) waste disposal areas that will remain inactive for more than 30 days; and 2) waste disposal areas that have reached the design waste fill grade.
Interglaciation	The warm periods between ice age glaciations. Often defined as the periods at which sea levels were close to present sea level.
Intermediate Level Waste	Typically exhibits levels of penetrating radiation sufficient to require shielding during handling and interim storage and contains significant quantities of long lived radionuclides.
Interstratified	A series of rock strata arranged in alternating beds.
Ion Exchange	A usually reversible exchange of one ion with another, either on a solid surface, or within a lattice. A commonly used method for treatment of liquid waste.
Ion-exchange Resins	A resin or polymer that acts as a medium for ion exchange.
Ionizing Radiation	For the purposes of radiation protection, radiation capable of producing ion pairs in biological material(s). **Note**: Ionizing radiation is constantly present in the environment and includes the radiation that comes from both natural and artificial sources, such as cosmic rays, terrestrial sources (radioactive elements in the soil), ambient air (radon), and internal sources (food and drink).
Isopach Map	A map illustrating variations in thickness of a geological unit, layer, or stratum. Isopachs are contour lines of equal thickness.
Kd	A dissociation constant; a specific type of equilibrium constant that measures the propensity of a larger object to separate (dissociate) reversibly into smaller components, as when a complex falls apart into its component molecules, or when a salt splits up into its component ions.
LC50	LC50 is the lethal concentration of a toxin that is required to kill 50% of the population.
Legacy Waste	Wastes inherited from other companies or facilities. With respect to CNL, this refers to the wastes generated from 65 years of past operation that are now in interim storage in the CRL site.
Leachate	A solution that has been in contact with soil or waste and, as a result, may contain some of the soluble or suspended constituents of the material.
Lampricide	A lampricide is any chemical designed to target the larvae of lampreys in river systems before they develop into parasitic adults. One lampricide is used in the headwaters of Lake Champlain and the Great Lakes to control the sea lamprey (*Petromyzon marinus*), an invasive species to these lakes.
Licensed Inventory	The maximum radioactivity of significant radionuclides that the NSDF will accept. Note: Significant radionuclides are the radionuclides that were identified in the NSDF Reference Inventory.
Life History Stages	The various forms in which an organism expresses or manifests itself in its development from the primary stage to its natural death (e.g., juvenile, adult).

Table 14.1-1: Glossary of Terms

Term	Definition
Lithic Scatters	Sites where prehistoric stone artefacts are found exposed, usually on the modern ground surface, having been disturbed from their original context and 'scattered' by natural or agricultural processes.
Littoral Zones	Near shore area where sunlight penetrates all the way to the sediment and allows aquatic plants (macrophytes) to grow.
Longitudinal Dispersivity	Dispersivity is an empirical property of a porous medium that determines the characteristic dispersion of the medium by relating the components of pore velocity to the dispersion coefficient across a longitudinal gradient.
Low Level Waste	Radioactive solid waste that contains material with radionuclide content above established clearance levels and exemption quantities, but that generally has limited amounts of long-lived activity.
Ludlum 44-9 Pancake Geiger-Mueller Detector	The Geiger-Muller pancake-type detector in the Model 44-9, made by Ludlum Measurements Inc., is arguably the most popular radiation detector used throughout the world. This detector is sensitive to alpha, beta, and gamma radiation, is enclosed within a rugged metal enclosure, and is conveniently shaped and sized for checking contamination on people and objects.
Measurement Indicators	Measurement indicators represent properties of the environment and Valued Components (VCs) that, when changed, could result in or contribute to an effect on a VC.
Metamorphism	The change of minerals or geologic texture (distinct arrangement of minerals) in pre-existing rocks (protoliths), without the protolith melting into liquid magma (a solid-state change). The change occurs primarily due to heat, pressure, and the introduction of chemically active fluids.
Metasedimentary	Sediment or sedimentary rock that appears to have been altered by metamorphism.
Mitigation	Measures aimed at eliminating, reducing or controlling the adverse effects of a licensed activity, substance, equipment or facility. Mitigation may include restitution for any damage caused by such effects, such as through replacement, restoration or compensation.
Mixed Waste	Radioactive waste that also contains hazardous substances.
Molybdenum	The chemical element of atomic number 42, a brittle silver-gray metal of the transition series, used in some alloy steels.
Mucocilliary	Relating to, or involving, cilia of the mucous membranes of the respiratory system.
Near Surface Disposal Facility	A facility for disposal of radioactive waste located at or within a few metres from the earth’s surface.
Nitrate	A salt or ester of nitric acid, containing the anion NO_3^- or the group —NO_3.
Nitrification/Denitrification	The biological oxidation of ammonia or ammonium to nitrite followed by the oxidation of the nitrite to nitrate. The transformation of ammonia to nitrite is usually the rate limiting step of nitrification. Nitrification is an important step in the nitrogen cycle in soil.
Nitrite	A salt or ester of nitrous acid, containing the anion NO_2^- or the group —NO_2.
Noble Gases	Any of the gaseous elements helium, neon, argon, krypton, xenon, and radon, occupying Group 0 (18) of the periodic table. They were long believed to be totally unreactive but compounds of xenon, krypton, and radon are now known.
Non-contact Water	Water that has not been in contact with waste materials.

Table 14.1-1: Glossary of Terms

Term	Definition
Notice of Commencement	A notice or letter that signifies the starting point for a project and the environmental assessment for the project.
Nuclear Facility, Sites	A facility and its associated land, buildings and equipment in which radioactive materials are produced, processed, used, handled, stored or disposed of on such a scale that consideration of safety is required.
Official Plan	Describes the upper, lower or single–tier municipal council's policies on how land in their community should be used.
Overburden	Material overlying the bedrock surface, including rock as well as soil and other unconsolidated (loose) material, such as glacial deposits, sand and sediment.
Pathway	The way in which project components or activities can cause potential effects to valued environmental or socio-economic components of the environment.
Permeameter Test	The permeameter test measures the permeability (also called hydraulic conductivity) of the soil at the bottom of a borehole, above the water table by temporarily saturating the soil at the bottom of the borehole. It measures the “field-saturated hydraulic conductivity”, which is commonly abbreviated as Kfs.
Perfluorocarbons	Organofluorine compounds with the formula CxFy, i.e., they contain only carbon and fluorine.
Pleistocene Period	Denoting the period (epoch) of geologic time prior to the Holocene. The Pleistocene is the geological epoch which lasted from about 2,588,000 to 11,700 years ago, spanning the world's most recent period of repeated glaciations.
Polychlorinated Biphenyls (PCBs)	Any of a class of toxic aromatic compounds, often formed as waste in industrial processes, whose molecules contain two benzene rings in which hydrogen atoms have been replaced by chlorine atoms.
Pool Riffle Sequence	Pool and riffle sequence is deep and shallow portions of an undulating stream bed. Pools are most easily seen in a meandering stream where the outer edge of each meander loop is deep and undercut; riffles form in the shallow water of the short, straight, wide reaches between adjacent loops
Pyrophoric Materials	Materials that are often water-reactive and will ignite when they contact water or humid air. They can be handled safely in atmospheres of argon or (with a few exceptions) nitrogen. Most pyrophoric fires should be extinguished with a Class D fire extinguisher for burning metals.
Qualitative	Relating to, measuring, or measured by the quality of something rather than its quantity.
Quantitative	Relating to, measuring, or measured by the quantity of something rather than its quality.
Radiation	The emission by a nuclear substance, the production using a nuclear substance, or the production at a nuclear facility of, an atomic or subatomic particle or electromagnetic wave with sufficient energy for ionization.
Radiation Field	Represents the energy lost from the source radiator to space.
Radioactive	Emitting or relating to the emission of ionizing radiation or particles. Exhibiting radioactivity. A radioactive material is a substance containing radioactivity above a specified level.

Table 14.1-1: Glossary of Terms

Term	Definition
Radioactive Decay	The spontaneous transformation of one radioisotope into one or more different isotopes (known as decay products or daughter products), accompanied by a decrease in radioactivity (compared to the parent material). This transformation takes place over a defined period of time (known as a half-life), as a result of electron capture; fission; or the emission of alpha particles, beta particles, or photons (gamma radiation or X-rays) from the nucleus of an unstable atom. Each isotope in the sequence (known as a decay chain) decays to the next until it forms a stable, less energetic end product. In addition, radioactive decay may refer to gamma-ray and conversion electron emission, which only reduces the excitation energy of the nucleus.
Radioactive Waste	For the purposes of waste management, any material (liquid, gaseous, or solid) that contains a radioactive nuclear substance, as defined in section 2 of the *Nuclear Safety and Control Act*, and which the owner has declared to be waste. In addition to containing nuclear substances, radioactive waste may also contain non-radioactive hazardous substances, as defined in section 1 of the *General Nuclear Safety and Control Regulations*.
Radioactivity	The spontaneous transformation of an atom's nucleus by expulsion of particles. Radioactivity can be accompanied by electromagnetic radiation. Solids, liquids or gases can be radioactive.
Radiocarbon Dated	Also referred to as carbon dating or carbon-14 dating, is a method for determining the age of an object containing organic material by using the properties of a radioactive isotope of carbon (C-14).
Radiological	Relating to the science of X-rays and other high-energy radiation. Of or pertaining to radiation or radioactivity.
Radionuclide	A nucleus (of an atom) that possesses properties of spontaneous disintegration (radioactivity). Nuclei are distinguished by their mass and atomic number.
Reasonably Foreseeable Developments	Industrial or construction projects and developments that are approved or under approval, and are likely to commence in the reasonably foreseeable future.
Reference Inventory	The radiological inventory of significant radionuclides that was used to inform the design and safety analysis.
Refuse Pit	Artifacts left behind when a settlement or activity area is abandoned.
Relic Shoreline	Shorelines of waterbodies that were present in past glaciation periods.
Remediation	Any measures that may be carried out to reduce the exposure from existing contamination through actions applied to the contamination itself (the source) or to the exposure pathways to humans.
Residual Effects	Environmental effects predicted to remain after the application of mitigation outlined in an environmental assessment. The predicted residual effects are considered for each Project phase.
Reverse Osmosis	Movement of a solvent out of a solution under pressure through a semipermeable membrane into pure solvent or a less concentrated solution at lower pressure. This process can be used to increase the radionuclide concentration in a solution. It can also be used to remove ions, molecules and larger particles from drinking water.
Sacrificial Liner	The sacrificial liner is a linear low-density polyethylene (LLDPE) geomembrane that promotes non-contact surface water runoff and minimizes precipitation infiltration.
Sheet Flow	Water, usually storm runoff, flowing in a thin layer over the ground surface.
Sievert	The International System of Units (SI) unit of equivalent dose and effective dose, equal to 1 joule/kilogram.

Table 14.1-1: Glossary of Terms

Term	Definition
Sorb	To take up and hold by either adsorption or absorption.
Sorption	The interaction of an atom, molecule or particle with the surface of a solid. A general term including absorption (sorption taking place largely within the pores of a solid) and adsorption (surface sorption with a non-porous solid). The processes involved may also be divided into chemisorption (chemical bonding with the substrate) and physisorption (physical attraction, for example by weak electrostatic forces).
Source Term	The amount and isotopic composition of material released (or postulated to be released) from a nuclear facility.
Spatial Boundary	The geographic extent of the study area.
Stage 1 assessment	A desktop assessment to identify areas where potential archaeological resources may exist.
Stage 2 assessment	The Stage 2 component of an Archaeological Assessment begins with test pit surveys completed in areas where archaeological potential was identified during the background study and property inspection (Stage 1). The second phase of Stage 2 involves “infilling” where at each positive test pit, further excavation is completed to determine if further inspection of the area is necessary.
Stage 3 assessment	The Stage 3 component of an Archaeology Assessment is a site-specific assessment and involves controlled surface pick up of material and excavation to determine the location and number of significant test pits.
Stage 4 assessment	Stage 4 in an Archaeological Assessment involves implementing long-term management strategies for those sites recommended for mitigation in Stage 3.
Stochastic effect	A radiation-induced health effect, the probability of occurrence of which is greater for a higher radiation dose and the severity of which (if it occurs) is independent of dose. **Note**: Stochastic effects may be somatic effects or hereditary effects, and generally occur without a threshold level of dose. Examples include cancer and leukemia.
Stratified	Formed or arranged into strata or layers.
Subsurface Water	Water that flows or collects beneath the Earth's surface.
Sulphur Hexafluoride	Organic, colorless, odorless, non-flammable, extremely potent greenhouse gases, which are excellent electrical insulators.
Surface water	Surface water is water collecting on the ground or in a stream, river, lake, wetland, or ocean.
Tailings	The waste material and water mixture left over after a mill removes the valuable rocks. The rock material in tailings is usually the size of sand grains or smaller. **Note**: Tailings that result from uranium milling contain long-lived radionuclides (such as thorium-230 and radium-226) produced from the decay of uranium, as well as trace metals like arsenic and nickel. They also contain chemical residues from the milling process.
Tarpaulin	Heavy-duty waterproof cloth, originally of tarred canvas.
Temporal Boundary	Timeframe during which project activities are actively occurring, including the duration of predicted residual effects.
Thermal Stratification	Refers to a change in the temperature at different depths in the lake, due to the change in the water's density with temperature. Cold water is denser than warm water and the epilimnion (surface layer) generally consists of water that is not as dense as the water in the hypolimnion (deeper layer).

Table 14.1-1: Glossary of Terms

Term	Definition
Thermoluminescent Dosimeters (TLD)	A type of radiation dosimeter. A TLD measures ionizing radiation exposure by measuring the intensity of visible light emitted from a crystal in the detector when the crystal is heated. The intensity of light emitted is dependent upon the radiation exposure.
Total Suspended Solids	Solids in water that can be trapped by a filter. TSS can include a wide variety of material, such as silt, decaying plant and animal matter, industrial wastes, and sewage. High concentrations of suspended solids can cause many problems for stream health and aquatic life.
Tritium	An isotope that occurs both naturally and as a by-product in nuclear reactors. Tritium is a radioactive isotope of hydrogen having two neutrons and one proton in its nucleus; hydrogen, by comparison, has only one proton. Tritium decays by emitting an electron (beta radiation) and has a half-life of 12.33 years.
Valued Component	Environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous Peoples, the scientific community or the public.
Volatile Organic Compounds	Organic compounds that easily become vapors or gases.
Waste Acceptance Criteria	Quantitative or qualitative criteria specified by the regulatory body, or specified by an operator and approved by the regulatory body, for radioactive waste to be accepted by the operator of a repository for disposal, or by the operator of a storage facility for storage.
Waste Streams	The total flow of solid waste from homes, businesses, institutions, and manufacturing plants that is recycled, burned, or disposed of in landfills, or segments thereof.
Wastewater	Used water from any combination of domestic, industrial, commercial or agricultural activities, surface runoff or stormwater, and any sewer inflow or sewer infiltration.
White Nose Syndrome	A fungal disease caused by *Pseudogymnoascus destructans* that affects hibernating bats by causing unusual winter behavior like abnormally frequent or abnormally long arousal from hibernation.

14.3 Units of Measure

Table 14.3-1: List of Units

Unit	Name
%	percent
<	less than
>	greater than
≤	less than or equal to
°	degree
°C	degrees Celsius
$	Canadian dollar unless otherwise noted
µm	micron
µg/g	micrograms per gram
µg/L	micrograms per litre
µg/m	micrograms per metre
µg/m^3	micrograms per cubic metre
µGy	microgray

Table 14.3-1: List of Units

Unit	Name
µGy/day	microgray per day
µGy/hr	microgray per hour
µGy/yr	microgray per year
µm	micrometre
µSv	microSievert
µSv/yr	microSieverts per year
Bq	becquerels
Bq/g	becquerels per gram
Bq/kg	becquerels per kilogram
Bq/L	becquerel per litre
Bq/m^2	becquerels per square metre
Bq/m^3	becquerels per cubic metre
Bq/yr	becquerels per year
BqMeV/year	becquerels-million electron volts per year
cm	centimetre
CO_2e	carbon dioxide equivalent
dB	decibel
g/cm^3	grams per cubic centimetre
g/day	grams per day
g (dw)/day	grams (dry weight) per day
H:V	horizontal distance to vertical rise
ha	hectare (10 000 m^2)
kcal/day	kilocalories per day
kg	kilogram
kg/day	kilogram per day
km	kilometre
km/hr	kilometres per hour
km^2	square kilometre
kV	kilovolt
kW/m^3	kilowatt per cubic metre
L/day	litres per day
L/s	litres per second
M	million

APPENDIX 1.0-1

Concordance Tables

1.0 TABLE OF CONCORDANCE TO THE CNSC GENERIC EIS GUIDELINES

Section in Generic Guideline	Requirement	Section in the EIS
Part 1	**BACKGROUND**	
1.0	**Introduction**	
	The purpose of this document is to provide information to proponents on the requirements for the preparation of an environmental impact statement (EIS) for a designated project to be assessed pursuant to the Canadian Environmental Assessment Act, 2012 (CEAA 2012). This document specifies the nature, scope and extent of the information required. Part 1 of this document provides guidance and general instruction on the preparation of the EIS, and part 2 outlines the information that must be included in the EIS.	Not Applicable
	Section 5 of the CEAA 2012 requires an assessment of the proposed project's potential environmental effects: 5. (1) For the purposes of this Act, the environmental effects that are to be taken into account in relation to an act or thing, a physical activity, a designated project or a project are: a) a change that may be caused to the following components of the environment that are within the legislative authority of Parliament: i. fish and fish habitat as defined in subsection 2(1) of the *Fisheries Act* ii. aquatic species as defined in subsection 2(1) of the *Species at Risk Act* iii. migratory birds as defined in subsection 2(1) of the *Migratory Birds Convention Act*, 1994 iv. any other component of the environment that is set out in Schedule 2 b) a change that may be caused to the environment that would occur: i. on federal lands ii. in a province other than the one in which the act or thing is done or where the physical activity, the designated project or the project is being carried out iii. outside Canada c) with respect to Aboriginal peoples, an effect occurring in Canada of any change that may be caused to the environment on: i. health and socio-economic conditions ii. physical and cultural heritage iii. the current use of lands and resources for traditional purposes iv. any structure, site or thing that is of historical, archaeological paleontological or architectural significance 5. (2) However, if the carrying out of the physical activity, the designated project or the project requires a federal authority to exercise a power or perform a duty or function conferred on it under any Act of Parliament other than this Act, the following environmental effects are also to be taken into account: a) a change, other than those referred to in paragraphs (1)(a) and (b), that may be caused to the environment and that is directly linked or necessarily incidental to a federal authority's exercise of a power or performance of a duty or function that would permit the carrying out, in whole or in part, of the physical activity, the designated project or the project b) an effect, other than those referred to in paragraph (1)(c), of any change referred to in paragraph (a) on: i. health and socio-economic conditions ii. physical and cultural heritage iii. any structure, site or thing that is of historical, archaeological, paleontological or architectural significance	Not Applicable
	The Canadian Nuclear Safety Commission (CNSC) will use the proponent's EIS and other information received during the environmental assessment (EA) process to prepare an EA report that will inform the issuance of a decision statement by the Commission. Therefore, the EIS must include a full description of the changes the project will cause to the environment that may result in potential effects on areas of federal jurisdiction (i.e., section 5 of the CEAA 2012) – including changes that are directly linked or necessarily incidental to any federal decisions that would permit the project to be carried out. The EIS should also include a list of key mitigation measures that the proponent proposes to undertake in order to avoid or minimize any adverse environmental effects of the project. It is the proponent's responsibility to provide sufficient data and analysis on potential changes to the environment.	Not Applicable

Section in Generic Guideline	Requirement	Section in the EIS
2.0	**Guiding Principles**	
2.1	**Government of Canada Interim Measures**	
	On January 27, 2016, the Minister of Environment and Climate Change Canada and the Minister of Natural Resources Canada announced an interim approach that includes principles and plans for major projects. These principles are the first part of a broader strategy to review and restore confidence in Canada's EA processes. In particular, the Government of Canada has introduced the principle that direct and upstream greenhouse gas emissions linked to the projects under review will be assessed. The proponent is expected to take the necessary steps to provide sufficient information and evidence in accordance with this principle. For more information on assessing greenhouse gas emissions, refer to section 5.1 (part 2).	Section 5.2.2 Greenhouse Gases
2.2	**EA as a Planning Tool**	
	An EA is a planning tool used to ensure that projects are considered in a careful and precautionary manner in order to avoid or mitigate possible environmental effects and to encourage decision makers to take actions that promote sustainable development.	Not Applicable
2.3	**Public Participation**	
	One of the purposes identified in the CEAA 2012 is to ensure opportunities for meaningful public participation during an EA. The CNSC ensures that the public is provided with opportunities to participate in the EA. Meaningful public participation is best achieved when all parties have a clear understanding of the proposed project as early as possible in the review process. The proponent is required to provide current information about the project to the public and especially to the communities likely to be most affected by the project.	Section 4.0 Public and Stakeholder Engagement
2.4	**Aboriginal Engagement**	
	A key objective of the CEAA 2012 is to promote communication and cooperation with Aboriginal peoples, which include First Nations, Inuit and Métis. The proponent is expected to engage with Aboriginal groups that may be affected by the project, as early as possible in the project planning process. The proponent will provide Aboriginal groups with opportunities to learn about the project and its potential effects, to communicate their concerns about the project's potential effects, and to discuss measures to mitigate those effects. The proponent is strongly encouraged to work with Aboriginal groups in establishing an engagement approach that is reasonable to both parties. The proponent will make reasonable efforts to consider traditional Aboriginal knowledge into the assessment of environmental impacts. For more information on considering Aboriginal traditional knowledge, refer to section 3.3.2 (part 1). Information gathered through the EA process and associated engagement by the proponent with Aboriginal groups will be used to inform decisions under the CEAA 2012. In providing information to the CNSC, the proponent will ensure any confidential information shared with them by Aboriginal groups is treated in the appropriate manner. This information will also contribute to the Crown's understanding of any potential adverse impacts of the project on potential or established Aboriginal or Treaty rights and the effectiveness of measures proposed to avoid or minimize those impacts, and will assist the Crown in meeting its duty to consult obligations. The proponent is encouraged to consult the following resources: ▪ REGDOC-3.2.2, Aboriginal Engagement (CNSC); and ▪ Aboriginal and Treaty Rights Information System (Indigenous and Northern Affairs Canada).	Section 6.0 Indigenous Interests
2.5	**Application of the Precautionary Approach**	
	In documenting the analyses included in the EIS, the proponent will demonstrate that all aspects of the project have been examined and planned in a careful and precautionary manner in order to avoid significant adverse environmental effects. The Canadian Privy Council Office's *A Framework for the Application of Precaution in Science-based Decision Making About Risk* (refer to bibliography) sets out guiding principles for the application of precaution to science-based decision making.	All EIS Sections and Appendices

Section in Generic Guideline	Requirement	Section in the EIS
3.0	**Preparation and Presentation of the EIS**	
3.1	**Guidance**	
	The proponent is encouraged to consult the CNSC's draft REGDOC-2.9.1, Environmental Protection: Environmental Policy, Assessments and Protection Measures for additional guidance on the preparation of the EIS. The proponent may also consider consulting the relevant EA policy and guidance documents provided on the Canadian Environmental Assessment Agency website. The proponent is further encouraged to consult with the CNSC and, if applicable, other federal authorities, during the planning and development of the EIS and supporting documentation.	All EIS sections and Appendices, see below
3.2	**Study Strategy and Methodology**	
	The proponent is expected to respect the intent of these guidelines and to consider the effects that are likely to arise from the project (including situations not explicitly identified in these guidelines), the technically and economically feasible mitigation measures that will be applied, and the significance of any residual effects. Except where specified by the CNSC, the proponent has the discretion to select the most appropriate methods to compile and present data, information and analysis in the EIS as long as the methods are transparent, justifiable and replicable. These guidelines may include matters that the proponent does not deem relevant or significant to the project. If such matters are omitted from the EIS, the proponent will clearly indicate it and provide a justification so that the CNSC, federal authorities, Aboriginal groups, the public and any other interested party will have an opportunity to comment on this decision. Where the CNSC disagrees with the proponent's decision, it will require the proponent to provide the specified information. The proponent must explain and justify methods used to predict impacts of the project on each valued component (VC) (see section 5.2.1 in part 2 of this document for the definition of valued component). VCs include biophysical and socio-economic components, the interactions among them, and their relationships within the environment. The information presented must be substantiated; in particular, the proponent must describe how the VCs were identified and what methods were used to predict and assess the project's potential adverse environmental effects on these components. The value of a component not only relates to its role in the ecosystem, but also to the value that humans place on it. The culture and way of life of the people using the area affected by the project may be considered VCs themselves. The EIS will also explain and justify methods used to identify mitigation measures and follow-up program elements. The EIS will document how scientific, engineering, traditional and local knowledge were used to reach conclusions. Assumptions will be clearly identified and justified. All data, models and studies will be documented such that the analyses are transparent and reproducible. All data collection methods will be specified. The uncertainty, reliability and sensitivity of models used to reach conclusions must be indicated. The sections in the EIS regarding the existing environment and the potential adverse environmental effects predictions and assessment must be prepared, using best available information and methods, to the highest standards in the relevant subject area. All conclusions must be substantiated. The EIS will identify all significant gaps in knowledge and understanding related to key conclusions, and the steps to be taken by the proponent to address these gaps. Where the conclusions drawn from scientific, engineering and technical knowledge are inconsistent with the conclusions drawn from traditional and local knowledge, the EIS will contain a balanced presentation of the issues and a statement of the proponent's conclusions.	Section 5.1 Environmental Assessment Approach Section 5.2 Atmospheric Environment Section 5.3 Geological and Hydrogeological Environment Section 5.4 Surface Water Section 5.5 Aquatic Environment Section 5.6 Terrestrial Environment Section 5.7 Ambient Radioactivity and Ecological Health Section 5.8 Human Health Section 5.9 Land and Resource Use Section 5.10 Socio-economic Environment Section 6.0 Indigenous Interests
3.3	**Use of Information**	
3.3.1	**Federal Coordination of Information or Knowledge**	
	Section 20 of the CEAA 2012 requires that every federal authority with specialist or expert information, or knowledge with respect to a project subject to an EA, make that information or knowledge available to the CNSC. The CNSC will coordinate the involvement, and notify the proponent, of federal departments and other jurisdictions with expert and specialist knowledge specific to the EA.	Not Applicable

Section in Generic Guideline	Requirement	Section in the EIS
3.3.2	**Community Knowledge and Aboriginal Traditional Knowledge**	
	Subsection 19(3) of the CEAA 2012 states that “the environmental assessment of a designated project may take into account community knowledge and Aboriginal traditional knowledge”. The proponent will consider community and Aboriginal traditional knowledge to which it has access or that is acquired through Aboriginal and public engagement activities, in keeping with appropriate ethical standards and obligations of confidentiality. Agreement should be obtained from Aboriginal groups regarding the use, management and protection of their existing traditional knowledge information during and after the EA. Where community and Aboriginal traditional knowledge has been considered by the proponent, the EIS will document the following: ▪ the traditional knowledge information gathered ▪ how the traditional knowledge information was gathered (e.g., interviews with key community leaders and elders, collaborative field research, Aboriginal traditional knowledge studies, etc.) ▪ the source of the traditional knowledge information ▪ how the traditional knowledge information gathered was taken into consideration by the proponent in the assessment, including both methodology (e.g., identifying VCs, establishing spatial and temporal boundaries, defining significance criteria) and analysis (e.g., baseline characterization, effects prediction, development of mitigation measures)	Section 6.0 Indigenous Interests
3.3.3	**Existing Information**	
	In preparing the EIS, the proponent is encouraged to make use of existing information relevant to the project. When relying on existing information to meet requirements of the EIS guidelines, the proponent will either include the information directly in the EIS or clearly direct the reader to where it may obtain the information (i.e., through cross-referencing). When relying on existing information, the proponent will also comment on how the data were applied to the project, separate factual lines of evidence from inference, and state any limitations on the inferences or conclusions that can be drawn from the existing information.	All EIS Sections and Appendices
3.3.4	**Confidential Information**	
	In implementing the CEAA 2012, the CNSC is committed to promoting public participation in the EA of projects and providing access to the information on which EAs are based. All documents prepared or submitted by the proponent or any other stakeholder in relation to the EA are posted or referenced on the Canadian Environmental Assessment Registry and/or the CNSC’s website and made available to the public upon request. For this reason, the EIS should not contain information that: ▪ is sensitive or confidential (i.e., financial, commercial, scientific, technical, personal, cultural or other nature) in accordance with the Privacy Act and the Access to Information Act, that is treated consistently as confidential, and the person affected has not consented to the disclosure ▪ may cause harm to a person or harm to the environment through its disclosure If the EIS contains information that should be treated as “confidential” or “protected” in accordance with the Privacy Act and the Access to Information Act, the proponent should identify and request to the CNSC that such information be treated accordingly.	All EIS Sections and Appendices

Section in Generic Guideline	Requirement	Section in the EIS
Part 2	**EIS CONTENT AND STRUCTURE** Part 2 of this document provides specific instructions for the content of each section in the EIS. The EIS as a whole must reflect the guiding principles in part 1 of this document.	
1.0	**Presentation and Organization of the EIS**	
	To facilitate the identification of the documents submitted, the title page of the EIS and its related documents will contain the following information: ▪ project name and location ▪ title of the document, including the term “environmental impact statement” ▪ subtitle of the document ▪ proponent name and contact information ▪ date	EIS Cover Page
	The EIS will be written in clear, precise language. A glossary of technical words, acronyms and abbreviations will be included. It will include charts, diagrams, tables, maps and photographs, where appropriate, to clarify the text. Perspective drawings that clearly convey the various components of the project will also be provided. Wherever possible, maps will be presented in common scales and datum to allow for comparison and overlay of mapped features. For purposes of brevity and to avoid repetition, cross-referencing within the EIS is preferred. The EIS may make reference to the information that has already been presented in other sections of the document, rather than repeating it. Detailed studies (including all relevant and supporting data and methodologies) will be provided in separate appendices and will be referenced by appendix, section and page in the text of the main document. The EIS will explain how information is organized in the document. This will include a list of all tables, figures, and photographs referenced in the text. A complete list of supporting literature and references will also be provided. A table of concordance, which cross references the information presented in the EIS with the information requirements identified in the EIS guidelines, will be provided. The proponent will provide copies of the EIS and its summary for distribution, as directed by the CNSC, including paper and electronic version in an unlocked, searchable PDF format.	All EIS Sections and Appendices Appendix 1.0-1 Concordance Tables Section 14.0 Glossary, Acronyms and Units
2.0	**Executive Summary**	
	For efficiency, the proponent may consider preparing a summary of the EIS in both of Canada’s official languages (French and English), which is to be provided to the CNSC at the same time as the EIS. The proponent is also encouraged to consider making the executive summary available in the language(s) spoken by Aboriginal communities in close proximity to the project (e.g., Cree, Dene). The summary will include the following: ▪ a concise description of all key components of the project and related activities ▪ a summary of the consultation conducted with Aboriginal groups, the public, and government agencies, including a summary of the issues raised and the proponent’s responses ▪ an overview of the key environmental effects of the project and proposed technically and economically feasible mitigation measures ▪ the proponent’s conclusions on the residual environmental effects of the project after taking mitigation measures into account and the significance of those effects The summary will be provided as a separate document and will have sufficient details for the reader to learn and understand the project, potential environmental effects, mitigation measures, the significance of the residual effects and follow-up program.	Executive Summary
3.0	**Introduction and Overview**	
3.1	**Project Overview**	
	The EIS will describe the project, key project components and associated activities, scheduling details, the timing of each phase of the project and other key features. If the project is a part of a larger sequence of projects, the EIS will outline the larger context. The overview is to identify the project’s key components, rather than providing a detailed description, which will follow in section 4 (part 2) of this document.	Section 1.1 Project Overview

Section in Generic Guideline	Requirement	Section in the EIS
3.2	**Project Location**	
	The EIS will contain a description of the geographical setting where the project will take place. This description should include those aspects of the project and its setting that are key to understanding the project's potential adverse environmental effects, including: ▪ geographical maps of the project location (at an appropriate scale) including project components, project boundaries of the proposed site with the Universal Transverse Mercator (UTM) coordinates – the lease boundary, site study area, local study area, regional study area, the major existing infrastructure, adjacent land uses and any important environmental features ▪ current land use in the area ▪ distance of the project facilities and components to any federal lands ▪ the environmental significance and value of the geographical setting in which the project will take place and the surrounding area ▪ environmentally sensitive areas, such as national, provincial and regional parks, ecological reserves, wetlands, estuaries, and habitats of federally (Schedule 1 of Species at Risk Act) or provincially listed species at risk and other sensitive areas ▪ description of local and Aboriginal communities ▪ traditional Aboriginal territories, treaty lands, and Indian reserve lands and Métis harvesting regions and/or settlements	Section 1.2 Project Location
3.3	**Regulatory Framework and the Role of Government**	
	The EIS should identify: ▪ the environmental and other regulatory approvals and legislation, including CEAA 2012, that are applicable to the project at the federal, provincial, regional and municipal levels ▪ government policies, resource management plans, planning or study initiatives pertinent to the project and/or EA and their implications ▪ any treaty or self-government agreements with Aboriginal groups that are pertinent to the project and/or EA ▪ any relevant land use plans, land zoning, or community plans ▪ regional, provincial and/or national objectives, standards or guidelines that have been used by the proponent to assist in the evaluation of any predicted environmental effects	Section 1.4 Regulatory Framework Section 5.1 Environmental Assessment Methodology Section 5.2 Atmospheric Environment Section 5.3 Geological and Hydrogeological Environment Section 5.4 Surface Water Section 5.5 Aquatic Environment Section 5.6 Terrestrial Environment Section 5.7 Ambient Radioactivity and Ecological Health Section 5.8 Human Health Section 5.9 Land and Resource Use Section 6.0 Indigenous Interests

Section in Generic Guideline	Requirement	Section in the EIS
4.0	**Project Description**	
4.1	**Purpose of the Project**	
	The EIS will describe the purpose of the project by providing the rationale for the project, explaining the background, the problems or opportunities that the project is intended to satisfy and the stated objectives from the perspective of the proponent. If the objectives of the project are related to broader private or public sector policies, plans or programs, this information should also be included.	Section 2.3 Purpose of the Project
4.2	**Alternative Means of Carrying out the Project**	
	The EIS will identify and consider the effects of alternative means of carrying out the project that are technically and economically feasible as described in appendix A, section A.3.2 Alternative means for carrying out the project, of the CNSC's draft REGDOC-2.9.1, Environmental Protection: Environmental Policy, Assessments and Protection Measures. The proponent will complete the following procedural steps for addressing alternative means: ▪ Identify and describe in sufficient detail the alternative means to carry out the project: ▪ develop criteria to determine the technical and economic feasibility of the alternative means ▪ identify those alternative means that are technically and economically feasible ▪ Identify the effects of each technically and economically feasible alternative means: ▪ identify those elements of each alternative means that could produce effects in sufficient detail to allow a comparison with the effects of the project ▪ the effects referred to above include both environmental effects and potential adverse impacts on potential or established Aboriginal and Treaty rights and related interests ▪ Describe the methodology used for the analysis of alternative means and the conclusion reached (i.e., preferred means). For further information regarding the "purpose of" and "alternative means", please consult the Agency's operational policy statement, titled Addressing "Purpose of" and "Alternative Means" under the Canadian Environmental Assessment Act, 2012". The CNSC recognizes that projects may be in the early planning stages when the EIS is being prepared. Proponents are strongly encouraged to conduct an environmental effects analysis where they have not made final decisions about the placement of project infrastructure, the technologies to be used, or if several options exist for various project components.	Section 2.5 Alternative Means for Carrying Out the Project
4.3	**Scope of Project**	
	The scope of project for the purposes of the EA includes all the phases, components, activities and federal decisions proposed by the proponent as described in the project description that has been determined to meet the requirements of the Prescribed Information for the Description of a Designated Project Regulations. The CNSC's Commission may also determine that other components and/or activities in relation to the project are to be included in the project scope. The proponent will consider all phases, components, activities and federal decisions identified in the scope of project as part of the effects assessment.	Section 3.0 Project Description
4.3.1	**Project Components**	
	The EIS will describe the project by presenting the project components, associated and ancillary works, and other characteristics that will assist in understanding the environmental effects.	Section 3.1.1 Project Overview
4.3.2	**Project Activities**	
	The EIS will include descriptions of each phase associated with the proposed project. This will include descriptions of the activities to be carried out during each phase, the location of each activity, expected outputs and an indication of the activity's magnitude and scale. Although a complete list of project activities should be provided, the emphasis will be on activities with the greatest potential to have environmental effects. Sufficient information will be included to predict environmental effects and address concerns identified by the public and Aboriginal groups. Highlight activities that involve periods of increased environmental disturbance or the release of materials into the environment. The EIS will include a summary of the changes that have been made to the project since originally proposed, including the benefits of these changes to the environment, Aboriginal peoples, and the public. The EIS will include a schedule including time of year, frequency, and duration for all project activities.	Section 3.1.4 Project Design Changes Section 3.2 Project Phases Section 3.3 Waste Strategy Section 3.4 Project Components and Activities

Section in Generic Guideline	Requirement	Section in the EIS
5.0	**Scope of the Environmental Assessment**	
5.1	**Factors to be Considered**	
	Scoping establishes the EA's parameters and focuses the assessment on relevant issues and concerns. The EA of the designated project must take into account the following factors, as listed in subsection 19(1) of the CEAA 2012: a) the section 5 environmental effects of the designated project (such as changes to fish and fish habitat, aquatic species, migratory birds), including the environmental effects of malfunctions or accidents that may occur in connection with the designated project, and any cumulative environmental effects likely to result from the designated project in combination with other physical activities that have been or will be carried out b) the significance of those environmental effects c) comments from the public that are received in accordance with the CEAA 2012 d) mitigation measures that are technically and economically feasible and that would mitigate any significant adverse environmental effects of the designated project e) the requirements of the follow-up program in respect of the designated project f) the purpose of the designated project g) alternative means of carrying out the designated project that are technically and economically feasible and the environmental effects of any such alternative means h) any changes to the designated project that may be caused by the environment i) the results of any relevant study conducted by a committee established under section 73 or 74 of the CEAA 2012 j) any other matter relevant to the EA that the CNSC requires to be taken into account, in accordance with the Nuclear Safety and Control Act Pursuant to subsection 19(2) of the CEAA 2012, the scope of the factors to be taken into account under paragraphs 19(1)(a), (b), (d), (e), (g), (h) and (j) is determined by the CNSC, as the responsible authority.	Section 2.0 Purpose and Alternative Means Section 3.0 Project Description Section 4.0 Public and Stakeholder Engagement Section 5.1 Environmental Assessment Approach Section 5.2 Atmospheric Environment Section 5.3 Geological and Hydrogeological Environment Section 5.4 Surface Water Section 5.5 Aquatic Environment Section 5.6 Terrestrial Environment Section 5.7 Ambient Radioactivity and Ecological Health Section 5.8 Human Health Section 5.9 Land and Resource Use Section 5.10 Socio-economic Environment Section 6.0 Indigenous Interests Section 7.0 Malfunctions and Accidents Section 8.0 Summary of Cumulative Effects Section 9.0 Summary of Significance of Residual Effects Section 10.0 Effects of the Environment on Project Section 11.0 Monitoring and Follow-up Programs
	To implement the Government of Canada interim measure with respect to upstream greenhouse gas emissions, the CNSC may require consideration of these types of emissions in the scope of the EA. On March 19, 2016, a definition of upstream GHG emissions was published by Environment Canada and Climate Change in the Canada Gazette. The proposed definition of upstream includes "*all industrial activities from the point of resource extraction to the project under review*." The processes that are to be considered as upstream activities will vary by the type of resource and the nature of the project under assessment. In general, upstream activities will include extraction, processing and handling as well as transportation. Where there is a reliable and feasible methodology for calculating upstream greenhouse gas emissions that are linked to the project, the proponent will be required to provide sufficient information to estimate these types of emissions. This information should be presented by individual pollutant and should be summarized in CO2 equivalent units per year. If upstream greenhouse gas emissions are not considered in the assessment, the proponent will provide a rationale in the EIS.	Section 5.2.2 Greenhouse Gases

Section in Generic Guideline	Requirement	Section in the EIS
5.2	**Scope of Factors**	
5.2.1	**Valued Components to be Examined**	
	Valued components (VCs) refer to environmental biophysical or human features that may be impacted by a project. The value of a component not only relates to its role in the ecosystem, but also to the value people place on it. For example, it may have scientific, social, cultural, economic, historical, archaeological or aesthetic importance. The EIS will identify the VCs linked to section 5 of the CEAA 2012, including the ones identified in section 9.2 (part 2) that may be affected by changes in the environment, as well as species at risk and their critical habitat as per the requirement outlined in section 79 of the Species at Risk Act (SARA). Under section 73 of SARA, the Minister of Environment and Climate Change Canada may grant permits authorizing an activity affecting a listed wildlife species or any part of its residence or critical habitat that would otherwise be prohibited. Should the proponent identify a listed wildlife species or any part of its residence or critical habitat that would be affected by the project activities, the proponent should consult directly with the Canadian Wildlife Service as early as possible in the process. The final list of VCs to be presented in the EIS will be completed according to the evolution and design of the project and reflect the knowledge on the environment acquired through public consultation and Aboriginal engagement. The EIS will describe what methods were used to predict and assess the potential adverse environmental effects of the project on these components. The VCs will be described in sufficient detail to allow the reviewer to understand their importance and to assess the potential for environmental effects arising from the project activities. The EIS will provide a rationale for selecting specific VCs and for excluding any VCs or information specified in these guidelines. Challenges with particular exclusions may arise, so it is important to document the information and criteria used to make each determination. Examples of justification include primary data collection, computer modelling, literature references, public consultation, expert input or professional judgement. The EIS will identify those VCs, processes, and interactions that were identified to be of concern during any workshops or meetings held by the proponent, or that the proponent considers likely to be affected by the project. In doing so, the EIS will indicate to whom these concerns are important and the reasons why, including environmental, Aboriginal, social, economic, recreational, and aesthetic considerations. If comments are received on a component that has not been included as a VC, these comments will be summarised and the rationale for excluding the VC will be provided.	Section 5.1.2 Valued Components Section 5.2.1.2 Valued Components – Air Quality Section 5.2.2.2 Valued Components – Greenhouse Gases Section 5.3.1.2 Valued Components – Geology Section 5.3.2.2 Valued Components – Hydrogeology Section 5.4.1.2 Valued Components – Hydrology Section 5.4.2.2 Valued Components – Surface Water Quality Section 5.5.2 Valued Components – Aquatic Environment Section 5.6.2 Valued Components – Terrestrial Environment Section 5.7.2 Valued Components – Ambient Radioactivity and Ecological Health Section 5.8.2 Valued components – Human Health Section 5.9.2 Valued Components – Land and Resource Use Section 5.10.2 Valued Components – Socio-economic Environment Section 6.3 Valued Components – Indigenous Interests

Section in Generic Guideline	Requirement	Section in the EIS
5.2.2	**Spatial and Temporal Boundaries**	
	The spatial and temporal boundaries used in the EA may vary depending on the VC and will be considered separately for each VC. The proponent is encouraged to consult with the CNSC, federal and provincial government departments and agencies, local government and Aboriginal groups, and take into account public comments when defining the spatial boundaries used in the EIS. The EIS will describe the spatial boundaries, including local and regional study areas, of each VC to be used in assessing the potential adverse environmental effects of the project and provide a rationale for each boundary. Spatial boundaries will be defined by taking into account, but not limited to, the following criteria: a) the physical extent of the proposed project, including any off-site facilities or activities b) the extent of aquatic and terrestrial ecosystems potentially affected by the project c) the extent of potential effects arising from noise, light and atmospheric emissions d) the extent to which traditional land use or treaty rights could potentially be affected by the project e) current land and resource use for residential, commercial, industrial, recreational, cultural and aesthetic purposes by communities whose areas include the physical extent of the project f) the size, nature and location of past, present and reasonably foreseeable projects and activities which could interact with items (b), (c), (d) and (e) g) community and Aboriginal traditional knowledge, ecological, and technical considerations The following geographic study areas should serve as the basis for developing project specific and effect-specific study areas: ▪ **Site study area:** The site study area is the project footprint (i.e., where project activities would be undertaken including the project's proposed facilities, buildings and infrastructure). ▪ **Local study area:** The local study area is defined as that area existing outside the site study area boundary, where measurable changes to the environment resulting from the proposed activities from any phase of the project, either through normal activities, or from possible accidents or malfunctions, may be anticipated. The boundaries must change if appropriate following an assessment of the spatial extent of potential effects. The geographic boundary will depend on the factor being considered (e.g., a local study area defined for the aquatic environment will differ from that defined for the atmospheric environment). ▪ **Regional study area:** The regional study area is defined as the area within which the potential effects of this project may interact with the effects of other projects, resulting in the potential for cumulative effects. The geographic boundary for the regional study areas are also specific to the factor being considered. Within the aforementioned study areas, the boundary of concern will extend to a depth that will include the full extent of the surface water and groundwater. The EA's temporal boundaries will span all phases of the project determined to be within the scope of the project as specified under section 4.3 above. If impacts are predicted after project decommissioning, this should be taken into consideration in defining boundaries. At a minimum, the assessment is expected to include the period of time during which the maximum impact is predicted to occur. Community and Aboriginal traditional knowledge should factor into decisions around temporal boundaries. If the temporal boundaries do not span all phases of the project, the EIS will identify the boundaries used and provide a rationale.	Section 5.2.1.3 Assessment Boundaries – Air Quality Section 5.2.2.3 Assessment Boundaries – Greenhouse Gases Section 5.3.1.3 Assessment Boundaries – Geology Section 5.3.2.3 Assessment Boundaries – Hydrogeology Section 5.4.1.3 Assessment Boundaries – Hydrology Section 5.4.2.3 Assessment Boundaries – Surface Water Quality Section 5.5.3 Assessment Boundaries – Aquatic Environment Section 5.6.3 Assessment Boundaries – Terrestrial Environment Section 5.7.3 Assessment Boundaries – Ambient Radioactivity and Ecological Health Section 5.8.3 Assessment Boundaries – Human Health Section 5.9.3 Assessment Boundaries – Land and Resource Use Section 5.10.3 Assessment Boundaries – Socio-economic Environment Section 6.4.3 Assessment Boundaries – Indigenous Traditional Land Use
6.0	**Public and Stakeholder Consultation**	
	In accordance with CNSC's REGDOC-3.2.1 (formerly REGDOC-99.3), Public Information and Disclosure, the EIS will describe the on-going and proposed participation activities that the proponent will undertake or that it has already conducted on the project. It will describe efforts made to distribute project information, as well information and materials that were distributed during the public consultation process. The EIS will indicate the methods used, where the consultation was held, the persons and organizations consulted, the concerns voiced and the extent to which this information was incorporated in the design of the project as well as in the EIS. The EIS will provide a summary of key issues raised related to the Project and its potential environmental effects, as well as describe any outstanding issues and ways to address them.	Section 4.0 Public and Stakeholder Engagement

Section in Generic Guideline	Requirement	Section in the EIS
7.0	**Aboriginal Engagement**	
	In accordance with the CNSC's REGDOC-3.2.2, Aboriginal Engagement, the EIS will describe the proponent's engagement activities with potentially affected Aboriginal groups. The EIS will include, and the proponent should consider engaging with potentially affected Aboriginal groups to obtain their views on, the following: ▪ the objectives of and the methods used for Aboriginal engagement activities ▪ each Aboriginal group's potential or established rights including geographical extent, nature, frequency, timing and maps and data sets (e.g., fish catch numbers) when this information is provided by a group to the proponent or available through public records ▪ comments, specific issues and concerns raised by Aboriginal groups and how the key concerns were responded to or addressed ▪ the potential adverse impacts of the project on potential or established Aboriginal or treaty rights effects of changes to the environment on Aboriginal peoples (health and socio-economic conditions; physical and cultural heritage, including any structure, site or thing that is of historical, archaeological, paleontological or architectural significance; and current use of lands and resources for traditional purposes) pursuant to paragraph 5(1)(c) of the CEAA 2012 ▪ VCs suggested by Aboriginal groups for inclusion in the EIS, whether they were included, and the rationale for any exclusions ▪ measures identified to mitigate or accommodate potential adverse impacts of the project on the potential or established Aboriginal or treaty rights and effects of changes to the environment on Aboriginal peoples, including suggestions raised by Aboriginal groups A suggested format for providing the information above is the creation of a tracking table of key issues raised by each Aboriginal group, including the concerns raised related to the project, proposed mitigation options, and where appropriate, a reference to the proponent's analysis in the EIS.	Section 6.0 Indigenous Interests

Section in Generic Guideline	Requirement	Section in the EIS
8.0	**Description of the Environment**	
8.1	**Baseline Environment**	
	The EIS will include a description of the environment, including the components of the existing environment and environmental processes, their interrelations and interactions as well as the variability in these components, processes and interactions over time scales appropriate to the EIS. In characterizing the environmental effects of the project, the proponent will consider the current baseline environment and environmental trends within the project area. The description of the existing baseline and the environmental trends should include a consideration of past projects and activities carried out by the proponent and/or others within the project area. Based on the scope of project described in section 4.3 (part 2), the EIS will present baseline information in sufficient detail to enable the identification of how the project could affect the VCs and an analysis of those effects. Should other VCs be identified during the conduct of the EA, the baseline condition for these components will also be described in the EIS. The baseline description should include results from studies done prior to any physical disruption of the environment due to initial project activities (e.g., site preparation). The proponent will use the information in appendix B of the CNSC's draft REGDOC- 2.9.1, Environmental Protection: Environmental Policy, Assessments and Protection Measures to develop the characterization of the baseline environment. If a federal decision (as per section 5(2) of the CEAA 2012) in relation to the project may result in environmental changes such as changes on federal lands, outside the province or Canada, the proponent will use the information in appendix A, section A.3.7, Socio-economic environment, of the CNSC's draft REGDOC-2.9.1, Environmental Protection: *Environmental Policy, Assessments and Protection Measures*, to describe the baseline conditions in relation to these potential changes.	Section 5.1.4 Description of the Existing Environment Section 5.2.1.4 Description of the Environment – Air Quality Section 5.2.2.4 Description of the Environment – Greenhouse Gases Section 5.3.1.4 Description of the Environment – Geology Section 5.3.2.4 Description of the Environment – Hydrogeology Section 5.4.1.4 Description of the Environment – Hydrology Section 5.4.2.4 Description of the Environment – Surface Water Quality Section 5.5.4 Description of the Environment – Aquatic Environment Section 5.6.4 Description of the Environment – Terrestrial Environment Section 5.7.4 Description of the Environment – Ambient Radioactivity and Ecological Health Section 5.8.4 Description of the Environment – Human Health Section 5.9.4 Description of the Environment – Land and Resource Use Section 5.10.4 Description of the Environment – Socio-economic Environment Section 6.4.4 Description of the Environment – Traditional Land and Resource Use

Section in Generic Guideline	Requirement	Section in the EIS
9.0	**Effects Assessment**	
9.1	**Predicted Changes to the Physical Environment**	
	The assessment will include a consideration of the predicted changes to the environment as a result of the project being carried out or as a result of any powers, duties or functions that are to be exercised by the federal government in relation to the project. These predicted changes to the environment are to be considered in relation to each phase of the project (i.e., construction, operation, decommissioning) and are to be described in terms of the following: ▪ magnitude ▪ geographic extent ▪ timing ▪ frequency ▪ duration, ▪ reversibility As changes to various parts of the physical environment may be inter-related as part of an ecosystem, the EIS will explain and describe the connections between the changes described. The proponent will use the information in appendix C of the CNSC's draft REGDOC- 2.9.1, *Environmental Protection: Environmental Policy, Assessments and Protection Measures*, to assess the environmental effects of the project.	Section 5.1.8 Residual Effects Analysis Classification and Determination of Significance Section 5.2.1.8 Residual Effects Classification and Determination of Significance – Air Quality Section 5.2.2.8 Residual Effects Classification and Determination of Significance – Greenhouse Gases Section 5.3.2.6 Residual Effects Analysis – Hydrogeology Section 5.4.1.6 Residual Effects Analysis – Hydrology Section 5.4.2.6 Residual Effects Analysis – Surface Water Quality Section 5.6.7 Residual Effects Assessment Results – Terrestrial Environment Section 5.7.8 Residual Effects Classification and Determination of Significance – Ambient Radioactivity and Ecological Health Section 5.8.8 Residual Effects Classification and Determination of Significance - Human Health Section 5.10.8 Residual Effects Classification and Determination of Significance - Socio-economic Environment
9.2	**Predicted Effects on Valued Components**	
	Based on the predicted changes to the environment identified in section 9.1 (part 2) above, the proponent is to assess the environmental effects of the project on the VCs identified as per section 5.2.1 (part 2). Based on the changes to the environment that have been identified in section 9.1 (part 2), additional VCs are to be selected based on the following: ▪ If there is the potential for the project to result in environmental changes on federal lands, another province, or another country, then VCs of importance not already identified above are to be listed in this section. ▪ If federal decisions about the project will lead to an environmental change, then these environmental changes are to be considered standalone VCs. All interconnections between VCs and between changes to multiple VCs will be described.	Section 5.1.6 Residual Effects Analysis Section 5.2.1.6 Residual Effects Analysis – Air Quality Section 5.2.2.6 Residual Effects Analysis – Greenhouse Gases Section 5.3.2.6 Residual Effects Analysis – Hydrogeology Section 5.4.1.6 Residual Effects Analysis – Hydrology Section 5.4.2.6 Residual Effects Analysis – Surface Water Quality Section 5.6.7 Residual Effects Assessment Results – Terrestrial Environment Section 5.7.6 Residual Effects Analysis – Ambient Radioactivity and Ecological Health Section 5.8.6 Residual Effects Analysis – Human Health Section 5.10.6 Residual Effects Analysis – Socio-economic Environment
9.3	**Accidents and Malfunctions**	
	The proponent will use the information in appendix A, section A.3.4, Malfunctions and accidents, of the CNSC's draft REGDOC-2.9.1, *Environmental Protection: Environmental Policy, Assessments and Protection Measures*, to assess the potential health and environmental effects from postulated accident and malfunction scenarios.	Section 7.0 Malfunctions and Accidents

Section in Generic Guideline	Requirement	Section in the EIS
9.4	**Cumulative Effects**	
	The proponent will use the information in appendix A, section A.3, Cumulative effects, of the CNSC's draft REGDOC-2.9.1, *Environmental Protection: Environmental Policy, Assessments and Protection Measures*, to assess the project's potential cumulative effects.	Section 8.0 Summary of Cumulative Effects
9.5	**Socio-economic Environment**	
	The proponent will use the information in appendix A, section A.3.7, Socio-economic environment, of the CNSC's draft REGDOC-2.9.1, Environmental Protection: *Environmental Policy, Assessments and Protection Measures*, to assess the project's indirect socio-economic effects.	Section 5.10 Socio-economic Environment
9.6	**Effects of the Environment on the Project**	
	The proponent will use the information in appendix A, section A.3.9, Assessment of effects of the environment on the project, of the CNSC's draft REGDOC-2.9.1, *Environmental Protection: Environmental Policy, Assessments and Protection Measures*, to assess the effects of the environment on the project (i.e., severe weather events).	Section 10.0 Effects of the Environment on the Project
10.0	**Mitigation Measures**	
	Every EA conducted under the CEAA 2012 will consider measures that are technically and economically feasible and that would mitigate any significant adverse environmental effects of the project. Measures that are technically and economically feasible include application of best industry practices, pollution prevention principles such as best available technology and techniques economically achievable (BATEA), and radiation protection principles such as keeping radiation exposure and doses as low as reasonably achievable (ALARA). Under the CEAA 2012, mitigation includes measures to eliminate, reduce or control the adverse environmental effects of a project, as well as restitution for damages to the environment through replacement, restoration, compensation or other means. Each measure will be specific, achievable, measurable and verifiable, and described in a manner that avoids ambiguity in intent, interpretation and implementation. Mitigation measures may be considered for inclusion as conditions in the EA decision statement and/or in other compliance and enforcement mechanisms provided by other authorities' permitting or licensing processes. As a first step, the proponent is encouraged to use an approach based on the avoidance and reduction of the effect(s) at the source. Such an approach may include the modification of the design of the project or relocation of project components. The EIS will describe the standard mitigation practices, policies and commitments that constitute technically and economically feasible mitigation measures and that will be applied as part of standard practice regardless of location (including the measures directed at mitigating adverse socio-economic effects). The EIS will then describe the project's environmental protection plan and its environmental management system, through which the proponent will deliver this plan. The plan will provide an overall perspective on how potentially adverse effects would be minimized and managed over time. The EIS will further discuss the mechanisms the proponent would use to require its contractors and sub-contractors to comply with these commitments and policies and with auditing and enforcement programs. The EIS will then describe mitigation measures that are specific to each environmental effect identified. Measures will be written as specific commitments that clearly describe how the proponent intends to implement them and the environmental outcome the mitigation is designed to address. The EIS will describe mitigation measures in relation to species and/or critical habitat listed under the Species at Risk Act (SARA). These mitigation measures will be consistent with any SARA permit, applicable recovery strategy and/or action plan. The EIS will specify the actions, works, minimal disturbance footprint techniques, best available technology, corrective measures or additions planned during the project's various phases to eliminate or reduce the significance of potential adverse effects. The impact statement will also present an assessment of the effectiveness of the proposed technically and economically feasible mitigation measures. The reason(s) for determining if the mitigation measure reduces the significance of a potential adverse effect will be made explicit. The proponent is also encouraged to identify mitigation measures for effects that are adverse although not significant. The EIS will indicate what other technically and economically feasible mitigation measures were considered, and explain why they were rejected. Trade-offs between cost savings and effectiveness of the various forms of mitigation will be justified. The EIS will identify who is responsible for the implementation of these measures and the system of accountability. For proposed mitigation measures for which there is little experience or that have questionable effectiveness, the potential environmental risks and effects – should those measures not be effective –will be clearly and concisely described. In addition, the EIS will identify the extent to which technological innovations will help mitigate environmental effects. Where possible, it will provide detailed information on the nature of these measures, their implementation and management and how these are integrated in the follow-up program.	Section 5.1.5 Project Interactions and Mitigation Section 5.2.1.5 Project Interactions and Mitigation – Air Quality Section 5.2.2.5 Project Interactions and Mitigation – Greenhouse Gases Section 5.3.1.5 Project Interactions and Mitigation – Geology Section 5.3.2.5 Project Interactions and Mitigation – Hydrogeology Section 5.4.1.5 Project Interactions and Mitigation – Hydrology Section 5.4.2.5 Project Interactions and Mitigation – Surface Water Quality Section 5.5.5 Project Interactions and Mitigation – Aquatic Environment Section 5.6.5 Project Interactions and Mitigation – Terrestrial Environment Section 5.7.5 Project Interactions and Mitigation – Ambient Radioactivity and Ecological Health Section 5.8.5 Project Interactions and Mitigation – Human Health Section 5.9.5 Project Interactions and Mitigation – Land and Resource Use Section 5.10.5 Project Interactions and Mitigation – Socio-economic Environment Section 6.4.5 Project Interactions and Mitigation – Traditional Land and Resource Use

Section in Generic Guideline	Requirement	Section in the EIS
11.0	**Conclusion on Significance**	
	The proponent will use the guidance and information in appendix A, section A.3.6, Significance of residual effects, of the CNSC's draft REGDOC-2.9.1, *Environmental Protection: Environmental Policy, Assessments and Protection Measures*, for the preparation of this section of the EIS.	Section 9.0 Summary of Significance of Residual Effects
12.0	**Follow-up Program**	
	The proponent will use the guidance and information in appendix A, section A.3.10 EA follow-up program, of CNSC's draft REGDOC-2.9.1, Environmental Protection: Environmental Policy, Assessments and Protection Measures for the preparation of this section of the EIS. Where applicable, the proponent will describe how the follow-up program relates to the project's environmental protection plan and environmental management system as mentioned in section 10 above. Environmental assessment effects predictions, assumptions and mitigation actions that are to be tested in the follow-up program must be converted into field-testable monitoring objectives. The monitoring design must include a statistical evaluation of the adequacy of existing baseline data to provide a benchmark for testing project effects, and the need for any additional pre-construction or pre-operational monitoring to establish a firmer project baseline. The proponent will propose a schedule for the follow-up program. The schedule should indicate the timing, frequency and duration of effect monitoring. This schedule would be developed after statistical evaluation of the length of time needed to detect effects given estimated baseline variability, probable environmental effect size and desired level of statistical confidence in the results (type 1 and type 2 errors). The description of the follow-up program will include any contingency procedures or plans or other adaptive management provisions as a means of addressing unforeseen effects, or for correcting exceedances, as required, so as to comply with benchmarks, regulatory standards or guidelines. The follow-up program will describe roles and responsibilities for the program and its review process, by both peers and the public. The EIS should provide discussion on the follow-up program's requirements, and include: ▪ objectives and structure of the follow-up program and the VCs targeted by the program ▪ tabular summary and explanatory text of the main components of the program including: ▪ a description of each monitoring activity under that component ▪ which of the two generic program objectives the activity is relevant to (e.g., verify EA predictions, determine effectiveness of mitigation measures) ▪ the specific statement from the EA that goes along with that generic objective and will be the focus for that activity (e.g., program objective: verify predicted effects; environmental assessment effect: no potential adverse effects) ▪ the specific monitoring objective for that activity ▪ planned schedule ▪ roles and responsibilities to be played by the proponent, regulatory agencies, Aboriginal people, local and regional organizations and others in the design, implementation and evaluation of the program results ▪ possible involvement of independent researchers ▪ program funding sources ▪ information management and reporting (reporting frequency, methods and format) ▪ possible opportunities for the proponent to include the participation of the public and Aboriginal groups, during the development and implementation of the program The follow-up program plan should be sufficiently described in the EIS to allow independent judgment as to the likelihood that it will deliver the type, quantity and quality of information required to reliably verify predicted effects (or absence of them) and confirm the effectiveness of mitigation measures.	Section 5.1.9 Monitoring and Follow-up Section 5.2.1.9 Monitoring and Follow-up – Air Quality Section 5.2.2.9 Monitoring and Follow-up – Greenhouse Gases Section 5.3.1.6 Monitoring and Follow-up – Geology Section 5.3.2.8 Monitoring and Follow-up – Hydrogeology Section 5.4.1.8 Monitoring and Follow-up – Hydrology Section 5.4.2.9 Monitoring and Follow-up – Surface Water Quality Section 5.5.6 Monitoring and Follow-up – Aquatic Environment Section 5.6.8 Monitoring and Follow-up – Terrestrial Environment Section 5.7.9 Monitoring and Follow-up – Ambient Radioactivity and Ecological Health Section 5.8.9 Monitoring and Follow-up – Human Health Section 5.9.6 Monitoring and Follow-up – Land and Resource Use Section 5.10.9 Monitoring and Follow-up – Socio-economic Environment Section 6.4.6 Monitoring and Follow-up – Traditional Land and Resource Use Section 11.0 Monitoring and Follow-up Programs

2.0 TABLE OF CONCORDANCE TO THE CNSC REGDOC 2.9.1 ENVIRONMENTAL POLICY, ASSESSMENTS, AND PROTECTION MEASURES

Section in REGDOC 2.9.1	Requirement	Section in the EIS
Appendix A	**Environmental Assessments under the Canadian Environmental Assessment Act, 2012**	
A.3	**Specific CEAA 2012 Environmental Assessment Requirements**	
	Where the information is common to both the EIS and the licence application, the applicant may provide the information in either the application or the EIS, with appropriate cross-referencing between the submissions. The applicant shall clearly indicate where the requirements of both the NSCA and CEAA 2012 are addressed. The EA of a designated project shall take into account the following factors as listed in subsection 19(1) of CEAA 2012: ▪ the environmental effects of the designated project, including the environmental effects of malfunctions or accidents that may occur in connection with the designated project and any cumulative environmental effects that are likely results from the designated project in combination with other physical activities that have been or will be carried out ▪ the significance of those environmental effects ▪ comments from the public that are received in accordance with CEAA 2012 ▪ mitigation measures that are technically and economically feasible and that would mitigate any significant adverse environmental effects of the designated project ▪ the requirements of the follow-up program in respect of the designated project ▪ the purpose of the designated project ▪ alternative means of carrying out the designated project that are technically and economically feasible and the environmental effects of any such alternative means ▪ any changes to the designated project that may be caused by the environment ▪ the results of any relevant study conducted by a committee established under section 73 or 74 of CEAA 2012 ▪ any other matter relevant to the EA that the responsible authority requires to be taken into account The EIS and supporting technical studies are completed to meet the requirements of CEAA 2012, paragraphs 19(1)(*a*), (*b*), (*d*), (*e*), (*f*), (*g*), (*h*) and, if appropriate, (*i*) and (*j*) in accordance with the scope of these factors as determined by the CNSC. The completion of the EIS and, as necessary, supporting technical studies is typically delegated to the applicant in accordance with section 23 of CEAA 2012. This regulatory document provides requirements and guidance to support project planning and early development of these documents by the applicant. These requirements and guidance do not negate the importance of pre-project consultation or the potential for project-specific EA guidelines.	All EIS Sections and Appendices
A.3.1	**Purpose of the Project**	
	Paragraph 19(1)(*f*) of CEAA 2012 states that the EIS shall identify the purpose of the project (defined as what is to be achieved by carrying out the project). For additional information, see Addressing “Purpose of” and “Alternative Means” under the Canadian Environmental Assessment Act, 2012 [17].	Section 2.3 Purpose of the Project
A.3.2	**Alternative Means for Carrying out the Project**	
	Paragraph 19(1)(*g*) of CEAA 2012 states that the EIS shall identify and describe alternative means to carry out the project that are, from the perspective of the applicant, technically and economically feasible. As identified by the proponent, the alternative means include options for locations, development, and implementation methods, routes, designs, technologies, mitigation measures, and so on. Alternative means may also be related to the construction, operation, expansion, decommissioning and abandonment of a physical work. The approach and level of effort applied to addressing alternative means is established on a project-by-project basis taking into consideration: ▪ the characteristics of the project ▪ the environmental effects associated with the potential alternative means ▪ the health or status of valued components (VCs) that may be impacted by the alternative means ▪ the potential for mitigation and the extent to which mitigation measures may address potential environmental effects ▪ the level of concern expressed by the public and Aboriginal groups The EIS should also describe the environmental effects of each alternative means. The criteria used to identify alternative means as unacceptable, and how these criteria were applied, should be described, as should the criteria used to examine the environmental effects of each remaining alternative means to identify the preferred alternative. For further guidance, consult *Addressing* *“Purpose of” and “Alternative Means” under the Canadian Environmental Assessment Act, 2012* [17].	Section 2.5 Alternative Means for Carrying Out the Project

Section in REGDOC 2.9.1	Requirement	Section in the EIS
A.3.3	**Environmental Effects**	
	Paragraph 19(1)(a) of CEAA 2012 states that the EA must take into account the environmental effects of the designated project. The environmental effects that must be considered in an EA under CEAA 2012 are also requirements under the NSCA. As described in section 4, the applicant should conduct an ERA in accordance with CSA 288.6, Environmental risk assessment at Class I nuclear facilities and uranium mines and mills [6].	Section 5.1 Environmental Assessment Approach Section 5.2 Atmospheric Environment Section 5.3 Geological and Hydrogeological Environment Section 5.4 Surface Water Section 5.5 Aquatic Environment Section 5.6 Terrestrial Environment Section 5.7 Ambient Radioactivity and Ecological Health Section 5.8 Human Health Section 5.9 Land and Resource Use Section 5.10 Socio-economic Environment Section 6.0 Indigenous Interests
A.3.4	**Malfunctions and Accidents**	
	Paragraph 19(1)(*a*) of CEAA 2012 states that malfunctions and accidents shall be assessed in the EA. Malfunctions and accidents should be separated into radiological and non-radiological (conventional). The applicant should provide an assessment of potential health and environmental effects resulting from postulated radiological and conventional malfunctions or accidents. The EIS should also include any mitigation measures such as monitoring, contingency, clean-up or restoration work in the surrounding environment that would be required during or immediately following the postulated malfunction and accident scenarios. The EIS should provide a description of postulated malfunction and accident sequences leading to a radiological or non-radiological release considering, as appropriate, internal events, external events and human-induced events, including their frequency and an explanation of how these events were identified, and any modeling that was performed. The applicant can use a bounding approach or use facility- or activity-specific information (for example, design, operation, projected environmental releases) in the assessment of radiological accidents and malfunctions. If a bounding approach is used, the applicant should provide a detailed rationale for the selection of each bounding scenario. The EIS should include the source, quantity, mechanism, pathway, rate, form and characteristics of contaminants and other materials (physical and chemical) likely to be released to the surrounding environment during the postulated malfunctions and accidents. **Note:** Malfunctions and accidents are reviewed in depth under the NSCA for licensing purposes (for example, under REGDOC-2.4.1, *Deterministic Safety Analysis* [18], REGDOC-2.4.2, *Probabilistic Safety Assessments for Nuclear Power Plants* [19] and RD-346, *Site Evaluation for New Nuclear Power Plants* [20]). These scenarios should be taken into consideration by the applicant when designing environmental protection measures (see section 4). If applicable, the applicant should use operating experience (OPEX) to identify any past abnormal operations, accidents and spills to the extent that they are relevant to the current assessment for the purposes of identifying malfunction and accident scenarios to be assessed.	Section 7.2 General Approach – Malfunctions and Accidents Section 7.3 Project Overview and Identification of Hazards – Malfunctions and Accidents Section 7.4 Radiological Malfunctions and Accidents Section 7.5 Conventional (Non-radiological) Malfunctions and Accidents
A.3.5	**Cumulative Effects**	
	Paragraph 19(1)(*a*) of CEAA 2012 states that the applicant shall assess any residual adverse environmental effects of the project in combination with other past, present or reasonably foreseeable projects and/or activities within the study area. The applicant should explain the approach and methods used to identify and assess cumulative effects. The approach and methods should be consistent with *Assessing Cumulative Environmental Effects under the Canadian Environmental Assessment Act, 2012* [21].	Section 8.0 Summary of Cumulative Effects

Section in REGDOC 2.9.1	Requirement	Section in the EIS
A.3.6	**Significance of Residual Effects**	
	Paragraph 19(1)(*b*) of CEAA 2012 states that the applicant shall assess the significance of any residual effects that persist, taking into consideration the proposed mitigation measures. These residual effects are identified during the ERA or a characterization of the environmental effects. In the EIS, the applicant should include a detailed analysis of the significance of each residual effect. The applicant should clearly explain the method and definitions used to describe the level of the residual adverse effect (for example, low, medium, or high) for each of the issues. The applicant should also describe any cumulative environmental effects that are likely to result from the designated project in combination with other physical activities that have been or will be carried on and how these levels were combined to reach an overall conclusion on the significance of the adverse effects for each valued component (VC). **Guidance** Some specific issues to be assessed are: ▪ magnitude of the effect ▪ spatial extent of the effect ▪ duration and frequency of the effect ▪ degree to which the effect can be reversed or mitigated ▪ ecological importance The method used to describe the level of the adverse effect should be transparent and reproducible. The EIS should identify additional criteria used to assign significance ratings to any predicted adverse effects. It should contain clear and sufficient information to enable the CNSC and the public to understand and review the applicant's judgement of the significance of effects. The applicant should define the terms used to describe the level of significance. In assessing significance against the criteria, the EIS should, where possible, employ relevant existing regulatory documents, environmental standards, guidelines or objectives such as prescribed maximum levels of emissions or discharges of specific hazardous substances into the environment or maximum acceptable levels of specific hazardous substances in the environment.	Section 9.0 Summary of Significance of Residual Effects
A.3.7	**Socio-economic Environment**	
	The applicant should characterize the socio-economic environment and identify all indirect socio-economic effects. An indirect effect is a secondary environmental effect that occurs as a result of a change that a project may cause to the environment. Paragraph 5(2)(b) of CEAA 2012 refers to any change to the environment caused by the project on health and socio-economic conditions, physical and cultural heritage, or any structure, site or thing that is of historical, archaeological, paleontological or architectural significance. For additional guidance, refer to *Technical Guidance for Assessing Physical and Cultural Heritage or any Structure, Site or Thing that is of Historical, Archeological, Paleontological or Architectural Significance under the Canadian Environment Assessment Act, 2012* [22].	Section 5.10 Socio-economic Environment
A.3.8	**Community and Aboriginal Traditional Knowledge**	
	Subsection 19(3) of CEAA 2012 states that community and Aboriginal traditional knowledge may be considered in the EA. CNSC staff will provide guidance to the applicant at the earliest possible stage in the EA process concerning the extent to which community and Aboriginal traditional knowledge shall be considered in the EA. For additional information, refer to: ▪ Considering Aboriginal traditional knowledge in environmental assessments conducted under the Canadian Environmental Assessment Act, 2012 [23] ▪ REGDOC-3.2.2, Aboriginal Engagement [10] (for further information on the CNSC's expectations of applicants for Aboriginal engagement)	Section 6.4 Traditional Land and Resource Use
A.3.9	**Assessment of Effects of the Environment on the Project**	
	Paragraph 19(1)(*h*) of CEAA 2012 states that the EIS shall take into account how the environment could adversely affect the project. The applicant shall also take into account any potential effects of climate change on the project, including an assessment of whether the project might be sensitive to changes in climate conditions during its lifecycle. Some adverse environmental conditions are flooding, severe weather, biophysical hazards (such as algae), geotechnical hazards and seismic events.	Section 10.0 Effects of the Environment on the Project

Section in REGDOC 2.9.1	Requirement	Section in the EIS
A.3.10	**EA Follow-up Program**	
	Paragraph 19(1)(e) of CEAA 2012 states that the EIS shall include a framework or preliminary program upon which EA follow-up actions will be managed throughout the life of the project. The applicant should design the follow-up program to verify the accuracy of the EA predictions and to determine the effectiveness of the measures implemented to mitigate the potential adverse environmental effects of the project. The applicant should also design the follow-up program to incorporate pre-project information that would provide the baseline data; compliance data such as established environmental quality criteria; regulatory documents, standards or guidelines; and real-time data consisting of observed data gathered in the field. As part of the follow-up program, the applicant should describe the compliance reporting methods to be used, including reporting frequency, methods and format. **Note:** The CNSC, in collaboration with other federal authorities (where applicable), verifies and monitors all EA follow-up activities through the CNSC licensing and compliance process. EA follow-up monitoring activities may be integrated within the applicant's environmental protection measures.	Section 5.1.9 Monitoring and Follow-up Section 5.2.1.9 Monitoring and Follow-up – Air Quality Section 5.2.2.9 Monitoring and Follow-up – Greenhouse Gases Section 5.3.1.6 Monitoring and Follow-up – Geology Section 5.3.2.8 Monitoring and Follow-up – Hydrogeology Section 5.4.1.8 Monitoring and Follow-up – Hydrology Section 5.4.2.9 Monitoring and Follow-up – Surface Water Quality Section 5.5.6 Monitoring and Follow-up – Aquatic Environment Section 5.6.8 Monitoring and Follow-up – Terrestrial Environment Section 5.7.9 Monitoring and Follow-up – Ambient Radioactivity and Ecological Health Section 5.8.9 Monitoring and Follow-up – Human Health Section 5.9.6 Monitoring and Follow-up – Land and Resource Use Section 5.10.9 Monitoring and Follow-up – Socio-economic Environment Section 6.4.6 Monitoring and Follow-up – Traditional Land and Resource Use Section 11.0 Monitoring and Follow-up Programs
Appendix B	**Characterization of the Baseline Environment for an Environmental Assessment under CEAA 2012**	
B.1	**Atmospheric Environment**	
	The atmospheric environment includes the climate conditions at the site and in the local and regional study areas. It includes the seasonal variations in weather conditions within the study areas, to allow the assessment of effects on the facility or activity. The applicant or licensee should provide a description of the existing ambient air quality in the study areas, with emphasis on characterizing radiological and non-radiological analytes. The description should include meteorological information such as air temperature, relative humidity, precipitation, wind speed and direction, atmospheric pressure, and solar radiation. It should also include the occurrence of weather phenomena (for example, lightning, temperature inversions and fog). Special consideration should be given to the analysis of extreme and rare meteorological phenomena (for example, tornadoes). Uncertainties should be described and taken into account when discussing the reliability of the information presented. The description should also include current ambient daytime and nighttime noise levels at the site and local study areas, and include information on its source(s), geographic extent and temporal variations. The description should provide ambient noise levels for other areas that could be affected by the facility or activity. Some examples are: ▪ increased traffic along transportation corridors to and from the site during construction ▪ receptors at residences and sensitive sites (such as hospitals, schools, daycare facilities, seniors' residences, and places of worship) The applicant or licensee should describe the influence of regional topography or other features that could affect weather conditions in the study areas. The baseline information should be sufficient to support the use of an atmospheric dispersion model to conduct the site-specific ERA and to support an assessment of the effects of the environment on the project (for example, tornadoes).	Section 5.2.1.4 Description of the Environment – Air Quality Section 5.2.2.4 Description of the Environment – Greenhouse Gases

Section in REGDOC 2.9.1	Requirement	Section in the EIS
B.2	**Surface Water Environment**	
	The surface water environment includes all surface water features and hydrology that affect surface water at the site or in the local and regional study areas. The applicant or licensee should include delineation of drainage basins at appropriate scales. When documenting the water quality of all surface water, the applicant or licensee should demonstrate the use of appropriate sampling and analytical protocols, for the range of analytical parameters with the potential to be influenced by the facility or activity. This information should be presented using tables, maps and figures to provide an understanding of surface water characteristics and conditions at the site and in the local and regional study areas. The applicant or licensee should describe hydrological regimes within the drainage basin, including seasonal fluctuations and year-to-year variability of all surface waters. The applicant or licensee should assess normal flow, flooding and drought properties of water bodies as well as the interactions between surface water and groundwater flow systems. The applicant or licensee should describe all water sources used for drinking water in the area, including source water intakes for drinking water treatment facilities. The baseline information should be sufficient to support the use of an aquatic dispersion model to conduct the site-specific ERA and to support an assessment of the effects of the environment on the facility or activity (for example, flooding). The applicant or licensee should document the sediment quality of all water bodies to be affected by the facility or activity, demonstrating the use of appropriate sampling and analytical protocols, for the range of analytical parameters with the potential to be influenced by the facility or activity. This information should provide an appropriate understanding of sediment characteristics and conditions on the site and in the local and regional study areas. The study design should be fully described, including the allocation of samples in space and time, measurement methods and results. The applicant or licensee should include an assessment of any limitations or gaps in the quality and extent of baseline data and methods, as well as the method(s) by which they have been addressed.	Section 5.4.1.4 Description of the Environment – Hydrology Section 5.4.2.4 Description of the Environment – Surface Water Quality
B.3	**Aquatic Environment**	
	The aquatic environment includes the aquatic and wetland species at the site and within the local and regional study areas, including the flora, fauna and their habitats. The applicant or licensee should seek information from relevant authorities (such as Environment and Climate Change Canada (ECCC), Fisheries and Oceans Canada (DFO) and provincial or territorial authorities) on aquatic and wetland species and habitat for the local and regional study areas. The applicant or licensee should also undertake independent studies to gather the necessary information. The applicant or licensee should include a description of the food chain and food web dynamics as a habitat component as this relates to fish populations, and potential effects resulting from the facility or activity (such as impingement and entrainment). The applicant or licensee should provide detailed habitat mapping that demonstrates habitat usage by fish within the study areas. This information should include depth profiles, substrate mapping, water temperature profiles, and a description of known and potential habitat usage (such as spawning, nursery, rearing, feeding and migratory) by fish that occur in the study areas. The applicant or licensee should identify any biological species of natural conservation status (that is, rare, vulnerable, endangered, threatened or uncommon at a federal, provincial or municipal level) and their critical habitats, if identified. The applicant or licensee should provide baseline characterization of radionuclide and hazardous substance levels in aquatic biota to support human and ecological risk assessment. The applicant or licensee should fully describe the study design, including the allocation of samples in space and time, measurement methods and results. The applicant or licensee should include an assessment of any limitations or gaps in the quality and extent of baseline date and methods, as well as the method(s) by which they have been addressed.	Section 5.5.4 Description of the Environment – Aquatic Environment
B.4	**Geological and Hydrogeological Environment**	
	The geological and hydrogeological environment includes the bedrock and overburden geology at both the local and regional scales.	

Section in REGDOC 2.9.1	Requirement	Section in the EIS
B.4.1	**Geology**	
	The applicant or licensee should characterize the geomorphology, topography, quaternary geology and soil characteristics, structural geology, petrology, geochemistry, economic geology and hydrogeology. The applicant or licensee should also describe the geomechanical properties that apply to the region and at the site that will be disturbed. The applicant or licensee should provide the geotechnical properties of the overburden, including shear strength and liquefaction potential, to allow for the assessment of slope stability and bearing capacity of foundations under both static and dynamic conditions. The description of the structural geology should include regional, local and site-specific documentation of fractures and faults. It should include a description of primary geological features and deformation fabrics both at the site and within the local and regional study areas. If applicable, the applicant or licensee should describe the coastal geomorphology and should include the characteristics of any lakefront or ocean bluffs, shoreline, and both near-shore zone and offshore zones. The baseline characterization should be sufficient to assess effects of the environment on the facility or activity (for example, seismic effects). The applicant or licensee should present a geological model that incorporates all overburden and bedrock information. If extrapolation is required to derive the stratigraphy, the applicant or licensee should explicitly discuss the uncertainties and the need for additional field investigations to reduce those uncertainties. The applicant or licensee should describe the geotechnical and geophysical hazards including the consideration of subsidence, uplift, seismicity (and active faulting), and consider the potential for movement at the ground surface (including co-seismic rupture) and earthquake ground motions. A seismic hazard assessment should be provided. Where appropriate, the narrative descriptions should be supplemented by geological maps, figures, cross-sections, borehole logs and photographs (with specific location information).	Section 5.3.1.4 Description of the Environment – Geology
B.4.2	**Hydrogeology**	
	The applicant or licensee should describe the hydrogeology at the site and in the local and regional study areas. The description should characterize the physical and geochemical properties of all overburden and bedrock hydrogeological units (from the ground surface to the uppermost basement unit, which is site dependent). Units may be characterized as aquifers or aquitards, and unit descriptions should include their geochemical characteristics, vertical and lateral permeabilities, transport mechanism (diffusion versus advection) and directions of groundwater flow. The applicant or licensee should identify the groundwater recharge and discharge areas, and describe in detail the groundwater interactions with surface waters. The applicant or licensee should present a conceptual and numerical hydrogeological model that discusses the hydrostratigraphy and groundwater flow systems. The applicant or licensee should provide a description of baseline groundwater quality at the site and in the local study area. The applicant or licensee should also describe local and regional potable groundwater supplies, including their current use and potential for future use.	Section 5.3.2.4 Description of the Environment – Hydrogeology
B.5	**Terrestrial Environment**	
	The terrestrial environment includes flora and fauna, their habitats, any wildlife corridors and the soil. The applicant or licensee should describe the terrestrial species at the site and within the local and regional study areas, including flora, fauna and their habitat. The applicant or licensee should identify all biological species risk (that is, endangered, threatened, special concern, extirpated at a federal, provincial or municipal level) known to occur in the area or where the site is within the range of the species. The applicant or licensee should describe the presence and importance of wildlife habitat within the study areas, including critical habitats for listed species (if identified). The applicant or licensee should also describe any wildlife corridors and physical barriers to movement. The applicant or licensee should identify all protected and conservation areas established by federal, provincial and municipal jurisdictions (for example, wilderness areas, parks, sites of historical or ecological significance, nature reserves, federal migratory bird sanctuaries and wildlife management areas). The applicant or licensee should describe the existing soil quality (including hazardous and radiological substance concentrations) for all study areas, as well as any additional soil quality parameters potentially relevant for modelling purposes (such as transport and bioavailability of contaminants of potential concern). The applicant or licensee should provide baseline characterization of radionuclide and hazardous substance levels in vegetation and other non-human biota to support human and ecological risk assessment. The characterization should also take into consideration the baseline conditions of other applicable environmental components (such as the atmospheric environment). The applicant or licensee should undertake independent studies to gather the necessary information as appropriate. The applicant or licensee should describe field studies in terms of representativeness of the target populations where possible. The applicant or licensee should fully describe the design of the study, including the allocation of samples in space and time, measurement methods and results. The applicant or licensee should include an assessment of any limitations or gaps in the quality and extent of baseline data and methods, as well as the method(s) by which they have been addressed.	Section 5. 6.4 Description of the Environment – Terrestrial Environment

Section in REGDOC 2.9.1	Requirement	Section in the EIS
B.6	**Ambient Radioactivity**	
	The ambient radioactivity arises from the sources, their activity levels and their origin, for all applicable environmental media (including air, soil, food, water, aquatic sediments and plant or animal tissue). The applicant or licensee should describe the ambient radiological conditions at the site and in the local and regional study areas. The applicant or licensee should include information on the existing conditions, including an inventory of sources, their activity levels and their origin (natural or anthropogenic), for all applicable environmental media. The applicant or licensee should fully describe the design of the study, including the allocation of samples in space and time, measurement methods and results. The description should include an assessment of any limitations or gaps in the quality and extent of the baseline data and methods, as well as the method(s) by which they have been addressed.	Section 5.7.4 Description of the Environment – Ambient Radioactivity and Ecological Health
B.7	**Human Health**	
	The potential effects of the facility or activity on human health include both radiological sources and non-radiological contaminants. The applicant or licensee should describe the current health profiles of the communities likely to be affected by the facility or activity, including information on population health of the communities in the local and regional study areas. The applicant or licensee should provide, to the extent available, information on current consumption of locally grown harvests and country foods, and the quality by food type, amounts consumed, parts consumed (whole body or specific organs).	Section 5.8.4 Description of the Environment – Human Health
B.8	**Aboriginal Land Use**	
	Aboriginal land and resource use includes lands, waters and resources of specific value; traditional activities and lifestyle; and traditional dietary habits. Traditional land use may include areas where traditional activities such as establishing seasonal camps, camping, travel on traditional routes, gathering of country foods and medicines (hunting, fishing, trapping, planting and harvesting) are being carried out. Traditional land use also includes spiritual sites of significance to Aboriginal people. The applicant or licensee should identify the lands, water and resources of specific social, economic, archaeological, cultural or spiritual value to Aboriginal people, including established and asserted Aboriginal or treaty rights that may be affected by the facility or activity. The applicant or licensee should describe Aboriginal land and resource use at the site and in the local and regional study areas. The applicant or licensee should identify traditional activities, including activities for food, social, ceremonial and other cultural purposes, in relation to such lands, waters and resources with a focus on the current use of lands, waters and resources for traditional purposes. The applicant or licensee should describe the traditional dietary habits and dependence on country foods and harvesting for other purposes, including harvesting of plants for medicinal purposes. The analysis should focus on the identification of potential adverse effects of the facility or activity on the ability of future generations of Aboriginal people to pursue traditional activities or lifestyle.	Section 6.4.4 Description of the Environment - Traditional Land and Resource Use
Appendix C	**Environmental Effects for an Environmental Assessment under CEAA 2012**	
C.1	**Atmospheric Environment**	
	The licensee should characterize the effects of the facility or activity on the atmospheric environment during all phases of the lifecycle for the facility or activity, including postulated accident and malfunction scenarios. The licensee should identify and characterize all atmospheric emissions (radiological and non-radiological) expected to be generated during all phases of the lifecycle for the facility or activity, including postulated accident and malfunction scenarios. This information should include average and maximum emissions from planned discharges, point sources and fugitive (non-point source) releases (including greenhouse gases). The licensee should complete modelling that incorporates baseline (or existing ambient) air quality in combination with the predicted site-specific atmospheric characteristics (such as shoreline fumigation) to assess potential effects on air quality, the transport of atmospheric contaminants and any associated exposure to humans and non-human biota receptors. The licensee should describe predicted effects of noise on terrestrial and aquatic species as well as on nearby residents and communities. The description should include both daytime and nighttime noise levels and tonal noise. The predicted sound levels should be compared against baseline levels and any guidelines published by recognized organizations.	Section 5.2.1.6 Residual Effects Analysis – Air Quality Section 5.2.2.6 Residual Effects Analysis – Greenhouse Gases

Section in REGDOC 2.9.1	Requirement	Section in the EIS
C.2	**Surface Water Environment**	
	The licensee should describe the effects of the facility or activity on the surface water environment during all phases of the lifecycle for the facility or activity, including accident and malfunction scenarios. The licensee should identify and characterize all liquid effluents that could be generated during all phases of the facility or activity. Some examples are: ▪ average and maximum emissions from point sources (concentrations/activity levels and volumes) ▪ planned discharges ▪ fugitive releases ▪ deposition from airborne particulates ▪ surface runoff	Section 5.4.1.6 Residual Effects Analysis – Hydrology Section 5.4.2.6 Residual Effects Analysis – Surface Water Quality
C.3	**Aquatic Environment**	
	For all phases of the lifecycle for the facility or activity, the licensee should describe the effects of the facility or activity on aquatic flora and fauna, and include a full accounting of effects on species of natural conservation status and their habitat. This evaluation should be based on results of field monitoring studies or predictions from an ecological risk assessment. The description should be clear on how predicted effects to the biota exposed to the stressor compare to the expected reference condition for unexposed biota on a biological population basis, taking natural variation into account. Predictions of effects should include sufficient detail to allow follow-up verification. Some potential effects are: ▪ effects on habitat, including aquatic vegetation and sensitive areas such as spawning grounds, nursery areas, winter refuges and migration corridors ▪ effects on aquatic species, including rare or sensitive species ▪ effects of blasting on fish and fish habitat on local aquatic systems ▪ contaminant exposures through environmental and food-chain transport ▪ effects on aquatic biota due to impingement and entrainment ▪ effects of infilling on loss of fish habitat and changes to productive capacity ▪ effects of thermal plume(s) on fish and fish habitat ▪ effects on wetlands Under the NSCA, the CNSC assesses the on-going operation of nuclear facilities and activities to ensure protection of the environment and the health and safety of persons. Under the Memorandum of Understanding between CNSC and Fisheries and Oceans Canada (DFO), the CNSC is responsible for conducting reviews of licence applications to assess the potential effects on fish and fish habitat, and to ensure that the assessment process considers the intent and requirements of the *Fisheries Act*, the *Species at Risk Act* and their associated regulatory and policy frameworks.	5.5.5 Project Interactions and Mitigations – Aquatic Environment
C.4	**Geological and Hydrogeological Environment**	
	The geological and hydrogeological environment includes the bedrock and overburden geology at both the local and regional scales.	
C.4.1	**Geology**	
	The licensee should fully describe any changes to the geology and geomorphology resulting from the facility or activity, including any interrelationships with the groundwater regime. The licensee should describe any changes to the environment resulting from the removal of bedrock and/or unconsolidated deposits. The licensee should also describe the disturbance of soils or sediments that may be stockpile, used for construction purposes or otherwise perturbed. The licensee should include an assessment of changes made that would affect coastal processes and features (such as changes to the shoreline morphology due to construction, erosion or sediment transport).	5.3.1.5 Project Interactions and Mitigations – Geology
C.4.2	**Hydrogeology**	
	The licensee should describe and assess any effects the facility or activity may have on the groundwater regime including the quantity and quality of groundwater and how these effects may influence surface waters. The licensee should carry out modelling as needed to develop and test the predicted effects.	Section 5.3.2.6 Residual Effects Analysis – Hydrogeology

Section in REGDOC 2.9.1	Requirement	Section in the EIS
C.5	**Terrestrial Environmental**	
	The licensee should describe the effects of the facility or activity on terrestrial fauna and flora and include a full accounting of effects on species with elevated conservation status and their habitat. This evaluation should be based on results of field monitoring studies or predictions from an ecological risk assessment. The description should be clear on how predicted effects to the biota exposed to the stressor compare to the expected “reference condition” for unexposed biota on a biological population basis taking into account natural variation. Predictions of the effects should include sufficient detail to allow follow-up verification. Some potential effects that should be considered are: ▪ loss of terrestrial habitat and the quality of lost habitat for relevant species ▪ disturbance of feeding, nesting or breeding habitats ▪ physical barriers to wildlife ▪ disruption, blockage, impediment and sensory disturbance (such as light effects, noise and vibration) of daily or seasonal wildlife movements (such as migration or home ranges) ▪ direct and indirect wildlife mortality ▪ reduction in wildlife productivity ▪ contaminant exposures through environmental and food-chain transport ▪ effects on biodiversity	Section 5.6.7 Residual Effects Assessment Results – Terrestrial Environment
C.6	**Ambient Radioactivity**	
	The licensee should describe the effects of the facility or activity on ambient radioactivity. Humans and non-human biota exposed to ambient radioactivity should be assessed for all relevant routes of exposure (both internal and external exposure scenarios). To support the assessment of human health (see section 3.2.7), the licensee should provide information on radiation levels to which members of the public may be exposed, including consideration of consumers of country food whose exposure pathways may differ due to cultural norms; for example, any dietary characteristics of Aboriginal peoples.	Section 5.7.6 Residual Effects Analysis – Ambient Radioactivity and Ecological Health
C.7	**Human Health**	
	The licensee should describe the potential effects of the facility or activity on the physical well-being of Aboriginal groups and other people resulting from biophysical effects, including the effects of the facility or activity on all environmental components (for example, atmospheric environment) and the resulting effects on human health. Some examples are: ▪ an analysis of the effects of the facility or activity on the health and safety of the public, including the possible effects from malfunctions and accidents (radiological and conventional) ▪ the predicted radiation doses to members of the public resulting from activities within the scope of the facility or activity and any resulting health effects ▪ a description of quantitative risk assessment modeling conducted, where necessary, for any malfunctions and accidents ▪ an assessment of the potential effects on human health from all non-radiological contaminants released from the facility or activity, through all potential exposure pathways ▪ potential effects of noise generated from the facility or activity on human receptors within the study area(s)	Section 5.8.6 Residual Effects Analysis – Human Health
C.8	**Aboriginal Land and Resource Use**	
	The licensee should identify any change that the facility or activity is likely to cause in the environment and any effect of any such change on the health and socio-economic conditions, physical and cultural heritage and on the current use of lands and resources for traditional purposes by any Aboriginal group including effects on hunting, trapping, fishing and gathering. The licensee should identify any concerns raised by Aboriginal people about the facility or activity in relation to any Aboriginal or treaty rights. For further information on the CNSC’s expectations of licensees for Aboriginal engagement, see REGDOC-3.2.2, Aboriginal Engagement. Amec Foster Wheeler Reference No.: TZ16018

W-8 Hydrograph - December 2016 to June 2018

Chalk River NSDF Investigation
Chalk River, Ontario
Amec Foster Wheeler Reference No.: TZ16018

APPENDIX 5.4-1

Ottawa River Elevations Recorded at Pembroke Station between 1950 and 2019

Table 1: Ottawa River Elevations Recorded at Pembroke Station between 1950 and 2019

Average Daily Surface Elevation (masl) per Month													
Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Monthly Average
1950	111.16	111.19	111.15	111.41	112.05	111.57	111.32	111.17	111.17	111.16	111.32	111.38	111.34
1951	111.33	111.35	111.49	112.67	112.01	111.44	111.52	111.30	111.29	111.74	112.10	111.81	111.67
1952	111.64	111.54	111.56	111.96	112.07	111.76	111.33	111.32	111.32	111.32	111.27	111.43	111.54
1953	111.50	111.58	111.81	112.38	111.72	111.37	111.24	111.14	110.98	111.14	111.10	111.18	111.43
1954	111.23	111.21	111.46	111.79	111.74	111.93	111.64	111.36	111.38	111.99	111.87	111.73	111.61
1955	111.62	111.55	111.49	112.00	111.66	111.36	111.16	111.05	111.03	111.20	111.73	111.59	111.45
1956	111.37	111.31	111.32	111.64	112.03	111.81	111.59	111.49	111.63	111.83	111.54	111.49	111.59

m = metres above sea level; '-' = no data.

APPENDIX 5.6-1

Valued Component Selection

Scientific Name	Common Name	Confirmed at CRL	Confirmed in LSA	Likelihood of Presence at CRL	Likelihood of Presence in LSA	Justification for Likelihood of Presence in LSA	Included as VC in EIS	Justification for Inclusion/Exclusion	COSEWIC[1]	SARA[2]	ESA[3]	G-Rank, S-Rank[4]
Mammals												
Canis lupus Lycaon	Eastern Wolf	Yes	No	Confirmed	Likely	Species present on-site; suitable habitat	No	Small footprint relative to home range; no evidence of dens reported by CNL in LSA; Project unlikely to have substantial effect	THR	SC	THR	G4G5TNR, S4
Myotis leibii	Eastern Small-footed Myotis	Yes	Yes	Confirmed	Confirmed	Species present on-site; suitable habitat	No	Not SARA-listed; bat VC covers many pathways	—	—	END	G4, S2S3
Myotis lucifugus	Little Brown Myotis	Yes	Yes	Confirmed	Confirmed	Species present on-site; suitable habitat	Yes	SARA-listed; included in bat VC	END	END	END	G3, S4
Myotis septentrionalis	Northern Myotis	Yes	Yes	Confirmed	Confirmed	Species present on-site; suitable habitat	Yes	SARA-listed; included in bat VC	END	END	END	G1G2, S3
Perimyotis subflavus	Tricolored Bat	Yes	Yes	Confirmed	Confirmed	Species present on-site; suitable habitat	Yes	SARA-listed; included in bat VC	END	END	END	G2G3, S3?
Puma concolor couguar	Eastern Cougar	No	No	Unlikely	Unlikely	Believed to occur primarily in remote northern parts of Ontario	No	Presence unlikely	—	—	END	G5, SU
Birds												
Ammodramus savannarum	Grasshopper Sparrow	No	No	Unlikely	Unlikely	No habitat available	No	Presence unlikely	SC	SC	SC	G5, S4B
Antrostomus vociferus	Eastern Whip-poor-will	Yes	Yes	Confirmed	Confirmed	Observed in LSA	Yes	Present in LSA; SARA-listed	THR	THR	THR	G5, S4B
Asio flammeus	Short-eared Owl	No	No	Likely	Unlikely	Little potential habitat	No	Little open habitat to support this species; low chance of important interaction with the Project	SC	SC	SC	G5, S2N, S4B
Cardellina canadensis	Canada Warbler	Yes	Yes	Confirmed	Confirmed	Observed in LSA	Yes	Present in LSA; SARA-listed	THR	THR	SC	G5, S4B
Chaetura pelagica	Chimney Swift	Yes	No	Confirmed	Unlikely	No man made structure; large-diameter cavity trees are identified as the natural habitat for the species, but only 59 of them have been recorded in the literature since 1840	No	Presence unlikely; suitable cavity trees uncommon in most forests within the species' breeding range.	THR	THR	THR	G5, S4B, S4N
Chlidonias niger	Black Tern	No	No	Unlikely	Unlikely	No breeding evidence in the area (OBBA)	No	Presence unlikely	NAR	—	SC	G4, S3B
Chordeiles minor	Common Nighthawk	Yes	No	Confirmed	Unlikely	Usually breeds on flat roofs	No	Presence unlikely	SC	THR	SC	G5, S4B
Coccothraustes vespertinus	Evening Grosbeak	Yes	No	Confirmed	Likely	Observed in the area during previous Christmas Bird Counts	No	Project not expected to have important interaction with the coniferous forest habitat of this species; represented by migratory birds VC	SC	SC	SC	G5, S4B

Note:

1) COSEWIC = Committee on the Status of Endangered Wildlife in Canada, END = Endangered; THR = Threatened; SC = Special Concern; NAR = Not at Risk.
2) SARA = *Species at Risk Act* Schedule 1. Part 1 (Extirpated - EXP), Part 2 (Endangered - END), Part 3 (Threatened - THR), Part 4 (Special Concern - SC).
3) ESA = Ontario *Endangered Species Act, 2007* and *O. Reg. 230/08 Species at Risk in Ontario List.* Schedule 1 (Extirpated - EXP), Schedule 2 (Endangered - END), Schedule 3 (Threatened - THR), Schedule 4 (Special Concern - SC)
4) Global Ranks (G-Rank) and Provincial Ranks (S-Rank) are rarity ranks assigned to a species or ecological communities by the Natural Heritage Information Centre (NHIC). These ranks are not legal designations. Rarity ranks are evaluated by NHIC on a continual basis and updated lists are produced periodically. Rank definitions: G1 or S1 (Critically Imperiled); G2 or S2 (Imperiled); G3 or S3 (Vulnerable); G4 or S4 (Apparently Secure); G5 or S5 (Secure); G#G# or S#S# (Range Rank); GNR or SNR (Not Ranked); GU or SU (Unrankable – Data Deficient); GX or SX (Presumed Extinct or Extirpated); GH or SH (Possibly Extinct or Extirpated – Historical); SNA (Not Applicable). Qualifiers: B = Breeding; N = Non-breeding; M = Migrant; ? = Inexact or uncertain numeric rank

CRL = Chalk River Laboratories; EIS = Environmental Impact Statement; LSA = local study area; VC = valued component; - = not listed/no status.

Note: RSA = regional study area; LSA = local study area. Structural class for each polygon were assigned to Forest Units primarily using age ranges from the Forest Management Plan for the Ottawa Valley Forest (Van Dyke 2011). In cases of polygons with poplar, jack pine, or white pine dominant stands, the Forest Management Guide for Great Lakes-St. Lawrence Landscapes (OMNR 2010) was used because it more accurately assigned stands as “mature” – at a younger age (poplar at 65+ years, jack pine at 60+ years, white pine at 75+ years) to be protective / err on side of conservatism for quantifying “mature” forest stand coverage within RSA and LSA).

Some numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

The following sections provide more detailed information on tree species composition and wildlife habitat value for the forest units within the Regional Study Area (RSA).

Hardwood Uniform Shelterwood (HDUS); Mixed Uniform – Shelterwood (MWUS)

The hardwood uniform shelterwood forest unit is comprised of the Great Lakes Landscape Guide forest units of hardwood uniform shelterwood (HWUS) and mixed uniform shelterwood (MWUS). This forest unit is a relatively minor unit in the Ottawa Valley Forest that is made up of mixed forests dominated by poplar species. Within the Management Unit, it also includes the following coniferous species: eastern white pine, balsam fir, red pine, and white spruce, and the following deciduous species: red maple, white birch, and red oak (Van Dyke 2011). Mature and old stands are considered to provide good habitat for cavity nesting species and depending on relative conifer content, can provide high mast food value (i.e., from red oak acorns, if a dominant species). The three stands of forest categorized as HDUS within the RSA have only deciduous tree species recorded; therefore, it is considered a deciduous forest type. All three stands are mature. The MWUS forest unit has the largest coverage of all units within the RSA (47.9% of total area) and individual stands of MWUS consist of all 3 forest types (coniferous, mixed, and deciduous). Many have almost exclusively poplar as the leading tree species. They also contain all successional stages present in the RSA (pre-sapling to mature). Within the LSA, MWUS stands comprise 21.7% of the total area, and all of the deciduous and mixed stands are between 60-80 years old (those over 80 years old are considered mature). All stands are dominated by poplar species, and some have relatively high red oak content (with attendant wildlife food value).

White Pine – Shelterwood (PWUS4)

This forest unit has the largest coverage and widest distribution in the Ottawa Valley Forest (Van Dyke 2011). It generally consists of eastern white pine dominated stands with sub-dominant eastern white and red pine. Poplar also occurs in this unit. Habitat value of this forest unit is high in mature and old stands with supercanopy eastern white pine which provide important raptor nesting habitat. Most of the stands of PWUS4 in the RSA are mixed stands with high poplar content. Most are also mature (80-100 years old), with the associated high wildlife

habitat value associated with supercanopy eastern white pine as well as mature poplar trees providing nesting and roosting habitat for secondary cavity nesting species. Within the LSA, the five stands are dominated by white pine but have high poplar content. They are all 100 years old, which makes them mature because they are white pine-leading stands; however, it should be noted if these forest stands were poplar species leading, they would be considered old growth, because poplar trees are considered old at 95 years of age. These forest stands therefore provide high quality nesting and roosting habitat for secondary cavity nesting (and roosting) species.

Intolerant Hardwoods – Clearcut (INTCC); Poplar (PO)

This forest unit is characterized by the dominance of shade-intolerant hardwood species and is an aggregate of the two single-species forest units of PO (poplar) and BW (white birch) from the Forest Management Guide for Great Lakes – St. Lawrence Landscapes (OMNR 2010). This unit includes forests dominated by all poplar species: trembling aspen (*Populus tremuloides*), large-toothed aspen (*P. grandidentata*), balsam poplar (*P. balsamifera*), as well as dwarf white birch (*Betula minor*). It comprises the second largest forest unit in the Ottawa Valley Forest and occurs throughout the Management Unit, but is more frequent in the northern half (Van Dyke 2011). It is considered to provide an important source of early successional habitat for wildlife with abundant forage during the pre-sapling to sapling stage, and important nesting habitat for cavity nesters (e.g., bats and various bird species) provided during the mature and old stages (Van Dyke 2011). Within the RSA, the stands of intolerant hardwoods and poplar range from pre-sapling to mature, with the majority of stands aged 60 to 80 years (immature to mature).

Tolerant Hardwoods – Selection (HDSEL)

This forest unit is relatively uncommon in the Ottawa Valley Forest and consists of mixed and deciduous stands dominated by sugar maple, other hardwood species, yellow birch, poplar, as well as spruce species and balsam fir. Mature stands provide valuable habitat for wildlife species that prefer the interior of mature, closed canopy forests (Van Dyke 2011). Within the RSA, there are only four stands (three deciduous and one mixed), and all are mature (80 years old).

Red Oak – Shelterwood (OrUS)

This forest unit is the third most prevalent in the Ottawa Valley Forest and contains a minimum of 30% oak (primarily red oak) (Van Dyke 2011). Other dominant species are deciduous (poplar, red maple) or coniferous (white pine, balsam fir), making stands of this unit deciduous or mixed, depending on individual stand composition. Acorns (mast) are a preferred game and non-game food source, and mature to old stands provide cavity nesting habitat (Van Dyke 2011). Within the RSA, there are deciduous and mixed stands of Red Oak Shelterwood, most of which are mature (80 years old). Within the LSA, there are two mixed stands of Red Oak Shelterwood bisected by the Perch Lake Swamp; both are mature (80 years old) and contain an even mix of poplar and red oak with some balsam fir.

Jack Pine – Clearcut (PJ1); Spruce-Fir Uniform Shelterwood (SFUS) (Mixed Upland Conifers – Clearcut)

Likely as a result of the age of the original FRI dataset for the RSA (1987 original source), the Ottawa Valley Forest Management Plan (Van Dyke 2011) describes the Mixed Upland Conifers – Clearcut forest unit, and not the Jack Pine and Spruce-Fir units in the FRI dataset. The Mixed Upland Conifers – Clearcut forest unit represents conifer-dominated stands typical of the boreal forest. Early successional stands provide important habitat and forage for wildlife and mature to old stands provide important habitat for species dependent on

old-growth conifer habitat (Van Dyke 2011). Within the RSA, most are coniferous stands, dominated by spruce species, red and white pine, and Jack pine. Some are mixed with sub-dominant poplar or white birch. Within the RSA, numerous stands of these two forest unit are plantations. Stand ages range from pre-sapling to mature. Within the LSA, this forest type makes up 7.1% of the total area. Some are immature coniferous stands dominated by spruce species (including Norway spruce), balsam fir and larch, others are mature mixed stands containing spruce and poplar species.

Red Pine – Clearcut (PrCC)

This forest unit is comprised of forests with minimum red pine composition of 70% and has relatively low coverage in the Ottawa Valley Forest. Natural stands with sufficiently high red pine composition are rare and the majority of these forest units in the Management Unit are plantations between 21-60 years old (sapling or immature) that were established on old field or relatively barren sites. The wildlife habitat value of these immature, largely mono-culture plantations is considered low, but improves over time as thinning and natural succession modifies the structure and composition of the stand (Van Dyke 2011). Within the RSA, these red pine stands are primarily mono-culture and plantations, ranging pre-sapling to mature, with most stands in the immature stage (40 to 70 years old).

a) Breeding evidence was determined from the Ontario Breeding Bird Atlas (OBBA; Cadman et al. 2007). N/A denotes a lack of observation in the OBBA survey squares that overlap with the Regional Study Area (i.e., 18UR19, 18US10 and 18US00).

b) Conservation status: END = Endangered; THR = Threatened; SC = Special Concern; NAR = Not at Risk, — = no status.

Abbreviations: LSA = Local Study Area; RSA = Regional Study Area; COSEWIC = Committed on the Status of Endangered Wildlife in Canada; SARA = *Species at Risk Act*; ESA = Ontario *Endangered Species Act, 2007*.

APPENDIX 5.6-4

Technical Memorandum GAL107-1547525 Bat Species at Risk (SARA) Section 73 Permitting Support

TECHNICAL MEMORANDUM

DATE January 24, 2018 **PROJECT No.** GAL107-1547525

TO Martin Klukas and Annie Morin
Canadian Nuclear Laboratories

CC

FROM Leigh Holt and Kyle Knopff **EMAIL** Leigh_Holt@golder.com; Kyle_Knopff@golder.com

BAT *SPECIES AT RISK ACT* (SARA) SECTION 73 PERMITTING SUPPORT

1.0 INTRODUCTION

Little brown myotis (*Myotis lucifugus*), northern myotis (*M. septentrionalis*) and tri-colored bat (*Perimyotis subflavus*) are listed as Endangered on Schedule 1 of the federal *Species at Risk Act* (*SARA*). The presence of all three SARA-listed species has been confirmed within the Canadian Nuclear Laboratories (CNL) Chalk River Laboratories (CRL) property. The Near Surface Disposal Facility (NSDF) Project is a development proposed by CNL within the federally-owned property and is the subject of an environmental assessment under the *Canadian Environmental Assessment Act, 2012*, summarised in an Environmental Impact Statement (EIS). The Project site, also known as the East Mattawa Road (EMR) site, is hereafter referred to as the site study area (SSA) to maintain consistency with the Terrestrial Environment Section of the EIS produced by Golder Associates Ltd. (Golder) (Golder 2017). The EIS predicted the NSDF Project footprint would permanently remove 28 ha of potential maternity roosting habitat from the SSA. This represents 2% of the available maternity roosting habitat in the CNL CRL property estimated for the EIS.

Concurrent with the preparation of the EIS, CNL initiated consultation with Environment and Climate Change Canada (ECCC) and submitted an application for a *SARA* Section 73 Permit (Application #831). The permit application was submitted to meet conditions of Section 73 of *SARA* and obtain approval for activities that would directly affect SARA-listed wildlife, including bats, which are incidental to carrying out the activity, but will affect individuals. Based on information provided in the EIS, the Permit application described predicted effects of the NSDF Project on bat maternity roosts and concluded that residences would not be affected because tree removal would occur outside of the maternity roosting period when roost trees would be unoccupied.

As part of their review of the *SARA* permit application, ECCC made the following comment:

> *The statement on page 25 of the application saying that bat maternity roosts that are unoccupied (e.g., in winter) are not considered residences is incorrect. Such roosts meet the definition of a residence in SARA and thus are protected on federal land by that Act. Activities that would damage or destroy them require a permit which can only be given if all permitting conditions identified in section 73 of SARA are met. In order for ECCC to determine if these conditions are met, it is important for ECCC to know whether there are roosts likely to be damaged or destroyed by your proposed activities and, if so, to have a sense of the importance of those roosts (e.g., how many bats are using them and when) and availability of suitable, unoccupied roosts in the area.*

Golder, Golder Associates and the GA globe design are trademarks of Golder Associates Corporation.

To address this comment, CNL designed and initiated field studies in spring and summer 2017 to verify the availability and occupancy of maternity roosting habitat in the SSA and within the remaining forested areas of the CRL property. The CRL property is hereafter referred to as the Regional Study Area (RSA) for consistency with the EIS. Two types of field studies were undertaken by CNL:

1) Forest stand assessments to identify suitable roost trees.

2) Acoustic monitoring of bat activity.

Golder was retained by CNL to provide analysis and assessment of the field data. The objectives of Golder's assessment were as follows:

- Assess forest stand data collected to refine and "ground truth" Golder's EIS predictions of potential maternity roosting habitat in the SSA and RSA to be "suitable" maternity roosting habitat.
- Calculate the availability of suitable roost tree habitat (i.e., number of suitable roost trees) within the SSA and RSA for stands where stand assessment plots were completed. Extrapolate stand-based estimates of suitable roost tree availability to other tree stands in the RSA where stand assessments were not conducted. Use these data to update estimates of available maternity roosting habitat in the SSA and RSA.
- Assess acoustic monitoring data to estimate roost occupancy by little brown myotis, northern myotis, and tri-colored bats, with consideration of roost tree use by all bat species present in the RSA. Use the acoustic data to compare occupancy levels of available roosting habitat in the SSA to the rest of the RSA.

Collectively, these analyses would be used to answer ECCC's question by estimating the number of potential maternity roosts that would be damaged or destroyed by the NSDF Project, estimating the number of alternative roosts that may be present in the RSA, and evaluating use of potential roosting habitats by bats (i.e., determine whether unoccupied roosting habitat is present).

2.0 DATA COLLECTION

All data used in the analyses presented here were collected by CNL and provided to Golder for analysis. This section summarizes the data collection methods employed by CNL to generate information about forest stands and bat activity.

2.1 Forest Stand Assessments

The objective of the forest stand assessments conducted by CNL was to refine the EIS predictions about the amount of potential maternity roosting habitat by enumerating suitable roost trees in plots within the SSA and within other forested stands throughout the remaining RSA (Figures 1 and 2)[1]. Stand assessments were conducted in fixed radius plots of 0.05 ha. The intensity of stand assessment field effort was higher in the SSA Forest Resources Inventory (FRI) stands than in the remainder of the RSA. The number of plots conducted within each FRI stand was highest (n= 31) in FRI stand 216 (a mature OrUS stand), which is within the SSA. There were only single plots conducted in 28 of the 32 FRI stands assessed outside of the SSA (i.e., 87.5% of assessed stands outside the SSA contained a single plot).

[1] Figures are attached at the end of the document.

Data that were collected for each tree assessed in each plot were: FRI stand ID, forest type, plot ID, species, quality (defined as live healthy trees without cavities considered acceptable growing stock [AGS], moribund trees considered unacceptable growing stock [UGS], and dead trees), diameter at breast height (DBH), cavity (if present, as C1 for nesting cavity, C2 for feeding cavity or C3 for escape cavity), decay class (1-5, modified from Watt and Caceres 1999), height, nest, and notes.

The data collected for the forest stand assessment were generally consistent with the Ontario Ministry of Natural Resources (OMNR) protocol for assessing potential maternity roost tree density within forest stands contained in the document: *Bats and Bat Habitats: Guidelines for Wind Power Projects* (OMNR 2011). Although intended for wind projects, a more generic guidance document has not yet been produced by the provincial government, and this guidance document has been recommended by provincial regulators (OMNRF 2015), and used by biologists, to assess forest stands that may represent maternity roosting habitat.

2.2 Acoustic Monitoring

Acoustic monitoring for bats was carried out by CNL across the RSA during June to August 2017 to confirm activity of the three SARA-listed bat species within the stands undergoing assessment of roost tree habitat potential, and within the area to be cleared for the NSDF Project (i.e., the SSA). This acoustic monitoring was undertaken using detectors set in a grid pattern within the SSA and randomly in the rest of the RSA (Figures 1 and 2).

Acoustic monitoring was also conducted at eight bat boxes installed as compensatory habitat to offset losses of maternity roost habitat associated with the NSDF project. These data were included in the analysis as general indicators of SARA-listed bat species activity.

Bat calls were analyzed by CNL staff to identify species. For each call recorded, CNL identified the species that emitted the call[2], and the time, date, and location that the call or “pass” was recorded[3]. Data for each recorded pass were provided by CNL on separate worksheets for each of the following four types of acoustic monitoring stations:

- RSA random points: 36 monitoring locations and 116 detector nights from 13 July to 11 August. Detectors were located throughout the RSA, outside of the SSA, and typically paired with forest stands where stand assessment data had been collected (Figure 1).
- NSDF grid: 44 monitoring locations and 104 detector nights from 22 June to 26 July. Detectors were located in a standardized grid pattern within the SSA.
- Exit surveys: 27 monitoring locations and 35 detector nights from 12 June to 21 June. Detectors were located adjacent to suitable roost trees within the SSA.
- Bat boxes: 8 monitoring locations and 20 detector nights from 21 June to 26 June. Detectors were located adjacent to bat boxes installed next to forested areas.

[2] Some calls are not of sufficiently high quality to distinguish between little brown myotis, northern myotis, or eastern small-footed myotis. These were recorded as undifferentiated “myotis” species.

[3] Bat data are generally reported interchangeably as calls or passes. An acoustic detector will record a series of calls emitted during echolocation by a bat, typically while in flight, so each set of calls recorded is from a single pass of a bat flying by a detector.

3.0 DATA ANALYSIS

3.1 Suitable Roost Trees

Forest stand data were analyzed using the following four steps to estimate the number of suitable roost trees present in the SSA and RSA.

- **Step 1** – Identify suitable roost trees from the data collected at each forest stand assessment plot.
- **Step 2** – Estimate the density of suitable roost trees in each forest stand for which plot data were collected.
- **Step 3** – Estimate the density of suitable roost trees within forest stands for which plot data were not collected.
- **Step 4** – Combine the information from the first three steps to estimate total number of suitable roost trees in the SSA and RSA.

These steps are elaborated in the following sections.

3.1.1 Suitable Roost Tree Criteria

Data from each plot were used to identify trees that had the potential to be used by roosting bats. All tree species were included, and the following criteria were applied to identify suitable roost trees:

1) Trees with a diameter at breast height (DBH) greater or equal to 25 cm.

2) Trees with a Quality assignment of:

    a. Dead – a tree that has died; and

    b. UGS – a moribund tree, potentially with cavities, declining health but still alive.

3) Dead trees with a minimum height of 10 m.

These criteria are consistent with the OMNR provincial guidelines for identifying suitable bat maternity roosting habitat (OMNR 2011) and with a meta-analysis undertaken by Fabianek et al. (2015). The meta-analysis evaluated 34 studies and 66 data sets on bat tree roost selection criteria across North America for 12 cavity-roosting species, including little brown myotis and northern myotis. Fabianek et al. (2015) concluded that the most consistent set of characteristics of roost tree selection by tree-roosting bats, in order of importance, were: tree diameter (minimum of approximately 20 cm DBH) and height (minimum of approximately 10 m), density of standing snags within the stand, lower elevation, and lower canopy closure. Characteristics that were found to be not significantly related to roost tree selection were: distance to water, tree density, slope, and the amount of bark remaining on the tree trunk.

3.1.2 Suitable Roost Tree Density in Forest Stands with Plot Data

Suitable roost trees identified in each plot were used to calculate the density of suitable roost trees in each FRI stand within which plot data were collected. The density of suitable roost trees per hectare was calculated by summing all suitable trees identified in plots in the stand and dividing by the number of plots multiplied by the area of the plots (i.e., 0.05 ha). An example calculation for FRI stand 216 in the SSA is provided in Table 1.

Table 1: Example Calculations of Suitable Roost Tree Density for FRI stand 216 (SSA).

FRI Stand ID	Plot ID	Number of Suitable Roost Trees
216	1	15
216	2	12
216	3	21

216	39	6
216	40	12
216	23b	10
Total:	**31 plots**	**407 total suitable roost trees**
Density of Suitable Roost Trees within Stand (trees/ha)	**Sum of suitable roost trees for all plots in the stand = 262.6 trees/ha** **(0.05 ha/plot) * (# plots)**	

3.1.3 Suitable Roost Tree Density in Forest Stands without Plot Data

There were insufficient stand assessment data collected to predict suitable roost tree density for every FRI forest unit type and stand age present in the RSA. Consequently, the average suitable roost tree densities were calculated for each age class for all FRI Forest Unit types combined (Table 2). FRI forest stands that were not field-assessed were assigned the average suitable roost tree value based on the age class of the stand. The

estimated density of suitable roost trees is highest in mature stands, followed by immature stands, then sapling stands (Table 2).

Table 2: Average Suitable Roost Tree Density by Forest Stand Age.

Forest Stand Age Class	Average Suitable Roost Tree Density (roost trees / ha)	Number of Stands Assessed (n)	Standard Deviation	Minimum	Maximum
mature	48.5	17	61.4	0	262.6
immature	30.8	16	43.3	0	140
sapling	30.0	2	42.4	0	60

3.1.4 Number of Suitable Roost Trees in the SSA and RSA

The total number of suitable roost trees within the forested stands of the SSA and within the rest of the forested stands of the RSA was estimated by multiplying either the field-assessed (Section 3.1.2) or assigned density (Section 3.1.3) of suitable roost trees by the area of each individual FRI stand and then summing the area of all stands within the SSA and RSA. Examples of stand level estimates are as follows:

- FRI stand 7 (immature 24.2 ha MWUS field-assessed stand). Suitable roost tree density was estimated at 140 trees/ha using the methods described in Section 3.1.2. The calculated number of suitable roost trees within FRI stand 7 is 3,386 (140 trees/ha * 24.2 ha).
- FRI stand 6 (immature 4.7 ha MWUS non-field assessed stand). Suitable roost tree density was estimated at 30.8 trees/ha using the methods described in Section 3.1.3. The calculated number of suitable roost trees within FRI stand 6 is 145 (30.8 trees/ha * 4.7 ha).

The identification of a relatively high number of suitable roost trees in forested stands classified as sapling was unexpected (i.e., 30 roost trees/ha; Table 2). Sapling tree stands in the RSA contain trees between 10 to 39 years old, depending on the composition of leading tree species. Sampling was low in sapling stands (Table 2) and a true sapling stand would not be expected to contain large numbers of suitable roost trees. Potential sources of error include sampling in plot locations that do not represent the broader FRI polygon or the age of the stand as recorded in the FRI dataset. To evaluate the importance of this potential error, total suitable bat roost tree density in all forested stands of the SSA and RSA was calculated with and without inclusion of suitable roost trees within sapling stands.

3.2 Roost Occupancy and Bat Activity

3.2.1 Bat Activity Levels

Activity levels for each of the three SARA-listed bat species were evaluated across the entire monitoring period (i.e., June – August; Section 2.2) using data from all detector locations (i.e., all four types; Section 2.2) to provide information about the spatial distribution of overall bat activity and compare this to the roost occupancy information. Bat activity levels were estimated using number of calls/passes per detector night. The total number of calls recorded was divided by the number of deployment nights for each detector, standardizing activity data among detectors deployed for different numbers of nights.

Calls made by myotis species (i.e., little brown myotis, northern myotis, or eastern small-footed myotis [*Myotis leibii*]) are similar and can be difficult to distinguish, especially if the quality of the recording is low or calls occur in cluttered habitat. In cases where clear assignment to a particular myotis species was not possible, calls were

recorded as undifferentiated “myotis” species calls. When considering activity levels of individual SARA-listed bat species, undifferentiated myotis sp. were grouped with both the little brown myotis and northern myotis activity levels because the unknown myotis species recorded could be either of those two species.

3.2.2 Roost Occupancy

Roost occupancy was inferred from bat calls/passes detected 30 minutes before sunset and 60 minutes after sunset, consistent with the emergence window described by the OMNR (2011). Sunset times changed over the course of the acoustic monitoring period and sunset was calculated using the National Oceanic and Atmospheric Administration sunset calculator (NOAA 2017) for a position centered on the RSA (latitude 46.047 degrees and longitude -77.402 degrees).

The emergence window is the period of the night where the likelihood of capturing the activity of a bat that has just emerged from a roost to forage for the night is highest. A bat recorded in flight during this period is more likely to have emerged from a roost tree in close proximity to the detector. Bats are capable of long distance flights each night and can fly at speeds up to 35 km/hr (Fenton and Barclay 1980). Distinguishing roost emergence from foraging or commuting activity is not possible later during the night because bats detected at these times may have traveled long distances from a roost (e.g., Cryan et al. 2001).

The total number of calls recorded during the emergence windows at each detector location was divided by the number of emergence window nights surveyed for the detector, standardizing activity data among detectors deployed for different numbers of nights.

Bat box survey locations did not provide information occupancy of natural roosts. Consequently, this survey type was excluded from the roost occupancy analysis. The combined datasets from NSDF Grid and RSA Random points resulted in a sample of 220 detector nights from which recorded roost emergence activity was used to predict occupancy in forest stands that were not monitored. The bat activity data from the Exit Survey locations within the SSA were included in roost occupancy estimates for only those stands where the data were collected.

The commonly accepted maternity roosting period in Ontario is between 1 June and 30 June (OMNR 2011, OMNRF 2017). However, female bats will likely continue to use a tree for roosting after the maternity roosting period and therefore, their presence at maternity roosts will likely extend beyond June (Environment Canada 2015). The analysis of roost occupancy for stands where monitoring took place therefore focused on the entire dataset for the Exit Surveys, NSDF Grid and RSA Random points (i.e., June to August).

Female little brown myotis sometimes have maternity roosts consisting of hundreds of individuals, whereas female tri-colored bats and northern myotis tend to roost alone or in small colonies (Environment Canada 2015). Males of all species roost singly or in small groups (Environment Canada 2015). Female and male bat calls are indistinguishable using acoustic data, and a single pass during the roost emergence window was considered sufficient to infer maternity roost occupancy. Occupied roosting habitat identified through this analysis may therefore include maternity roosts of various sizes and other roost types (i.e., male roosts). The number of passes per detector night during the nightly emergence window (30 minutes before sunset to 60 minutes after sunset) provides an indication of the amount of roost use in the vicinity of a detector.

The number of bat passes per detector night during the nightly emergence window was estimated for the three SARA-listed species combined, and separately for all other bats combined (i.e., silver-haired bat [*Lasionycteris noctivagans*], big brown bat [*Eptesicus fuscus*], hoary bat [*Lasiurus cinereus*], eastern red bat [*Lasiurus borealis*],

and eastern small-footed myotis[4]). Consideration of other tree-roosting bats not listed under SARA, but present within the RSA, is useful to help identify occupancy and availability of roosting habitat. Bats that are not SARA-listed may occupy roosts that may then be unavailable to SARA-listed bats.

3.2.3 Intensity of Roost Occupancy in Forest Stands with Acoustic Monitoring Data

The intensity of roost occupancy by bats in FRI stands where acoustic monitors were deployed was estimated directly from the data collected in that stand (inclusive of NSDF Grid and Exit Survey datasets within the SSA, and RSA Random points datasets outside the SSA), using the average number of calls per detector emergence window. For example, there were 23 NSDF Grid monitoring locations and 17 Exit Survey locations within FRI stand 216. The sum of calls recorded across all 40 detector locations was divided by the total number of detector nights for all detector locations (n = 83). Calculations were made separately for the combined number of SARA-listed species calls (n = 52) and combined number of all bat species calls (n = 257). Overall, for stand 216, there were 0.63 calls per detector night of SARA-listed species (52 calls divided by 83 detector nights) and 3.1 calls per detector night of all bat species (257 calls divided by 83 detector nights).

3.2.4 Intensity of Roost Occupancy in Forest Stands without Acoustic Monitoring Data

In a manner similar to that described in Section 3.1.3, the average number of calls recorded per detector emergence window in each forest age class was used to estimate the intensity of roost occupancy in forest stands for which no acoustic data were available. Only two of the four acoustic datasets were used for this purpose: the NSDF Grid and RSA Random points. The reason for this is that the locations for acoustic monitoring in the NSDF Grid and RSA Random points datasets were selected in a similar manner (i.e., on a grid pattern, or completely randomly generated location, not targeting specific features), and there was a more equivalent distribution of survey effort within the SSA and RSA by only including these two datasets, although survey effort in forested stands in the SSA remains higher than survey effort in forested stands in the RSA.

Average intensity of roost occupancy was assigned to each forest stand for which no acoustic data were collected according to age of the stand. Average intensity of roost occupancy was calculated for these bat groupings:

- Combined calls from the three SARA-listed species (little brown myotis, northern myotis, undifferentiated myotis, and tri-colored bats) (Table 3), to predict roost tree occupancy of the SARA-listed species.
- Combined calls from all bat species present (the three SARA-listed species plus eastern small-footed myotis, silver-haired bat [*Lasionycteris noctivagans*], big brown bat [*Eptesicus fuscus*], hoary bat [*Lasiurus cinereus*] and eastern red bat [*Lasiurus borealis*]) (Table 4), to predict roost tree occupancy by all tree roosting bat species occurring on the CRL property / RSA.

[4] Eastern small-footed myotis may also be included with SARA listed bats in analyses that use undifferentiated myotis data.

Table 3: Average number of passes of SARA-listed Species during the roost emergence window in different forest age classes.

Forest Stand Age Class	SARA-listed Species Calls/Detector Night[5] (Emergence Window)	Detector Nights (n)	Standard Deviation	Minimum # Calls (per night)	Maximum # Calls (per night)
Mature	0.66	124	1.9	0	11
Immature	0.16	74	0.4	0	2
Sapling	0.14	7	0.4	0	1

Table 4: Average number of passes of all bats during the roost emergence window in different forest age classes.

Forest Stand Age Class	ALL Species Calls/Detector Night (Emergence Window)	Detector Nights (n)	Standard Deviation	Minimum # Calls (per night)	Maximum # Calls (per night)
Mature	6.6	124	15.9	0	125
Immature	4.4	74	6.3	0	42
Sapling	3.1	7	2.8	0	7

3.2.5 Roost Tree Occupancy Index

To obtain an index of roost tree occupancy, the field-assessed or predicted intensity of roost use was divided by the field-assessed or predicted density of suitable roost trees within each FRI stand. The resulting index provides relative levels of roost tree occupancy and can be used to evaluate the availability of suitable and unoccupied roosts. Stands with a high roost tree occupancy index score (i.e., relatively high intensity of roost use / roost tree density) may contain few suitable and occupied roosts, whereas stands with a low roost tree occupancy index score (i.e., relatively low intensity of roost use / roost tree density) likely contain suitable unoccupied roosting habitat.

The roost tree occupancy index was used to:

- Estimate of the relative amount of roost occupancy for all bat species combined in each FRI stand in the SSA and RSA (intensity of roost use by all bats / density of roost trees).
- Estimate the relative amount of roost occupancy of the three SARA-listed bat species in each FRI stand in the SSA and RSA (intensity of roost use by SARA listed bats / density of roost trees).
- Examine relative roost occupancy in forested stands in the RSA to determine the potential for bats displaced by the NSDF Project to be accommodated in alternate suitable and unoccupied roosting habitat.

[5] The species included were little brown myotis, northern myotis, undifferentiated myotis (which could be either SARA-listed species or eastern small-footed myotis), and tri-colored bat.

4.0 RESULTS

4.1 Suitable Roost Trees

The CRL property (RSA) is dominated by forested ecosystems and the estimated number of suitable roost trees for the entire property, including suitable roost trees in sapling stands, exceeds 116,000 (Table 5). The number of suitable roost trees varies across the study area (Figure 3), but is substantially higher in stand 216, which encompasses most of the area to be affected by the NSDF Project footprint (SSA), compared to elsewhere in the RSA (Figure 3; Table 5). This difference may be an artifact of sampling intensity, which was much higher in stand 216 than in other forested stands in the RSA (Figures 1 and 2). Of the 32 forest stands surveyed outside of the SSA, 28 had a single plot conducted, 1 had 2 plots, and 2 had 3 plots. Certainty in the average roost tree density found in stand 216, where data were collected at 31 plot locations, is therefore much higher than certainty in the average roost tree density in other parts of the RSA.

Table 5: Estimated Number of Suitable Roost Trees in the SSA and RSA.

Study Area	Number of Suitable Roost Trees[a]	Area (ha)	Average Roost Tree Density (#/ha)
RSA outside of SSA	110,405	3,514	31
SSA	6,485	37	175
Total (CRL Property)	116,890	3,551[b]	33

[a] Includes sapling stands

[b] The total area considers the total area within the CRL property covered by the FRI dataset and excludes aquatic habitat and minor gaps and slivers in GIS. For that reason, there is a discrepancy between this value and the total RSA area (if total of suitable + unsuitable habitat is added, the total is 3,853 ha)

As indicated in Section 3.1.1, the high number of suitable roost trees found in forest stand assessments within stands identified as sapling in the FRI data was surprising. When sapling stands were excluded from the suitable roost tree analysis, the calculated total number of suitable roost trees in the RSA outside of the SSA is 108,551, a difference of 1,853 trees or 1.68%. The small difference is due to the relatively small area of sapling forest stand coverage in the RSA. Because the effect of sapling stand inclusion on total suitable roost tree calculations was negligible, sapling stands were retained for the calculations presented in Table 5 and for other analyses undertaken in this assessment.

4.2 Maternity Roost Habitat Availability

One of the objectives of estimating the number of suitable roost trees in forest stands in the RSA and SSA was to evaluate whether the predictions of the EIS developed for the NSDF Project were supported by the forest stand assessment data. The EIS for the NSDF Project presented coarse-scale estimation of potential maternity roost habitat within the SSA and RSA by assuming that maternity roost habitat for little brown myotis and northern myotis would be present in the following habitat types:

- Mature forest stands.
- Mature treed swamps.

The forest stand assessment data indicate that a large number of suitable maternity roost trees are also present in immature stands in the RSA, and that some sapling stands in the RSA may also contain suitable roost trees. Consequently, the amount of habitat containing suitable roost trees within the CNL property is likely higher than originally estimated in the EIS (Figures 3 and 4; Table 6).

Table 6: Changes to Availability of Bat Maternity Roost Tree Habitat as a result of the NSDF Project using the Original EIS Model and an Updated Model that incorporates all Forest Classes

Model	Roost Habitat Class	Regional Study Area				Local Study Area			
		Base Case [ha]	Application Case [ha]	Change in Area [ha]	Percent Change [%]	Base Case [ha]	Application Case [ha]	Change in Area [ha]	Percent Change [%]
Original EIS Habitat Suitability	Suitable	1,149	1,121	-28	-2	83	54	-28	-34
	Unsuitable	2,704	3,732	28	1	125	153	28	23
Updated Habitat Suitability	Suitable	2,943	2,909	-34	-1	114	81	-34	-30
	Unsuitable	910	944	34	4	93	126	34	37

ha = hectare; % = percent

However, the coarse habitat models used in the EIS and the updated model presented in Table 6 do not account for stand quality because they treat all forest stands as equivalent. Although suitable roosting habitat may be present more broadly in the RSA than predicted in the EIS, the relative stand quality estimated by density of suitable roost trees is much higher in the LSA and SSA than elsewhere in the RSA (Figures 3 and 4; Table 5). Consequently, although Table 6 indicates that the relative loss of roosting habitat caused by the NSDF project would decline from 2% of the RSA to 1% of the RSA (i.e., less important), the loss of individual suitable roost trees caused by the NSDF project would be 6,485 trees, representing 5.5% of all suitable roost trees estimated for the RSA.

4.3 Bat Activity Levels

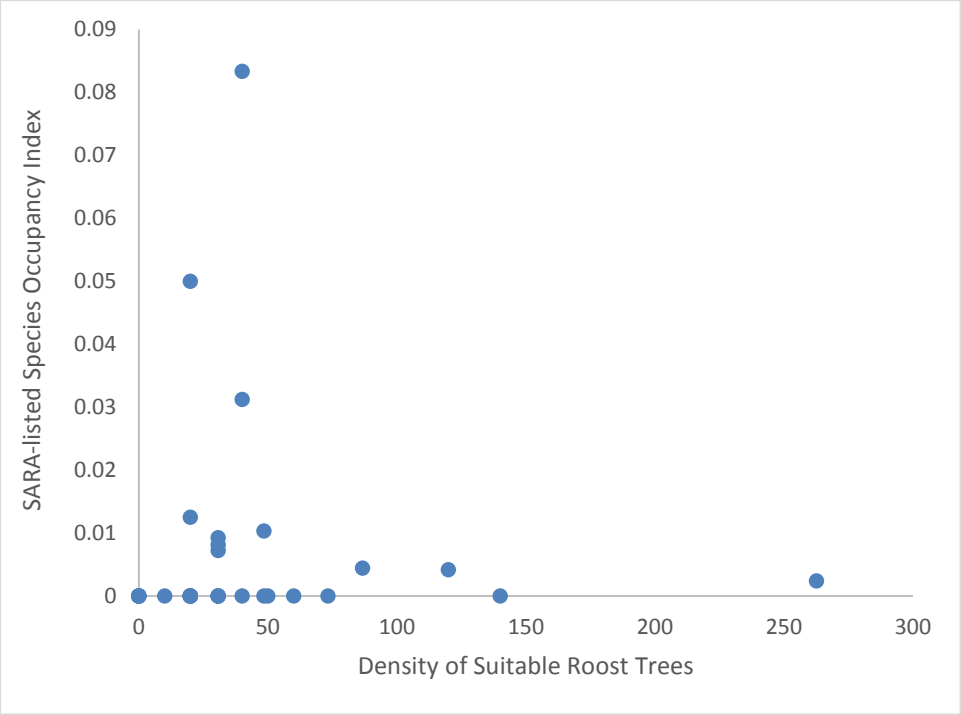
Bat passes representing roost emergence, foraging, and commuting activity at detectors in the RSA were most commonly assigned to little brown myotis (Figure 5), followed by northern myotis (Figure 6), and then tri-colored bats (Figure 7).

Little brown myotis activity was detected throughout the RSA and SSA (Figure 5). Activity levels were similar at most sampling stations where little brown myotis were detected, but activity was elevated at three detectors located around the perimeter of Perch Lake (Figure 5). This is expected, because Perch Lake likely serves as a high-quality foraging habitat feature on the RSA landscape that attracts many bats each night. Bats foraging at Perch Lake could have traveled from roosts located several kilometers away (Cryan et al. 2001).

The activity of northern myotis was also evenly distributed throughout the RSA but at a lower level than little brown myotis activity (Figure 6). Similar to what was observed for little brown myotis activity (Figure 5), there were many detectors within the SSA that had no calls of northern myotis recorded, but many that did (Figure 6). Although there were no areas with especially high peaks in northern myotis activity recorded in the RSA, activity was highest at detectors deployed near Perch Lake.

Tri-colored bats had much lower general activity levels detected throughout the RSA than either of the two myotis species (Figure 7). Recordings of tri-colored bats were made at only eight detectors. This is not unexpected, because tri-colored bats were relatively rare in parts of Ontario, even prior to the arrival of white nose syndrome (WNS), which is a deadly fungal infection transmitted among bats in winter hibernacula and is the primary factor driving the Endangered listing of little brown myotis, northern myotis, and tri-colored bats under SARA (Environment Canada 2015). WNS has caused precipitous bat population declines in some parts of Ontario (Environment Canada 2015).

4.4 Roost Tree Occupancy



The combined primary emergence window acoustic monitoring results of all acoustic monitoring programs conducted in the SSA (including Exit Surveys), as well as the results of the stand assessments are provided in Table 7.

Table 7: SARA-species occupancy and suitable maternity roost data from the SSA

Stand ID	Age Class	# SARA-listed Species calls/detector night (primary emergence window)	# ALL Species calls/detector night (primary emergence window)	Density of Suitable Roost Trees (trees/ha)	Area of stand within SSA (ha)	Calculated # Suitable Roost Trees (within SSA)
215	Mature	Predicted – 0.66	Predicted – 6.55	Predicted – 48.5	0.02	0.76
216	Mature	0.63	3.10	262.6	22.7	5951.6
218	Mature	0	0	50	0.9	44.3
219	Mature	0	19.31	Predicted – 48.5	3.6	175.4
221	Mature	Predicted – 0.66	Predicted – 6.55	Predicted – 48.5	0.008	0.40
222	Immature	0.29	0.86	Predicted – 30.8	2.4	74.8
223	Immature	0.25	2	Predicted – 30.8	1.6	49.3
232	UCL	Not assessed (not treed)			0.005	-
354	Mature	0.38	13.54	86.7	2.2	188.2
501	UCL	Not assessed (not treed)			3.8	-
				Totals:	**37.2**	**6,485**

Despite the very high density of suitable roost trees in the SSA, which is dominated by stand 216, the number of calls per detector night in the primary emergence window was slightly below the average predicted for other mature stands in the RSA (0.63 compared to 0.66, see Table 7). The maximum number of passes of SARA-listed bats in the SSA was 10 passes per detector night in the primary emergence window. There were many detector locations for which no SARA-listed bats recorded. Within stand 216, for example, there were 30 detector locations out of 40 with no SARA-listed bats recorded. Although suitable roost trees are very abundant in stand 216, the available data indicate that many of them remain unoccupied. This intensity of roost use by SARA-listed bats estimated from acoustic detectors deployed in the SSA is consistent with individual roosting bats or small groups. The acoustic data yielded no evidence of large maternal roosting colonies of little brown myotis in the SSA.

Using data from stands in the SSA and in other parts of the RSA where both stand assessments and acoustic monitoring was conducted, there were many instances where stands containing suitable roost trees had no activity recorded by SARA-listed bats, indicating a degree of vacancy in available suitable roost tree habitat throughout much of the RSA (Plot 1). There is also variability among stands, and stands with intermediate densities of suitable roost trees (between 25 and 50) had the highest occupancy index scores. Many plots with higher numbers of suitable roost tree densities had much lower occupancy index scores, likely because suitable roost trees are so abundant in these stands and only a small number of them are occupied (e.g., stand 216 in the SSA).

Plot 1: SARA-listed bat species occupancy index as a function of the number of suitable roost trees present within stands having both acoustic monitoring and stand assessments conducted.

The calculated roost tree occupancy index varied among forested stands in the RSA (Figure 8). The weighted circles depicted in Figure 8 are positioned on the centroid of each FRI forest stand, and the relative size of each circle represents the roost tree occupancy index score within the stand. As shown on Figure 8, the proportion of SARA-listed bat species roost occupancy compared to other non-listed bat species is generally low throughout the RSA. Considering occupancy as a whole, only a small number of forest stands had relatively high roost tree occupancy index values, with one occurring on the west margin of the CRL property boundary, and another within the north portion of the SSA. The majority of stands had relatively low to moderate occupancy index values, even in cases where substantial numbers of suitable roost trees were present (compare Figure 3 to Figure 8). Based on these data, it can be inferred that stands with lower relative roost tree occupancy likely contain suitable roosting habitat that is currently unoccupied.

5.0 DISCUSSION AND CONCLUSION

The objective of the analyses presented in this technical memorandum was to provide answers to the questions posed by ECCC in their review of CNL's SARA Section 73 permit application. The question posed by ECCC can be divided into three sub-questions, as follows:

- Will roosts used by SARA listed bats be damaged or destroyed by the NSDF Project?
- What is the importance of these roosts for SARA listed bats?
- What is the availability of suitable, unoccupied roosts in the area?

Each of these sub-questions is answered in the following sections.

5.1 Will roosts used by SARA listed bats be damaged or destroyed by the NSDF Project?

Forest plot data collected by CNL demonstrate a high density of suitable roost trees for bats in forest stands encompassing the SSA. The density of suitable roost trees within these stands is higher than in any other forest stands in the RSA, although increased survey intensity in other stands in the RSA may alter this conclusion. Acoustic monitoring in the SSA during the roost emergence window indicates that SARA-listed bats are roosting in suitable roost trees in the SSA, although estimated occupancy per suitable roost tree is lower than most other stands in the RSA. Overall, the data strongly support a conclusion that some roosts used by SARA-listed bats will be damaged or destroyed by the NSDF Project, but that potential roost tree occupancy is low.

5.2 What is the importance of these roosts for SARA listed bats?

Suitable roost trees in the SSA are likely used by SARA-listed bat species both as maternity roosts and for other types of roosting (e.g., roosts used by males). Data collected during the roost emergence window in the SSA did not identify intensity of roost occupancy values consistent with maternal roosts used by large numbers of little brown myotis[6]. Data coverage within the SSA was high (Figure 2), but lack of detection of large maternal roosting colonies of little brown myotis does not guarantee that none are present. A precautionary conclusion given the amount of available habitat would be that some larger maternal roosting colonies of little brown myotis could be present in the SSA.

Under the provincial wind power guidance for assessing candidate maternity roost stands and individual roost trees (OMNR 2011), confirmation of endangered bats roosting in a single roost tree within a stand is sufficient to designate the entire forest stand as confirmed Significant Wildlife Habitat for bat maternity colonies. Using this definition, forest stands within the SSA can be considered Significant Wildlife Habitat for bat maternity colonies.

As part of the question about the importance of roosts in the SSA, ECCC wanted to understand how many bats used the roosts and when. Precisely determining roost tree occupancy rates by bats is difficult (OMNR 2017); this difficulty is compounded in large areas containing high densities of suitable roost trees, such as the SSA. The SSA contains thousands of suitable roost trees and completing roost surveys (visual or acoustic) for the entire SSA is impractical. Thus, uncertainty remains about the timing of roost use and precise number of bats using roosting habitat in the SSA. However, a reasonable conclusion given the available data would be that the SSA contains important roosting habitat for SARA listed bats, although it does not appear to be more important than other forested stands in the RSA when occupancy is considered.

Based on the number of suitable roost trees present in the SSA, the number of bats that currently use the SSA as roosting habitat and would be displaced by the NSDF Project could be substantial. No other forest stands in the RSA contain as many suitable roost trees. However, suitable roost tree density in forest stands in the SSA is better understood than in other stands in the RSA because sampling intensity was much higher in the SSA. Higher sampling intensity in other parts of the RSA in the future may identify additional stands with higher suitable roost tree density. Moreover, despite the high density of suitable roost trees in the SSA, occupancy index scores were lower than in many other stands in the RSA, suggesting that many of the suitable roost trees present in the SSA remain unoccupied.

[6] Northern myotis and tri-colored bats are not expected to roost in large maternal colonies (Environment Canada 2015).

5.3 What is the availability of suitable, unoccupied roosts in the area?

Understanding the occupancy rates for available suitable roost trees in the RSA is important for evaluating the importance of removing roosting habitat in the SSA. If suitable roost trees outside of the SSA are already fully occupied, there would potentially be insufficient vacancy to accommodate bats displaced from the SSA as a result of the NSDF Project. In this case, the effects of tree removal in the SSA would have greater consequences for displaced bats. If suitable roost trees outside of the SSA are vacant, then displaced bats from the SSA can be accommodated and the effects of removing suitable roost tree from the SSA will have lower consequences for bats. Other important habitats, such as foraging habitats associated with Perch Lake, would not change as a result of the NSDF Project and bats would be able to access these important habitats from alternate roost sites up to several kilometers away (Cryan et al. 2001).

Although the density of suitable roost trees is higher in the SSA than it is in other parts of the RSA, suitable roosting habitat is abundant throughout the RSA. The majority of stands had relatively low to moderate occupancy index values, even in cases where substantial numbers of suitable roost trees were present. Most occupied roosting habitat was occupied at relatively low levels by bats that are not SARA-listed. These results indicate that a large number of suitable unoccupied roost trees are present in the RSA and that these likely are more than sufficient to accommodate SARA-listed bats displaced by the NSDF Project.

The presence of WNS in populations of little brown myotis, northern myotis, and tri-colored bats overlapping the RSA has not been confirmed; however, Environment Canada (2015) estimates that populations of little brown myotis, northern myotis, and tri-colored bats have been reduced by 94% in WNS-affected provinces such as Ontario (Environment Canada 2015). If local populations have been affected by WNS, the population will be well below the size required for roost trees to be limiting. Bats are known to use other suitable roosts if previously used roosts are removed outside of the roosting season (Silvis et al. 2015). This evidence provides additional support for the inference that the amount of vacant tree roosting habitat available in the RSA following construction of the NSDF Project will be sufficient to accommodate SARA-listed bats displaced from the SSA.

5.4 Conclusion

The combined results of the analyses described in this technical memorandum support the predictions of the EIS for the NSDF Project. Implementing the NSDF Project will very likely result in the damage or destruction of suitable and seasonally occupied maternity roosts for all three SARA-listed bat species within the SSA. Although the roosts removed by the NSDF Project may be used by large numbers of SARA-listed bats, especially little brown myotis and northern myotis, the NSDF Project would remove the roosts during winter when they are unoccupied. The data collected by CNL during the summer of 2017 indicates that suitable maternity roost trees that are currently unoccupied are present in the RSA outside of the SSA in sufficient abundance to accommodate the three SARA-listed bats that will be displaced as a result of the NSDF Project. This finding is supported even though the density of roost trees calculated in the RSA outside of the SSA was much lower than the number observed in the SSA. The conclusion would be even stronger if additional survey effort identified that a higher number of suitable roost trees are present in the RSA outside of the SSA.

6.0 CLOSURE

We trust the information contained in the technical memo meets your requirements at this time. If you have any further questions or concerns, please do not hesitate to contact the undersigned.
